

# First Observation of the Charmless Baryonic Decay $B^+ \rightarrow \bar{\Lambda} p \bar{p} p$

R. Aaij *et al.*\*  
(LHCb Collaboration)

 (Received 25 August 2025; accepted 25 November 2025; published 22 December 2025)

A search for the charmless baryonic decay  $B^+ \rightarrow \bar{\Lambda} p \bar{p} p$  is performed using proton-proton collision data recorded by the LHCb experiment, corresponding to an integrated luminosity of  $5.4 \text{ fb}^{-1}$ . The branching fraction for this decay is measured for the first time relative to that of the topologically similar decay  $B^+ \rightarrow J/\psi K^+$ , with  $J/\psi \rightarrow \bar{\Lambda} p K^-$ . The branching fraction is measured to be  $\mathcal{B}(B^+ \rightarrow \bar{\Lambda} p \bar{p} p) = (2.15 \pm 0.35 \pm 0.12 \pm 0.28) \times 10^{-7}$ , where the first uncertainty is statistical, the second is systematic, and the third arises from the uncertainty in the normalization channel branching fraction. The  $CP$  asymmetry is measured to be  $\mathcal{A}_{CP} = (5.4 \pm 15.6 \pm 2.4)\%$ , where the uncertainties are statistical and systematic. The background-subtracted invariant-mass distributions of  $\bar{\Lambda} p$  and  $\bar{p} p$  pairs exhibit pronounced enhancements at both kinematic thresholds, in contrast to a uniform phase-space distribution.

DOI: [10.1103/3pcs-dxtm](https://doi.org/10.1103/3pcs-dxtm)

Studies of exclusive  $B$ -meson decays to final states containing both baryons and mesons have been ongoing since the late 1980s [1]. Several baryonic  $B$  decay modes have been observed, including three-body final states such as  $p \bar{p} K^+$ ,  $p \bar{p} \pi^+$ ,  $p \bar{p} K_S^0$ , and  $p \bar{p} K^*(892)^+$  [2,3], as well as four-body modes like  $p \bar{p} \pi^+ \pi^-$  and  $p \bar{p} K^+ K^-$  [4]. In the standard model, these decays proceed via  $b \rightarrow u$  tree-level and  $b \rightarrow s(d)$  electroweak penguin diagrams, providing a valuable laboratory for studying direct  $CP$  violation and testing hadronic models [5,6].

Unlike mesonic modes, baryonic  $B$  decays exhibit a unique feature known as threshold enhancement: a pronounced peak near the invariant-mass threshold of the baryon-antibaryon pair [2,3]. Final states with two baryon-antibaryon pairs are particularly intriguing, as they probe hadronization dynamics beyond those accessible with a single pair [7].

The LHCb Collaboration recently reported the first observation of a four-body charmless fully baryonic weak decay,  $B^0 \rightarrow p \bar{p} p \bar{p}$  [8], which mainly proceeds via a  $b \rightarrow u$  tree-level internal  $W$ -boson emission [7]. The measured branching fraction,  $\mathcal{B}(B^0 \rightarrow p \bar{p} p \bar{p}) = (2.2 \pm 0.4 \pm 0.1 \pm 0.1) \times 10^{-8}$ , is approximately 2 orders of magnitude lower than those of analogous four-body baryonic  $B$  decays, such as  $B^0 \rightarrow p \bar{p} \pi^+ \pi^-$  [4]. To explain the overall observed suppression, form factors that describe the evolution of

short-distance systems to those with baryons in the final state have been proposed [7]. In this approach, a *double-enhancement* mechanism in baryon-pair formation was also proposed. It increases the decay rate in the limited regions of phase space where one or both baryon pairs are produced near threshold. With this effect, the decay  $B^+ \rightarrow \bar{\Lambda} p \bar{p} p$  (The inclusion of charge-conjugate processes is implied throughout, except in the discussion of asymmetries.), which proceeds via a combination of via a combination of  $b \rightarrow u$  tree level suppressed by Cabibbo-Kobayashi-Maskawa (CKM) matrix elements and  $b \rightarrow s$  electroweak loop amplitudes, is expected to have a branching fraction of  $\mathcal{B}(B^+ \rightarrow \bar{\Lambda} p \bar{p} p) = (7.4_{-0.2}^{+0.6} \pm 0.03_{-2.6}^{+3.6}) \times 10^{-7}$  [7], where the uncertainty arises from nonfactorizable QCD corrections, the CKM matrix-element inputs, and form-factor modeling. The comparatively large branching fraction of this decay offers a promising opportunity to study the mass spectra of baryon pairs and explore baryon-pair formation mechanisms. The mass spectra may reveal resonant structures such as the  $X(1835)$  and  $X(2085)$ , which are interpreted as baryonium-like bound states [9,10]. In addition, owing to the interference between tree-level and penguin diagrams in the low  $m(\bar{\Lambda} p)$  and  $m(\bar{p} p)$  mass regions, sizeable direct  $CP$  asymmetries are possible [11].

In this Letter, the  $B^+ \rightarrow \bar{\Lambda} p \bar{p} p$  decay is studied using proton-proton ( $pp$ ) collision data collected by the LHCb experiment over the period 2016–2018 at a center-of-mass energy  $\sqrt{s} = 13 \text{ TeV}$  and corresponding to an integrated luminosity of approximately  $5.4 \text{ fb}^{-1}$ . The branching fraction of the signal decay is measured relative to that of the topologically similar normalization mode,  $B^+ \rightarrow J/\psi(\rightarrow \bar{\Lambda} p K^-) K^+$ , using a simultaneous fit across all data-taking periods. In addition, this Letter presents a study of the  $m(\bar{\Lambda} p)$  and

$m(\bar{p}p)$  spectra and  $CP$  asymmetry in a purely baryonic four-body decay.

The LHCb detector [12,13] is a single-arm forward spectrometer covering the pseudorapidity range  $2 < \eta < 5$ , designed for the study of particles containing  $b$  or  $c$  quarks. The detector used for this analysis includes a high-precision tracking system consisting of a silicon-strip vertex detector (VELO) surrounding the  $pp$  interaction region [14], a large-area silicon-strip detector located upstream of a dipole magnet with a bending power of about 4 Tm, and three stations of silicon-strip detectors and straw drift tubes [15] placed downstream of the magnet. The tracking system provides measurements of the track momentum and impact parameter (IP) and is used to reconstruct the primary  $pp$  interaction vertex (PV), where the IP is the shortest distance between the extrapolation of a track and a PV. Different types of charged hadrons are distinguished using particle identification (PID) information from two ring-imaging Cherenkov detectors [16]. The  $\Lambda \rightarrow p\pi^-$  decay is reconstructed in two distinct categories depending on whether the decay products are reconstructed in all tracking detectors (*long*) or in all but the VELO (*downstream*). While candidates in the long category have better mass, momentum, and vertex resolution than those in the downstream category, the downstream category accounts for two-thirds of the total  $\Lambda$  yield.

Online event selection is performed by a trigger [17] that consists of a hardware stage, based on information from the calorimeter and muon systems, followed by a two-level software stage, which applies a full event reconstruction. At the hardware stage, events are required to have a muon with high transverse momentum ( $p_T$ ) or a hadron, photon, or electron with high transverse energy in the calorimeters. The first-level software trigger requires one or two tracks that are likely to originate from  $B$  decays. The second-level software trigger requires a two-, three-, or four-track secondary vertex with a significant displacement from any PV. A multivariate algorithm [18] is used to identify secondary vertices consistent with the decay of a  $b$  hadron.

Simulated samples are used to study the properties of the signal, normalization, and background channels. PYTHIA [19] generates  $pp$  collisions using an LHCb-specific configuration [20]. Decays of unstable particles are described by EvtGen [21], in which final-state radiation is generated using PHOTOS [22]. The interactions of generated particles with the detector material, and their responses, are implemented using the Geant4 toolkit [23,24], as described in Ref. [25]. Simulated signal and normalization decays are generated using phase-space models.

Off-line candidates are selected by exploiting the characteristic topology and kinematic features of four-body decays to final states containing a  $\Lambda$  baryon. The preselection requires loose track quality and applies minimal kinematic requirements to the  $\Lambda$  and  $B^+$  candidates. All charged tracks except those used to reconstruct  $\Lambda$

candidates must originate from within the VELO and are required to have a good track-fit quality. Fake tracks, which are reconstructed from detector hits that do not correspond to real particles, are rejected by applying a selection on the fake-track probability [26]. A minimum  $p_T$  of 250, 200, and 400 MeV/ $c$  is required for the proton, kaon, and  $\Lambda$  baryon, respectively. Each track must have a significant  $\chi_{\text{IP}}^2$ , where  $\chi_{\text{IP}}^2$  is defined as the difference between the vertex fit  $\chi^2$  of a PV reconstructed with and without the considered track. Candidate  $\Lambda$  baryons are formed by combining proton and pion track candidates that are fitted to a common decay vertex. A loose PID requirement on the proton from the  $\Lambda$  baryon is applied at this stage. For  $\Lambda$  candidates in the long category, the selection algorithm further requires that the decay vertices of the  $\Lambda$  baryon and the associated  $B^+$  candidate are well separated. The  $\Lambda$  decay products must satisfy  $|m(p\pi) - M_\Lambda| < 6 \text{ MeV}/c^2$ , where  $M_\Lambda$  is the known  $\Lambda$  mass [27]. Candidate  $B^+$  mesons are reconstructed by combining a  $\Lambda$  candidate with three charged final-state particles into a common vertex. Both the  $B^+ \rightarrow \bar{\Lambda}p\bar{p}p$  and the  $B^+ \rightarrow J/\psi(\rightarrow \bar{\Lambda}pK^-)K^+$  decay chains are fitted constraining the  $\Lambda$  mass to its known value [27]. The PV that fits best to the flight direction of the  $B^+$  candidate is taken as the associated PV. The angle between the  $B^+$  momentum direction and the displacement vector from the PV to the  $B^+$  decay vertex is required to be less than  $2.5^\circ$ . The  $B^+$  candidate is also required to have  $p_T > 3000 \text{ MeV}/c$  and a large decay length significance, defined as the  $\chi^2$  of the separation between the  $B^+$  decay vertex and the associated PV, ensuring a clear displacement from the PV.

The final selection of  $B^+$  candidates uses the two most powerful variables that discriminate between signal and background:  $\chi_{\text{IP}}^2$  of the  $B^+$  candidate, defined as the difference between the vertex fit  $\chi^2$  of a PV reconstructed with and without the  $B^+$  meson, and the product of the nominal particle-identification classifiers of the three charged final-state particles,  $\prod_i \mathcal{P}_i$ . The  $\chi_{\text{IP}}^2$  distribution for signal is approximately that of  $\chi^2$  for one degree of freedom. Each classifier,  $\mathcal{P}_i$ , is derived from an artificial neural network and ranges between 0 and 1, peaking near unity for correctly identified particles and near zero for misidentified ones [13]. Using  $B^+ \rightarrow \bar{\Lambda}p\bar{p}p$  data in the sideband mass regions, defined as  $m(\bar{\Lambda}p\bar{p}p) \in [4700, 5049] \cup [5529, 5800] \text{ MeV}/c^2$ , along with simulated  $B^+$  signal decays, the selection criteria are optimized separately for the long and downstream categories to enhance the signal significance  $S/\sqrt{S+B}$ , even if the signal is somewhat lower than that expected. Here,  $S$  and  $B$  denote the expected signal and background yields within the signal region  $m(\bar{\Lambda}p\bar{p}p) \in [5254, 5304] \text{ MeV}/c^2$ . A common requirement  $\log(\chi_{\text{IP}}^2) < 1.8(1.6)$ , along with a selection on the variable  $\prod_i \mathcal{P}_i > 0.6(0.7)$ , is applied to the long (downstream)  $\Lambda$  category for the signal and normalization channels. With respect to preselection criteria,

FIG. 1. Invariant-mass distributions of (left)  $B^+ \rightarrow \bar{\Lambda}p\bar{p}p$  with  $m(\bar{p}p) < 2850 \text{ MeV}/c^2$  and (right)  $B^+ \rightarrow J/\psi(\rightarrow \bar{\Lambda}pK^-)K^+$  candidates, after combining the long and downstream  $\Lambda$  categories and requiring all selection criteria described in the text. The fit results are shown together with the fit model components. The hashed cyan bands represent the  $\pm 1\sigma$  model uncertainties from the covariance matrices of the best-fit parameters.

the final selection criteria reduces background by a factor of 5 while retaining about 65% of the signal. To avoid experimenter bias, data in the  $B^+ \rightarrow \bar{\Lambda}p\bar{p}p$  signal region are examined only after all selection criteria are finalized.

Reconstruction efficiencies for signal and normalization channels are evaluated using simulated decays generated uniformly in phase space. To correct the kinematic distributions in the simulated samples, candidates are assigned weights derived from background-subtracted  $B^+ \rightarrow H_{c\bar{c}}(\rightarrow \bar{\Lambda}pK^-)K^+$  candidates, where  $H_{c\bar{c}}$  represents a  $J/\psi$  or  $\eta_c$  meson. Weighting depends on  $\chi_{\text{IP}}^2$  of the  $B^+$  candidate, track multiplicity in the event, and the momentum of each final-state particle. Additionally, the invariant-mass distributions of the two-body combinations of the final-state particles in simulation are corrected to match the corresponding distributions in data. For the normalization channel, the  $m(pK^-)$  versus  $m(\bar{\Lambda}K)$  distributions are corrected, while for the signal channel, the  $m(\bar{\Lambda}p)$  versus  $m(\bar{p}p)$  distributions are corrected to better match the data after the decay is observed.

Several  $B^+$  decays with intermediate charmonium resonances can contribute to the  $\bar{\Lambda}p\bar{p}p$  final state, including  $B^+ \rightarrow \bar{\Lambda}pJ/\psi(\rightarrow \bar{p}p)$  and  $B^+ \rightarrow \bar{\Lambda}p\eta_c(\rightarrow \bar{p}p)$ . The  $B^+ \rightarrow \bar{\Lambda}p\bar{p}p$  candidates are divided into three disjoint categories: noncharmonium candidates with  $m(\bar{p}p) < 2850 \text{ MeV}/c^2$ ,  $B^+ \rightarrow \bar{\Lambda}p\eta_c(\rightarrow \bar{p}p)$  candidates with  $|m(\bar{p}p) - M_{\eta_c}| < 40 \text{ MeV}/c^2$ , and  $B^+ \rightarrow \bar{\Lambda}pJ/\psi(\rightarrow \bar{p}p)$  candidates with  $|m(\bar{p}p) - M_{J/\psi}| < 30 \text{ MeV}/c^2$ , where  $M_{\eta_c}$  and  $M_{J/\psi}$  are the known  $\eta_c$  and  $J/\psi$  masses [27]. The wider window for  $B^+ \rightarrow \bar{\Lambda}p\eta_c(\rightarrow \bar{p}p)$  than for  $B^+ \rightarrow \bar{\Lambda}pJ/\psi(\rightarrow \bar{p}p)$  accounts for the larger  $\eta_c$  natural linewidth.

The invariant-mass distributions  $m(\bar{\Lambda}p\bar{p}p)$  with  $m(\bar{p}p) < 2850 \text{ MeV}/c^2$  and  $m(\bar{\Lambda}pKK)$  are shown in Fig. 1. Because of the different available phase space, the final-state particles in the signal decay have lower momenta, resulting in an improved reconstructed mass resolution. Unbinned maximum-likelihood fits are performed to determine the signal yields. The signal shapes

are described by a modified Gaussian function with tails on both sides of the peak (double-sided Crystal Ball [28], DSCB) whose values are fixed from simulation. The  $B^+$  mass and width are allowed to vary independently. The background shapes are described by linear functions with coefficients that are free to vary. The  $B^+$  signal yield obtained from the fit to the  $m(\bar{\Lambda}p\bar{p}p)$  selected candidates is  $N(B^+ \rightarrow \bar{\Lambda}p\bar{p}p) = 78 \pm 12$  events, accounting for statistical uncertainties only.

The absolute branching fraction  $\mathcal{B}(B^+ \rightarrow \bar{\Lambda}p\bar{p}p)$  is determined from a simultaneous unbinned maximum-likelihood fit to the signal and the normalization channels. In the normalization channel  $B^+ \rightarrow J/\psi(\rightarrow \bar{\Lambda}pK^- + \text{c.c.})K^+$ , decays of  $B^+ \rightarrow \eta_c(\rightarrow \bar{\Lambda}pK^- + \text{c.c.})K^+$ , and nonresonant  $B^+ \rightarrow \bar{\Lambda}pK^+K^-$  and  $B^+ \rightarrow \Lambda\bar{p}K^+K^+$  can produce physics backgrounds. To account for these,  $B^+ \rightarrow J/\psi(\rightarrow \bar{\Lambda}pK^- + \text{c.c.})K^+$  candidates are divided into three categories based on the invariant mass  $m(\bar{\Lambda}pK^-)$ : (i) candidates with  $|m(\bar{\Lambda}pK^-) - M_{J/\psi}| < 30 \text{ MeV}/c^2$  are considered from  $B^+ \rightarrow J/\psi(\rightarrow \bar{\Lambda}pK^-)K^+$  decay, (ii) candidates with  $|m(\bar{\Lambda}pK^-) - M_{\eta_c}| < 30 \text{ MeV}/c^2$  are considered from  $B^+ \rightarrow \eta_c(\rightarrow \bar{\Lambda}pK^-)K^+$  decay [The  $m(\bar{\Lambda}pK^-)$  observed width is approximately  $13.8 \text{ MeV}/c^2$  for  $\eta_c \rightarrow \bar{\Lambda}pK^-$  and  $4.2 \text{ MeV}/c^2$  for  $J/\psi \rightarrow \bar{\Lambda}pK^-$ ], and (iii) candidates with  $3200 < m(\bar{\Lambda}pK^-) < 3300 \text{ MeV}/c^2$  are considered from charmless  $B^+ \rightarrow \bar{\Lambda}pK^+K^-$  and  $B^+ \rightarrow \Lambda\bar{p}K^+K^+$  decays. For each decay mode, the invariant-mass distributions  $m(\bar{\Lambda}pK^+K^-)$  and  $m(\Lambda\bar{p}K^+K^+)$  are modeled using DSCB functions. The background yields of  $B^+ \rightarrow \eta_c(\rightarrow \bar{\Lambda}pK^-)K^+$ ,  $B^+ \rightarrow \bar{\Lambda}pK^+K^-$ , and  $B^+ \rightarrow \Lambda\bar{p}K^+K^+$  decays in category (i) are extrapolated from the  $B^+$  signal yields in categories (ii) and (iii). Individual contributions within the  $J/\psi$  mass window are estimated using extrapolations from simulated data.

The background-subtracted invariant-mass spectra of  $\bar{\Lambda}p$  and  $\bar{p}p$  pairs, obtained using the *sPlot* technique in the  $m(\bar{\Lambda}p\bar{p}p)$  dimension [29], are shown in Fig. 2. The two

FIG. 2. Distributions of background-subtracted (left)  $m(\bar{\Lambda}p_I)$  and (middle)  $m(\bar{p}p_{II})$  for  $B^+ \rightarrow \bar{\Lambda}p\bar{p}p$  events in data compared with phase-space simulation, where the proton  $p_I$  yields the lower invariant mass  $m(\bar{\Lambda}p)$  with  $\bar{\Lambda}$  baryon. Right: two-dimensional distribution of  $m(\bar{\Lambda}p_I)$  and  $m(\bar{p}p_{II})$  in data.

identical protons in the final state are distinguished based on the invariant masses formed with the  $\bar{\Lambda}$  baryon. The proton that yields the lower invariant mass  $m(\bar{\Lambda}p)$  is labeled as  $p_I$ . The other proton,  $p_{II}$ , is paired with the antiproton to form the second baryon-antibaryon combination. A double threshold enhancement is observed, indicated by the clear accumulation of events in the lower left-hand corner of the weighted  $[m(\bar{\Lambda}p_I), m(\bar{p}p_{II})]$  distribution, as well as by the peaks near the kinematic thresholds in the  $m(\bar{\Lambda}p_I)$  and  $m(\bar{p}p_{II})$  spectra. Similar results, obtained by pairing the proton and antiproton with the lower invariant mass, are shown in the End Matter.

The  $m(\bar{\Lambda}p\bar{p}p)$  distribution of candidates with  $|m(\bar{p}p) - M_{n_c}| < 40 \text{ MeV}/c^2$  is shown in Fig. 3. The signal shape is modeled by a DSCB function and the background by a threshold function of the form  $(x - x_0)^\beta$ , where  $x_0 \equiv M_{\bar{\Lambda}} + M_{n_c} + M_p$  and  $\beta$  is a free parameter of the fit. The yield in this region is  $N[B^+ \rightarrow \bar{\Lambda}p\eta_c(\rightarrow \bar{p}p)] = 2.9 \pm 1.9$  events. The yield in the region  $|m(\bar{p}p) - M_{J/\psi}| < 30 \text{ MeV}/c^2$  is  $N[B^+ \rightarrow \bar{\Lambda}pJ/\psi(\rightarrow \bar{p}p)] = 16.4 \pm 4.2$  events. This is consistent with estimates from the known branching

fractions  $\mathcal{B}(B^+ \rightarrow \bar{\Lambda}pJ/\psi)$  and  $\mathcal{B}(J/\psi \rightarrow p\bar{p})$  [27] and the number of events observed in the normalization channel.

The dominant sources of systematic uncertainty affecting the branching fraction measurements are listed in Table I, and include those associated with the fit models, efficiencies, PID performance, and the branching fraction of the normalization channel.

Three sources of associated systematic uncertainties are estimated from simulation. First are the uncertainties on the nominal efficiencies due to the sizes of the simulated samples. Second are the uncertainties due to the weights used for correcting kinematic differences between simulation and data, assessed by recalculating the branching fractions without applying the weights. The resulting deviation is taken as a conservative estimate of the associated uncertainty. Third are uncertainties on the tracking efficiencies, due to the detector material budget distribution or to the particle interaction cross-sections, that lead to uncertainties on the efficiency ratios. Differences between PID efficiencies in data and simulation are corrected using a combination of simulated and data calibration samples. The signal shapes are varied in two ways: the DSCB function parameters are varied within their uncertainties, and the signal shape is modified to

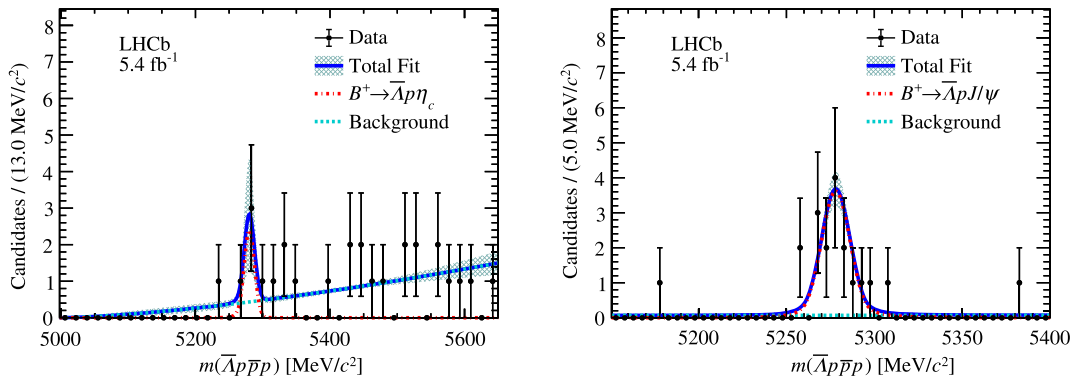

FIG. 3. Invariant-mass distribution of (left)  $B^+ \rightarrow \bar{\Lambda}p\eta_c(\rightarrow \bar{p}p)$  candidates with  $|m(\bar{p}p) - M_{n_c}| < 40 \text{ MeV}/c^2$  and (right)  $B^+ \rightarrow \bar{\Lambda}pJ/\psi(\rightarrow \bar{p}p)$  candidates with  $|m(\bar{p}p) - M_{J/\psi}| < 30 \text{ MeV}/c^2$ , after combining the long and downstream  $\Lambda$  categories and requiring all selection criteria described in the text. The fit results are shown together with the fit model components. The hashed cyan bands represent the  $1\sigma$  model uncertainty on the covariance matrix of the best-fit parameters.

TABLE I. Summary of relative systematic uncertainties on (A)  $\mathcal{B}(B^+ \rightarrow \bar{\Lambda} p \bar{p} p)$  and (B)  $\mathcal{B}(B^+ \rightarrow \bar{\Lambda} p \eta_c (\rightarrow \bar{p} p))$ , in percent. The total systematic uncertainty is computed as the square root of the sum of squared sum in quadrature of individual contributions. There is no model correction for  $B^+ \rightarrow \bar{\Lambda} p \eta_c (\rightarrow \bar{p} p)$  decay due to the small size of this component. The last row indicates the relative statistical uncertainty.

| Systematic source                | A    | B    |
|----------------------------------|------|------|
| Simulated sample size            | 0.6  | 0.6  |
| Kinematic correction             | 1.4  | 1.4  |
| Tracking                         | 1.2  | 1.2  |
| PID                              | 3.1  | 2.0  |
| Signal shape                     | 2.9  | 31.1 |
| Background shape                 | 1.2  | 2.4  |
| Model correction (signal)        | 2.7  | ...  |
| Model correction (normalization) | 1.6  | 1.6  |
| Nonresonant                      | ...  | 22.9 |
| Total systematic                 | 5.8  | 38.8 |
| Statistical uncertainty          | 16.4 | 65.5 |

include a Gaussian function together with the DSCB function. For the  $B^+ \rightarrow \bar{\Lambda} p \bar{p} p$  decay, the background model is replaced by a second-order polynomial function. For the  $B^+ \rightarrow \bar{\Lambda} p \eta_c (\rightarrow \bar{p} p)$  decay, the threshold background shape is replaced by an exponential function. Concerning the correction of decay models for signal and normalization channels in simulation, the parameters that affect the performance of the weighting algorithm are varied individually, and the total efficiencies are recalculated using the alternative sets of weights, with the largest deviation taken as a systematic uncertainty. For  $B^+ \rightarrow \bar{\Lambda} p \bar{p} p$  decay, an alternative correction based on the decay model shown in Fig. 4 is implemented and the resulting deviation is taken as an additional contribution to the systematic uncertainty associated with the signal model correction. For the  $B^+ \rightarrow \bar{\Lambda} p \eta_c (\rightarrow \bar{p} p)$  decay, the dominant systematic uncertainties relate to the signal shape and the potential contribution from charmless

$B^+ \rightarrow \bar{\Lambda} p \bar{p} p$  decay, which is estimated by extrapolating the observed yield with  $m(\bar{p} p) < 2850 \text{ MeV}/c^2$  into the  $\eta_c$  mass window.

The  $CP$  asymmetry of the  $B^+ \rightarrow \bar{\Lambda} p \bar{p} p$  decay rate integrated over the phase space is measured by fitting the  $B^+$  and  $B^-$  samples separately, as shown in the End Matter, using the same procedure as for the branching fraction measurement. The yields vary independently, while the shape parameters are shared between the  $B^+$  and  $B^-$  candidates. The raw asymmetry ( $A_{\text{raw}}$ ) between the  $B^+$  and  $B^-$  signal yields is found to be  $(5.6 \pm 15.5)\%$ . To obtain the  $CP$  asymmetry, this must be corrected as per

$$\mathcal{A}_{CP} = A_{\text{raw}} - A_{\text{prod}} - A_{\text{det}},$$

where  $A_{\text{prod}}$  is the production asymmetry of  $B^\pm$  mesons and  $A_{\text{det}}$  is the sum of the instrumental asymmetries in detection ( $A_{\text{D}}$ ), PID ( $A_{\text{PID}}$ ), and trigger ( $A_{\text{trigger}}$ ) of particles and antiparticles.

The production asymmetry has been measured by LHCb to be  $(-0.7 \pm 0.3)\%$  [30]. The trigger asymmetry arises from differences in trigger efficiencies between charge-conjugated final states. The efficiency for a charged hadron to be responsible for the affirmative decision of the hardware trigger is determined as a function of  $p_{\text{T}}$ , separately for positively and negatively charged particles [17]. The asymmetry introduced by the hardware trigger for candidates is determined to be  $A_{\text{trigger}}^{\bar{\Lambda} p \bar{p} p} = (0.03 \pm 0.18)\%$ . The proton detection asymmetry is evaluated as a function of momentum using the method developed in Ref. [31], and is measured to be  $A_{\text{D}}^{p \bar{p} p} = (1.15 \pm 0.66)\%$ . The detection asymmetry for the  $\Lambda$  baryon is estimated by parametrizing the detection asymmetries of the proton and pion as functions of their momentum and, in the case of the pion, also pseudorapidity [31,32], and is measured to be  $A_{\text{D}}^{\bar{\Lambda}} = (-1.49 \pm 0.26)\%$ . The PID asymmetry is evaluated using calibration samples that account for differences in PID efficiency between positively and negatively charged tracks and is determined to be  $A_{\text{PID}}^{p \bar{p} p} = (0.18 \pm 1.50)\%$ .

FIG. 4. Distributions of background-subtracted (left)  $m(\bar{p} p_1)$  and (middle)  $m(\bar{\Lambda} p_2)$  for  $B^+ \rightarrow \bar{\Lambda} p \bar{p} p$  events in data compared with phase-space simulation, where the proton  $p_1$  yields the lower invariant mass with antiproton. Right: two-dimensional distribution of  $m(\bar{p} p_1)$  and  $m(\bar{\Lambda} p_2)$  in data.

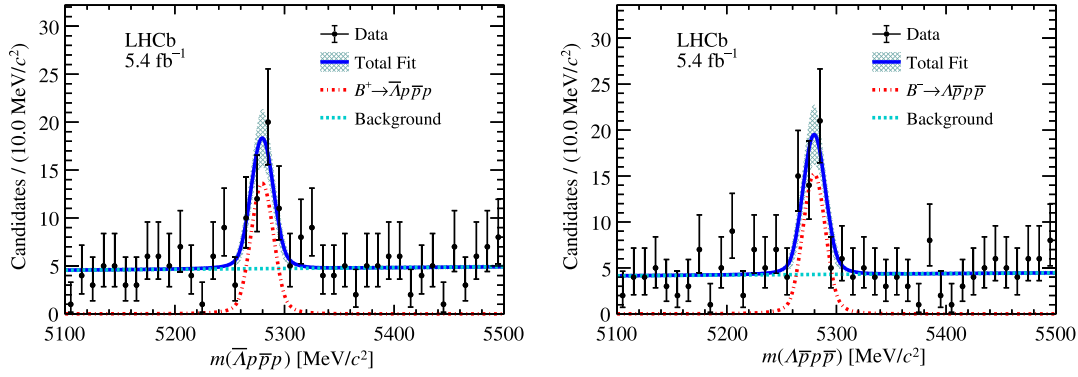

FIG. 5. Invariant-mass distribution of (left)  $B^+ \rightarrow \bar{\Lambda} p \bar{p} p$  and (right)  $B^- \rightarrow \Lambda \bar{p} p \bar{p}$  candidates, after combining the long and downstream  $\Lambda$  categories and requiring all selection criteria described in the text. The fit results for these samples are shown together with the fit model components. The hashed cyan bands represent the  $1\sigma$  model uncertainty on the covariance matrix of the best-fit parameters.

The PID asymmetry from the  $\Lambda$  baryon is negligible due to its loose selection criteria.

The estimation of model-related systematic uncertainties in the determination of  $A_{\text{raw}}$  is performed using the same procedure as for the branching fraction measurement. The differences between the raw asymmetries determined by the two sets of fits are added in quadrature, and the resulting value is taken as a systematic uncertainty. Altogether with the uncertainties on external asymmetries, the  $CP$  asymmetry is measured to be  $\mathcal{A}_{CP} = (5.4 \pm 15.6 \pm 2.4)\%$ .

In summary, a new charmless and purely baryonic decay mode of the  $B^+$  meson,  $B^+ \rightarrow \bar{\Lambda} p \bar{p} p$ , is observed. The signal yield is measured to be  $N(B^+ \rightarrow \bar{\Lambda} p \bar{p} p) = 78 \pm 12$  events. The branching fraction relative to the normalization channel is determined to be  $\mathcal{B}(B^+ \rightarrow \bar{\Lambda} p \bar{p} p) / \mathcal{B}(B^+ \rightarrow J/\psi(\rightarrow \bar{\Lambda} p K^-) K^+) = (0.245 \pm 0.040 \pm 0.014)$ , where the uncertainties are statistical and systematic, respectively. The branching fraction is measured to be

$$\mathcal{B}(B^+ \rightarrow \bar{\Lambda} p \bar{p} p) = (2.15 \pm 0.35 \pm 0.12 \pm 0.28) \times 10^{-7},$$

where the first uncertainty is statistical, the second systematic, and the third arises from the external branching fraction of the normalization channel. This result is lower than, but in reasonable agreement with, a SM prediction of  $\mathcal{B}(B^+ \rightarrow \bar{\Lambda} p \bar{p} p) = (7.4_{-0.2}^{+0.6} \pm 0.03_{-2.6}^{+3.6}) \times 10^{-7}$  [7], where the uncertainty arises from nonfactorizable QCD corrections, the CKM matrix-element inputs, and form-factor modeling. The  $CP$  asymmetry is measured to be  $\mathcal{A}_{CP} = (5.4 \pm 15.6 \pm 2.4)\%$ , with the first uncertainty statistical and the second systematic. The background-subtracted mass spectra exhibit a clear double-threshold enhancement in both baryon-antibaryon invariant-mass distributions close to their thresholds, which plays an enhancing factor [7] in the  $B^+ \rightarrow \bar{\Lambda} p \bar{p} p$  decay and may reveal resonant structures such as the  $X(1835)$  baryonium bound state [9].

In the region defined by  $|m(\bar{p} p) - M_{n_c}| < 40 \text{ MeV}/c^2$ , the yield of  $B^+ \rightarrow \bar{\Lambda} p \eta_c(\rightarrow \bar{p} p)$  is  $N[B^+ \rightarrow \bar{\Lambda} p \eta_c(\rightarrow \bar{p} p)] = 2.9 \pm 1.9$  events. The corresponding branching fraction is

$$\mathcal{B}(B^+ \rightarrow \bar{\Lambda} p \eta_c(\rightarrow \bar{p} p)) = (8.3 \pm 5.4 \pm 3.2 \pm 1.1) \times 10^{-9},$$

where the first uncertainty is statistical, the second systematic, and the third arises from the external branching fraction of the normalization channel. The 90% confidence level upper limit on the branching fraction is  $\mathcal{B}(B^+ \rightarrow \bar{\Lambda} p \eta_c(\rightarrow \bar{p} p)) < 2.1 \times 10^{-8}$ .

The measurement of  $\mathcal{B}(B^+ \rightarrow \bar{\Lambda} p \bar{p} p)$  constrains models of perturbative QCD effects in multibody baryonic final states, particularly in regions where large theoretical uncertainties remain [7]. The threshold enhancements manifested in this Letter highlight the rich dynamics of baryonic  $B$  decays and should stimulate further theoretical studies.

*Acknowledgments*—We express our gratitude to our colleagues in the CERN accelerator departments for the excellent performance of the LHC. We thank the technical and administrative staff at the LHCb institutes. ## End Matter

*Additional baryon-antibaryon mass spectra*—Another study of baryon-antibaryon invariant-mass spectra in the  $B^+ \rightarrow \bar{\Lambda} p \bar{p} p$  decay is shown in Fig. 4. The two identical protons in the final state are distinguished based on the invariant mass formed with the antiproton rather than with the  $\bar{\Lambda}$  baryon. The  $\bar{p} p$  combination that yields the lower invariant mass is labeled as  $\bar{p} p_1$ . The remaining proton,  $p_2$ , is then paired with the  $\bar{\Lambda}$  baryon to form the second baryon-antibaryon combination.

As expected due to the definition of the pairs, the enhancement here is greater for  $m(\bar{p} p)$  than in Fig. 2 and less for  $m(\bar{\Lambda} p)$ . Qualitatively, however, the conclusion is the same and enhancements are observed in the lower left-hand corner of the scatter plot and in both projections.

*Fit to different charged B samples*—Figure 5 shows the fits to the  $B^+ \rightarrow \bar{\Lambda} p \bar{p} p$  and  $B^- \rightarrow \Lambda \bar{p} p \bar{p}$  samples for the measurement of  $\mathcal{A}_{CP}$ .

<sup>a</sup>Deceased.

<sup>b</sup>Also at Lamarr Institute for Machine Learning and Artificial Intelligence, Dortmund, Germany.

<sup>c</sup>Also at Università degli Studi di Milano-Bicocca, Milano, Italy.

<sup>d</sup>Also at Università di Roma Tor Vergata, Roma, Italy.

<sup>e</sup>Also at Università di Modena e Reggio Emilia, Modena, Italy.

<sup>f</sup>Also at Department of Physics and Astronomy, University of Victoria, Victoria, Canada.

<sup>g</sup>Also at Università di Ferrara, Ferrara, Italy.

<sup>h</sup>Also at Universidade Estadual de Campinas (UNICAMP), Campinas, Brazil.

<sup>i</sup>Also at Università di Bologna, Bologna, Italy.

<sup>j</sup>Also at Università di Genova, Genova, Italy.

<sup>k</sup>Also at Scuola Normale Superiore, Pisa, Italy.

<sup>l</sup>Also at Università degli Studi di Milano, Milano, Italy.

<sup>m</sup>Also at Center for High Energy Physics, Tsinghua University, Beijing, China.

<sup>n</sup>Also at Universidad Nacional Autónoma de Honduras, Tegucigalpa, Honduras.

<sup>o</sup>Also at Università di Cagliari, Cagliari, Italy.

<sup>p</sup>Also at Centro Federal de Educação Tecnológica Celso Suckow da Fonseca, Rio De Janeiro, Brazil.

<sup>q</sup>Also at Università di Bari, Bari, Italy.

<sup>r</sup>Also at Università di Perugia, Perugia, Italy.

<sup>s</sup>Also at LIP6, Sorbonne Université, Paris, France.

<sup>t</sup>Also at Università di Pisa, Pisa, Italy.

<sup>u</sup>Also at Hangzhou Institute for Advanced Study, UCAS, Hangzhou, China.

<sup>v</sup>Also at Università di Padova, Padova, Italy.

<sup>w</sup>Also at Università di Bergamo, Bergamo, Italy.

<sup>x</sup>Also at Universidad de Ingeniería y Tecnología (UTEC), Lima, Peru.

<sup>y</sup>Also at Università di Siena, Siena, Italy.

<sup>z</sup>Also at Università della Basilicata, Potenza, Italy.

<sup>aa</sup>Also at Universidad de Alcalá, Alcalá de Henares, Spain.

<sup>bb</sup>Also at Università di Urbino, Urbino, Italy.
