

## ORAL PRESENTATIONS

**SUNDAY, DECEMBER 16**

### **Symposium 1: Cell Fate Decisions**

1

#### **Lgr5 Stem Cells in self-renewal and cancer.**

*H. Clevers<sup>1</sup>; <sup>1</sup>Hubrecht Institute, Royal Netherlands Academy of Arts and Sciences & University Medical Centre Utrecht, Utrecht, Netherlands*

The intestinal epithelium is the most rapidly self-renewing tissue in adult mammals. We originally defined *Lgr5* as a Wnt target gene, transcribed in colon cancer cells. Two knock-in alleles revealed exclusive expression of *Lgr5* in cycling, columnar cells at the crypt base. Using an inducible Cre knock-in allele and the Rosa26-*LacZ* reporter strain, lineage tracing experiments were performed in adult mice. The *Lgr5*<sup>+</sup> crypt base columnar cells (CBC) generated all epithelial lineages throughout life, implying that it represents the stem cell of the small intestine and colon. Similar observations were made in hair follicles and stomach epithelium.

Single sorted *Lgr5*<sup>+</sup> stem cells can initiate ever-expanding crypt-villus organoids in 3D culture. Tracing experiments indicate that the *Lgr5*<sup>+</sup> stem cell hierarchy is maintained in these organoids. We conclude that intestinal crypt-villus units are self-organizing structures, which can be built from a single stem cell in the absence of a non-epithelial cellular niche. The same technology has now been developed for the *Lgr5*<sup>+</sup> stomach stem cells.

Intestinal cancer is initiated by Wnt pathway-activating mutations in genes such as APC. As in most cancers, the cell of origin has remained elusive. Deletion of APC in stem cells, but not in other crypt cells results in progressively growing neoplasia, identifying the stem cell as the cell-of-origin of adenomas. Moreover, a stem cell/progenitor cell hierarchy is maintained in early stem cell-derived adenomas, lending support to the "cancer stem cell"-concept.

Fate mapping of individual crypt stem cells using a multicolor Cre-reporter revealed that, as a population, *Lgr5* stem cells persist life-long, yet crypts drift toward clonality within a period of 1-6 months. *Lgr5* cell divisions occur symmetrically. The cellular dynamics are consistent with a model in which the resident stem cells double their numbers each day and stochastically adopt stem or TA fates after cell division. *Lgr5* stem cells are interspersed between terminally differentiated Paneth cells that are known to produce bactericidal products. We find that Paneth cells are CD24+ and express EGF, TGF- $\alpha$ , Wnt3 and the Notch ligand Dll4, all essential signals for stem-cell maintenance in culture. Co-culturing of sorted stem cells with Paneth cells dramatically improves organoid formation. This Paneth cell requirement can be substituted by a pulse of exogenous Wnt. Genetic removal of Paneth cells in vivo results in the concomitant loss of *Lgr5* stem cells. In colon crypts, CD24+ cells residing between *Lgr5* stem cells may represent the Paneth cell equivalents. We conclude that *Lgr5* stem cells compete for essential niche signals provided by a specialized daughter cell, the Paneth cell.

2

#### **Gene Regulatory Networks Governing Hematopoietic Stem Cell Development and Identity.**

*T. Enver<sup>1</sup>; <sup>1</sup>UCL Cancer Institute, University College London, London, United Kingdom*

Several studies have addressed questions about transcriptional regulation within particular hematopoietic cell compartments. Few, however, have attempted to capture the transcriptional

changes that occur during the dynamic transition from one compartment to another. We have profiled gene expression as multipotential progenitors underwent commitment and differentiation to two alternative lineages, focusing on the first 3 days of differentiation when the majority of decisions about cell fate are made. We have combined this with genome-wide identification of the targets of three key transcription factors before and after differentiation; GATA-2, usually associated with the stem/progenitor compartment; GATA-1 (erythroid); and PU.1 (myeloid). We used correlation analyses to associate transcription factor binding with particular modules of co-expressed genes, alongside detailed sequence analysis of bound regions. Dynamic modelling of TF relationships has predicted novel interactions that have been validated experimentally. These approaches have highlighted novel regulators of stem cell fate decisions and - informed our understanding of GATA factor switching. Overall, the data reveal greater degree of complexity in the interplay between GATA-1, 2 and PU.1 - in regulating hematopoiesis than has hitherto been described, and highlights the importance of a genome-wide approach to understanding complex regulatory systems. A significant challenge in the field is how to relate these types of population-based data to the action of transcriptional regulators within single cells where cell fate decisions ultimately are effected. As a step toward this, we have generated single cell profiles of gene expression for a limited set of transcriptional regulators in self-renewing and committed blood cells and used these data to build a stochastic computational model, which affords exploration of commitment scenarios *in silico*. The data highlight the 'noisiness' of transcription in multipotential cells, and we have computationally captured modes of regulation that may contribute to heterogeneous gene expression. We suggest that individual cells may enter lineage commitment through different routes; data on instruction of commitment through perturbation of individual regulators is in support of this view.

3

### **Asymmetric cell division and spindle orientation in neural stem cells - from *Drosophila* to humans.**

Juergen A. Knoblich<sup>1</sup>; <sup>1</sup>*Institute of Molecular Biotechnology, Austrian Academy of Sciences, Vienna, Austria*

When we think of mitosis, we commonly have a process in mind where a cell gives rise to two identical daughter cells. In whole organisms, however, many cell divisions are actually asymmetric and give rise to two daughter cells of different size, shape or developmental fate. Asymmetric cell divisions are particularly important in stem cells, as they allow those cells to generate both self-renewing and differentiating daughter cells, an ability that is common to all stem cells. We therefore use stem cells in the developing brain of both fruitflies and mice as a model to understand the principle mechanisms that regulate and orient asymmetric cell divisions. More recently, we have extended our efforts to mammalian model systems, where mutations in regulators of basic cell biological processes like the orientation of the mitotic spindle are known to cause strong brain malformations resulting in severe mental retardation. As recent experiments have shown striking differences between human and mouse brain development, we have made an effort to establish experimental strategies where those regulators and their effects on brain development can be studied in a human setting.

### **Bruce Alberts Award for Excellence in Science Education**

4

### **International Institute for Collaborative Cell Biology and Biochemistry (IICCB). Building a network to share and inspire.**

*L. C. Cameron<sup>1</sup>; <sup>1</sup>Laboratorio de Bioquímica de Proteínas, Universidade Federal do Estado do Rio de Janeiro, Rio de Janeiro, Brazil*

In 2000 we organized the first international symposium on myosin V in my home city of Rio de Janeiro. That meeting became part of the foundation for a series of courses focused on hands-on research training and education workshops to train the next generation of international scientists, with particular emphasis on Central and South American students who have limited opportunities to interact directly with international scientists. My colleagues and I founded The International Institute for Collaborative Cell Biology and Biochemistry (IICCB). The IICCB is a network of world experts who want to share their expertise and knowledge to inspire students, who in future will be the scientific leaders in the respective fields of biochemistry, cell biology and biotechnology. Our vision is to invigorate a new generation of international scientific cooperation by exposing young scientists to diverse, multidisciplinary learning experiences via organizing various workshops, conferences and symposia. At these events, leading established scientists connect with each other and share their wealth of experience with the next generation of scientists who, in turn, act as ambassadors to their colleagues. We organized more than 25 of these workshops, international conferences and courses in Brazil, Uruguay, Mexico, and the United States (we had more than 1600 attendees). Subject areas include topics in cell biology (calcium signaling, intracellular transport, and other aspects of the cytoskeleton), biochemistry, biophysics, and systems biology. These training courses have had a great impact on the students, exposing them to North American and European science. Many have gone on to work in the laboratories of the U.S. and European faculty who have participated, and the courses have sparked multiple intercontinental collaborations. We are now planning to expand to other regions of Brazil and Americas and to motivate colleagues to promote courses in other Latin America countries, Africa and Asia. In addition, we are working to consolidate the IICCB with more dependable funding from national and international agencies. We hope that we can continuously grow a friendly network of science all over the world.

### **E.E. Just Lecture**

5

#### **Decoding the biology of human genome polymorphisms in African Americans.**

*G. M. Dunston<sup>1,2</sup>, T. Mason<sup>2</sup>, J. Lindesay<sup>3</sup>; <sup>1</sup>Microbiology, Howard University, Washington, DC, <sup>2</sup>National Human Genome Center, Howard University, Washington, DC, <sup>3</sup>Computational Physics Laboratory, Howard University, Washington, DC*

The completion of the Human Genome Project introduced a new knowledge system for decoding biology based on the science of information structured in DNA sequence variation. Single nucleotide polymorphisms (SNPs) are a system of common variation widely distributed across the genome, where two or more forms of the DNA sequence are found at a given site, with the rarest form occurring at a frequency of one percent or greater in the population. Recently, our Biophysics Research and Development Group has applied first principles of thermodynamics and statistical physics in studying the informatics of SNPs, as dynamic sites in the genome. From our perspective of SNPs as complex dynamical systems, we derived a new biophysical metric for interrogating the information content (IC) present in SNP haploblocks. This metric facilitates translation of biochemical sequence variation into a biophysical metric

derived from Boltzmann's canonical ensemble used in information theory. Our normalization of this information metric (NIC) allows for comparison of SNP haploblocks across different sites in the genome. We found that low NIC scores in the human leukocyte antigen-disease related (HLA-DR) region, illumined molecular pathways of innate immune mechanisms functional in host adaptation to environmental stressors, such as pathogens. In our approach, we were able to relate NIC to biologically relevant functional knowledge embedded in the structure of common sequence variation. We are exploring new perspectives of human population biology interfacing genomics and theoretical physics at the frontier of life sciences.

## Minisymposium 1: Cancer Cell Biology

6

### In vivo imaging of dynamic interactions within the haematopoietic stem cell niche.

*C. Lo Celso<sup>1</sup>; <sup>1</sup>Imperial College London, London, United Kingdom*

Haematopoietic stem cells (HSC) reside within the bone marrow, therefore their microenvironment (or niche) has been traditionally inaccessible to direct observation. Despite numerous functional studies demonstrating that several bone marrow stroma cells regulate HSC function and number, still very little is known about the anatomical location of HSC during steady state and in response to several types of stimuli, including leukaemia development. It is an open question whether HSC firmly localise within a specific niche or whether they migrate between different niches, defined by distinct bone marrow microenvironments, where they receive different stimuli. Other open questions are whether leukaemia development affects HSC-niche interactions and whether leukaemia stem cells (LSC) and HSC compete for niche space.

Confocal/two-photon hybrid microscopy allows visualization at single cell resolution of transplanted haematopoietic stem and progenitor cells (HSPC) in the calvarium bone marrow of live mice. FACS-purified, ex-vivo labelled HSPC populations can be visualised upon their initial arrival in the niche (homing) and following the first divisions (early engraftment). We showed that long-term repopulating (LT) HSPC selectively localize proximal to osteoblasts within a few hours from transplantation, whereas their progeny are more distal and we collected further evidence that LT-HSPC and their progeny localization near osteoblasts correlates with positive transplantation outcome. Finally, we used a mouse model of acute myeloid leukaemia based on retroviral transduction of the MLL-AF9 oncogene and observed that leukaemic cells corresponding to different stages of disease progression follow distinct homing patterns. In particular, granulocyte-monocyte precursors (L-GMP), an established LSC population, share the same homing pattern of normal GMP rather than that of LT-HSPC. This indicated why MLL-AF9 LSC are insensitive to niche-derived signals that otherwise affect normal HSC function.

7

### Autophagy dependent secretion of interleukin-6 facilitates cancer cell invasion.

*J. Debnath<sup>1</sup>, R. Lock<sup>1</sup>, C. Kenific<sup>1</sup>, E. Salas<sup>1</sup>; <sup>1</sup>Pathology, University of California, San Francisco, San Francisco, CA*

To date, the pro-tumor functions of autophagy have been largely attributed to its ability to promote tumor cell fitness and survival. We now demonstrate a new role for autophagy regulators (ATGs) in facilitating tumor cell motility, extracellular matrix invasion, and in vivo metastatic capacity. In Ras-transformed epithelial cells, RNAi-mediated depletion of ATGs

profoundly inhibits invasive behavior in three-dimensional (3D) culture and restores multiple aspects of normal epithelial architecture, including polarized deposition of basement membrane and cell-cell junctional integrity. Furthermore, lung metastases in vivo are attenuated upon autophagy inhibition in Ras-transformed epithelial cells and in Polyoma Middle T (PyMT) breast tumor cells.

Importantly, the invasion defect in autophagy-deficient cells is completely rescued upon treatment with conditioned media from autophagy-competent counterparts, indicating that intact autophagy is required for the elaboration of secreted pro-invasive factors. In support, we identify the pro-invasive cytokine interleukin-6 (IL6) as one of the critical factors whose secretion is ATG dependent. Upon ATG knockdown, Ras-transformed cells fail to secrete IL6 into the conditioned media, although both IL6 transcription and translation remain intact. Moreover, function-blocking studies and rescue experiments using recombinant IL6 substantiate that this cytokine is both necessary and sufficient to restore invasion in autophagy-deficient cells. In addition to IL6, autophagy-defective cells exhibit reduced levels of other pro-invasive molecules, including Wnt5a and matrix metalloproteinase 2 (MMP2). Addition of Wnt5a partially rescues the invasion defect in autophagy depleted H-Ras<sup>V12</sup> cells, while pharmacological MMP-2 inhibition potently suppresses invasion. Overall, these results support that autophagy mediates the coordinate production of multiple secreted factors that favor invasion in oncogenic epithelial cells. They also point to a broader role for autophagy in carcinoma progression, namely facilitating invasion during dissemination and metastasis.

8

**GATA3 suppresses metastasis, promotes differentiation and modulates the tumor microenvironment by regulating microRNA-29b expression.**

*J. Chou<sup>1</sup>, J. Lin<sup>1</sup>, A. Brenot<sup>1</sup>, J-W. Kim<sup>1</sup>, S. Provot<sup>1</sup>, Z. Werb<sup>1</sup>; <sup>1</sup>Anatomy, Univ. of California, San Francisco, San Francisco, CA*

Despite advances in our understanding of breast cancer, patients with metastatic disease have poor prognoses. GATA3 is a transcription factor that specifies and maintains mammary luminal epithelial cell fate, and its expression is lost during breast cancer progression. Indeed, low GATA3 expression correlates with poor prognosis in human patients. Here, using human and mouse breast cancer cells, we show that GATA3 promotes differentiation, suppresses metastasis and alters the tumor microenvironment by inducing miR-29b expression. Consistent with miR-29b being downstream of GATA3, miR-29b is enriched in better prognostic, luminal breast cancers and increases luminal gene expression. Mechanistically, miR-29b inhibits metastasis by directly targeting a network of pro-metastatic regulators involved in angiogenesis, collagen remodeling and extracellular matrix proteolysis, including *VEGF*, *ANGPTL4*, *PDGF*, *LOX* and *MMP9*. In addition, miR-29b targets *TGFB*, thereby indirectly regulating epithelial plasticity. Loss of miR-29b, even in GATA3-expressing cells, increases metastasis and promotes a mesenchymal phenotype. This discovery that regulating tumor microenvironmental genes and differentiation through a GATA3-miR-29b axis inhibits cancer metastasis opens up new possibilities for therapeutic intervention in breast cancer.

9

**aPKC iota/lambda regulates Hh signaling during basal cell carcinoma growth.**

*S. X. Atwood<sup>1</sup>, M. Li<sup>1</sup>, J. Y. Tang<sup>1</sup>, A. E. Oro<sup>1</sup>; <sup>1</sup>Dermatology, Stanford University School of Medicine, Stanford, CA*

Basal cell carcinoma (BCC) initiation and expansion requires high levels of Hedgehog (Hh) signaling. While Smoothed (Smo) inhibitors are effective, early tumor resistance illustrates the

need for additional downstream targets for therapy. Here we identify atypical Protein Kinase C  $\iota/\lambda$  (aPKC) as a novel BCC oncogene essential for Hh signaling. Genetic knockdown using shRNA against aPKC, or pharmacological inhibition of aPKC, inhibits proliferation, Hh signaling, and ciliogenesis of the murine BCC cell line ASZ001. Genome-wide transcriptome analysis of BCC cells reveals pharmacological inhibition of aPKC or Smo target similar pathways. aPKC is a Hh target gene that is overexpressed in mouse and human BCCs and functions downstream of Smo to bind and phosphorylate Gli1, resulting in maximal DNA binding and Hh activation. Consistent with its role in regulating Hh signaling, application of a topical aPKC inhibitor suppresses Hh signaling and tumor growth in primary murine BCC tumors. As acquired drug resistance is a growing problem, we also demonstrate Smo antagonist-resistant BCC cells and human tumors overexpress active aPKC and pharmacological inhibition of aPKC suppresses proliferation. These results demonstrate polarity signaling is critical for Hh-dependent processes and suggest aPKC may be a new therapeutic target for the treatment of naïve and resistant BCCs.

10

### **BRAF<sup>V600E</sup> and PI3'-kinase signaling pathways cooperate to regulate protein translation in human melanoma cells.**

*J. M. Silva<sup>1</sup>, C. Bulman<sup>1</sup>, M. McMahon<sup>1</sup>; <sup>1</sup>Helen Diller Family Comprehensive Cancer Center and Department of Cellular and Molecular Pharmacology, University of California, San Francisco, San Francisco, CA*

The most common genetic alteration in metastatic melanoma is a T1799A transversion that encodes BRAF<sup>V600E</sup> resulting in the constitutive activation of the BRAF→MEK→ERK MAP kinase pathway. In many cases, the conversion of BRAF<sup>V600E</sup> expressing melanocytes to melanoma cells also requires activation of the PI3'-kinase signaling pathway, which can occur through the silencing of the tumor suppressor PTEN, a PI3'-lipid phosphatase. To explore the mechanisms of cooperation between the BRAF<sup>V600E</sup> and PI3'-kinase signaling pathways, we applied pharmacological inhibitors of each pathway to BRAF<sup>V600E</sup> expressing human melanoma-derived cell lines. Our data demonstrated that blockade of BRAF<sup>V600E</sup>→MEK→ERK signaling inhibited the phosphorylation of the cap-dependent translational regulators, p70<sup>S6K</sup>, ribosomal protein S6 (rpS6), and 4EBP1, whereas inhibition of PI3'-kinase only suppressed rpS6 and 4EBP1 phosphorylation. In addition, blockade of BRAF<sup>V600E</sup>→MEK→ERK or PI3'-kinase also led to the inhibition of melanoma cell proliferation. Moreover, simultaneous inhibition of both BRAF<sup>V600E</sup> and PI3'-kinase signaling showed that these two pathways cooperate to regulate protein synthesis through mTORC1-dependent effects on rpS6 and 4EBP1. However, pharmacological inhibition of the downstream PI3'-kinase effector, AKT, only had modest effects on cell growth and p70<sup>S6K</sup>, rpS6, or 4EBP1 phosphorylation, even in melanoma cells that contain mutated or amplified AKT. Taken together, these data suggest that BRAF<sup>V600E</sup> and PI3'-kinase cooperate to regulate melanoma proliferation and protein translation independent of AKT activation and combined targeting of BRAF<sup>V600E</sup> and PI3'-kinase signaling may help to enhance the therapeutic efficacy in patients with mutations that activate both of these pathways.

11

### **Widespread potential for growth factor-driven resistance to anti-cancer kinase inhibitors.**

*J. Settleman<sup>1</sup>, T. Wilson<sup>1</sup>; <sup>1</sup>Genentech, South San Francisco, CA*

Mutationally-activated kinases, including EGFR, HER2, ALK, ABL, PDGFR, c-KIT, and BRAF, define a clinically validated class of targets for cancer drug therapy. However, the efficacy of kinase inhibitors in patients whose tumors harbor such alleles is invariably limited by innate or acquired drug resistance. As molecular mechanisms of resistance have begun to be elucidated,

a recurrent theme is the engagement of survival signals redundant to those transduced by the targeted oncogenic kinase. Cancer cells typically express multiple receptor tyrosine kinases (RTKs), and many of these can potentially mediate signals that converge on common and critical downstream cell survival effectors - most notably, PI-3 kinase (PI3K) and MAP kinase (MAPK). Consequently, a change in the production or availability of ligands for such RTKs, either through autocrine tumor cell production or paracrine contribution by tumor stroma, could confer resistance to inhibitors of an oncogenic kinase with a similar downstream signaling output. Indeed, using a large panel of kinase-“addicted” cancer cell lines, we found that the vast majority of such cells can be “rescued” from drug sensitivity by simply exposing them to one or more RTK ligands that engage redundant survival effectors. Among the findings with immediate clinical implications was the observation that hepatocyte growth factor (HGF), which is widely expressed in tumour stroma, confers resistance to the BRAF inhibitor PLX4032 in BRAF mutant melanoma cells, and to the HER2 kinase inhibitor lapatinib in HER2 amplified breast cancer cells. These observations highlight the extensive redundancy of RTK-transduced signalling in cancer cells and the potentially broad role of widely expressed RTK ligands in both innate and acquired resistance to drugs targeting oncogenic kinases.

## Minisymposium 2: Cell Mechanics and Intermediate Filaments

12

### From isolated filaments to polymer-bundles in cells.

S. Koester<sup>1</sup>; <sup>1</sup>Institute for X-Ray Physics, Georg-August-University Goettingen, Goettingen, Germany

The polymeric nature of intermediate filaments (IF) leads to a great variety of intracellular structures which determine mechanical properties and thereby the diverse cytoskeletal functions. In order to understand the physical basis of the phenomena that are observed in cells, we combine *in vitro* experiments involving purified protein with cell studies.

In a bottom-up approach, the mechanical rigidity of individual IFs, characterized by their persistence length, is measured while taking into account confinement effects which cellular components encounter *in vivo*. In a cell, however, the situation is more complex since the individual IFs form networks of bundles and thereby interactions within and between such supramolecular assemblies have to be taken into account. The structure of the bundles is assessed by novel X-ray nanodiffraction methods while the dynamics are captured by fluorescence life-cell imaging. All the above mentioned experiments are performed in specifically tailored microfluidic sample environments. By this approach we are able to mimic and precisely control close-to-physiological conditions

13

### The effect of small heat shock proteins on intermediate filament networks.

J. Kayser<sup>1</sup>, M. Haslbeck<sup>2</sup>, H. Grabmayr<sup>1</sup>, J. Buchner<sup>2</sup>, H. Herrmann<sup>3</sup>, A. R. Bausch<sup>1</sup>; <sup>1</sup>Physics Department, Technische Universität München, Garching, Germany, <sup>2</sup>Department of Chemistry, Technische Universität München, Garching, Germany, <sup>3</sup>Deutsches Krebsforschungszentrum, Heidelberg, Germany

Despite their importance and abundance, very little is known about the physics of intermediate filaments. The largest subgroup of the intermediate filament protein family comprises keratins, with 28 type I (acidic) and 26 type II (basic) keratins. Their principal assembly subunit is a heterodimeric coiled-coil complex of one acidic and one basic keratin. Due to the antiparallel

fashion in which these dimers connect to tetrameric complexes, the basic module for filament assembly, the resulting filaments are apolar and exhibit a surprising degree of dynamics and restructuring within cells. While the assembly kinetics in the early stages of filament assembly has been addressed, their growth and association into filamentous networks is still an enigmatic process. By in vitro studies with reconstituted 8/18 keratins, we demonstrate an inherent tendency to interact with each other under physiological salt conditions. The structure of the resulting network is determined by the competition of filament elongation and lateral association to bundles. Small heat shock proteins modulate the association kinetics and cause a drastic alteration of network structure and morphology. This seems to be an essential tool for cells to regulate the organization of their intermediate filament cytoskeleton.

14

**Vimentin dynamics and microtubule crosstalk during fibroblast migration.**

*J. D. Tytell<sup>1</sup>, L. Ding<sup>1</sup>, N. Costigliola<sup>1</sup>, J-H. Su<sup>1</sup>, G. Danuser<sup>1</sup>; <sup>1</sup>Cell Biology, Harvard Medical School, Boston, MA*

Overexpression of the intermediate filament protein vimentin is a key biomarker for metastasis. Conversely, fibroblasts lacking vimentin expression are defective in wound healing and in maintaining persistent, directional migration. These data suggest that vimentin might play an important role in regulating cell migration. However, very few studies have addressed the dynamics and function of vimentin polymers in migrating cells. One clue to vimentin's role in migration comes from its interactions with microtubules, another cytoskeletal polymer that establishes and maintains cell polarity. It has been documented that vimentin assembly depends on microtubules and microtubule dependent motor proteins. However, whether vimentin affects microtubule organization and dynamics in migrating cells is unknown. To address these questions, we investigated vimentin dynamics in randomly migrating fibroblasts expressing mEmerald-Vimentin. We found that vimentin is a highly dynamic filament on a slightly longer time scale than microtubules. Vimentin filaments are oriented parallel to the direction of migration, are recruited quickly into the leading edges of migrating cells and dynamically cycle from the exterior to the interior of the cells even in stationary cells. Therefore, contrary to previous belief, vimentin is a highly dynamic polymer that changes structure concurrent with cell movement. The fact that vimentin localizes dynamically to the same places as microtubules during migration but on a slightly longer timescale suggested that vimentin might help stabilize the direction of movement perhaps by feeding back to microtubules. In order to analyze the dynamics of vimentin and microtubules simultaneously, we tracked microtubule growth by following microtubule plus ends over time. We find that a subset of dynamic microtubules follow along vimentin tracks and another subset follow vimentin towards the leading edge and then continue past the vimentin track into the leading edge of cells. From these data, we hypothesize a template model whereby microtubules enter the leading edge first and recruit vimentin fibers, which in turn serve as a support for the more dynamic microtubules to continue growth in that direction, thus establishing a positive feedback loop leading to increased memory of cell polarity. Without vimentin, microtubules would still establish polarity but lose polarity more rapidly leading to decrease in migration in a given direction.

15

**Cell stiffness correlates with cell volume.**

*M. Guo<sup>1</sup>, E. Zhou<sup>2</sup>, F. Mackintosh<sup>3</sup>, J. Fredberg<sup>2</sup>, J. Lippincott-Schwartz<sup>4</sup>, D. Weitz<sup>1</sup>; <sup>1</sup>SEAS, Harvard University, Cambridge, MA, <sup>2</sup>Medical School, Harvard University, Cambridge, MA, <sup>3</sup>Physics, Vrije Universiteit, Amsterdam, Netherlands, <sup>4</sup>Cell Biology and Metabolism, National Institutes of Health, Bethesda, MD*

Cells usually have a certain size, and their size has been shown to be correlated to gene expression across species. There are careful studies about standard cell sizes of different species, as well as cell size changes during stages of the cell cycle. Furthermore, people have shown that cells change their spreading area, stiffness, gene expression and even stem cell fate when grown on substrates of varying stiffness. However, whether cell size changes for the same cell type under varying micromechanical environments, and whether this is related to the observed phenomenological changes is not known. Here we show that height and volume of single adherent cells decrease when grown on a stiffer 2D substrate, while spreading area increases. When cell spreading area is confined by micropatterning on stiff substrate, we find cell volume is dependent inversely on their spreading area. We further measure cell stiffness with optical magnetic twisting cytometry. By controlling their volume in three different ways – varying substrate stiffness, cell spreading areas, and osmotic pressure in the medium – we find that cell stiffness correlates with cell volume but not substrate stiffness. Cells can be soft on a stiff substrate by changing only the spreading area; they can be stiff on a soft substrate by increasing osmotic pressure. Furthermore, we show that vimentin may be involved in cellular volume regulation.

16

**Lamin mutations that cause muscle defects disturb nuclear mechanics and nucleo-cytoskeletal coupling**

*M. Zwerger<sup>1</sup>, D. E. Jaalouk<sup>2</sup>, M. Lombardi<sup>3</sup>, M. Mauermann<sup>4</sup>, H. Herrmann<sup>4</sup>, L. L. Wallrath<sup>5</sup>, J. Lammerding<sup>6</sup>; <sup>1</sup>Department of Biochemistry, University of Zurich, Zurich, Switzerland, <sup>2</sup>American University of Beirut, Beirut, Lebanon, <sup>3</sup>Brigham and Women's Hospital, Boston, MA, <sup>4</sup>German Cancer Research Institute, Heidelberg, Germany, <sup>5</sup>University of Iowa, Iowa City, IA, <sup>6</sup>Biomedical Engineering/Weill Institute for Cell and Molecular Biology, Cornell University, Ithaca, NY*

**Objective:** Mutations in the *LMNA* gene that encodes the nuclear envelope proteins lamin A and C cause a plethora of human diseases (laminopathies), including muscular dystrophies, cardiomyopathies, and familial partial lipodystrophy. It remains unclear how mutations in a single gene that is ubiquitously expressed result in such often tissue-specific diseases. Since lamins A and C are the main contributors to nuclear stiffness, we hypothesized that lamin mutations associated with muscular phenotypes could impair the structural properties of the nuclear lamin network, weakening the nuclear integrity and resulting in cells more susceptible to mechanical stress.

**Methods:** We measured nuclear stiffness in fibroblasts derived from patients with diverse laminopathies and in lamin A/C-deficient mouse embryonic fibroblasts (MEFs) engineered to stably express physiological levels of specific lamin A mutants. In a subset of cells, we also probed nucleo-cytoskeletal coupling with a custom-developed microneedle assay. To address the effect of diverse lamin mutations on the ultrastructural level, we observed the *in vitro* assembly of purified mutant and wild-type lamins. To assess the *in vivo* effect of lamin mutations in muscle, we measured nuclear stiffness in body wall muscle of *Drosophila melanogaster* models of muscle laminopathies.

**Results:** Patient fibroblasts carrying *LMNA* mutations associated with muscular dystrophies had ‘softer’ nuclei than cells from healthy controls. In contrast, fibroblasts from lipodystrophy patients had normal nuclear mechanics. Extending our studies to MEFs expressing a panel of lamin A mutations, we found that four of the 15 lamin A mutations tested caused decreased nuclear stiffness. Importantly, all four mutations were associated with laminopathies affecting muscle tissue, whereas mutations linked to lipodystrophy had no effect on the structural function of lamin A. Of note, most mutations linked to muscular disease also showed disturbed nucleo-cytoskeletal coupling. Extending these studies to muscle tissue, we found that mutant lamins alter the stiffness of nuclei in isolated *Drosophila* body wall muscle, where nucleo-cytoskeletal coupling is also perturbed.

**Conclusions:** *LMNA* mutations associated with muscular laminopathies can cause impaired nuclear mechanics, which is consistent with increased cellular sensitivity to mechanical stress that could contribute to the muscle-specific phenotypes associated with the laminopathies. In conclusion, our results demonstrate the importance of lamins A and C on nuclear mechanics in laminopathies, but also indicate that additional factors such as altered nucleo-cytoskeletal coupling influence the disease outcome.

17

### The nuclear mechanostat that scales with tissue stiffness and amplifies lineage: lamin-A,C.

J. Swift<sup>1</sup>, I. Ivanovska<sup>1</sup>, T. Harada<sup>1</sup>, J. Pinter<sup>2</sup>, A. Buxboim<sup>1</sup>, J-W. Shin<sup>1</sup>, M. Tewar<sup>2</sup>, D. W. Speicher<sup>3</sup>, D. E. Discher<sup>1</sup>; <sup>1</sup>University of Pennsylvania, Philadelphia, PA, <sup>2</sup>Bioengineering, University of Pennsylvania, Philadelphia, PA, <sup>3</sup>Wistar Institute, Philadelphia, PA

Tissue can be soft like brain, stiff like muscle, or rigid like bone. Proteomic profiling of human and mouse tissues and cells reveals that the nucleoskeletal protein lamin-A,C scales with various collagens and with tissue microelasticity, E. Among the many cell structure and nuclear components quantified here, lamin-A,C acts most clearly as a “mechanostat” in increasing as  $\sim E^{0.7}$ , whereas B-type lamins are nearly constant. Lamin-A,C dominates in stiff tissues and has been implicated in aging and diseases that impact muscle, bone, and fat but rarely brain or marrow, and nuclei in stiff tissue cells also prove much stiffer than nuclei from softer tissues. Mesenchymal stem cell differentiation *in vitro* further shows that lamin-A,C amplifies lineage signals from matrix, with low lamin-A,C favoring a soft tissue fate and high levels favoring stiff tissue. Regulation of lamin-A,C occurs at multiple levels, with conformational changes in isolated nuclei revealing its direct response to stress. Systematic relations thus exist between tissue stress and stiffness and the nucleus.

## Minisymposium 3: Cell Migration and Motility

18

**Olfactory microvillous neurons arise from the neural crest in a Sox10-dependent manner.**A. Saxena<sup>1</sup>, B. N. Peng<sup>1</sup>, M. E. Bronner<sup>1</sup>; <sup>1</sup>Biology, Caltech, Pasadena, CA

The cranial ganglia and sense organs (nose, ears) arise from two cell types: neural crest cells and ectodermal placodes. Both undergo cell migrations and/or dynamic cell rearrangements to reach their final configuration. Interestingly, most cranial peripheral neurons are derived from the placodes, with glia cells coming from the neural crest. In the olfactory system, the classical view has been that the olfactory placode forms all olfactory sensory neurons. In contrast, here we show that cranial neural crest cells migrating from the midbrain/rostral forebrain-level neural tube are the primary source of microvillous sensory neurons within the olfactory epithelium.

Using photoconversion-based fate mapping and live cell tracking coupled with laser ablation in zebrafish embryos, we followed neural crest precursors as they migrated from the neural tube to surround the olfactory epithelium where they condensed to form the nasal cavity. Eventually, a subset of these cells, coexpressing Sox10 protein and a neurogenin1 reporter, ingressed into the olfactory epithelium, intercalated amongst placode-derived cells, and differentiated into microvillous sensory neurons. Loss-of-function analysis revealed a critical role for Sox10 in microvillous neurogenesis. Taken together, these findings demonstrate for the first time a cranial neural crest migratory contribution to olfactory sensory neurons and provide important insights into the assembly of the nascent olfactory system.

19

**Coordinate Control of Core EMT Regulatory Factor function is Essential for Migratory and Invasive Behavior.**C. LaBonne<sup>1</sup>; <sup>1</sup>Department of Molecular Biosciences, Robert H. Lurie Comprehensive Cancer Center, Northwestern University, Evanston, IL

A small group of core transcription factors, including Twist, Snail, Slug, and Sip1, control epithelial-mesenchymal transitions (EMTs) and motility during both embryonic development and tumor metastasis. Little is known, however, about how these factors are coordinately regulated in order to mediate the requisite behavioral and fate changes in a context dependent manner. We recently showed that a key mechanism for regulating Snail protein function during neural crest development is through modulating its stability. We have extended these studies to show that the stability of Twist and Sip1 is also regulated by the ubiquitin-proteasome system, and remarkably, that the same E3 ubiquitin ligase that regulates Snail, partner of paired (Ppa), also controls the function of these other core EMT factors. This demonstrates that a common regulatory mechanism has evolved to coordinately control the function of these structurally diverse proteins as they direct migratory and invasive behavior.

Building upon these important findings, we present evidence that members of the group of core EMT regulatory factors physically interact with one another to control each others function, and that their activities are coordinately regulated by a key extra-cellular signaling pathway. Collectively, these provocative findings suggest that the factors that regulate developmental and pathological EMTs and neural crest migration constitute a molecular machine whose activities are tuned temporally and spatially to ensure their proper, coordinated, function. We report a small molecule inhibitor that can be used to intervene in this coordinated regulation in a highly temporally specific manner to allow novel insights into the control of migratory behavior.

20

### **Role of inflammatory regulator NLRP10-like on macrophage and neutrophil migration behaviors during microglia development in zebrafish.**

*C. E. Shiau<sup>1</sup>, W. S. Talbot<sup>1</sup>; <sup>1</sup>Stanford University School of Medicine, Stanford, CA*

Nod-like receptor (NLR) genes have essential functions in innate immunity as intracellular pattern recognition receptors and mediators of inflammation. Here we report a characterization of a mutation, st73, that causes a loss of CNS-resident macrophages called microglia in zebrafish, but no overt general morphological phenotypes. The st73 lesion introduces a premature stop codon at the beginning of a novel member of the NLR gene family that lacks leucine rich repeats, which are present in all human NLR family members except NLRP10. Based on this shared domain structure, we tentatively named the zebrafish gene NLRP10-like. Despite the absence of microglia in larvae, we found that microglia precursor cells (primitive macrophages) are present in mutants. In the mutants, primitive macrophages are anomalously large and rounded, and they lack the ability to migrate into the brain to form microglia. Furthermore, we also uncovered striking defects in the other innate immune cells, the neutrophils, that are indicative of systemic inflammation. Contrary to the migration-deficient macrophages in the st73 mutants, we found an upsurge of highly motile neutrophils in circulation, on the yolk, as well as inside the brain, which is normally devoid of neutrophils. High levels of mRNA encoding pro-inflammatory cytokines, including interleukin-1 beta and tnf-alpha, confirms the presence of inflammation in the mutants. Taken together, our data implicate NLRP10-like as an endogenous repressor of inflammation, and also suggest that inflammation can both promote and inhibit migration of innate leukocytes depending on the cellular context.

21

### **A GEF/GAP modulator defines locomotory and invasive protrusion polarity in migrating tumor cells.**

*J. Bravo-Cordero<sup>1,2</sup>, V. Sharma<sup>1,2</sup>, M. Roh-Johnson<sup>1,2</sup>, X. Chen<sup>1</sup>, R. Eddy<sup>1</sup>, J. S. Condeelis<sup>1,2</sup>, L. Hodgson<sup>1,2</sup>; <sup>1</sup>Anatomy and Structural Biology, Albert Einstein College of Medicine of Yeshiva University, Bronx, NY, <sup>2</sup>Gruss Lipper Biophotonics Center, Bronx, NY*

Locomotory and invasive protrusions are essential first steps that precede tumor cell invasion and migration. Spatial control of actin polymerization is necessary to achieve directional protrusion during cell migration. By using a RhoC biosensor we show that the localization of RhoC activity is crucial to maintain actin polymerization asymmetry in order to sculpt the amplitude and the shape of locomotory and invasive protrusions. This spatial localization of RhoC activity is necessary to place active cofilin right at the leading edge of locomotory protrusions by phosphorylating cofilin behind it. Here we show that RhoC activation at leading edge protrusions is regulated by a p190RhoGEF/p190RhoGAP module that spatially restricts actin barbed end distribution to shape lamellipodia during protrusion. The same mechanism is used to shape invadopodia into needle shaped protrusions. This mechanism reveals a dynamic plasticity in the distribution and amplitude of barbed ends, which can be modulated by fine-tuning RhoC activity by upstream GEFs and GAPs for directed cell motility. p190RhoGEF/p190RhoGAP are able to dynamically tune the location and amplitude of actin barbed ends in protrusions through direct effects on RhoC/Cofilin pathway. In addition, our data show that RhoC is an important component of the cellular steering-mechanism during chemotaxis by defining where actin polymerization takes place in response to external signals.

22

**Focal adhesion kinase (FAK) reactivates endocytically recycled integrin to allow the reassembly of focal adhesions.**

G. P. Nader<sup>1</sup>, E. Ezratty<sup>1,2</sup>, G. Gundersen<sup>1</sup>; <sup>1</sup>Columbia University, New York, NY, <sup>2</sup>Rockefeller University, New York, NY

Integrin recycling and focal adhesion (FA) turnover are key events in cell migration. Yet, the relationship between integrin recycling and focal adhesion turnover is not well-defined. In particular, how the activation state of the integrin is controlled during endocytic recycling and reassembly into FAs is unknown. Here, we used the synchronous disassembly of FAs and accompanying integrin endocytosis triggered by microtubule regrowth (Ezratty et al., 2009; Chao & Kunz, 2009) as a model system to understand factors involved in the recycling of integrins and their reassembly into FAs upon return to the cell surface. In 3T3 fibroblasts, FA reassembly began 30 min after microtubule-induced FA disassembly and correlated with a return of endocytosed  $\alpha 5 \beta 1$  integrin to the cell surface.  $\alpha 5 \beta 1$  integrin was detected in both Rab5- and Rab11-positive endosomes and dominant negative Rab5 and Rab11 blocked FA reassembly. Rab11 knockdown also blocked FA reassembly and the return of surface integrin. Focal adhesion kinase (FAK) was detected in the Rab11 recycling endosomes and FAK mutants FAK-Y397F (autophosphorylation/Src binding site) and FAK-K454R (kinase dead) rescued FA disassembly but not reassembly in FAK<sup>-/-</sup> cells, showing that FAK kinase activity is critical for FA reassembly but not for disassembly. Src associates with FAK-pY397 and has been implicated in FA reassembly (Yeo, et al., 2006). We found that Src was transiently associated with newly formed FAs and that both Src inhibitor (PP2) and FAK inhibitor (PF228) reversely blocked FA reassembly (without affecting disassembly). Interestingly, PP2, but not PF228 blocked the recycling of integrins to the cell surface, suggesting that Src functioned in returning integrin to the cell surface, but FAK functioned only after the return. To test whether FAK functioned in integrin activation following integrin recycling, we used Mn<sup>2+</sup> to artificially activate integrins in FAK and Src inhibited cells. Mn<sup>2+</sup> stimulated FA reassembly only in cells treated with PF228, showing that integrin activation bypasses the requirement for FAK during FA reassembly. Similarly, Mn<sup>2+</sup> rescued cell adhesion to fibronectin in FAK inhibited but not Src inhibited cells. These results provide the first evidence that FAK and Src kinase activities contribute to FA reassembly by controlling recycling and reactivation of endocytosed integrin. The need for reactivation of recycled integrins suggests that only unengaged integrin is returned to the cell front to ensure that integrin will be available for establishing new FAs during cell migration.

23

**LOV-TRAP: A broadly applicable, genetically encoded system to control protein activity with light through controlled sequestration at membranes.**

H. Wang<sup>1</sup>, A. Winkler<sup>2</sup>, E. Hartmann<sup>2</sup>, R. A. Hallett<sup>3</sup>, B. Kuhlman<sup>3</sup>, I. Schlichting<sup>2</sup>, R. Liu<sup>4</sup>, K. M. Hahn<sup>1</sup>; <sup>1</sup>Department of Pharmacology, University of North Carolina Chapel Hill, Chapel Hill, NC, <sup>2</sup>Department of Biomolecular Mechanisms, Max Planck Institute for Medical Research, Heidelberg, Germany, <sup>3</sup>Department of Biochemistry and Biophysics, University of North Carolina Chapel Hill, Chapel Hill, NC, <sup>4</sup>Eshelman School of Pharmacy and Carolina Center for Genome Sciences, University of North Carolina Chapel Hill, Chapel Hill, NC

The kinetics and subcellular localization of protein activity is precisely controlled to regulate protein interactions and to create specific signaling networks. To study this important aspect of cell signaling, genetically encoded methods are being developed to control protein activity with light in living cells and animals (1-4). Here we describe a new approach that promises to be broadly applicable and is simple to apply. Through an in vitro selection from a protein domain library with more than 10<sup>13</sup> unique sequences using mRNA display, we developed Zdark, a

small protein based on the Z domain (5) that binds only to the dark state of the LOV2 domain from *Avena sativa* phototropin (Figure 1). The LOV2 domain undergoes a large, reversible conformational change induced by light between 400 and 500 nm. Zdark binds to the dark state of LOV2 with a  $K_d$  of  $\sim 100$ nM, but shows no detectable binding to the lit state. In our new method (dubbed LOV-TRAP for LOV trapping and release of active protein) the LOV domain is anchored at an intracellular membrane (to date the mitochondrial and plasma membranes) and the protein of interest is fused to Zdark. In the dark, the Zdark-protein fusion is sequestered at a membrane where it cannot interact with its targets (here the mitochondria). Upon irradiation, LOV binding of the Zdark-protein conjugate breaks down, releasing the Zdark-protein fusion. Release is rapid ( $< 0.5$  secs) and reversible. We have demonstrated this for repeated light/dark cycles and have introduced mutations to vary the kinetics of return to the dark state. To date, we have completed caging of VAV2, Rac1 and RhoA. Progress with other targets will be described, as will the use of the approach to control protein dimerization. Crystal structure and NMR data will be presented to illuminate the Zdark-LOV interaction. Applications of LOV-TRAP in studies of cell motility will be described.

## **Minisymposium 4: Integrated Research and Teaching and Its Benefits to Faculty and Students**

24

### **Integrated Introductory Science Curriculum for Undergraduates at Princeton.**

*D. Botstein<sup>1</sup>; <sup>1</sup>Genomics and Molecular Biology, Princeton University, Princeton, NJ*

For the past eight years, we have offered a series of courses, taken in the freshman and sophomore years that provide students with strong quantitative preparation for a major in any scientific discipline. The program is designed to help students retain the connections between their ultimate choice of major and the other disciplines. The curriculum is founded on the expectation that much of the most important science of the future, though based on the classical disciplines, will lie in areas that span two or more of them. The curriculum covers the core material of introductory physics, chemistry, biology (genetics and biochemistry), and computer science, all in an integrated manner in the equivalent of six semester courses taken in the first two years of college. The central role of mathematics as a universal language of science is emphasized throughout. The integrated science program is proving to be excellent preparation for a very broad range of majors (and ultimately, careers). About  $\frac{1}{2}$  the students major in some area of biology, about one-third in physics or computer science, with the remainder scattered over the remaining scientific disciplines and engineering. The curriculum is especially valuable for students interested in bridging the traditional barriers between the biological and the physical sciences.

25

**Beyond the cookbook: a rigorous, research-based lab course for all.**

*T. Stearns<sup>1</sup>, D. Hekmat-Scafe<sup>2</sup>, P. Seawell<sup>2</sup>, S. Brownell<sup>2</sup>, M. Kloser<sup>3</sup>, M. Cyert<sup>2</sup>; <sup>1</sup>Depts. of Biology and Genetics, Stanford University, Stanford, CA, <sup>2</sup>Biology, Stanford, Stanford, CA, <sup>3</sup>Education, Stanford, Stanford, CA*

Introductory laboratory courses at large research universities often suffer from a "cookbook" methodology, insufficient focus on the scientific method, and lack of faculty involvement, all of which reinforce the perceived schism between research and teaching. We have undertaken a complete revision of the Stanford University introductory biology laboratory course, taken by 250 students per year, with the aim of providing students a rigorous, research-based experience that addresses an important question and uses modern research tools.

Based on a previous experience with a lab course of more limited size, we assessed that the target sophomore-level students are best engaged by research problems relevant to human biology, but are best able to accomplish research using a model organism. We chose to use yeast cells to assess the phenotypic defects of mutant alleles of the human p53 tumor suppressor derived from tumors. Over the 10-week quarter, students work as pairs in small lab sections. They assess the location of their mutation on the p53 structure and make testable hypothesis about the possible defect based on p53-related background information. The students assay transcriptional activation of reporter genes in yeast, test the level of their p53 mutant protein, assay DNA binding in vitro, and evaluate nuclear localization. In some experiments students can customize the assay for their mutant (e.g. incubation temperature, transcriptional reporter). In all experiments, the instructors stress the importance of controls and the power of comparing data with other students working on the same p53 mutant allele. The course culminated with a group poster session, again stressing interaction and discussion.

Although there is great variability in experimental skill levels, most students were able to generate data that, when considered in aggregate with all groups working on the same allele, led to a consistent model for the defect associated with that allele. We plan to engage course students in summer research projects to generate complete and validated data that can be submitted for publication.

Revision of a large, existing laboratory course presents particular challenges. We developed the course over a two-year pilot period, run concurrently with the existing course, with a smaller number of students. We used assessment during the pilot period to direct changes to the course. Most satisfyingly, students in the pilot course identified aspects of authentic research such as data analysis and analytical thinking as the most important aspect of the course at the end of the quarter, concepts that were largely missing from the previous course.

26

**The Genomics Education Partnership: An undergraduate team research experience.**

*M. J. Wolyniak<sup>1</sup>, K. L. Clase<sup>2</sup>, A. L. Goodman<sup>3</sup>, W. Leung<sup>4</sup>, D. Lopatto<sup>5</sup>, G. C. Regisford<sup>6</sup>, J. A. Roecklein-Canfield<sup>7</sup>, A. G. Rosenwald<sup>8</sup>, C. D. Shaffer<sup>4</sup>, A. Sreenivasan<sup>9</sup>, S. C. Elgin<sup>4</sup>;*  
<sup>1</sup>Hampden-Sydney College, Hampden-Sydney, VA, <sup>2</sup>Purdue University, West Lafayette, IN, <sup>3</sup>California Polytechnic State University, San Luis Obispo, CA, <sup>4</sup>Washington University, St. Louis, MO, <sup>5</sup>Grinnell College, Grinnell, IA, <sup>6</sup>Prairie View A&M University, Prairie View, TX, <sup>7</sup>Simmons College, Boston, MA, <sup>8</sup>Georgetown University, Washington, DC, <sup>9</sup>California State University-Monterey Bay, Seaside, CA

Research into how students learn science has confirmed that inquiry-driven research experiences that address important biological questions are more successful at producing scientifically literate students with good critical thinking skills than traditional content-driven laboratory classes. The Genomics Education Partnership (GEP), a consortium of faculty from over 90 colleges and universities with different characteristics and missions, uses comparative

genomics to engage students in research within the regular academic year. GEP curriculum has been adapted to many different settings, from a short module in a genetics course to the core of a laboratory course. The current GEP research project focuses on the evolution of the Muller F element (a largely heterochromatic domain) in five *Drosophila* species (*D. melanogaster*, *D. erecta*, *D. ananassae*, *D. grimshawi* and *D. mojavensis*). GEP undergraduates work to improve the draft genomic sequences and/or annotate these improved sequences. More than 4.2 million bases of draft sequence have been improved and hundreds of gene models produced using evidence-based manual annotation, leading to student poster presentations and collaborative publications in the scientific literature. The flexibility in the way GEP materials can be used means that each faculty member can adapt the materials in a manner that best suits his or her unique pedagogical goals. Anonymous surveys of GEP faculty and students show a high level of satisfaction with this active-learning approach. GEP students show similar self-reported gains in scientific problem solving and data assessment when compared to students who have participated in traditional summer research, as well as comprehension gains on a quiz about genes and genomes. The GEP pedagogical model offers an exciting opportunity for institutions with limited genomics resources and/or expertise to engage undergraduates in a research experience that will more fully prepare them for future careers in the life sciences. We invite additional faculty to join us (no previous training in bioinformatics required; see <http://gep.wustl.edu>; training workshops will be held summer 2013). Supported by HHMI grant # 52005780 to SCRE.

27

### **The flip-side of integrating research and teaching: the research laboratory as a classroom.**

T. A. Frey<sup>1</sup>, L. J. Runyen-Janecky<sup>2</sup>, O. A. Quintero<sup>2</sup>; <sup>1</sup>Department of Biology, Dickinson College, Carlisle, PA, <sup>2</sup>Department of Biology, University of Richmond, Richmond, VA

Undergraduate independent research projects provide opportunities to aid student growth towards the independence required for a professional career. In addition to producing publishable work, the goal of an independent study project is to help students transition from viewing knowledge as something that is provided to realizing that they can participate in the analysis, interpretation, and creation of new knowledge. Just like any other skill, the expertise required to become an effective scientist is learned. However, students accustomed to traditional courses can struggle when faced with less structured experiences like independent study. Even if a student is receiving course credit for an independent project, traditional coursework can seem more important because of the internal checkpoints (exams and assignments) by which a student can easily gauge success. Additionally, since the emphasis for independent research projects is often placed on the actual doing of experiments, students can be left without a proper understanding of the preparation, effort, and “skills away from the bench” required of an effective researcher. Here we describe student-centered approaches designed to aid students in transitioning from traditional coursework to independent research by overlaying a structure onto independent study. Projects are built around a formal syllabus. They also contain specific mechanisms to assess student progress, generating feedback useful in improving the experience for all involved. From the onset of the project, student involvement is key to developing an individualized plan that is tailored to the goals of both mentor and student. Written materials relevant to working as a scientist (such as searching the scientific literature, presenting one’s own research, and keeping a lab notebook) are provided to supplement oral instruction. To introduce students to the idea of external review and accountability, a portion of their final grade comes from an external reviewer. Assessments in the middle and at the end of the experience allow for the students and mentors to revise and improve the project for the next iteration. Student feedback indicates that participants have a realistic understanding of the

complexity of the scientific endeavor, beyond what is necessary to complete their specific experiments. Those that choose to enter graduate programs are well prepared--those that have chosen other careers have developed a skill set that will help them to be successful professionals.

28

**Rising to the challenge of 'Vision and Change in Undergraduate Biology Education'.**

*S. M. Wick<sup>1</sup>, R. Wright<sup>2</sup>, D. Matthes<sup>2</sup>; <sup>1</sup>Plant Biology, University of Minnesota, St. Paul, MN, <sup>2</sup>Genetics, Cell Biology and Development, University of Minnesota, Minneapolis, MN*

In 2009 AAAS published a call for reform in undergraduate biology education based on several guiding recommendations: Integrate Core Concepts and Competencies throughout the Curriculum, Focus on Student-Centered Learning, Promote a Campuswide Commitment to Change, and Engage the Biology Community in the Implementation of Change. The College of Biological Sciences at the University of Minnesota-Twin Cities has established courses and programs to meet several aspects of the recommendations found in the Vision and Change report. We provide coursework that emphasizes student-centered learning, problem solving, team responsibilities, and core concepts and competencies both at a foundational biology and in some upper division courses, including cell biology. Other instructors are noticing the increased preparation and critical thinking skills of students who have participated in student-centered courses, and graduates of these courses report they are better prepared for upper division work, lab research and graduate school than students in traditional lecture courses. We established a series of Conversations on Teaching and Learning as one element of a commitment to creating a community of biology scholars dedicated to improving undergraduate courses and contributing to the teaching and learning literature. We also have begun a Scientific Teaching Program for advanced graduate students and postdocs in biology as a way to introduce them to principles of effective teaching that include classroom diversity, active learning and assessment, as informed by current literature. All participants practice what they have learned by working on a team to create a small instructional module in their sub-discipline. As current or former teaching assistants, they typically recognize the power of this education reform and are eager to put its principles into action as the next generation of biology educators.

29

**A science research network: Analysis of the undergraduate experience.**

*J. J. Thompson<sup>1</sup>, J. B. Glisson<sup>1</sup>, E. L. Dolan<sup>1</sup>; <sup>1</sup>Biochemistry & Molecular Biology, University of Georgia, Athens, GA*

We are studying a network of undergraduate institutions collaborating in biological research to examine the impact of network participation on undergraduate researchers. Specifically, we aim to: (1) identify and characterize the individuals (i.e., "actors") with whom undergraduates interact as they conduct their research; (2) characterize the nature and function of these interactions; and (3) determine the extent to which undergraduates use the network as a bridge to form connections with new individuals in the broader scientific community.

Actors in the network include faculty principal investigators, undergraduates, and postdoctoral researchers. Surveys and interviews are our primary data collection strategies, which are designed to determine with whom undergraduates interact and their motivations for interacting, as well as the strengths, functions, and outcomes of those interactions. For each potential dyad (i.e., pair of people in the network), we asked respondents to report on the existence of interactions, and their perceptions of the importance and influence of each interaction. For the five relationships they indicate as most important, we asked interviewees to report mode,

frequency, and content of the interactions (e.g., technical, intellectual, professional, educational, personal). We also collected network emails, network wiki posts, and other network records, which we will analyze to corroborate or refute inferences made from interview data.

We are conducting a systematic content analysis of interview data and social network analysis of survey data to address the following research questions: (1) What kinds of relationships do undergraduates form and which do they consider the most important or influential? (2) To what degree is networking beyond the lab group or institution viewed as central versus tangential to undergraduates' day-to-day research experience? (3) To what extent do undergraduates' interactions with different actors reflect theoretically predicted variables related to social capital, such as brokerage (serving as a "go between"), cultural capital (demonstrating values or norms within the research group or scientific community), mentorship (forming a relationship toward the undergraduate's professional and personal development), rapport (experiencing an affinity or connection), and reciprocity (engaging in an exchange that reinforces mutual obligation)?

Results from these analyses will serve as a foundation for developing hypotheses of how participating in distributed, collaborative science research influences undergraduate researchers. These results will also lay a foundation for exploring how research networks change, especially from an undergraduate perspective.

## Minisymposium 5: Molecular Motors

30

### RNA on the move: Single molecule reconstitution of *ASH1* mRNA transport by a class V myosin from budding yeast.

*T. E. Sladewski*<sup>1</sup>, *C. S. Bookwalter*<sup>1</sup>, *M-S. Hong*<sup>2</sup>, *K. M. Trybus*<sup>1</sup>; <sup>1</sup>*Department of Molecular Physiology & Biophysics, University of Vermont, Burlington, VT,* <sup>2</sup>*Laboratory of Cell Biology, National Heart, Lung, and Blood Institute, National Institutes of Health, Bethesda, MD*

Myo4p, one of two class V myosins from budding yeast, can continuously transport and asymmetrically localize more than 20 different mRNAs to the bud tip via actin cables. *ASH1*, the most well-studied localizing mRNA, represses mating-type switching in the daughter cell. Here we reconstitute *ASH1* mRNA transport at the single molecule level using TIRF microscopy. We previously showed that when two single-headed Myo4p/She3p motors are recruited by the tetrameric mRNA binding protein She2p, a processive complex is formed (Krementsova et al., JCB 195:631, 2011). She3p is a tightly bound subunit of Myo4p that also binds She2p. Here we increase the complexity of the system by adding Alexa-labeled mRNA cargo to purified motors and She2p near physiological ionic strength (140 mM KCl). At this salt concentration, movement is only seen in the presence of mRNA. Cargo thus stabilizes the ternary complex, which provides a necessary checkpoint to ensure that only cargo-bound motors move processively in the cell. Native *ASH1* mRNA has four different localization elements, or "zipcodes", each of which can bind She2p. To understand why localizing transcripts have multiple zipcodes, we altered zipcode number and type. The most striking difference was an increase in the frequency of motor movement on actin with increased zipcode number, suggesting that a multi-zipcode transcript more effectively recruits a pair of motors. Increasing protein and mRNA concentrations to force zipcode occupancy further enhanced frequency and run length, as expected for motion driven by multiple motors. Metal-shadowed images of motor-mRNA complexes showed as many as eight motor heads (4 dimers) bound to a single native *ASH1* mRNA. These images suggested that the full potential for transport may not be realized on

single actin filaments. A comparison of movement of native *ASH1* mRNA on single filaments versus actin bundles showed this was true: run length and frequency were both significantly higher on actin bundles, which mimic the actin cables found *in vivo*. These studies highlight how building complexity *in vitro*, by using full-length motors coupled to their native cargo, is essential to fully understand at a mechanistic level how these motors function within the cell.

31

### Characterization of dynein by single-molecule investigations *in vivo*.

V. Ananthanarayanan<sup>1</sup>, M. Schattat<sup>1</sup>, S. Vogel<sup>1</sup>, A. Krull<sup>1</sup>, N. Pavin<sup>1,2</sup>, I. Tolic-Norrelykke<sup>1</sup>;  
<sup>1</sup>Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, Germany, <sup>2</sup>Department of Physics, University of Zagreb, Zagreb, Croatia

Cytoplasmic dynein is a motor protein that exerts force on microtubules and in doing so, drives a myriad of intracellular activities including mitotic spindle positioning and chromosome movements in meiotic prophase. To generate these forces, dynein needs to be anchored, with the anchoring sites being typically located at the cell cortex. The key question is: By what mechanism do single dyneins accumulate at sites where they can generate large collective forces? Here, we directly observe single dyneins in fission yeast, which allowed us to identify the main steps of the dynein binding process: (i) from the cytoplasm to the microtubule, and (ii) from the microtubule to the cortical anchors Mcp5. We uncovered that dyneins on the microtubule move, surprisingly, either in a diffusive or a directed manner, with the switch from diffusion to directed movement occurring upon binding of dynein to the cortex. This was further confirmed by abolishing the cortical-binding ability of the anchor (Mcp5-PH $\Delta$ ). We were thus able to force dynein on the microtubule bound to Mcp5-PH $\Delta$  to switch to directed movement, providing further evidence to the idea that dynein is 'activated' upon binding to its anchor. This dual behavior of dynein on the microtubule, together with the two steps of binding, constitute the mechanism by which dyneins find cortical anchors in order to generate large-scale movements in the cell.

32

### Single molecule fluorescence and optical trapping applied to molecular motors: Two can do it better than one.

*P. R. Selvin<sup>1</sup>, M. Tonks-Hoffman<sup>1</sup>, B. H. Blehm<sup>1</sup>, K. M. Trybus<sup>2</sup>, C. L. Berger<sup>2</sup>, T. A. Schroer<sup>3</sup>, A. Yildiz<sup>4</sup>, Y. R. Chemla<sup>1</sup>; <sup>1</sup>Physics Dept., Univ. of Illinois, Urbana-Champaign, Urbana, IL, <sup>2</sup>Department of Molecular Physiology and Biophysics, University of Vermont, Burlington, VT, <sup>3</sup>Department of Biology, Johns Hopkins University, Baltimore, MD, <sup>4</sup>Physics Dept., Univ. of California, Berkeley, Berkeley, CA*

Kinesin and dynein are molecular motors that move in opposite directions on a microtubule. They often act on the same cargo, causing the cargo to frequently switch direction. Whether this back-and-forth motion results from a coordinating complex or from a tug-of-war between the two motors is currently unknown. We have applied single molecule fluorescence to determine that they are undergoing a synergistic tug-of-war. By synergistic, we mean that the combination of the two motors is able to bypass roadblocks along the microtubule. Furthermore, using an in vivo optical trap, and by comparing directional stall forces in vivo and in vitro, we found when cargo is going in the positive microtubule direction, kinesin and dynein are pulling, with the dynein walking backwards. The net stall force equals the stall force of kinesin ( $\approx 7$  pN) minus the stall forces of the number of dyneins ( $1.1 \text{ pN} \times \text{ND}$ , where  $\text{ND} = 0$  to  $6$ ). When moving in the negative microtubule direction, the stall force is just equal to a multiple of dynein's stall force ( $1.1 \text{ pN} \times \text{ND}$ ), implying that kinesin has fallen off the microtubule.

33

### Molecular adaptations in dynein for generation of large forces inside cells.

*A. Rai<sup>1</sup>, A. Rai<sup>1</sup>, A. J. Ramaiya<sup>1</sup>, R. Jha<sup>1</sup>, R. Mallik<sup>1</sup>; <sup>1</sup>Biological Sci, Tata Institute of Fundamental Research, Mumbai, India*

The unit generator of force inside living cells is often a motor protein that exerts a tiny force of 1-10 piconewtons. However, many processes in cells require much larger forces and must therefore rely on motors working in a team. How collective force is generated by such teams of motors is fundamentally important, but has evaded understanding. To investigate this, we develop a new model system for optical trapping directly inside living cells that overcomes certain caveats and technical hurdles with earlier in vivo force measurements. This allows us to measure the function of endogenous cellular motor-assemblies with a precision comparable to in vitro bead assays.

We make the paradoxical observation that weak dynein motors team up to generate very large forces whereas stronger kinesins fail as a team. We show that dynein's improved teamwork arises from this motor's unique ability to vary stepsize in response to load, i.e. to shift gears (Mallik et al, Nature 2004). Each dynein motor in a team speeds up or slows down, depending on the load it experiences. Dyneins therefore bunch closer together when hauling load, and consequently share load better to work efficiently as a team. We provide multiple independent lines of experimental evidence to support this hypothesis, and bring out precise mechanistic details of this process.

These results connect single-molecule properties of motors to their biologically relevant cellular functions, and suggest that nature has designed different motor proteins to adapt them for specific functions. More specifically, our work shows why dynein, the only known geared motor, needs a gear inside cells.

34

### **A novel split kinesin assay to identify the motor proteins that interact with distinct vesicle populations**

*M. Bentley<sup>1</sup>, H. Decker<sup>1</sup>, B. Jenkins<sup>1</sup>, G. Banker<sup>1</sup>; <sup>1</sup>Jungers Center, Oregon Health & Science University, Portland, OR*

An essential step for understanding the regulation of kinesin-driven vesicle transport is to identify the kinesins that move specific vesicle populations. Previous studies using biochemical strategies have shown interactions between kinesins, kinesin adaptors, and putative cargo proteins, but it has been difficult to confirm that these interactions are required for vesicle transport by direct assays in living cells. To elucidate all of the kinesins that interact with a given vesicle population we developed a novel imaging-based assay. Our approach involves expression of a “split-kinesin” consisting of separate constructs encoding a kinesin tail and a kinesin motor domain that can be assembled using chemical heterodimerization. The kinesin tail contains the cargo binding domain and can bind vesicles, but it is incapable of influencing their movement because it lacks a motor domain. The motor domain is constitutively active and moves along microtubules, but cannot move vesicles because it lacks a cargo binding domain. When these two components are linked together using a rapamycin homolog paradigm, their assembly leads to a rapid and profound change in the trafficking pattern of only the vesicles that bind the expressed kinesin tail domain. By expressing a series of all relevant kinesin tails, all of the kinesins capable of binding the vesicles of interest can be identified.

We used this technique in rat embryonic fibroblasts to identify members of the Kinesin-3 family that are present on endosomes and lysosomes. Interestingly, different members of this family are associated with different vesicle populations: KIF13A and KIF13B are present on early endosomes, while KIF1A and KIF1Bbeta are present on late endosomes and lysosomes. We also showed that in some cases two different members of the Kinesin-3 family are present on the same vesicle at the same time.

In cultured hippocampal neurons, we used this strategy to identify three members of the Kinesin-3 family that mediate the selective transport of dendritically polarized cargoes. Intriguingly, two of the three dendritic kinesins also mediate the axonal transport of other vesicle populations, confirming the hypothesis that kinesins can be steered into the axon or the dendrites depending on whether they interact with an axonal or dendritic cargo.

We believe that this method could be broadly utilized for studying motor protein-vesicle interactions in a variety of cell types.

35

### **Kinesin-mediated microtubule sliding drives axon outgrowth in *Drosophila* neurons.**

*W. Lu<sup>1</sup>, P. Fox<sup>1</sup>, M. Lakonishok<sup>1</sup>, M. Davidson<sup>2</sup>, V. Gelfand<sup>1</sup>; <sup>1</sup>Department of Cell and Molecular Biology, Northwestern University Feinberg School of Medicine, Chicago, IL, <sup>2</sup>National High Magnetic Field Laboratory and Department of Biological Science, The Florida State University, Tallahassee, FL*

How neurons extend axons is a key long-standing question in neuronal cell biology. Recently, our lab revealed a novel role of the microtubule motor kinesin-1 in driving microtubule-microtubule sliding and formation of long processes in tissue culture cells. Here, we use *Drosophila* embryonic neurons as a model system to study whether a similar mechanism operates in axon outgrowth. By using transgenic flies that carry a photoconvertible tubulin, EOS- $\alpha$ tub, we are able to track microtubule dynamics at different stages of embryonic neuron development in culture. We observe that microtubules are very actively sliding in young developing neurons. Within a few minutes, microtubules photoconverted within a small area are found to be distributed throughout the full neuron by sliding. Furthermore, these sliding microtubules push directly against the cytoplasmic membrane of the growing neurite tip and

very often become looped, suggesting that sliding microtubules generate mechanical force for axon extension during neuronal development. In mature, fully-developed neurons, microtubules become very stationary, and very little sliding can be detected. The strong correlation between microtubule sliding and axon growth rate strongly suggests that microtubule sliding can contribute to axon growth. Consistent with these findings, we demonstrate that neither actin depolymerization nor inhibition of microtubule polymerization blocks axon extension at initial stages of neuronal development. Finally, we have data to show that kinesin-1 powers microtubule sliding, which is important for axon growth in young neurons. These results reveal a novel mechanism driving initial axonal outgrowth in *Drosophila* neurons. Due to the high evolutionary conservation of kinesin-1, a similar mechanism may function in other neurons.

## Minisymposium 6: Regulation/Organization of the Genome

36

### In vivo single-molecule biochemistry of chromosome replication and segregation in bacteria.

*D. Sherratt*<sup>1</sup>, *R. Reyes-Lamothe*<sup>1</sup>, *A. Badrinarayanan*<sup>1</sup>, *E. Nicolas*<sup>1</sup>, *O. Henry*<sup>1</sup>, *A. Kapanidis*<sup>2</sup>, *S. Uphoff*<sup>2</sup>, *M. Leake*<sup>2</sup>; <sup>1</sup>Dept. Biochemistry, University of Oxford, Oxford, United Kingdom, <sup>2</sup>Dept. Physics, University of Oxford, Oxford, United Kingdom

By using a range of live cell imaging techniques that allow us count, track, position and assess the turnover of individual components of the replication and segregation machines in *Escherichia coli*, we have established new insight into the action of these molecular machines. Furthermore, by being able to deplete or replete rapidly components of these machines in vivo, we observe the consequences of these changes to cellular and chromosome behavior. The SMC complex MukBEF, TopoIV and FtsK act in *E. coli* chromosome segregation. MukBEF accumulates in foci containing on average 10 dimer of dimer complexes, consistent with them being ATP-bound. The foci typically position at midcell and/or the cell quarter positions, in the same region as the replication origins, with the positioning being cell cycle and replication independent. The dwell time of individual complexes in these foci is ~50 s. Because Muk- cells are defective in chromosome segregation and have their origins mispositioned, we propose that MukBEF acts in chromosome segregation by correctly positioning origins and other loci. MukBEF interacts with TopoIV in vivo to target it to the replication origins, where it may preferentially act in the unlinking of newly replicated sisters.

37

### Elucidating chromosomal organization and dynamics in bacterial cells using fluorescence microscopy and theoretical modeling.

A. J. Spakowitz<sup>1</sup>, M. Diaz de la Rosa<sup>1</sup>, S. Weber<sup>2,3</sup>, J. Therio<sup>2</sup>, S. H. Hong<sup>4</sup>, L. Shapiro<sup>4</sup>, H. McAdams<sup>4</sup>; <sup>1</sup>Chemical Engineering, Stanford University, Stanford, CA, <sup>2</sup>Biochemistry, Stanford University, Stanford, CA, <sup>3</sup>Chemical Engineering, Princeton University, Princeton, NJ, <sup>4</sup>Department of Developmental Biology, Stanford University, Stanford, CA

A cell packages its DNA within a cellular compartment that is orders of magnitude smaller than the DNA's unconfined radius. In this state, chromosomal DNA is accessed by regulatory proteins and transiently forms looped regulatory complexes. Thus, the fundamental physical mechanisms that dictate the organization and the dynamic motion of chromosomal DNA play an important role in a range of biological processes. Our research combines experimental imaging of chromosomal DNA and theoretical modeling to reveal the in vivo chromosomal behavior within *E. coli* and *Caulobacter crescentus*. Tracking of fluorescently labeled chromosomal loci in live *E. coli* cells reveals a robust scaling of the mean square displacement as  $\tau^{0.39}$ . Brownian dynamics simulations show that this anomalous behavior cannot be fully accounted for by the classic Rouse or reptation models for polymer dynamics. Instead, the observed motion arises from the characteristic relaxation of the Rouse modes of the DNA polymer within the viscoelastic environment of the cytoplasm. To demonstrate these physical effects, we exploit our general analytical solution of a polymer embedded in a viscoelastic medium, which exhibits remarkable agreement with our in vivo measurements. We then experimentally demonstrate a strong dependence of the motion on ATP hydrolysis, suggesting a critical impact of biologically driven fluctuations on in vivo dynamics. We then turn to *Caulobacter crescentus* to determine the structural organization of chromosomal DNA by assessing the distribution of distances between two loci. The distance between two fluorescently labeled DNA loci of various inter-loci contour lengths  $n$  is measured in *Caulobacter crescentus*. For DNA segments less than about 300 kb, the mean inter-loci distance  $\langle r \rangle$  scale as  $n^{0.22}$ , and cell-to-cell distributions of the inter-loci distance  $r$  is a universal function of  $r/n^{0.22}$  with broad cell-to-cell variability. For DNA segments greater than about 300 kb, the mean inter-loci distances scale as  $n$ , in agreement with previous observations. Predictions from Brownian dynamics simulations of the packing of supercoiled DNA polymers in an elongated cell-like confinement are consistent with our experimental results, and simulated inter-loci distance distributions predict that confinement leads to "freezing" of the supercoiled configuration. We conclude that the chromosome structure is supercoiled locally and elongated at large length scales and that in vivo crowding prevents the chromosome from reaching an equilibrium arrangement. We show that the structural "freezing" of the *Caulobacter* chromosome is consistent with the dynamic measurements within *E. coli* by determining the length-dependent relaxation times of chromosomal DNA.

38

### Single molecule dynamics governing the initiation of antigen-receptor gene assembly.

G. Lovely<sup>1,2</sup>, M. Linden<sup>3</sup>, P. Ramesh<sup>4</sup>, D. Schatz<sup>5</sup>, D. Baltimore<sup>1,2</sup>, R. Phillips<sup>1,2,4,6</sup>; <sup>1</sup>Biochemistry and Molecular Biophysics, California Institute of Technology, Pasadena, CA, <sup>2</sup>Biology, California Institute of Technology, Pasadena, CA, <sup>3</sup>Biochemistry and Biophysics, Stockholm University, Stockholm, Sweden, <sup>4</sup>Applied Physics, California Institute of Technology, Pasadena, CA, <sup>5</sup>Immunobiology, Yale University, New Haven, CT, <sup>6</sup>Bioengineering, California Institute of Technology, Pasadena, CA

Immunological memory is a hallmark of jawed-vertebrate evolution. It is controlled by antigen-receptors that directly bind the molecules committed to memory. Antigen-receptor gene assembly or variable, diversity and joining (VDJ) recombination is a DNA rearrangement process that generates trillions of antigen-receptors during the development of the adaptive

immune system. The repertoire of receptors are partitioned amongst two cell-types, B lymphocytes carrying antibodies or immunoglobulins and T lymphocytes equipped with T cell receptors. The macromolecular machine that carries out the assembly reactions is aptly named the V(D)J recombinase, and consists of recombination activating genes (RAG) 1 and 2. The RAG proteins bind and recombine two conserved recombination signal sequences (RSS) flanking V, D and J gene segments that have a nonamer, a spacer of 12 or 23 bps and a heptamer. However, *in vitro* studies on RAG1 and RAG2 have been extraordinarily difficult, and as a result RAG biochemistry has remained in a stasis. The current state of RAG biochemistry is bolstered by fragmented successes on RSS-encoded oligonucleotide DNA substrates, limiting a comprehensive understanding of V(D)J recombination on biologically relevant DNA length scales, and previous studies conducted on long DNA substrates are at best phenomenological. To ameliorate this issue, we developed a single molecule assay to capture the entire range of behavior exhibited by RAG1/RAG2 and accessory DNA bending high-mobility group protein (HMGB1) in real-time. We observed the V(D)J recombinase binding and bending RSS-encoded long DNA substrates with single or multiple RSSs. We knocked out binding by the V(D)J recombinase using mutations in RSSs that were previously shown to ablate recombination in B lymphocytes. We directly observed cooperative binding and bending by the V(D)J recombinase and HMGB1 in the presence of one or more RSSs and we uncovered strict concentration thresholds and RSS-spacer requirements for robust cooperativity and dynamic bending. Our novel single molecule system is poised to elucidate the dynamics that go into every trillionth reaction carried out by the V(D)J recombinase.

39

### **Theoretical model of cooperative binding in heterochromatin formation.**

P. J. Mulligan<sup>1</sup>, E. F. Koslover<sup>2</sup>, A. J. Spakowitz<sup>1,2</sup>; <sup>1</sup>Chemical Engineering, Stanford University, Stanford, CA, <sup>2</sup>Biophysics, Stanford University, Stanford, CA

Gene regulation in eukaryotes requires the segregation of silenced genomic regions into densely packed heterochromatin, leaving the active genes in euchromatin regions more accessible. We introduce a model that connects the presence of epigenetically inherited histone marks, methylation at histone 3 lysine-9 (H3K9), to the physical compaction of chromatin fibers via the binding of heterochromatin protein 1 (HP1).

We generate optimized chromatin-fiber structures from a model based on the mechanical properties of the DNA and the steric interactions of the DNA and nucleosomes. These structures, which show qualitative agreements with 30nm fibers found from *in vitro* experiments, determine the spatial position of the H3K9 sites<sup>1</sup>. In our binding model for HP1, these sites can be either unmethylated or tri-methylated; tri-methylated H3K9 appears to be a critical epigenetic signal for heterochromatin formation. We show how the spatial arrangement of these sites leads to heterogeneous bridging of HP1 between sites, affecting the cooperative binding of HP1 molecules. We consider binding both to single fibers as well as multiple fibers packed in arrays similar to possible *in vivo* conditions.

Our model demonstrates some of the key physical features that are necessary to explain several experimental observations, including the phase segregation of heterochromatin regions and the increased HP1 concentration in these regions<sup>2</sup>. In particular, we find that strong cooperative interactions among the HP1 proteins are necessary to see the phase segregation of heterochromatin and euchromatin regions. From *in vitro* experiments on HP1 binding<sup>3</sup>, we calculated the binding energy difference between the unmethylated and tri-methylated states to be small (less than 2kT). This small difference allows the cell to use physiologically realizable

concentrations of HP1 to condense highly methylated regions at higher concentrations and decondense these regions at lower concentrations. Finally, we explore under what circumstances there is a threshold of methylation over which the fibers will compact; this threshold provides a buffer against small losses of methylation such as those that occur during cell division<sup>4</sup>. Many of the observations that we make about the HP1 system are guided by general thermodynamics principles and thus could play a role in other DNA organizational processes such as the binding of linker histones.

### **An octameric CENP-A nucleosomal population is present at the human centromeres throughout the cell cycle.**

A. Padeganeh<sup>1</sup>, A-M. Ladouceur<sup>1</sup>, J. Boisvert<sup>1</sup>, J. Ryan<sup>1</sup>, J. Dorn<sup>1</sup>, P. S. Maddox<sup>1,2</sup>; <sup>1</sup>IRIC, University of Montreal, Montreal, QC, Canada, <sup>2</sup>Department of Pathology and Cell Biology, University of Montreal, Montreal, QC, Canada

Centromeres are chromosomal loci upon which the mitotic kinetochores form to mediate faithful inheritance of genetic material to the daughter cells. A key feature of centromeres is the replacement of canonical histone H3 with the histone variant Centromere Protein A (CENP-A) in centromeric nucleosomes. Presence of CENP-A is presumed to mark the centromeric identity via an epigenetic mechanism. Recently, debate over the composition of CENP-A-containing nucleosomes has been intensified by conflicting observations proposing several models and dynamics for CENP-A nucleosomes. These models vary in terms of the identity and quantity of the components, number of CENP-A molecules, nucleosomal dimensions and DNA wrapping. Thus, we aimed to address the composition of CENP-A nucleosomes by developing a high-resolution single molecule imaging method using in-vivo assembled nucleosomes. Total internal reflection fluorescence microscopy (TIRFM) was coupled to a single nucleosome-immunoprecipitation technique to visualize CENP-A nucleosomes. We then used a photobleaching-assisted copy number counting technique (PA-CNC) to determine the number of CENP-A-YFP molecules per individual nucleosome. In order to investigate the presence of other histones in CENP-A nucleosomes, we integrated indirect single-molecule immunofluorescence to our TIRFM assay. Our data suggest that CENP-A dimers and H2B molecules are found in a major population of CENP-A nucleosomes throughout the cell cycle. Characterisation of the secondary population with a single CENP-A molecule is currently underway. All together, our data suggest the presence of octameric CENP-A nucleosomes as a constitutive population throughout the human cell cycle.

41

### **Structure of active, dimeric human telomerase.**

D. Rhodes<sup>1</sup>, S. Sandin<sup>2</sup>, A. Sauerwald<sup>2</sup>, J. Lingner<sup>3</sup>; <sup>1</sup>School of Biological Sciences, Nanyang Technological University, Singapore, Singapore, <sup>2</sup>MRC Laboratory of Molecular Biology, Cambridge, United Kingdom, <sup>3</sup>Swiss Institute for Experimental Cancer Research (ISREC), Ecole Polytechnique Fédérale de Lausanne (EPFL), 1015 Lausanne, Switzerland

In eukaryotes, telomerase counteracts telomere erosion to prevent cellular senescence. Telomerase contains a large RNA subunit TER and a protein catalytic subunit TERT that reverse transcribes the TER template sequence into telomeric DNA. Whether the telomerase

functions as monomer or dimer has been a matter of debate. I will describe recent results that show that human telomerase contains two TERT subunits which both bind a telomeric DNA substrate, and that catalytic activity requires both TERT active sites to be functional, providing unambiguous evidence that human telomerase functions as a dimer. I will also present the first three-dimensional structure of active, full-length human telomerase dimer as determined by single particle electron microscopy in negative stain. This structure reveals the spatial relationship between RNA and TERT subunits, and hence provides important insights into the architecture of the telomerase enzyme.

## Minisymposium 7: Signal Transduction/Signaling Networks

42

### Encoding cellular information through p53 dynamics in individual cells.

*J. Purvis<sup>1</sup>, K. Karhohs<sup>1</sup>, C. Mock<sup>1</sup>, E. Batchelor<sup>2</sup>, A. Loewer<sup>3</sup>, G. Lahav<sup>1</sup>; <sup>1</sup>Systems Biology, Harvard Medical School, Boston, MA, <sup>2</sup>Laboratory of Pathology, National Cancer Institute, NIH, Bethesda, MD, <sup>3</sup>Berlin Institute for Medical Systems Biology, Max Delbrueck Center for Molecular Medicine, Berlin-Buch, Germany*

Many signaling molecules exhibit complex dynamical behaviors, yet little is known how these dynamics affect cellular responses. In this talk I will focus on the dynamics of p53, a critical tumor-suppressive protein that controls genomic integrity and cell survival. The dynamics of the p53 response are different for different stimuli. Double strand breaks caused by gamma radiation, trigger a series of p53 pulses with fixed amplitude and duration. The number of pulses increases with higher damage. In contrast, UV triggers a single p53 pulse with a dose-dependent amplitude and duration. Comparison of the networks responding to these damages allowed us to identify specific molecular feedbacks that shape these distinct dynamical responses. Using a combination of single cell experiments and computational modeling, we identified a sequence of precisely timed drug additions that switch p53 dynamics from pulsatile into sustained in response to gamma radiation, and we tested the resulting behavior in cells. Our results show that different dynamical patterns of p53 alter the selection and timing of gene expression and perturb cellular outcomes. Pulsing p53 led to the activation of target genes associated with cell cycle arrest, DNA repair, and regulation of p53 itself. Genes associated with irreversible cellular fates, such as apoptosis and senescence, showed no induction in response to p53 pulses. In contrast, when p53 pulses were altered to produce a non-pulsing, sustained p53 signal, genes associated with apoptosis and senescence were induced. Our study shows that p53 dynamics affect cell fate decisions and suggests that perturbing protein dynamics in a controlled way can be a useful tool for pushing cells into a desirable outcome.

43

### Engineered manipulation of signaling networks: Novel control of kinase activation and interactions dissects parallel Src pathways.

*A. V. Karginov<sup>1</sup>, D. Tsygankov<sup>2</sup>, M. E. Berginski<sup>3</sup>, E. D. Trudeau<sup>2</sup>, P-H. Chu<sup>2</sup>, J. J. Yř, S. M. Gomez<sup>3</sup>, T. C. Elston<sup>2</sup>, K. M. Hahn<sup>2</sup>; <sup>1</sup>Pharmacology, University of Illinois at Chicago, Chicago, IL, <sup>2</sup>Pharmacology, UNC-Chapel Hill, Chapel Hill, NC, <sup>3</sup>Biomedical Engineering, UNC-Chapel Hill, Chapel Hill, NC*

Spatio-temporal control of signaling is orchestrated by a complex network of interactions between scaffolding and enzymatic components. Current tools typically cannot activate a specific protein and simultaneously cause it to interact with one specific downstream target,

which would be of great value in dissecting the organization of signaling networks. Here we provide such a tool, and use it to determine the role of individual Src-mediated signaling pathways in stimulation of different cell morphological changes. Protrusive activity of a cell and its adhesion to extracellular matrix is regulated by Src via multiple interactions. Focal adhesion kinase (FAK) and p130Cas can bind and activate Src, propagating signals through parallel pathways. Localization of Src in the cytoplasm or at the plasma membrane also determines the function of Src. Thus, we focused specifically on activation of Src acting through FAK or through p130Cas, or at different locations (cytoplasm versus plasma membrane). An engineered, "insertable" FKBP12 protein (iFKBP) was introduced into the catalytic domain of Src, while FKBP12-rapamycin binding domain (FRB) was attached to the specific downstream effector. This rendered the kinase inactive until rapamycin, added to the extracellular medium, induced heterodimerization with FRB. Using this technology we restricted Src activation to the complex it formed with FRB-bearing downstream targets. Simple activation of Src, without targeting specific downstream molecules, led to cell spreading, reorganization of focal adhesions, and the production of filopodia and lamellipodial protrusions. Using the new approach, dubbed RapR-TAP, we showed that activation of Src specifically in complex with FAK led to focal adhesion rearrangement and only slow lamellipodial protrusion, while activation in complex with p130Cas led to rapid spreading and filopodia formation, but no apparent effects on focal adhesions. Comparing Src activation in the cytosol versus at the plasma membrane showed that membrane localization is necessary to stabilize protrusions, whereas cytoplasmic Src drives rearrangement of focal adhesions. The novel method presented here isolates specific differences between parallel Src-induced signaling events, and demonstrates the feasibility of a broadly generalizable strategy to activate specific kinase-mediated signaling pathways in living cells.

44

#### Single-cell signaling dynamics reveal the logic of early response gene transcription driven by NF- $\kappa$ B.

R. E. Lee<sup>1,2</sup>, K. Savery<sup>1</sup>, S. Gaudet<sup>1,2,1</sup>; *Cancer Biology, Dana-Farber Cancer Institute, Boston, MA, <sup>2</sup>Genetics, Harvard Medical School, Boston, MA*

NF- $\kappa$ B is a family of dimeric transcription factors that regulate many genes— associated with inflammation, cellular proliferation and survival as well as carcinogenesis. In the absence of extracellular signals, NF- $\kappa$ B exists in complexes with inhibitory I $\kappa$ B proteins. The I $\kappa$ B/NF- $\kappa$ B complexes are actively exported from the nucleus and NF- $\kappa$ B is therefore predominantly localized to the cytoplasm. Inducers of the canonical NF- $\kappa$ B pathway promote rapid degradation of I $\kappa$ B proteins, releasing NF- $\kappa$ B. The unmasked nuclear localization sequence of free NF- $\kappa$ B directs it to the nucleus, where it can access the promoter regions of its target genes. For this reason, the degree of NF- $\kappa$ B pathway activation is often equated with the amount of nuclear NF- $\kappa$ B even though the correlation between NF- $\kappa$ B localization and the NF- $\kappa$ B-dependent transcriptional response has not been determined in single cells. What does an individual cell 'read' from a translocation event? Does the transcriptional response reflect a simple ON/OFF switch, or is the response proportional to a specific aspect of this dynamic translocation event? In this work we examine the relationship between tumor necrosis factor (TNF)-induced NF- $\kappa$ B translocation dynamics and the associated transcriptional response. We have developed a live-cell to fixed-cell workflow where we first image TNF-induced NF- $\kappa$ B (p65/RelA) translocation dynamics and then count, in the same cells, the number of mRNA transcripts for NF- $\kappa$ B target genes detected by single-molecule fluorescence in situ hybridization (smFISH). Correlating NF- $\kappa$ B translocation dynamics to the number of transcripts for three rapidly induced NF- $\kappa$ B-driven genes, we find that the quantity of nuclear NF- $\kappa$ B at any single time point provides little information about its activation state. Instead, cells interpret changes in NF- $\kappa$ B localization,

measuring fold-change of nuclear NF- $\kappa$ B. Each cell retains a 'memory' of its pre-ligand state and evaluates translocation events relative to this previous state. We found that the relationship between fold-change of nuclear NF- $\kappa$ B and transcription in individual cells could not be predicted from existing computational models of the NF- $\kappa$ B pathway. These observations have led us to a new model that provides insight into the regulatory circuitry that quantitatively controls NF- $\kappa$ B-dependent early response gene transcription. Our results strongly suggest that competitive protein-DNA interactions provide a 'memory' required for fold-change detection.

45

**Sharpin-dependent linear-ubiquitination of FADD is required for anti-apoptosis pathway.**

*F. Ikeda<sup>1</sup>, B. Wanko<sup>1</sup>; <sup>1</sup>Institute of Molecular Biotechnology (IMBA), Vienna, Austria*

Ubiquitin is one of the most sophisticated and versatile post-translational modifications. Depending on how ubiquitin molecules are linked as chains and modify the substrate, they regulate different biological functions and cellular signals. Recent findings indicate that Sharpin plays a critical role in TNF- $\alpha$ -induced NF- $\kappa$ B signaling by linear (Met 1-linked, tandem repeated, head-to-tail) ubiquitination of NEMO (NF- $\kappa$ B essential modulator). Sharpin is key subunit of an E3 ligase complex, LUBAC (Linear Ubiquitin chain Assembly Complex), which specifically generates linear ubiquitin chains. The phenotype of Sharpin deficient Cpdm (Chronic proliferative dermatitis mice) mice shows heavy inflammation in multiple organs including skin, gut and esophagus. Interestingly, we observed drastic apoptosis in keratinocytes of Cpdm mice determined by cleaved Caspase 3 expression. We have reported that TNF- $\alpha$ -induced apoptosis in Cpdm MEFs is controlled through Caspase 8 and FADD both of which are essential components of DISC (death-inducing signaling complex). However, it remains unclear how mechanistically Sharpin regulates apoptosis signaling pathway. We found that FADD is ubiquitinated by LUBAC in vitro. Moreover, TNF- $\alpha$ -induced apoptosis in Cpdm MEFs was rescued by expressing FADD-linear di-ubiquitin chain chimera, strongly suggesting that Sharpin plays an important role in anti-apoptosis signaling by linearly ubiquitinating FADD. In this meeting, novel functions of Sharpin in regulation of anti-apoptosis signaling pathways will be presented.

46

**Regulation of mRNA export by PI3 Kinase / AKT signal transduction.**

*J. A. Nickerson<sup>1</sup>, A. J. Quaresma<sup>1</sup>; <sup>1</sup>Cell and Developmental Biology, University of Massachusetts Medical School, Worcester, MA*

Regulation of the nuclear export of specific mRNAs could be an important mechanism for modulating translatable, cytoplasmic levels of messages. This could be especially important in regulating the expression of genes that have mRNAs with short half-lives in the cytoplasm. UAP56, ALY/REF, and NXF1 are mRNA export factors that sequentially bind at the TRanscription/EXport (TREX) complex located at the 5' end of a nuclear mRNA. NXF1, recruited last to the complex, may subsequently bind at nuclear pores for export of the mRNP complex to the cytoplasm. These three mRNA export proteins are also reported to associate with the Exon Junction Complex (EJC) that forms 20-24 nucleotides upstream of each exon-exon junction during splicing and then remains with the processed mRNA. We used Fluorescence Recovery after Photobleaching (FRAP) as a screen to identify signal transduction pathways that regulate the binding of mRNA export and EJC core proteins in macromolecular complexes at RNA splicing speckled domains, and at an integrated chromosomal array of actively transcribed  $\beta$ -globin transgenes arranged in tandem. The fraction of UAP56, ALY/REF, and NXF1 tightly bound in complexes was reduced by drug inhibition of the PI3 kinase / AKT branch of the phosphatidylinositol signal transduction pathway, as was the tightly bound fraction

of the core EJC proteins eIF4A3, MAGOH, and Y14. Inhibition of the mTOR mTORC1 pathway, which can be activated by AKT, also decreased the tight binding of MAGOH. Inhibition of the AKT pathway increased the nuclear export of bulk poly(A) RNA and of a subset of spliced mRNAs. A similar increase in export after AKT inhibition was observed for sets of mRNAs transcribed from both intron-containing and intron-less histone genes. Taken together, our results show that the PI3 kinase / AKT signal transduction pathway regulates mRNA export complex assembly, affecting the rate of nuclear export and the extent of nuclear retention for specific mRNAs.

47

### **Systematically mapping the sequence space of a protein-protein interface.**

A. Podgornaia<sup>1</sup>, M. T. Laub<sup>1,2</sup>; <sup>1</sup>Biology, Massachusetts Institute of Technology, Cambridge, MA, <sup>2</sup>Howard Hughes Medical Institute, Cambridge, MA

Signal transduction pathways rely on transient yet specific protein-protein interactions. How a limited set of amino acids can enforce cognate protein interactions while excluding undesired pairings remains poorly understood, even in cases where the contacting residues have been identified on both protein partners. To tackle this challenge, we developed a systematic mutagenesis approach to examine all possible combinations of residues that support a protein-protein interaction in a bacterial two-component signaling pathway. These pathways, typically consisting of a histidine kinase and a cognate response regulator, are an ideal model system for studying protein-protein interactions as they rely almost exclusively on molecular recognition for specificity. The kinase uses four key residues to recognize the regulator in both phosphorylation and dephosphorylation reactions, and to prevent docking with all non-cognate regulators. To better understand this specificity, we comprehensively mapped the sequence space of the interface formed by *Escherichia coli* histidine kinase PhoQ and its partner PhoP. We developed a robust high-throughput assay for assessing kinase and phosphatase activity *in vivo* using fluorescence-activated cell sorting. We then used this assay to screen a library of 20<sup>4</sup> (160,000) PhoQ variants in which we completely randomized the four key specificity-determining residues. Using deep sequencing, we identified ~2,500 variants that can phosphorylate and dephosphorylate PhoP as well as the wild-type PhoQ. Strikingly, PhoQ can interact with PhoP via many sets of interfacial residues that are completely different from the wild type. This combinatorial approach to mapping sequence space also reveals interdependencies between individual amino acids. For instance, although the introduction of a bulky residue into wild-type PhoQ typically disrupts the interaction with PhoP, certain changes to neighboring residues can compensate and restore interaction. Conversely, we find examples of individual mutations that are tolerated by wild-type PhoQ, but which disrupt the signaling pathway when combined. These findings highlight the power of comprehensively mapping sequence space relative to screens that only examine substitutions at individual sites. We are currently characterizing the fitness of signal-responsive mutants relative to the wild type and assessing whether these variants have other, detrimental consequences for the cell.

## **Minisymposium 8: Stem Cells and Induced Pluripotency**

### **BMP-SMAD-ID signaling axis supports reprogramming to pluripotency.**

Y. Hayashi<sup>1</sup>, E. C. Hsiao<sup>2</sup>, S. Sami<sup>1</sup>, M. Lancero<sup>1</sup>, C. R. Schlieve<sup>2</sup>, T. Nguyen<sup>1</sup>, K. Yano<sup>3</sup>, A. Nagahashi<sup>3</sup>, M. Ikeya<sup>3</sup>, Y. Matsumoto<sup>3</sup>, I. Asaka<sup>3</sup>, J. Toguchida<sup>3</sup>, B. R. Conklin<sup>1</sup>, S. Yamanaka<sup>1,3</sup>;

<sup>1</sup>*Gladstone Institute of Cardiovascular Disease, San Francisco, CA*, <sup>2</sup>*UCSF, San Francisco, CA*,  
<sup>3</sup>*Kyoto University, Kyoto, Japan*

Reprogramming somatic cells to pluripotent stem cells represents an exciting new paradigm in biology and medicine. We developed a technology to generate induced pluripotent stem cells (iPSCs) by transducing defined factors, such as OCT4, SOX2, KLF4, and C-MYC, into somatic cells. These defined factors are transcription factors that regulate gene expression important in self-renewal and pluripotency; however, the efficiency of iPSC generation remains very low. Cytokine-induced cell signaling can affect the efficiency of iPSC generation, but the precise effects and mechanisms required for the reprogramming are still unclear. We hypothesized that the activation of BMP-SMAD signaling pathway enhances the efficiency of iPSC generation. We found that the efficiency of iPSC generation from the human dermal fibroblasts (HDFs) obtained from patients of fibrodysplasia ossificans progressiva (FOP) with the R206H mutation in ACVR1 gene, which leads to hyperactivation of BMP-SMAD pathway, was much higher than that of normal HDFs. The Inhibition of BMP-SMAD signaling by adding Dorsomorphin or LDN-193189 or by transducing SMAD6 or SMAD7 to FOP-HDFs decreased the efficiency of iPSC generation. Conversely, the activation of BMP-SMAD signaling by transducing mutant ACVR1 (R206H) or SMAD1 or by adding BMP4 recombinant protein to normal HDFs in specific period of reprogramming increased the efficiency of iPSC generation. Furthermore, inhibitor of DNA binding (ID) genes, which are direct targets of BMP-SMAD signaling, increase the efficiency of iPSC generation from normal HDFs and are required for iPSC generation. Our results indicate that the BMP-SMAD-ID axis is critical for efficiently generating iPSCs. In addition, our findings suggest that human genetic diseases such as FOP may favor more efficient iPSC generation, and that these pathways could provide methods for improving the efficiency of iPSC generation.

### Direct lineage reprogramming to generate neural cell types.

M. Wernig<sup>1</sup>; <sup>1</sup>Stanford University, Stanford, CA

Cellular differentiation and lineage commitment are considered robust and irreversible processes during development. We hypothesized that expression of neural lineage-specific transcription factors could directly convert fibroblasts into neurons and identified a combination of only three factors that suffice to rapidly and efficiently convert mouse fibroblasts into functional neurons in vitro. These induced neuronal (iN) cells expressed multiple neuron-specific proteins, generated action potentials, and formed functional synapses.

One of the outstanding question was whether a defined non-ectodermal cell can be converted into iN cells given the heterogeneity of fibroblast cultures. We therefore tested whether (endoderm-derived) hepatocytes can be reprogrammed to iN cells. Surprisingly, using the same 3 transcription factors primary mouse hepatocytes could be converted very efficiently into iN cells with the ability to generate action potentials upon depolarization as well as to form synaptic contacts with primary neurons. A genetic lineage-tracing system was employed to prove that the cell of origin of iN cells were indeed endodermal cells. Moreover, gene expression studies on the global and single cell level confirmed not only the induction of a neuronal transcriptional program but also the efficient silencing of the hepatocyte-specific expression pattern. This transcriptional silencing was extensive but not complete on both population and single cell level. We therefore conclude that iN cells are not a hybrid cell with equal identities of the starting cell and neurons, but cells with a predominant neuronal identity with an epigenetic or transcriptional memory of the starting cell population.

Finally, we reasoned it would be desirable to generate a proliferative neural precursor cell population from fibroblasts given the limitations of expandability of iN cells. We followed a similar strategy that was successful to identify the iN cell factors and screened 11 factors to eventually identify Sox2 and FoxG1 as critical factors that are sufficient to induce neural precursor cells (iNPCs) with the potential to differentiate into neuronal and astroglial, but not oligodendroglial cell types. The addition of Brn2 conferred the ability to differentiate also into oligodendroglial cells. When Sox2 was omitted from the combination iNPCs were generated with differentiation potential into both glial cell types but the neuronal differentiation was less robust with the generation of only immature neuronal cells. However, when transplanted into the myelin-deficient shiverer mouse brain, the cells incorporated well into the white matter tracts, differentiated into oligodendrocytic cells expressing an array of lineage specific markers including Olig2, O4, and myelin basic protein and ensheathed host axons.

### Regulation of adult neurogenesis by c-myc.

A. M. Denli<sup>1</sup>, C. Zhao<sup>1</sup>, M. N. Kagalwala<sup>1</sup>, I. S. Gallina<sup>1</sup>, F. H. Gage<sup>1</sup>; <sup>1</sup>Salk Institute for Biological Studies, La Jolla, CA

Stem cells play an important role not only during development but also in maintenance of the adult organisms. Adult neurogenesis is a process through which new neurons are born in the adult brain with potential links to learning and memory as well as neurological disorders. Neurogenesis takes place in the subgranular zone (SGZ) of the dentate gyrus (DG) of the hippocampus and the subventricular zone (SVZ) of the lateral ventricles. In the hippocampus, newborn neurons mature to become excitatory granule cells that integrate into the existing circuitry. Adult neurogenesis is driven by relatively quiescent radial glia cells that infrequently divide and give rise to a proliferative cell population, most of which differentiate to adopt a

neuronal cell fate. While the cell types involved in adult neurogenesis have been relatively well-characterized, we are far from a full understanding of the underlying molecular mechanisms. The highly conserved transcriptional regulator c-myc is an essential for development and can also act as a proto-oncogene. Only a minority of studies on c-myc has been carried out in normal adult stem cells. In general, a clear picture of c-myc function remains to emerge, due to context-dependence, overlapping expression patterns with other myc family members, weak transcriptional activator function as well as low expression levels in adult cells. c-myc is involved in diverse processes such as cell growth, proliferation, apoptosis and differentiation: phenomena intimately linked to neural stem cell biology. We have hypothesized that c-myc may have a function in early steps of adult neurogenesis.

We first confirmed expression of c-myc in the adult dentate gyrus as well as cultured adult hippocampal progenitor cells (AHPs). c-myc bound to its known transcriptional targets and regulated their expression in AHPs, suggesting that c-myc was functional in this context. Expression of c-myc was downregulated upon differentiation and knockdown of c-myc led to enhanced differentiation, whereas overexpression of c-myc inhibited differentiation of AHPs. Retroviral overexpression of c-myc in the adult hippocampus led to an early increase in proliferation followed by an inhibition of subsequent differentiation. Interestingly, further analysis suggested that c-myc might have a direct role in early differentiation. In summary, our data points to a novel role for c-myc in regulation of not only cell proliferation but also cell fate in adult neurogenesis. We will discuss possible mechanisms of c-myc function and its potential role in adult stem cell biology.

51

### **Regulated subnuclear gene positioning restricts neural stem cell competence in *Drosophila*.**

M. Kohwi<sup>1</sup>, J. Lupton<sup>1</sup>, S-L. Lai<sup>1</sup>, M. Miller<sup>1</sup>, C. Q. Doe<sup>1</sup>; <sup>1</sup>Institute of Neuroscience, University of Oregon, Eugene, OR

Progressive loss of stem/progenitor competence to specify earlier-born cell fate is a fundamental process of development whose mechanisms are little understood. Using a combination of DNA fluorescent *in situ* hybridization (FISH) and immunostaining in intact *Drosophila* embryos, we visualized changes in genome architecture *in vivo* as neuroblasts (neural stem cells) undergo rapid (~1hr) transcriptional transitions within the developing central nervous system. We tracked the subnuclear position of the gene locus encoding the transcription factor Hunchback (Hb), which specifies early-born temporal identity. We found that the *hb* gene progresses through three states: transcriptionally active, transcriptionally inactive but inducible, and finally, permanently silenced. We found that when the *hb* gene is transcriptionally active or inducible, the *hb* gene locus is positioned in the nuclear interior, and the neuroblast is competent to specify early-born identity. In contrast, when the *hb* gene is permanently silenced, we found its locus is positioned at the nuclear lamina, a highly repressive domain. Strikingly, the timing of this repositioning correlates precisely with the time neuroblast competence is lost. When the nuclear lamina is disrupted, the *hb* locus is positioned away from the nuclear envelope, and the competence window, as defined by the duration *hb* is transcriptionally inducible, is extended. Furthermore, we identified a neuroblast nuclear factor, Distal antenna (Dan) whose expression perfectly matches the neuroblast competence window. Prolonging Dan expression prevented repositioning of the *hb* locus to the nuclear lamina and extended neuroblast competence, suggesting it may play a role in regulating gene architecture in neuroblasts. We propose that gene reorganization is a mechanism by which stem cell competence to specify particular fates becomes restricted during development. These data may provide insight into mechanisms that can be harnessed to reverse loss of stem cell competence for tissue replacement therapies.

52

**Mechanism of asymmetric division in adult stem cells.**S. Srinivasan<sup>1</sup>, M. T. Fuller<sup>1</sup>; <sup>1</sup>Developmental Biology, Stanford University, Stanford, CA

Regulation of adult stem cell divisions confers regenerative capacity and plasticity in tissues. Stem cells can divide symmetrically, a mechanism used during development or after injury to expand cell numbers, or asymmetrically to maintain normal tissue homeostasis. A key mechanism in setting up the symmetric or asymmetric outcome of stem cell divisions is the programmed orientation of the mitotic spindle. The specialized microenvironment in which adult stem cells reside, the stem cell niche, may regulate stem cell divisions, and thereby tissue plasticity and regenerative capacity, by influencing the orientation of the mitotic spindle. *Drosophila* male germline stem cells (GSCs) normally divide asymmetrically, providing a system to study mechanisms regulating orientation of stem cell divisions in context of the niche. The hub, a component of the niche in this system, orients the centrosomes in GSCs during interphase and eventually the mitotic spindle to enable the asymmetric outcome of stem cell division by providing 1) spatial cues via E-cadherin mediated adherens junctions that maintain a centrosome adjacent to the hub-GSC interface throughout the cell cycle and 2) the Unpaired ligand that activates the JAK-STAT pathway in GSCs, which is required to maintain centrosome orientation. We have discovered that the forkhead domain containing transcription factor Jumu, a target of activated STAT, regulates asymmetric division in GSCs. Our data suggests that *jumu* function is not required for maintenance of GSCs at the hub via adherens junctions but is required for correct centrosome positioning in GSCs, suggesting that Jumu functions downstream of the spatial cues provided by the adherens junctions to orient centrosomes. We also discovered that the NuMA homolog *Mushroom body defect (mud)*, a target of Jumu in *Drosophila* embryos identified by the ModENCODE project, is expressed in GSCs and is required for proper centrosome orientation in GSCs. *mud* mutant GSCs exhibit normal adherens junctions between the hub and GSCs suggesting that Mud, like Jumu, functions downstream of the adherens junctions to orient centrosomes. This study demonstrates that a transcriptional network downstream of the signal from the niche regulates the outcome of adult stem cell division.

53

**BAF53A enforces the epidermal progenitor state by re-targeting the SWI/SNF/BAF chromatin remodeling complex away from differentiation gene promoters.**X. Bao<sup>1</sup>, J. Tang<sup>2</sup>, V. Lopez-Pajares<sup>1</sup>, S. Tao<sup>1</sup>, K. Qu<sup>1</sup>, G. R. Crabtree<sup>2</sup>, P. A. Khavari<sup>1</sup>; <sup>1</sup>Dermatology, Stanford University, Stanford, CA, <sup>2</sup>Howard Hughes Medical Institute, Stanford University, Stanford, CA

Epidermal progenitors suppress expression of terminal differentiation genes. Recently, epigenetic mediators of DNA and histone modification have been identified as dynamically regulating such repression, including DNMT1, JMJD3, Polycomb, and HDAC1/2. These data indicate a role for multiple classes of epigenetic regulators in this process, however, the impact of epigenetic chromatin remodelers, such as the ATPase driven multi-subunit BAF (SWI/SNF) complex, is not fully characterized. To address this, we performed loss of function studies of multiple complex subunits in epidermal tissue. Conditional BAF53A (ACTL6A) gene deletion in mice was found to abolish epidermal progenitor maintenance and to induce differentiation, leading to a failure of epidermal self-renewal. Similar findings in organotypic human epidermis were observed with BAF53A depletion via RNAi, where ectopically expressed BAF53A also suppressed differentiation, indicating that BAF53A enforces the undifferentiated cell state. Depletion of key components of multiple histone acetyltransferase and chromatin remodeling complexes with which BAF53A can physically associate identified a phenocopy only with the

BAF250A (ARID1A) BAF complex subunit. Paradoxically but consistent with prior knockout mouse studies, depletion BRG1/BRM ATPase subunits impaired differentiation gene induction, suggesting that BAF53A functions as an anti-differentiation component of the BAF complex. Consistent with this, BAF53A is down-regulated during normal differentiation. Mechanistically, chromatin immunoprecipitation (ChIP) experiments demonstrated that BAF53A impairs binding of the BRG1/BRM-containing BAF complex to differentiation gene promoters, including key regulators such as of KLF4, blocking their induction. These data indicated that BAF53A maintains the undifferentiated progenitor state by opposing BAF complex-enabled differentiation via genomic re-targeting of this chromatin remodeling complex away from differentiation gene promoters.

## Keith R. Porter Lecture

### Cell Biology of Virus Entry.

A. Helenius<sup>1</sup>; <sup>1</sup>Institute of Biochemistry, ETH Zurich, Zurich, Switzerland

When viruses enter animal cells, most of them follow a stepwise program that involves attachment, activation of signaling pathways, endocytosis, penetration into the cytosol, intracellular transport, and finally uncoating of the viral genome. Since all of these steps depend on host cell functions, hundreds of cellular proteins end up assisting viruses in different stages of entry and thus inadvertently participating in the demise of the cell and in pathogenesis. However, the dependence on host cell functions makes viruses sensitive to perturbations that affect cellular processes ranging from macropinocytosis to endosome maturation and nuclear import. Therefore, viruses provide powerful tools to analyze cell function, and it may be possible to inhibit infection by blocking specific host cell functions.

Using high-end light microscopy, automated high-throughput siRNA and drug screening as well as biochemical approaches, we have analyzed the entry of viruses of different families. We find five distinct entry routes with penetration occurring through the plasma membrane, in early endosomes, in late endosomes, in macropinosomes, and in the ER. In several cases, a list of host genes involved is known from screens and detailed molecular mechanisms are emerging. In the Keith Porter lecture, I will describe the general concepts in early virus/host cell interaction, and describe in some detail the entry strategies used by influenza virus, which enters by membrane fusion in late endosomes, vaccinia virus, which triggers macropinocytosis, and SV40, a non-enveloped virus that penetrates through the ER membrane.

**Probing mechanisms of axonal and neuronal vesicle trafficking using human induced pluripotent stem cells.**

L. S. Goldstein<sup>1</sup>; <sup>1</sup>*Cellular and Molecular Medicine, Neurosciences, UC San Diego and Sanford Consortium for Regenerative Medicine, La Jolla, CA*

Human pluripotent stem cells provide enormous opportunities to treat disease using cell replacement and related cell therapy approaches. But human pluripotent stem cells are also an important new tool for biomedical discovery in a human model system. Since humans are a large, long-lived organism with a complex brain, a rich evolutionary history, and substantial genetic variation across large and accessible populations, there are likely to be new biological mechanisms and phenomena that can be discovered using these cells. In my talk, I'll describe our initial forays into probing basic biological features of axonal trafficking and transport in human neurons made from human embryonic and human induced pluripotent stem cells. I will also describe new insights into two different diseases: Alzheimer's Disease and Niemann Pick Type C. For Alzheimer's Disease, I will describe how we are using quantitative methods for kinesin-1 localization to test whether duplications of the amyloid precursor protein gene that cause hereditary Alzheimer's Disease cause pathological phenotypes by altering kinesin-1 loading on axonal vesicles. I will also describe new work that reveals how Alzheimer's Disease genetic risk alleles at the SORL1 locus alter neuronal phenotypes. For Niemann Pick Type C, I will discuss recent studies that have led to the identification of a previously unrecognized intracellular cholesterol transport system.

56

**Choanoflagellate colony development as a simple model for animal multicellularity.**

N. King<sup>1</sup>; <sup>1</sup>*Molecular and Cell Biology, University of California, Berkeley, Berkeley, CA*

The evolution of animals from their single celled ancestors represents one of the major transitions in life's history. The origin of animals was shaped by extensive genomic and gene regulatory innovations, co-option of pre-existing genes to new functions in cell adhesion and signaling, rising atmospheric and oceanic oxygen concentrations, and the subsequent influence of new selective pressures. By studying choanoflagellates, the closest living relatives of animals, my lab aims to reconstruct the biology of the last common ancestor of animals. I will discuss our recent findings regarding the ancestry of animal gene families and the potential connection between genome evolution and animal origins. In addition, I will describe our development of a colony-forming choanoflagellate, *Salpingoeca rosetta*, as a new model for investigating the origin of animal multicellularity. Through our study of *S. rosetta*, we have discovered that a developmental switch in choanoflagellates is regulated by a secreted signal from environmental bacteria. Explaining how the intersection of genetic novelty, gene co-option, and environmental interactions contributed to the transition to multicellularity has important implications both for understanding early animal evolution and for identifying the foundations of animal cell biology.

57

**Developing a model system to study regeneration.**A. Sánchez Alvarado<sup>1</sup>; <sup>1</sup>HHMI/Stowers Institute, Kansas City, MO

Regeneration remains one of the last untamed frontiers of developmental biology. It is amongst the oldest biological problems known to humankind, dating back to antiquity in many cultures and, perplexingly, still awaiting for a satisfactory mechanistic explanation. As such, its history is rich, and its study encompasses the work and attention of generations of biologists. So why has so little mechanistic progress been made in this field to date? One likely explanation is that the organisms that currently make the workforce of biomedical research, having been selected primarily for their accessibility to genetic studies, are not particularly good exponents of regenerative capacities (e.g., *Drosophila*, nematodes and mice). That animal models had to be selected for their capacity to be prodigious egg layers, or have very large litters in order to do genetics are relatively modern criteria for selecting animal models. However, the advent of molecular biology, genomics and their attendant technologies allow us an unprecedented opportunity to plumb the depths of biology thus far beyond the reach of genetics research. This morning I will tell you the story of one such organism, the planarian *Schmidtea mediterranea* and how it is helping us unravel the mystery of animal regeneration.

**Teaching *in concert*: a novel approach to interdisciplinary collaborative project-based instruction.**A. L. Goodman<sup>1</sup>, A. Dekhtyar<sup>1</sup>; <sup>1</sup>California Polytechnic State University, San Luis Obispo, CA

We developed and piloted a novel approach to interdisciplinary instruction that enables undergraduate students in life sciences to work “in concert” with computer science students to solve biological problems. Our approach relies on well-defined **interdependent** roles for biology (BIO) and computer science (CS) students in a research project.

We recognize distinct learning objectives for each major and implement them in two separate courses taught side-by-side: Bioinformatics Applications for BIO majors and Bioinformatics Algorithms for CS majors. We rely on separate lectures for each group of students. Students work as part of an interdisciplinary team in a joint project-based computer laboratory. The following workflow was applied to five increasingly difficult assignments throughout a 10-week quarter: (1) BIO students are presented with a biological question, (2) they figure out what data is required to answer the question and write program requirements, (3) CS partners write programs, (4) BIO and CS students collaborate on testing the program, (5) BIO students use the program to answer the original question. We designed the assignments around the research project conducted by the Genomics Education Partnership (GEP, [www.gep.wustl.edu](http://www.gep.wustl.edu)): annotation of fruit fly genomes and comparative analysis of different genome regions.

We tested this approach with 24 BIO and 35 CS students. Our assessment included evaluation of student artifacts by partners from another discipline and by instructors, as well as self-assessment using voluntary confidential surveys (86.4 % response rate). Program requirements produced by BIO students improved or greatly improved in 82% of the evaluations by CS students. An increase in student confidence to collaborate with colleagues on interdisciplinary work was reported by 74.5% of the respondents. Our data indicate that students appreciate and mutually benefit from interdisciplinary interactions.

The following factors appear critical to the success of our approach: (1) modular organization of the course with learning objectives explicitly aligned to the research objectives; (2) clearly defined student roles and sufficient time allotted to each assignment for meaningful in-class interactions; (3) well-balanced team constitution and sufficient problem-solving and independent learning skills to ensure team success. The independent learning skills were reinforced among biology students by using an “inverted” classroom approach, where students spent most lecture time discussing the material and homework assignments completed outside of class. We believe that our approach can be adapted to a wide range of interdisciplinary project/course combinations and seek collaborations with other programs to test this hypothesis.

### **IRE1 $\alpha$ induces thioredoxin-interacting protein to activate the NLRP3 inflammasome and promote programmed cell death during ER stress.**

*A. Lerner<sup>1</sup>, J-P. Upton<sup>2</sup>, P. Praveen<sup>1</sup>, R. Ghosh<sup>1</sup>, A. Igbaria<sup>1</sup>, V. Nguyen<sup>1</sup>, B. Backes<sup>1</sup>, Y. Nakagawa<sup>1</sup>, Q. Tang<sup>1</sup>, S. Oakes<sup>2</sup>, F. Papa<sup>1</sup>, A. Trusina<sup>1</sup>; <sup>1</sup>Medicine, University of California, San Francisco, San Francisco, CA, <sup>2</sup>Pathology, University of California, San Francisco, San Francisco, CA*

When unfolded proteins accumulate to irremediably high levels within the endoplasmic reticulum (ER), intracellular signaling pathways called the unfolded protein response (UPR) become hyperactivated to cause programmed cell death. We discovered that thioredoxin-interacting protein (TXNIP) is a critical node in this “Terminal UPR.” TXNIP becomes rapidly induced by IRE1 $\alpha$ , an ER bifunctional kinase/endoribonuclease (RNase). Hyperactivated IRE1 $\alpha$  increases TXNIP mRNA stability by reducing levels of a TXNIP destabilizing micro-RNA, miR-17. In turn, elevated TXNIP protein activates the NLRP3 inflammasome, causing Caspase-1 cleavage and interleukin 1 $\beta$  (IL-1 $\beta$ ) secretion. Txnip gene deletion reduces pancreatic  $\beta$ -cell death during ER stress, and suppresses diabetes caused by proinsulin misfolding in the Akita mouse. Finally, small molecule IRE1 $\alpha$  RNase inhibitors suppress TXNIP production to block IL-1 $\beta$  secretion. In summary, the IRE1 $\alpha$ -TXNIP pathway is used in the terminal UPR to promote sterile inflammation and programmed cell death, and may be targeted to develop effective treatments for cell degenerative diseases.

60

### **The apoptosis inhibitor ARC alleviates the ER stress response to promote $\beta$ -cell survival in diabetes.**

*W. McKimpson<sup>1</sup>, J. Weinberger<sup>1</sup>, L. Czerski<sup>1</sup>, M. Zheng<sup>1</sup>, M. Crow<sup>2</sup>, J. Pessin<sup>1</sup>, S. Chua<sup>1</sup>, R. Kitsis<sup>1</sup>; <sup>1</sup>Albert Einstein College of Medicine, Bronx, NY, <sup>2</sup>Johns Hopkins University, Baltimore, MD*

Type 2 diabetes involves both insulin resistance and “failure” of  $\beta$ -cells, the cells responsible for insulin secretion. An important component of  $\beta$ -cell failure is cell loss by apoptosis. ARC (Apoptosis Repressor with Caspase Recruitment Domain) is an inhibitor of apoptosis that is highly expressed in cardiac and skeletal myocytes and neurons. ARC possesses the unusual property of antagonizing both the extrinsic (death receptor) and intrinsic (mitochondria/endoplasmic reticulum (ER)) cell death pathways. We discovered that ARC protein is abundant in cells of the pancreatic islets, including >99.5% of mouse and 73% of human  $\beta$ -cells. Moreover, we found that deletion of nol3, encoding ARC, markedly exacerbates

hyperglycemia and further impairs glucose tolerance in diabetic (*ob/ob*) mice, and this is accompanied by pancreatic islet disorganization and increases in  $\beta$ -cell apoptosis. ER stress is a major component of type 2 diabetes and an important trigger of  $\beta$ -cell death. Genetic gain- and loss-of-function studies in cultured cells demonstrated that ARC inhibits  $\beta$ -cell apoptosis elicited by the ER stressors tunicamycin, thapsigargin, and the free fatty acid palmitate. Unexpectedly, inhibition of cell death by ARC is mediated by suppression of the ER stress response, a novel function of ARC. Further analysis showed that ARC acts distal to ER stress sensors PERK and IRE1 $\alpha$  to suppress induction of CHOP, a transcription factor that activates both genes involved in resolving ER stress and genes involved in cell death. In pancreatic islet tissue stimulated with palmitate, depletion of ARC augments CHOP abundance and apoptosis, which is dramatically rescued by deletion of CHOP. Taken together, these data demonstrate that ARC is a previously unrecognized inhibitor of  $\beta$ -cell apoptosis in type 2 diabetes, and its protective effects are mediated through a novel mechanism involving suppression of the ER stress response pathway.

61

***Developmentally programmed mega-autophagy executes nuclear destruction during yeast gametogenesis.***

M. Eastwood<sup>1</sup>, M. Meneghini<sup>1</sup>; <sup>1</sup>Molecular Genetics, University of Toronto, Toronto, ON, Canada

While studies of the budding yeast *Saccharomyces cerevisiae* have provided fundamental insights into the mechanisms of autophagy, the roles of cell death pathways in yeast are less well understood. We have discovered that developmentally-programmed nuclear “death” (PND) is executed during the gametogenesis phase of the yeast lifecycle, a process more commonly known as sporulation. In response to carbon deprivation, sporulating cells subject only a fraction of their meiotic products to cellularization. Under such nutritionally-stressful conditions, we observe widespread PND. We have determined that PND is accomplished by collaborating autophagic and apoptotic-like pathways. Our live-cell imaging indicates that PND coincides with the post-meiotic permeabilization and lysis of the vacuole (lysosome). PND also occurs in the absence of autophagosome biogenesis, suggesting that it is driven by the coincident release of lytic vacuolar contents rather than canonical macroautophagy. Vacuolar rupture, or mega-autophagy, is a form of autophagy principally characterized during plant cell death and resembles lysosomal membrane permeabilization events which contribute to programmed cell death in animals. Quite interestingly, yeast PND invokes the cleavage of genomic DNA into nucleosomal fragments, a hallmark event of mammalian apoptosis. The production of nucleosomal DNA fragments requires the yeast orthologue of endonuclease G, a mitochondrial nuclease which mediates DNA fragmentation during apoptosis in metazoans. Our most recent work has focused on using genetic approaches to understand how the self-destructive events which underlie PND are coordinated with known aspects of sporulation. Mega-autophagy appears to be triggered after the progression through the pachytene stage of meiosis. Cells arrested prior to this point maintain intact vacuoles, while those arrested beyond pachytene execute robust vacuolar rupture, even if spore construction is incomplete. This suggests that the pachytene checkpoint is the final point of surveillance before the bulk degradation of the mother cell is initiated through mega-autophagy. Our characterization of yeast PND demonstrates further diversity in cell death programs, and illuminates a developmental function of conserved apoptotic-like pathways in a unicellular microbe. We also present an example of autophagic pathways coordinating to destroy whole nuclei in response to nutritional stress.

62

### **Lysosomes as novel regulators of gene expression, organelle biogenesis, and autophagy induction.**

*J. Martina<sup>1</sup>, R. Puertollano<sup>1</sup>; <sup>1</sup>National Institutes of Health, Bethesda, MD*

One of the most fundamental issues in cell biology is how cells integrate growth-stimulating and inhibitory signals to ultimately regulate a diversity of key cellular functions, including gene expression, autophagy, organelle biogenesis, and cell growth. mTOR is a serine/threonine kinase that regulates proliferation, cell cycle, and autophagy in response to energy levels, growth factors, and nutrients. mTOR responds to numerous stresses and its dysregulation leads to cancer, metabolic disease, and diabetes. Activation of the mTORC1 complex occurs at lysosomes and the recruitment of mTORC1 to this compartment is regulated by the Rag family of small GTPases.

Here we described how mTORC1 controls the activation of the transcription factor EB (TFEB), a master regulator of the expression of autophagic and lysosomal genes. Under nutrient-rich conditions, mTORC1 phosphorylates TFEB in S211, thus promoting binding of TFEB to the cytosolic chaperone 14-3-3 and retention of TFEB in the cytosol. Upon amino acids deprivation, dissociation of the TFEB/14-3-3 complex results in delivery of TFEB to the nucleus and up-regulation of genes that leads to induction of autophagy, biogenesis of lysosomes, and increased lysosomal degradation.

We also identify the molecular mechanism that mediates recruitment of TFEB to lysosomes, a critical step in the regulation of this transcription factor by mTORC1. We found that TFEB interacts with active, but not inactive, Rags GTPases via the surface interface containing the switch regions of the Rags G domain. Depletion of endogenous Rags, inactivation of Rags by starvation, or expression of dominant negative Rags prevents recruitment of TFEB to lysosomes and abolishes mTORC1-dependent phosphorylation and inactivation of TFEB. In contrast, expression of active Rags is sufficient to induce association of TFEB with lysosomal membranes. The first 30 residues of TFEB are both, necessary and sufficient for interaction with active Rags and recruitment to lysosomes, while a stretch of arginines in the central portion of TFEB functions as a nuclear import signal. Importantly, Rag GTPases also mediate amino acid-dependent recruitment of the transcription factor MITF to lysosomes, thus suggesting that the Rag complex might have a more general role in the regulation of gene expression.

Overall, our work provides new insight for understanding the novel and exciting role of lysosomes as signaling centers that synchronize environmental cues with gene expression, energy production, and cellular homeostasis.

63

### **Regulation of mammalian autophagy by class II and III PI 3-kinases through PI3P synthesis.**

*K. Devereaux<sup>1,2</sup>, C. Dall'Arm<sup>2</sup>, Y. Ogasawara<sup>3</sup>, X. Zhou<sup>4</sup>, F. Wang<sup>4</sup>, A. Yamamoto<sup>3</sup>, G. Di Paolo<sup>1,2</sup>; <sup>1</sup>Department of Pathology and Cell Biology, Columbia University Medical Center, New York, NY, <sup>2</sup>Taub Institute for Research on Alzheimer's Disease and the Aging Brain, Columbia University Medical Center, New York, NY, <sup>3</sup>Department of Animal Bio-Science, Nagahama Institute of Bio-Science and Technology, Shiga, Japan, <sup>4</sup>Department of Cell Biology and Neurobiology, Duke University Medical Center, Durham, NC*

Autophagy requires the biogenesis of autophagosomes (APs), which are large multilamellar vesicles that sequester cytoplasmic substrates and undergo a maturation process ultimately leading to their fusion with lysosomes. Previous studies have suggested that local production of phosphatidylinositol-3-phosphate (PI3P) by class III phosphatidylinositol 3-kinase (PI3K) (i.e., Vps34) is required for AP biogenesis at specialized sites of the endoplasmic reticulum called

"omegasomes". Remarkably, studies in the first mammalian Vps34 conditional knockout mice hinted that Vps34 may not be essential for autophagy in neurons. However, in more recent studies using different mouse models, Vps34 was proposed to be required for autophagy in T-cells, fibroblasts, heart and liver tissue. Given these two contradictory sets of findings, the precise role of Vps34 for the functionality of autophagy remains an outstanding question. Here we show by electron microscopy that AP formation still occurs in *Vps34*<sup>-/-</sup> mouse embryonic fibroblasts (MEFs), although fewer APs and autophagolysosomes are formed upon nutrient deprivation. Corroborating these results, long-lived protein degradation assays show a ~50% reduction in (macro)autophagy efficacy and autophagy assays show reduced formation of LC3 puncta and LC3 conjugation as well as a dramatic reduction in the recruitment of the PI3P effector WIPI-1 to sites of AP nucleation in starved *Vps34*<sup>-/-</sup> MEFs. These findings indicate that Vps34 is important, but not essential for AP formation, and suggest that alternate, autophagy-relevant sources of PI3P exist in mammals. Although Vps34 is believed to be the predominant source of PI3P, class II PI3Ks can also produce this lipid and have been shown to mediate other PI3P-dependent processes. We found that silencing class II isoforms in either the wild-type or *Vps34*<sup>-/-</sup> MEFs reduces autophagy, suggesting a positive regulatory role for the class II in this process. In conclusion, our studies indicate that both class II and III PI3Ks contribute functionally-relevant pools of PI3P for AP biogenesis.

64

**Selective autophagy in the control of cellular homeostasis.**

Autophagy, the cellular process by which protein and organelles undergo degradation in lysosomes, can take place through very different mechanisms. This work focuses in a selective type of autophagy, known as chaperone-mediated autophagy (CMA), that contributes to the degradation of a specific subset of cellular proteins in lysosomes. CMA is active in most mammalian cell types, but its activity varies depending on cell type and cellular conditions. Although there is some level of basal CMA activity, maximal activation of this pathway occurs during stress or in conditions leading to increased amount of misfolded/damaged proteins. Degradation by CMA requires the presence of a targeting motif in the substrate protein, a set of cytosolic and lysosomal chaperones and a receptor protein at the lysosomal membrane, the lysosome-associated membrane protein type 2A (LAMP-2A).

CMA activity is upregulated in response to different type of stress such as nutritional stress, oxidative stress and exposure to compounds inducing conformational changes of particular cytosolic proteins. In addition, activation of CMA is also observed in response to agents inducing ER-stress, and this autophagic pathway remains active during the period that follows the stress. Failure to upregulate CMA after ER stress leads to cell death. We have characterized the mechanisms by which active CMA contributes to return ER to homeostasis and have analyzed the consequences for the biology of this organelle of the reduced CMA observed under different pathological conditions and in aging.

### Local apoptosis, mitochondrial turnover and neurodegeneration.

M. Sheng<sup>1</sup>, B. Bingol<sup>1</sup>, A. Erturk<sup>1</sup>; <sup>1</sup>Department of Neuroscience, Genentech, South San Francisco, CA

Loss of synapses and death of neurons are hallmarks of neurodegenerative disease such as Alzheimer's disease, but also characteristic of normal postnatal brain development in mammals. Morphological synapse elimination -- together with its functional correlate, long-term depression (LTD) of synaptic strength -- are natural processes that sculpt the brain, akin to programmed cell death (also termed apoptosis). Remarkably, LTD and synapse elimination share common molecular mechanisms with apoptosis. The mitochondrial (or intrinsic) pathway of apoptosis, culminating in caspase-3 activation, is required for LTD in hippocampal neurons. This pathway is activated transiently, moderately and locally in the vicinity of synapses to weaken and eliminate synapses -- in the absence of cell death. Local activation of the mitochondrial apoptosis pathway in the dendrites of neurons by an optogenetic approach is sufficient to cause local loss of synapses and retraction of dendrite branches, without neuronal death. Beta-amyloid (A $\beta$ , which accumulates in the brain of Alzheimer's patients) co-opts the same "synaptic apoptosis" pathway to impair synaptic plasticity, which could contribute to the synapse dysfunction and loss of Alzheimer's disease.

In Parkinson's disease (the second most common neurodegenerative disease), much evidence points to mitochondrial dysfunction as a major pathophysiologic mechanism. Mutations in PINK1 (a protein kinase) and Parkin (an E3 ubiquitin ligase) cause familial Parkinson's disease and impair mitochondrial turnover by autophagy (mitophagy). We have screened for genes that regulate mitophagy in order to identify potential therapeutic targets for improving mitochondrial quality control in neurons.

66

### Toxic $\alpha$ -synuclein oligomer accumulation and endoplasmic reticulum stress is mechanistically linked to $\alpha$ -synucleinopathy in vivo.

E. Colla<sup>1</sup>, B. Schneider<sup>2</sup>, P. Coune<sup>2</sup>, P. H. Jensen<sup>3</sup>, J. C. Troncoso<sup>4</sup>, M. K. Lee<sup>5</sup>; <sup>1</sup>Scuola Normale Superiore, Pisa, Italy, <sup>2</sup>Ecole Polytechnique Fédérale de Lausanne, Lausanne, Switzerland, <sup>3</sup>Aarhus University, Aarhus, Denmark, <sup>4</sup>Johns Hopkins University, Baltimore, MD, <sup>5</sup>University of Minnesota, Minneapolis, MN

In Parkinson's disease (PD) and other  $\alpha$ -synucleinopathies,  $\alpha$ -synuclein ( $\alpha$ S) abnormalities are directly implicated in the disease pathogenesis. Currently, both  $\alpha$ S fibrils and prefibrillar  $\alpha$ S oligomers have been proposed as the pathogenic species. However, because the  $\alpha$ S oligomers are only observed *in vitro*, the *in vivo* pathologic significance of  $\alpha$ S oligomers and the *in vivo* mechanisms of neurotoxicity are unknown. To study mechanisms of  $\alpha$ S toxicity, we examined the subcellular distribution of normal and abnormal  $\alpha$ S in brain. We show that while most of  $\alpha$ S is found in the cytosol, a fraction of  $\alpha$ S, but not highly related  $\beta$ S, is found in the lumen of the endoplasmic reticulum/microsomes(ER/M) *in vivo*. With aging,  $\alpha$ S level in ER increases and forms toxic oligomers that accumulate with the progression of  $\alpha$ -synucleinopathy. Accumulation of ER/M  $\alpha$ S oligomers is followed by the occurrence of aberrant ER stress/unfolded protein response where the ER chaperones are induced without the activation of phospho-eIF2 $\alpha$ /CHOP. Further, increased ER-associated polyubiquitin accumulation and activation of ER stress-associated caspases indicate that  $\alpha$ -synucleinopathy directly causes ER dysfunction that contributes to neurodegeneration. Significantly, treatment with Salubrinal, an anti-ER stress

compound, significantly attenuates disease manifestations in both the transgenic mouse model and an AAV- $\alpha$ S rat model of  $\alpha$ -synucleinopathy. The results show that  $\alpha$ S oligomers and ER-stress are pathologically relevant for PD. Further, alleviating chronic ER stress represents a new therapeutic strategy for PD and related diseases.

67

### **Rescue of dopaminergic neuron mitochondrial dysfunction and degeneration in parkin mutants.**

*J. Burman<sup>1</sup>, S. Yu<sup>1</sup>, A. Poole<sup>1</sup>, T. Dhillon<sup>1</sup>, R. Decal<sup>1</sup>, L. Pallanck<sup>1</sup>; <sup>1</sup>Genome Sciences, University of Washington, Seattle, WA*

Parkinson disease (PD) is a prevalent age-related neurodegenerative disorder, the motor deficits of which result from the selective degeneration of dopaminergic neurons in the substantia nigra of the midbrain. The molecular underpinnings of PD are poorly understood, but studies of mitochondrial toxins, and the characterization of genes involved in rare heritable forms of PD implicate mitochondrial dysfunction as a primary cellular defect. However, whether genetic defects associated with heritable forms of PD influence mitochondrial function in dopaminergic neurons remains unknown. To address this question we have developed a flow cytometry-based method to measure mitochondrial membrane potential and mitochondrial abundance from individual neural subsets isolated from the adult *Drosophila* brain. Our findings indicate that down regulation of the PINK1/Parkin pathway causes depolarized mitochondria to accumulate in dopaminergic neurons, and that genetic manipulation of mitochondrial dynamics factors can rescue this phenotype. Complementary experiments utilizing isolated cholinergic neurons show that dopaminergic neurons accumulate depolarized mitochondria to a greater extent than cholinergic neurons, suggesting that dopaminergic neurons are subject to a more toxic intracellular environment or lack alternative mitochondrial quality control mechanisms. Finally, we find that the degeneration of dopaminergic neurons, observed in the brains of adult parkin null mutant animals, is rescued by genetic manipulation of the mitochondrial fission, fusion and autophagy machinery. Ongoing experiments to test hypotheses related to mitochondrial dysfunction in PD, including the prediction that genes involved in heritable forms of PD maintain cellular function by promoting the elimination of dysfunctional mitochondria, will be discussed.

68

### **Dose-dependent and mutant-enhanced neurotoxicity in mice expressing wild type or ALS-linked mutants of FUS/TLS.**

*S-C. Ling<sup>1</sup>, P. Parone<sup>2</sup>, S. Da Cruz<sup>2</sup>, H. Ilieva<sup>2</sup>, O. Platoshyn<sup>3</sup>, D. Salazar<sup>2</sup>, S. Tokunaga<sup>2</sup>, D. Swing<sup>4</sup>, L. Tessarollo<sup>4</sup>, M. Marsala<sup>3</sup>, C. E. Shaw<sup>5</sup>, D. W. Cleveland<sup>1</sup>; <sup>1</sup>Ludwig Institute and Dept. of Neurosciences, University of California, San Diego, La Jolla, CA, <sup>2</sup>Ludwig Institute, University of California, San Diego, La Jolla, CA, <sup>3</sup>Department of Anesthesiology, University of California, San Diego, La Jolla, CA, <sup>4</sup>Mouse Cancer Genetics Program, National Cancer Institute, Frederick, MD, <sup>5</sup>Institute of Psychiatry, King's College London, London, UK*

Mutations in two ubiquitously expressed nucleic-acid binding proteins, TDP-43 (TAR-DNA binding protein-43 KDa) and FUS/TLS (fused in sarcoma/translocated in liposarcoma), cause amyotrophic lateral sclerosis (ALS) and frontotemporal lobar degeneration (FTLD). Abnormal aggregates of these two proteins are present in inherited and sporadic ALS, FTLD, and other neurodegenerative diseases, independent of mutations in either gene. We show here that broad expression within the nervous system of wild type or either of two ALS-linked mutants of human FUS/TLS produces progressive motor phenotypes, including abnormal gait, glial activation,

degeneration of motor and sensory axons, and loss of spinal cord motor neurons, accompanied by denervation-induced muscle fibrillations, all of which are characteristics of ALS. Expression of wild type or ALS-linked mutants of human FUS/TLS downregulates endogenous mouse FUS/TLS expression at both mRNA and protein levels, illustrating an auto-regulation mechanism for FUS/TLS. Furthermore, generation of homozygote or double heterozygotes expressing human wild type FUS/TLS cause rapidly progressive neurological phenotypes and dose-dependent lethality accompanied by widespread neurodegeneration. Taken together, our results demonstrate that (1) mice expressing ALS-linked mutation in FUS/TLS develop earlier progressive motor deficits and early mortality than mice expressing comparable level of wild type human FUS/TLS, and (2) a surprisingly small increase in increased expression of wild type FUS/TLS sharply accelerate neurodegeneration, providing a basis for FUS/TLS involvement in pathogenesis in the absence of mutation.

69

**Amyloid- $\beta$  signals through tau to drive ectopic neuronal cell cycle re-entry in Alzheimer's disease.**

*M. E. Seward<sup>1</sup>, E. Swanson<sup>1</sup>, E. D. Roberson<sup>2</sup>, G. S. Bloom<sup>1</sup>; <sup>1</sup>University of Virginia, Charlottesville, VA, <sup>2</sup>University of Alabama at Birmingham, Birmingham, AL*

Cognitive decline in Alzheimer's disease (AD) is caused by synaptic dysfunction, the ultimate cause of which is neuron death. Most normal adult neurons are permanently post-mitotic, but AD neurons frequently re-enter the cell cycle, fail to complete mitosis, and die up to a year later. This ectopic pathway for neuronal cell cycle re-entry (CCR) apparently accounts for the death of a substantial fraction of the neurons that are lost during typical cases of AD and thus represents a crucial, but poorly understood aspect of AD pathogenesis. We now report the fundamental features of this pathway. Exposure of primary wild type (WT) neurons to amyloid- $\beta$  (A $\beta$ ) oligomers caused CCR and activation of 3 protein kinases, fyn, PKA and CaMKII, which respectively phosphorylated tau on Y18, S409 and S416. In tau knockout (KO) neurons A $\beta$  oligomers failed to induce CCR, but did activate all 3 kinases. CCR was restored in tau KO neurons by expressing WT tau, but not tau with non-phosphorylatable Y18F, S409A or S416A mutations. Tau phosphorylation at Y18, S409 and S416 catalyzed respectively by fyn, PKA and CaMKII must therefore occur to induce CCR. In contrast, 2 other prominent tau kinases, GSK3 $\beta$  and MARK/Par-1 were not activated by A $\beta$  oligomers under identical conditions. To determine if neuronal CCR *in vivo* requires tau, we examined hAPPJ20 mice, which overexpress mutant human amyloid precursor protein (APP) and accumulate A $\beta$  deposits, on an endogenous WT tau or tau KO background. Nearly 60% of cortical neurons in 6-month-old hAPPJ20/WT tau mice expressed the G1 marker, cyclin D1, which was undetectable in hAPPJ20/tau KO mice, or in WT or tau KO parental controls. These results establish a novel, 3 stage biochemical pathway that explains why A $\beta$  toxicity requires tau, and thus represent a major advance towards understanding seminal pathogenic events in AD. An especially noteworthy feature of this destructive pathway is that it is established by A $\beta$  and tau independently of their respective incorporation into plaques and tangles, the histopathological hallmarks of AD brain.

**The highly conserved CAP-Gly domain of dynactin interacts with EB3 to enhance the initiation of retrograde axonal transport of multiple cargos.**

*A. J. Moughamian<sup>1</sup>, E. L. Holzbaur<sup>1</sup>; <sup>1</sup>Physiology, University of Pennsylvania, Philadelphia, PA*

Mutations in the CAP-Gly domain of the p150<sup>Glued</sup> subunit of dynactin cause two distinct neurodegenerative diseases: an inherited form of Parkinson's disease, Perry syndrome, and

distal hereditary motor neuropathy 7B (HMN7B). Dynactin is a required cofactor for the minus-end directed microtubule motor cytoplasmic dynein. We recently reported a novel function for the CAP-Gly domain of dynactin in neurons, demonstrating that this domain is crucial for the efficient flux of lysosomes from the distal axon. Here, we show that multiple cargo types including mitochondria, early endosomes, signaling endosomes and APP vesicles all require the CAP-Gly domain of dynactin for efficient retrograde transport from the distal axon but not for sustained organelle transport along the axon. Thus, while these cargos undergo distinct forms of motility in the axon, they all require the CAP-Gly domain for efficient transport initiation. To further investigate the mechanisms involved in the initiation of dynein-mediated retrograde transport, we examined the role of dynamic microtubules. We observed an increase in the local concentration of EB3-positive microtubule plus-ends in the distal axon. This region of enhanced dynamicity of the microtubule cytoskeleton corresponds to the region of the distal axon where dynactin is enriched. The CAP-Gly domain directly interacts with EB3 and this interaction is inhibited by the neurodegenerative mutations. We find that knockdown of EBs in primary neurons disrupts transport initiation specifically from the distal axon. Together these data suggest that both dynamic microtubules and EBs are important in dynactin-mediated transport initiation. Consistent with our model, the neurodegenerative mutations in dynactin cause a failure to localize p150<sup>Glued</sup> to the distal axon and an inhibition of retrograde flux. The dynein-binding protein, Lis1, is a distinct disease-associated protein that has also been proposed to function as a transport initiation factor for dynein. However, in contrast to the CAP-Gly domain of dynactin and EBs, Lis1 is required for both transport initiation from the distal axon as well as sustained bidirectional transport along the axon. Further, Lis1 is not enriched in the distal axon. These data suggest that Lis1 and dynactin act through distinct mechanisms to initiate dynein-mediated organelle transport in neurons.

### Generating a dynamic kinetochore-microtubule interface.

*I. M. Cheeseman<sup>1</sup>; <sup>1</sup>Department of Biology, MIT, Whitehead Institute, Cambridge, MA*

To ensure equal chromosome segregation during mitosis, the macromolecular kinetochore must remain attached to depolymerizing microtubules, which drive poleward chromosome movement. Depolymerizing microtubules undergo a dramatic structural change resulting in the formation of curved protofilaments. How kinetochores remain attached to depolymerizing microtubules and harness the force produced during this process has yet to be defined in vertebrates. We have analyzed key players in this process including the conserved Ndc80 complex and the metazoan Ska1 complex. We demonstrate that the conserved kinetochore-localized Ska1 complex can track with depolymerizing microtubule ends. In contrast, the Ndc80 complex, lacks tracking activity on its own. Importantly, we demonstrate that the Ska1 complex can impart its tracking capability to the Ndc80 complex. This work defines an integrated kinetochore-microtubule interface formed by the Ska1 and Ndc80 complexes that can remain attached to depolymerizing microtubules.

72

### Differences in Ran regulation and the microtubule-associated protein TPX2 contribute to interspecies spindle scaling in *Xenopus* egg extracts.

K. Helmke<sup>1</sup>, R. Heald<sup>1</sup>; <sup>1</sup>Department of Molecular and Cell Biology, University of California Berkeley, Berkeley, CA

A bipolar, microtubule (MT)-based spindle performs the crucial and universal function of segregating chromosomes during eukaryotic cell division, but spindle size, assembly mechanism and architecture vary depending on the organism and cell type. We previously established an egg extract system that recapitulates size differences between meiotic spindles of the frog *Xenopus laevis* and its smaller relative *Xenopus tropicalis*, and identified differential phosphorylation of the MT severing factor katanin as a spindle length scaling mechanism. However, katanin activity does not fully account for meiotic spindle differences between the two species. Interestingly, we have found that the small *X. tropicalis* spindles are resistant to inhibition of RCC1, the chromatin-bound nucleotide exchange factor that generates a gradient of RanGTP, whereas the large *X. laevis* spindles are disrupted with concomitant mislocalization of downstream factors including the spindle MT-associated protein TPX2. Interestingly, TPX2 is present at three-fold higher levels in *X. tropicalis* extract and is missing a 7 amino acid insertion found in *X. laevis* TPX2 that introduces two consensus Polo kinase phosphorylation sites. When added to *X. laevis* extract in equal amounts, both *X. tropicalis* TPX2 and an *X. laevis* TPX2 mutant lacking the 7 amino acid insertion induce dramatic MT nucleation compared to wild-type *X. laevis* TPX2. We are testing the hypothesis that phosphorylation inhibits TPX2 activity in *X. laevis* extract, causing a decrease in MT nucleation that affects spindle size. Consistent with this model, addition of excess TPX2 to *X. laevis* extract reduced spindle length. Higher levels and activity of TPX2 may decrease average MT length in the *X. tropicalis* spindle, and could also act to decrease kinesin-5 dependent MT sliding. Both of these mechanisms would limit the distance that a spindle MT slides poleward in its lifetime, thereby decreasing steady state spindle length. Thus, differences in meiotic spindle size in the two *Xenopus* species are accompanied by changes in MT nucleation and stability that reflect differences in spindle architecture and assembly pathway.

73

### Molecular mechanisms governing extrinsic forces in mitotic spindle organization.

M. Kwon<sup>1,2</sup>, M. Bagonis<sup>2</sup>, G. Danuser<sup>2</sup>, D. Pellman<sup>1,2</sup>; <sup>1</sup>HHMI, Pediatric Oncology, Dana-Farber Cancer Institute, Boston, MA, <sup>2</sup>Cell Biology, Harvard Medical School, Boston, MA

The presence of supernumerary centrosomes in cancer cells often creates the potential for catastrophic multipolar divisions. However, many cancer cells successfully divide because of mechanisms that suppress multipolar mitoses by clustering their extra centrosomes. Our functional genomic study has previously identified key pathways contributing to centrosome organization in cancer cells. In addition to spindle intrinsic forces, we found that cell adhesion patterns can determine the fate of mitosis whether they divide into two (bipolar) or more (multipolar). Yet, the mechanism by which actin and adhesion-dependent forces to control the fidelity of mitosis remain unclear at the molecular level. One model proposes that sites of strong cell matrix adhesion are imprinted as an actin rich structure called retraction fibers during mitosis, and the retraction fibers serve as cortical cues to concentrate force generators and regulators to pull centrosomes. By imaging cancer cells plated on fibronectin micropatterns, here we demonstrate that Myo10, an unconventional myosin identified from our genome-wide screen, is an essential component linking retraction fiber-mediated forces to astral microtubules (MTs) during spindle organization. Myo10 specifically localizes along and to the tips of the retraction fibers. When cells with extra centrosomes were plated on Y-shaped fibronectin

micropatterns, control cells divide tripolar toward Y-adhesion axis; however, cells depleted of Myo10 undergo bipolar division independent of retraction fiber positions, suggesting that Myo10 is a force coupler from retraction fibers to centrosomes. We have hypothesized that intrinsic properties of MTs adjacent to retraction fibers are altered to favor stable interaction between astral MTs and cell cortex. To uncover heterogeneity of MT dynamics in relation to retraction fibers, we have performed live cell imaging of GFP-EB3 with high spatio-temporal resolution in cells plated on fibronectin micropatterns where retraction fiber positions are precisely manipulated. We have developed a system that quantifies and visualizes MT dynamics in different subregions of cells by an automated computer program capable of tracking GFP-EB3 comets. This approach uncovered heterogeneity of MT dynamics around retraction fiber regions. Interestingly, our analyses have revealed that Myo10 is in part responsible for promoting the long-lived and long distance travelling MTs. Taken together, these results suggest that Myo10 is a key adhesion-dependent regulator that confers heterogeneity of mitotic cortex by coupling cell geometry/adhesion to mitotic fidelity and genome stability.

74

### **Mechanisms of chromosome segregation on acentrosomal oocyte spindles in *C. elegans*.**

*C. Muscat*<sup>1</sup>, *K. Torre-Santiago*<sup>1</sup>, *J. A. Powers*<sup>2</sup>, *S. M. Wignall*<sup>1</sup>; <sup>1</sup>*Molecular Biosciences, Northwestern University, Evanston, IL,* <sup>2</sup>*Indiana University, Bloomington, IN*

It was recently reported that kinetochores are not essential for chromosome separation in *C. elegans* oocytes, suggesting that acentrosomal spindles in these cells employ a novel segregation mechanism<sup>1</sup>. We previously found that lateral microtubule bundles surround homolog pairs (bivalents) during prometaphase, and proposed that congression is facilitated by movement of chromosomes along these bundles<sup>2</sup>. Therefore, we set out to investigate whether lateral microtubule associations could mediate segregation as well.

Using high- and super-resolution imaging we found that lateral microtubule-chromosome associations are present in oocyte spindles throughout anaphase. In early anaphase, the poles broaden so that microtubule bundles are arranged in a parallel array. Chromosomes move towards spindle poles (marked with KLP-18 and ASPM-1 antibodies), and in late anaphase were found outside most of the pole staining, near the microtubule ends. At this stage microtubule bundles in the central spindle converge while splitting around the chromosomes near the poles, maintaining their lateral associations. Therefore, chromosomes potentially move poleward along laterally-associated microtubules arranged in a parallel configuration; once segregation is complete the bundles converge and the spindle disassembles.

Multiple proteins, including members of the Chromosome Passenger Complex (CPC), form a ring around the center of each bivalent during congression<sup>2</sup>. While CPC components redistribute to microtubules in anaphase, some midbivalent proteins persist as rings between separating chromosomes that elongate into linear structures and then disappear<sup>1</sup>. Intriguingly, we found changes in the behavior of these structures in oocytes with segregation defects, suggesting the presence of a mechanism that monitors the success of chromosome separation. When lagging chromosomes were present, elongation of the ring structures into linear elements was delayed; they often remained as rings through late anaphase and in these instances microtubule bundles did not converge, instead they maintained a parallel arrangement. Moreover, while the CPC kinase Aurora B redistributed to the spindle in wild type anaphase, when lagging chromosomes were present it remained associated with the ring structures. These results reveal that ring disassembly is a regulated event that may respond to the status of chromosome separation, and raises the possibility that the rings function to space parallel microtubules so that chromosomes can move along them. We therefore propose that there is a checkpoint acting to keep the spindle in an "early anaphase" configuration until chromosomes have properly

separated, to increase the fidelity of kinetochore-independent chromosome segregation on acentrosomal spindles.

**Central spindle formation through the regulation of microtubule depolymerization during cytokinesis.**

R. Uehara<sup>1</sup>, Y. Tsukada<sup>1</sup>, G. Goshima<sup>1</sup>; <sup>1</sup>Nagoya University, Nagoya, Japan

During anaphase, microtubule (MT) bundles interdigitate in an antiparallel manner to form multiple "stem bodies" in the central region of the central spindle. The stem bodies align at the cell's equatorial plane, provide scaffolds for signaling molecules that are required for progression of cytokinesis, and thus form the cell division plane. As ingression of the cleavage furrow proceeds, the stem bodies gather into a cluster at the intercellular bridge to provide a scaffold for the abscission machinery that completes cytokinesis. However, how the stem bodies align at the very center of the dividing cell and enable proper control of cytokinesis is poorly understood. We performed the live imaging of HeLa cells expressing the RACGAP1-GFP marker, and found that the position of each stem body constantly fluctuated both parallel and perpendicularly to the division axis, but was always confined to the equatorial region throughout anaphase; this uncovered the dynamic nature of the division plane. Taxol treatment led to stem body misalignment, indicating that dynamic MTs are required for proper positioning of the stem body. Cells depleted of the MT-depolymerizing kinesin Kif2A also had misaligned stem bodies, along with abnormally elongated central spindle MT bundles. The results of the functional living-cell assays showed that Kif2A controls the length of the central spindle MT bundles by localizing to the ends of the central spindle and depolymerizing the MTs in that region. Inhibition of the chromosomal passenger complex (CPC) resulted in excess accumulation of Kif2A in the inner region of the central spindle, and consequently, the central spindle became abnormally short and unstable, and it oscillated parallel to the division axis. These results suggest a model where the CPC prevents Kif2A access to the central region of the central spindle near the stem bodies, and thereby limits Kif2A-dependent MT depolymerization to the distal ends of the central spindle. We propose that this CPC- and Kif2A-dependent fine-tuning of MT depolymerization contributes to the stability and symmetry of the central spindle, which are essential for proper positioning of the stem bodies.

76

**A gain of function screen for miRNAs regulating mitosis.**

J. Fededa<sup>1,2</sup>, B. Mierzwa<sup>1,2</sup>, R. Stanyte<sup>1,2</sup>, M. Held<sup>2</sup>, D. W. Gerlich<sup>1,2</sup>; <sup>1</sup>IMBA, Institute of Molecular Biotechnology of the Austrian Academy of Sciences, Vienna, Austria, <sup>2</sup>Institute of Biochemistry, ETH Zurich, Zurich, Switzerland

A growing body of evidence indicates that miRNAs play an important role in the control of cell cycle progression, particularly at the G1/S transition. The function of miRNAs in regulating the expression of genes encoding for mitotic factors, however, remains vastly unexplored.

To address the role of miRNAs in mitosis, we performed a genome-wide gain of function screen using a library of miRNA-mimicking oligomers. Based on a live-cell imaging assay, we identified several miRNAs whose overexpression perturbed mitotic progression. Detailed phenotypic follow-up analysis revealed that overexpression of some candidate miRNAs affected mitotic spindle architecture, leading to mono- or multipolar spindles. These phenotypes were associated with delayed mitotic progression and a high incidence of polyploidization.

To investigate the molecular basis of the observed phenotypes, we investigated transcriptome changes upon overexpression of the miRNA candidates. Amongst the genes whose expression was altered by candidate miRNA overexpression, we identified several genes with ontologies related to the observed phenotypes, bearing predicted target sites in their 3'UTRs. Several of these down-regulated genes were validated by expression reporter constructs as direct targets of the candidate miRNAs. Moreover, siRNA-mediated depletion of these direct targets elicited similar phenotypes compared to over-expression of the corresponding regulatory miRNA. Our study thus identifies miRNAs that regulate mitosis genes, and suggests that misregulation of these regulatory miRNAs can lead to aneuploidy by mitosis failure, which may have implications for cancerogenesis.

### **How cells exploit extracellular matrix fibrils as mechano-chemical signal converters.**

*V. Vogel<sup>1</sup>; <sup>1</sup>Department of Health Sciences and Technology, Laboratory of Applied Mechanobiology, Zurich, Switzerland*

Since the physical and biochemical properties of extracellular matrix provide critical differentiation cues to cells, from stem cells to angiogenesis to cancer, it is of major importance to gain mechanistic insights how mechanical stretching of extracellular matrix molecules can alter various cell functions. Cells utilize mechanical forces to actively assemble and stretch the ECM fibers that surround them, and finally to remodel their microenvironments. To learn at the molecular level how mechanical forces are sensed and are translated into biochemical signals that can regulate the underpinning mechanotransduction events, many new assays and techniques have to be developed to probe how the stretching of proteins alters their structure-function relationships. With a focus on fibronectin, FRET-probes and stretch assays will be discussed that allow to probing the mechanical strain of fibronectin in cell culture and in microtissues, and how the stretching of proteins might alter their binding sites, as well as their biochemical display. Also bacteria take advantage of the fact that cells pull on extracellular matrix fibers and can thereby destroy bacterial binding motifs. For example, the multivalent binding motif on fibronectin that is recognized by the adhesins that *Staphylococcus aureus*, can be destroyed by stretching the fibers. We then analysed the design of altogether 32 bacterial adhesins that all target the same N-terminal fibronectin type 1 domains and found that they differ significantly in their ability to detect the mechanical strain of fibronectin fibers. The mechanical strain of extracellular matrix has never been considered before in the description of adhesion and host invasion by bacteria before. Finally, we analysed how stem cells respond to (or perhaps even utilize) the stretching of extracellular matrix fibers to regulate differentiation processes. Deciphering how proteins can serve as mechano-chemical signalling switches is thus not only essential to learn how cells probe and respond to their environments, but it has also far reaching implications in tissue engineering, systems biology and medicine.

78

**Dynamics and molecular organization of focal adhesions described at the nanoscale.**C. C. DuFort<sup>1</sup>, M. J. Paszek<sup>1</sup>, M. Rubashkin<sup>1</sup>, M. Davidson<sup>2</sup>, K. Thorn<sup>3</sup>, V. M. Weaver<sup>4</sup>;<sup>1</sup>Department of Surgery, University of California, San Francisco, San Francisco, CA, <sup>2</sup>National High Magnetic Field Laboratory, Florida State University, Tallahassee, FL, <sup>3</sup>Department of Biochemistry and Biophysics, University of California, San Francisco, San Francisco, CA,<sup>4</sup>Departments of Surgery & Anatomy & Bioengineering and Therapeutic Sciences, University of California, San Francisco, San Francisco, CA

Focal adhesions are the conduits through which cells receive and interpret mechanical and physical cues from the extracellular matrix and serve a critical role in the transmission of force, wound healing, motility, and morphogenesis. While their role as intricate molecular machines is well appreciated, little is known about their overall organization at the nano-scale. It has been previously hypothesized that focal adhesion complexes are highly spatially conserved structures. However, our results suggest that there are specific nano-scale changes to focal adhesion architecture that appear to be directly correlated with regions of varying cell-generated contractility and motility phenotypes. To further our understanding of focal adhesion structure and function, the three-dimensional organization and spatial orientation of proteins comprising focal adhesion complexes with precisions of ~5 nm along the optical axis and diffraction-limited laterally was revealed with a scanning-angle variant of fluorescence interference contrast microscopy. Utilizing this technique, a library of focal adhesion protein locations including paxillin, focal adhesion kinase, vinculin, N and C-terminal labeled talin, and zyxin was developed. Each protein was found to be stratified to distinct layers and localizations within individual focal adhesion complexes over a vertical range of ~60 nm. To observe how these proteins were evolving over time, dynamic studies in 3D of adhesions present in cells with varying motility phenotypes was performed through the development and utilization of adhesion tracking algorithms. We focused our studies on the proteins paxillin and vinculin, which have both been implicated in force-dependent mechanotransduction and focal adhesion maturation. Our results show that paxillin and vinculin are localized into spatially distinct regions relative to one another during processes such as adhesion maturation, where we find that paxillin moves downward relative to vinculin, which stayed in approximately the same vertical position. We also observe that there is a dependence upon nano-scale adhesion architecture on mechanical force, in which paxillin undergoes a marked increase in height of approximately 8 nm after 5 minutes of inhibition of cell contractility with the Rho kinase inhibitor Y-27632. Additionally, we describe the effects of Rac1 and RhoA activation on focal adhesion maturation and organization dynamically at the molecular level, with implications for understanding the complex protein-protein interactions occurring during processes such as maturation, motility, and force-transmission during mechanotransduction.

**New single-chain Rac1 biosensor shows GTPase function in invadopod dynamics.**Y. Moshfegh<sup>1</sup>, J. Bravo-Cordero<sup>1</sup>, J. Condeelis<sup>1</sup>, L. Hodgson<sup>1</sup>; <sup>1</sup>Anatomy & Structural Biology, Albert Einstein College of Medicine, Bronx, NY

Members of the Rho family of small GTPases are heavily involved in cell motility and migration, and are thought to participate in the regulation of cancer metastasis. To study the function of Rac1 in highly invasive tumor cell migration, we developed a novel, genetically-encoded Rac1 FRET biosensor based on an intra-molecular design. The new biosensor is a substantial

improvement over the previous-generation Rac1 biosensor because of its single-chain arrangement, ensuring an equimolar distribution of FRET donor and acceptor, and producing a more accurate readout. Additionally, our design maintains the correct C-terminal lipid modification of full-length Rac1, enabling proper interaction with upstream regulators (GEFs, GAPs, and GDIs).

We used this new biosensor to explore the molecular basis for the involvement of Rac1 in the turnover dynamics of invadopodia, which are F-actin-rich protrusions with proteolytic activity that are exclusive to invasive tumor cells and are thought to be crucial for cell invasion and metastatic phenotypes. The biosensor has shown that there is an exclusion of Rac1 activity from the core of the invadopodial structures of MTLn3 rat carcinoma cells. This exclusion dissipates and Rac1 activity is elevated when stable invadopods disappear, suggesting that a lack of Rac1 activity is necessary for invadopod maintenance, and activation of the GTPase could possibly be involved in disassembly. PAK1, one of the major downstream effectors of Rac1, phosphorylates cortactin, which is a key protein in these structures, and upon this kinase activity, PAK1 releases cortactin. Taken together, we have developed a model for the mechanism of invadopod disassembly, where Rac1 activation in the core of an invadopodium will induce kinase activity of PAK1, which will phosphorylate cortactin, causing a destabilization of the invadopod's principal structural molecule and therefore leading to dissolution. This mechanism may be critical for the proper turnover of the invasive structures during migration and invasion of tumor cells in vivo, where a balance of invasive invadopodial matrix-degradation activity and the protrusive force of leading edge projections must be carefully coordinated to achieve a maximally invasive phenotype.

80

**The tumor suppressor adenomatous polyposis coli controls the direction a cell extrudes from an epithelium.**

*T. W. Marshall<sup>1</sup>, J. Delalande<sup>1</sup>, I. Lloyd<sup>1</sup>, I. Nathke<sup>2</sup>, J. Rosenblatt<sup>1</sup>; <sup>1</sup>Huntsman Cancer Institute, University of Utah, Salt Lake City, UT, <sup>2</sup>Cell and Developmental Biology, University of Dundee, Dundee, United Kingdom*

Cell extrusion is the process of active removal of either live or apoptotic cells from epithelium. In this process, cells are squeezed out through an actomyosin based mechanism. Cells can extrude apically into the lumen or basally into the underlying tissue, depending on whether actin and myosin contract at the cell base or apex, respectively. We previously found that microtubules in cells surrounding a dying cell target p115 RhoGEF to the actin cortex to control where contraction occurs. However, what controls microtubule targeting to the cortex and whether the dying cell also controls the extrusion direction were unclear. Here we find that the tumor suppressor adenomatous polyposis coli (APC) controls microtubule targeting to the cell base to drive apical extrusion. Whereas wild-type cells preferentially extrude apically, cells lacking APC or expressing an oncogenic APC mutation prefer to extrude basally. Surprisingly, although APC controls microtubule reorientation and attachment to the actin cortex in cells surrounding the dying cell, it does so by controlling actin and microtubules within the dying cell. APC disruptions that are common in colon and breast cancer may promote basal extrusion of tumor cells, which could enable their exit and subsequent migration.

**Localized tensional forces on PECAM-1 elicit a global mechanotransduction response via the integrin-RhoA pathway.**

C. Collins<sup>1</sup>, C. Guilly<sup>2</sup>, C. Welch<sup>3</sup>, E. T. O'Brien<sup>4</sup>, K. Hahn<sup>3</sup>, R. Superfine<sup>4</sup>, K. Burridge<sup>2</sup>, E. Tzima<sup>1</sup>; <sup>1</sup>Cell and Molecular Physiology, University of North Carolina at Chapel Hill, Chapel Hill, NC, <sup>2</sup>Cell and Developmental Biology, University of North Carolina at Chapel Hill, Chapel Hill, NC, <sup>3</sup>Pharmacology, University of North Carolina at Chapel Hill, Chapel Hill, NC, <sup>4</sup>Physics and Astronomy, University of North Carolina at Chapel Hill, Chapel Hill, NC

Mechanical forces regulate cell behavior and function during development, differentiation, and tissue morphogenesis. In the vascular system, forces produced by blood flow are critical determinants of not only morphogenesis and function, but also pathological conditions such as atherosclerosis. Endothelial cells (ECs) have numerous mechanotransducers, including platelet endothelial cell adhesion molecule-1 (PECAM-1) at cell-cell junctions and integrins at cell-matrix adhesions. Recent work has focused on integrin-mediated force transduction and force-dependent assembly of adhesion complexes. However, the processes by which forces are transduced into biochemical signals and subsequently translated into cellular responses downstream of PECAM-1 are poorly understood. Here, we use magnetic tweezers to examine mechanochemical signaling in response to direct force application on PECAM-1. We demonstrate that localized tensional forces on PECAM-1 result in, surprisingly, global signaling responses. Specifically, force-dependent activation of phosphatidylinositol 3-kinase (PI3K) downstream of PECAM-1 promotes cell-wide activation of integrins and the small GTPase RhoA. Activation of these signaling molecules is required for force-induced changes in cytoskeletal architecture, including growth of focal adhesions and adaptive cytoskeletal stiffening. Taken together, our work provides insight into the spatiotemporal regulation of mechanochemical signaling downstream of PECAM-1. Furthermore, we provide the first evidence of a global signaling event in response to a localized mechanical stress. Importantly, these data provide a possible mechanism for the differential stiffness of vessels exposed to distinct hemodynamic force patterns *in vivo*.

82

**Inhibition of PI3K/mTOR leads to adaptive resistance in matrix-attached cancer cells.**

T. Murañen<sup>1</sup>, L. Selfors<sup>1</sup>, M. Iwanicki<sup>1</sup>, G. B. Mills<sup>2</sup>, J. S. Brugge<sup>1</sup>; <sup>1</sup>Department of Cell Biology, Harvard Medical School, Boston, MA, <sup>2</sup>Department of Systems Biology, MD Anderson Cancer Center, Houston, TX

Previously we found that phosphatidylinositol 3-kinase (PI3K) activation is critical for anchorage-independent survival of cancer cells, due to its ability to prevent apoptosis and rescue metabolic impairments of cells lacking natural matrix attachment. Because alterations in the PI3K pathway are common in breast, endometrial, and ovarian cancers and are thought to serve as major drivers of proliferation and survival in these cancers, we investigated the effects of drugs that inhibit PI3K/mTOR on growth and survival of tumor cell spheroids cultured in reconstituted basement membranes. Interestingly, there was a dichotomous response to PI3K/mTOR inhibitors in the tumor spheroids; matrix-attached cells were resistant to PI3K/mTOR inhibitors, whereas cells in the middle of the spheroids, lacking matrix-attachment, underwent cell death. The resistance of matrix attached cells is associated with up-regulation of a cellular program that resembles evolutionarily well-conserved responses to nutrient/growth factor deprivation and leads to up-regulation of signaling pathways required for cancer cell survival, such as IGF1R, EGFR and Bcl-2. Inhibition of components of this program abrogates resistance to PI3K/mTOR inhibition in immortalized and primary human breast and ovarian cancer cells as well as ovarian cancer xenografts (Cancer Cell (2012), 21:227-39).

We have now further characterized the components of this pathway leading to the resistance of matrix-attached cancer cells, and more specifically studied the role of the integrins and cell adhesion molecules required for the survival of the cancer cells under PI3K/mTOR inhibition. Several integrins are upregulated upon PI3K/mTOR inhibition both at transcriptional and translational level. Inhibition of beta1 integrin is not sufficient to abrogate the resistance, but rather inhibition of several integrins and/or downstream signaling components is needed to inhibit the adaptive resistance in matrix-attached cancer cells. We are currently further investigating how matrix attachment provides a permissive context for upregulation of the adaptive response to PI3K/mTOR inhibition.

#### **TMEM115 as a Golgi stack protein regulating retrograde transport.**

*W. Hong<sup>1</sup>; <sup>1</sup>Institute of Molecular and Cell Biology (IMCB), Singapore, Singapore*

The Golgi apparatus is a central sorting station for proteins destined for various post-Golgi compartments as well as proteins recycling between the early secretory pathways. In order to identify new Golgi proteins, we have search for transmembrane proteins at Human Protein Atlas at <http://www.proteinatlas.org/> and carefully analysed the localization of 103 proteins. Several Golgi-localized proteins were identified and two (TMEM115 & TMEM87A) of them have conserved counterparts in the yeast and fly. We have analysed in detail TMEM115, which was earlier reported as PL6 with its lost expression in renal clear cell carcinomas (J. Pathol. (2008) 214, 46-57). Double-labeling of TMEM115 with various Golgi markers suggests that it is primarily localized to the Golgi stack and its C-terminal hydrophilic region was revealed to be exposed to the cytoplasm. Functionally, brefeldin A-induced recycling of Golgi proteins back to the endoplasmic reticulum was inhibited when TMEM115 level was reduced by knockdown or increased upon over-expression, suggesting proper levels of TMEM115 is important for the recycling pathway. Co-immunoprecipitation experiment showed that TMEM115 interacts with all the subunits of COG complex, whose absence or knockdown also inhibited retrograde recycling. Knockdown of TMEM115 in HeLa cells also reduced cell proliferation. These results suggest that TMEM115 is a Golgi stack protein regulating retrograde transport and is involved in cell proliferation.

84

#### **Multiple factors function together to regulate ER structure and dynamics.**

*G. Voeltz<sup>1</sup>; <sup>1</sup>Molecular Cellular Developmental Biology, CU Boulder, Boulder, CO*

The endoplasmic reticulum (ER) has an elaborate and dynamic structure that is conserved throughout eukaryotes. We are interested in how ER shape is regulated to generate a functional organelle. We have studied three major mechanisms that influence the 3-D structure of the ER. ER shape is determined by membrane shaping proteins, dynamics on the cytoskeleton, and interactions with other organelles. These forces work together to distribute this organelle throughout the cytoplasm and generate the complexity of ER functional domains. In turn, we have recently demonstrated that ER shape and dynamics also influence the distribution and dynamics of other organelles. I will discuss the dynamic interplay between the various mechanisms that regulate the elaborate structure of the ER and the organelles that it contacts.

85

### **A molecular network for the transport of the TI-VAMP/VAMP7 vesicles from cell center to periphery.**

*T. Galli<sup>1</sup>, A. Burgo<sup>1</sup>, V. Proux-Gillardeaux<sup>1</sup>, E. Sotirakis<sup>1</sup>, P. Bun<sup>2</sup>, A. Casano<sup>1</sup>, A. Verraes<sup>1</sup>, R. K. Liem<sup>3</sup>, E. Formstecher<sup>4</sup>, M. Coppey-Moisan<sup>2</sup>; <sup>1</sup>Inserm Erl U950, Institut Jacques Monod, Paris, France, <sup>2</sup>Institut Jacques Monod, Paris, France, <sup>3</sup>Department of Pathology and Cell Biology, Columbia University College of Physicians and Surgeons, New York, NY, <sup>4</sup>Hybrigenics, Paris, France*

The compartmental organization of eukaryotic cells is maintained dynamically by vesicular trafficking. SNARE proteins play a crucial role in intracellular membrane fusion and need to be targeted to their proper donor or acceptor membrane. The molecular mechanisms that allow for the secretory vesicles carrying the v-SNARE TI-VAMP/VAMP7 to leave the cell center, load onto microtubules, and reach the periphery to mediate exocytosis are largely unknown. Here, we show that the TI-VAMP/VAMP7 partner Varp, a Rab21 guanine nucleotide exchange factor, interacts with GolginA4 and the kinesin 1 Kif5A. Activated Rab21-GTP in turn binds to MACF1, an actin and microtubule regulator, which is itself a partner of GolginA4. These components are required for directed movement of TI-VAMP/VAMP7 vesicles from the cell center to the cell periphery. The molecular mechanisms uncovered here suggest an integrated view of the transport of vesicles carrying a specific v-SNARE toward the cell surface.

86

### **The ARL3 Arf-like GTPase targets myristoylated and farnesylated proteins to the membrane of primary cilia via its UNC119 and PDE6D effector proteins.**

*P. K. Jackson<sup>1</sup>, K. J. Wright<sup>1</sup>; <sup>1</sup>Research Oncology, Genentech Inc, S. San Francisco, CA*

The membrane of the primary cilium is a highly specialized compartment that organizes proteins to achieve spatially ordered signaling. Disrupting ciliary organization leads to diseases called ciliopathies, with phenotypes ranging from retinal degeneration and cystic kidneys to neural tube defects. How proteins are selectively transported to and organized in the primary cilium remains unclear. Using a proteomic approach, we identified

ARL3 effector proteins including the UNC119 and PDE6D, which we find are carrier proteins for a host of ciliary myristoylated proteins and farnesylated proteins. Previously, we found UNC119 uses a phenylalanine-rich  $\beta$ -sandwich to bind myristoylated ciliopathy protein nephrocystin-3 (NPHP3) and a group of other myristoylated proteins [Genes & Development 25: 2347 (2011)]. The ARL3 GTPase cycle facilitated transport of these proteins through the ciliary transition zone and insertion into the ciliary membrane.

We now show that PDE6D, a prenyl-binding protein acts as a specific facilitator for prenylated proteins to cross the transition zone. Using tandem affinity purification, we identified the ciliary farnesylated protein INPP5E involved in ciliopathies (Joubert/MORM syndromes) and other proteins as a cargo of PDE6D. PDE6D binds to INPP5E in a farnesyl-dependent manner, via a leucine-rich  $\beta$ -sandwich structure similar to UNC119. Mutations in the ARL3 binding domain of PDE6D fail to bind ARL3, but are still localized to the ciliary base. Specific mutations in many of the components of the ARL3 trafficking mechanism cause strong ciliopathies, showing both retinal degeneration and cystic kidney disease (nephronophthisis). A first mechanism by which ARL3 crosses the transition zone will be presented. We will also detail how the trafficking of INPP53, a 5'-inositol phosphatase can create specific ciliary membrane subdomains with distinct phosphoinositide isoforms and associated phosphoinositide binding proteins. Our studies of ARL3 effectors detail a general mechanism by which prenylated and myristoylated

proteins can be inserted into the ciliary membrane to organize specialized signaling regions and how this mechanism is compromised in many retinal-renal ciliopathies.

87

### **Glycosphingolipid-driven membrane bending in clathrin-independent endocytosis of pathogens and signaling receptors.**

*L. Johannes<sup>1</sup>; <sup>1</sup>UMR144 CNRS, Institut Curie, Paris Cedex 05, France*

Several endocytic processes exist that do not require the activity of clathrin, and it has been a conundrum to know how the plasma membrane is bent in these cases. Our previous studies have uncovered a novel mechanism through which nanodomain construction by glycosphingolipid-binding toxins (Shiga and cholera toxins) or polyoma viruses (SV40) induces membrane curvature changes and drives the clathrin-independent formation of plasma membrane invaginations, leading to the endocytic uptake of these pathogens or pathogenic factors into cells (Nature 450, 670-675; NCB 12, 11-18). We could show that actin polymerization on Shiga toxin-induced endocytic tubule membranes alone is sufficient to induce scission in a process that requires membrane reorganization and domain formation (Cell 140, 540-553). Our data suggests that tubule membranes are poised in a metastable state such that an appropriate inducer can cause lipid segregation, thereby generating domain boundary forces that trigger line tension-driven squeezing of the tubules membranes leading to scission. We could indeed provide evidence that Shiga toxin-induced endocytic tubules are also enriched in glycosphingolipid species that are not the direct toxin receptors (Traffic 11, 1519-1529). This lipid co-sorting mechanism is dominant over curvature-mediated lipid sorting, and to be efficient, theoretical arguments suggest that the tubule membrane compositions must be close to demixing. The possibility that this concept can be generalized opens exciting perspectives on how lipid repartitioning can be exploited for membrane mechanics (Cell 142, 507-510). With Jitu Mayor, we have now analyzed how cortical actin dynamics contributes to glycosphingolipid clustering on active membranes, which facilitates toxin uptake into cells (manuscript in preparation). With Rob Parton, Katharina Gaus, and Robert Nabi, we have studied cellular proteins that use glycosphingolipids for membrane mechanics, thereby regulating the cell surface dynamics of various markers with critical roles in physiological processes such as cell migration. We found that galectin-3 functionally integrates structural carbohydrate information of cargo proteins (CD44, beta1-integrin...) with the membrane mechanical potential of glycosphingolipids to drive the glycosphingolipid-dependent formation of clathrin-independent carriers (manuscript in revision). Galectins thereby appear to function as adaptors that cluster glycosylated receptors and glycosphingolipids into nanoenvironments that then undergo membrane curvature changes according to similar mechanisms as we have described for Shiga and cholera toxins and SV40.

### **CORVET and HOPS functions in *C. elegans*.**

*J. A. Solinger<sup>1</sup>, A. Spang<sup>1</sup>; <sup>1</sup>Biozentrum, University of Basel, Basel, Switzerland*

CORVET and HOPS are tethering complexes in the endosomal pathway in yeast. They share a common core and differ only in two subunits, which are important for the interaction with Rab GTPases. We show here that both complexes also exist in metazoans, although one of the CORVET subunits is not conserved in *C. elegans* and mammalian cells. In contrast, one of the core components, the SM protein Vps33 is present in two isoforms VPS-33.1 and VPS-33.2, each of which is specific for one complex. The effect of knockdown of individual HOPS and CORVET components was studied in oocytes, in epithelial cells and in coelomocytes. These

analyses revealed that the predominant role of the CORVET complex is to promote homotypic fusion of early endosomes and the fusion of endosomal carriers with early endosomes, while the HOPS complex performs functions in endosome maturation and endolysosome formation. Moreover, different tissues appear to depend more on HOPS function than others. The specificity of CORVET and HOPS complex function is at least in part dependent on the individual VPS-33 subunit. Finally, our analysis reveals functions of individual HOPS and CORVET components that are independent of the function of the tethering complexes.

## Minisymposium 14: Microtubule Organization and Dynamics

89

### Conformation-based mechanisms in a microtubule polymerase.

P. Ayaz<sup>1</sup>, X. Ye<sup>1</sup>, C. A. Brautigam<sup>1</sup>, L. M. Rice<sup>1</sup>; <sup>1</sup>*Biophysics, University of Texas Southwestern Medical Center, Dallas, TX*

Stu2p/XMAP215/Dis1 family proteins are evolutionarily conserved regulatory factors that use  $\alpha\beta$ -tubulin-interacting TOG (tumor overexpressed gene) domains to catalyze fast microtubule growth. Catalysis requires that these polymerases discriminate between unpolymerized and polymerized forms of  $\alpha\beta$ -tubulin, but how they do so has remained unclear. To address this question, we determined the structure of the TOG1 domain from Stu2p bound to yeast  $\alpha\beta$ -tubulin. TOG1 preferentially binds a “curved” conformation of  $\alpha\beta$ -tubulin that cannot be incorporated into microtubules, contacting  $\alpha$ - and  $\beta$ -tubulin surfaces distinct from those involved in microtubule assembly. TOG1 binding to  $\alpha\beta$ -tubulin apparently excludes equivalent binding of a second TOG domain. Conformation-selective interactions with  $\alpha\beta$  explain how TOG-containing polymerases discriminate between unpolymerized and polymerized forms of  $\alpha\beta$ -tubulin, and how they selectively recognize the growing end of the microtubule.

90

### Knockdown of microtubule polymerase XMAP215 can increase microtubule polymerization in *Xenopus laevis* neuronal growth cones.

L. A. Lowery<sup>1</sup>, L. Ding<sup>1</sup>, M. Baird<sup>2</sup>, M. Davidson<sup>2</sup>, G. Danuser<sup>1</sup>, D. Van Vactor<sup>1</sup>; <sup>1</sup>*Department of Cell Biology, Harvard Medical School, Boston, MA*, <sup>2</sup>*National High Magnetic Field Laboratory, Florida State University, Tallahassee, FL*

Proper neural connections, essential to nervous system function, depend upon precise navigation by the neuronal growth cone. A fundamental problem in growth cone cell biology is how guidance pathways are integrated to coordinate cytoskeletal dynamics, thus driving accurate steering. To address this question, we focus on the plus-ends of microtubules (MTs), which explore the growth cone periphery and play a key role in growth cone steering. MT plus-end dynamics are regulated by a conserved family of proteins called ‘plus-end-tracking proteins’ (+TIPs). Yet, it is still unclear how +TIPs interact with each other and with plus-ends to control MT behavior, especially in the developing nervous system. Here, we address this question by investigating the function of the traditional MT polymerase, XMAP215, during neurite outgrowth. When XMAP215 function is reduced, neurite outgrowth is severely compromised. By using automated, quantitative imaging analysis following acquisition of high-resolution live-imaging data of tagged +TIPs within cultured *Xenopus laevis* growth cones, we were surprised to discover that partial knock-down of XMAP215 leads to a 30% increase in MT plus-end velocity. This is unexpected given that XMAP215 is known to have MT polymerase activity. There are at least two possible mechanisms by which this increase in MT plus-end velocity may occur in

growth cones, either by affecting the polymerization/depolymerization rate directly, or by changing MT translocation rates through the regulation of MT interaction with other cellular structures. We have tested between these two models using quantitative fluorescence speckle microscopy, and we find that MT translocation rates are indistinguishable between controls and XMAP215 knockdown. Thus, reducing the function of the traditional MT polymerase XMAP215 leads to increased rates of MT polymerization in cultured *Xenopus* growth cones. We are currently investigating the mechanism by which this occurs, as well as how these changes in growth cone MT polymerization correlate with the reduced axon outgrowth phenotype that we also observe.

91

**Microtubule-associated proteins control microtubule nucleation from templates.**

*M. Wieczorek<sup>1</sup>, S. Bechstedt<sup>1</sup>, G. Brouhard<sup>1</sup>; <sup>1</sup>Biology, McGill University, Montreal, QC, Canada*

Cells nucleate new microtubules continuously, but the kinetics of nucleation is arguably the least understood aspect of microtubule dynamics. While microtubules can form spontaneously in vitro,  $\gamma$ -tubulin ring complexes ( $\gamma$ -TURCs) serve as template structures for microtubule nucleation in cells. Many microtubule-associated proteins (MAPs) have also been implicated in microtubule nucleation, but their direct role in the templating process is unclear. To determine the role of MAPs in templated nucleation, we have developed a quantitative assay that allows us to study the kinetics of microtubule nucleation from centrosomes ( $\gamma$ -TURCs), axonemes, and single microtubule templates using purified components. We found that templated nucleation is highly cooperative and that this cooperativity is independent of the type of template used. Performing the assay in the presence of different MAPs indicates that both catastrophe frequencies and growth rates influence the ability of a template to nucleate microtubules. Certain MAPs also changed the strength of cooperativity in the nucleation process. We directly demonstrate that MAPs can both enhance and inhibit templated nucleation by distinct mechanisms. These findings provide a means by which cells can control the numbers and locations of their microtubules throughout development and the cell cycle.

92

**The kinesin-8 Kip3 drives a distinct dynamic to non-dynamic midzone transition required to terminate spindle elongation.**

*R. S. Rizk<sup>1</sup>, K. DiScipio<sup>1</sup>, K. G. Proudfoot<sup>1</sup>, M. L. Gupta<sup>1</sup>; <sup>1</sup>Molecular Genetics and Cell Biology, University of Chicago, Chicago, IL*

Kinesin-8 is a microtubule (MT) motor with conserved roles in chromosome alignment and spindle function. Its importance in facilitating spindle disassembly at the end of mitosis was recently demonstrated in budding yeast. Combining molecular genetics with live imaging and FRAP analysis our data reveal a novel role for the budding yeast Kinesin-8, Kip3, in regulating spindle length during anaphase. In order to examine the role of Kip3 prior to spindle disassembly we challenged the cells with an anaphase arrest. Control spindles stopped elongating as they obtained a length approximately equal to the cell diameter. However, in the absence of Kip3 spindles exceeded the cell length by at least 2-fold with elongation rates similar to typical anaphase, suggesting that the same activities that drive anaphase elongation continue to drive hyper-elongation. Surprisingly, spindles in other mutant cells, such as *ip1-321*, in which spindles slightly over-elongate maintained their bent morphology without progressing into hyper-elongation during anaphase arrest. These results eliminate the idea that Kip3 suppresses spindle length in conjunction with cortical compression forces, and implicate a role for Kip3 at the spindle midzone. FRAP of the midzone showed that MTs were highly dynamic during

spindle elongation. In control spindles, MT dynamics were dramatically suppressed once spindles obtained proper length. However, in the absence of Kip3, MTs remained highly dynamic. Furthermore, in *kip3* deletion cells with straight, buckled, or hyper-elongated spindles we found that midzone lengths were unaltered compared to control cells, demonstrating that excess MT polymerization in the absence of Kip3 at the midzone is tightly coupled to antiparallel MT sliding and spindle hyper-elongation. To decouple these processes we deleted the antiparallel sliding motor Kip1, Kinesin-5, which reduces rates of anaphase spindle elongation. In *kip1, kip3* deletion strains the midzone length was significantly longer compared to those in *kip3* deletion strains. Taken together, our results support a model in which Kip3 acts as a switch to drive a distinct dynamic to non-dynamic midzone transition in order to prevent spindle hyper-elongation and maintain structural integrity of the spindle. RR was supported by T32 HL094282 & the American Heart Association postdoctoral fellowship.

93

#### **Microtubule function is diversified by tubulin carboxy-terminal tails.**

J. Moore<sup>1</sup>, M. Costanzo<sup>2</sup>, C. Boone<sup>2</sup>, J. A. Cooper<sup>3</sup>; <sup>1</sup>Cell and Developmental Biology, University of Colorado School of Medicine, Aurora, CO, <sup>2</sup>University of Toronto, Toronto, Canada, <sup>3</sup>Washington University, St Louis, MO

Microtubules provide tracks for diverse transport and force generation processes in cells. Although a number of microtubule-binding proteins and motors have been identified, how the microtubule track contributes to these mechanisms is poorly understood. The carboxy-terminal tail regions (CTTs) of  $\alpha$ - and  $\beta$ -tubulin subunits are likely to play a critical role. CTTs facilitate electrostatic interactions at the microtubule surface, are major sites of tubulin posttranslational modification, and exhibit high sequence variation amongst tubulin isoforms in humans. CTTs may, therefore, represent important hubs for regulating microtubule function by modulating interactions at the surface. Here we investigate the roles of CTTs by examining a series of mutants that alter CTT structure in budding yeast. We find that CTTs are not essential for life, but loss of  $\alpha$ - or  $\beta$ -tubulin CTTs causes discrete defects in microtubule function. Neither is necessary for microtubule stability; however, the  $\beta$ -tubulin CTT specifically promotes microtubule dynamics. To identify how CTTs contribute to function, we use synthetic genetic array analysis to map the genetic interaction networks of CTT mutants. Our results indicate that mutants in  $\alpha$ - and  $\beta$ -tubulin have divergent consequences, including effects on EB1 and dynein. We investigate these phenotypes using live-cell analysis of protein and network dynamics. In addition, our screen identified many unexpected interactions that suggest novel roles for tubulin in cells.

94

#### **TUBB3 mutations cause axon misguidance and cytoskeletal changes in congenital fibrosis of the extraocular muscles 3 (CFEOM3).**

Y. Song<sup>1,2</sup>, S. Chew<sup>2</sup>, R. Tweedie-Cullen<sup>1</sup>, J. Steen<sup>1</sup>, E. Engle<sup>1,3</sup>; <sup>1</sup>Neurology, Children's Hospital Boston, Boston, MA, <sup>2</sup>Neurology, Harvard Medical School, Boston, MA, <sup>3</sup>HHMI, Boston, MA

Congenital Fibrosis of the Extraocular Muscles (CFEOM) is a group of eye movement disorders that can result from genetic errors in cranial axon growth and guidance. We previously identified the CFEOM3 gene as TUBB3, which encodes the neuron-specific  $\beta$ 2-tubulin isotype III. TUBB3 mutations cause CFEOM as well as additional nervous system disorders associated with aberrant axon guidance and maintenance, which may result from changes in microtubule dynamics and/or abnormal MAP binding. Several disease-associated TUBB3 substitutions reside at putative kinesin motor interaction sites on  $\beta$ 2-tubulin, such as E410K, which causes severe CFEOM3, anterior commissure/corpus callosum hypoplasia with associated social and

intellectual disabilities, Kallmann syndrome (anosmia and hypogonadotropic hypogonadism), facial weakness, and progressive axonal sensorimotor polyneuropathy. Although clinical abnormalities suggest multiple axon guidance defects caused by mutations in this cytoskeletal gene, molecular mechanisms remain unclear. Previously, we showed altered microtubule dynamics in several CFEOM mutations. We have now developed a mouse model harboring the human TUBB3E410K mutation and found axon misguidance in multiple regions of the Tubb3E410K embryonic nervous system. Moreover, through biochemical and mass spectrometry studies, we have found alterations in motor protein-microtubule interactions. Therefore, altered motor-microtubule interactions, which may affect microtubule dynamics and/or axonal transport, may explain the etiology of CFEOM3, as well as elucidate molecular pathways essential for axon guidance and circuit formation in the mammalian nervous system.

## Minisymposium 15: Physical and Computational Tools for Cell Biology

95

### Analysis of single-cell transcriptomes reveals gene expression states that drive key transitions in cellular subpopulations.

A. P. May<sup>1</sup>, J. Shuga<sup>1</sup>, P. Chen<sup>1</sup>, X. Wang<sup>1</sup>, J. Wang<sup>1</sup>, A. Leyrat<sup>1</sup>, S. Weaver<sup>1</sup>; <sup>1</sup>Research and Development, Fluidigm Corporation, South San Francisco, CA

Biological phenomena in multi-cellular populations are fundamentally driven by the collective properties of individual cells that make up the population. Despite this, our understanding of molecular networks from either cell cultures or tissues are based on measurements made from the entire population with the implicit assumption that all cells behave similarly or that averaged signals from the population accurately describe the underlying molecular architecture of all cells in that group. A growing body of data collected from individual cells has started to challenge these basic assumptions and increasingly suggests that properties driving lineage choice, developmental fate and disease states emerge from the transcriptional and signaling architectures of distinct sub-populations of cells. We have developed a system for the routine preparation of hundreds of full-length mRNA-sequencing libraries in parallel, enabling detailed descriptions of transcription in cell populations at the level of the individual cell. Characterization of transcriptional heterogeneity within nominally homogeneous K562 cell populations in tissue culture reveals a wide spectrum of variation in gene expression and coupling of modules within signaling networks. In addition, we are investigating the changes that drive key transitions during cell differentiation and tumor formation.

96

### Quantitative dissection of gene regulation through DNA loop formation.

J. Boedicker<sup>1</sup>, H. Garcia<sup>2</sup>, S. Johnson<sup>3</sup>, R. Phillips<sup>1</sup>; <sup>1</sup>Applied Physics, Caltech, Pasadena, CA, <sup>2</sup>Physics, Caltech, Pasadena, CA, <sup>3</sup>Biochemistry and Molecular Biophysics, Caltech, Pasadena, CA

The study of genetic circuits has reached a state of maturity that permits direct and stringent comparison between theories of transcriptional regulation and the response of living cells. We have developed and tested such models of gene expression based on equilibrium statistical mechanics. The models require only a few input parameters: binding energies of proteins, copy numbers of molecular components, and the mechanical properties of DNA. These parameters are measured in simple control experiments and used to predict gene expression levels for genetic circuits involving different combinations of these parameters. Such first principles

biological models require no fitting parameters and make quantitative and precise predictions about gene regulation over a wide range of parameter space.

Equations derived from these models define the input-output function of each genetic circuit, and predict how each system component modulates gene expression. We independently tuned each parameter of the model and experimentally tested whether the gene circuit responded as predicted. Model predictions were tested by creating these genetic circuits in *E. coli*, and using fluorescent reporters to quantify the level of gene expression for each circuit. We tuned transcription factor copy number over two orders of magnitude and varied the operator binding energies resulting in several orders of magnitude change in dissociation constants.

Next we implemented the model to examine the role of DNA mechanical properties in the context of transcription factor-mediated loop formation. The tetrameric transcription factor Lac repressor is able to increase the level of gene repression by binding to two operators and looping the intervening DNA. We use this system to ask whether the sequence-dependent flexibility of the DNA in the loop influences gene expression. By incorporating DNA sequences with known sequence-dependent flexibilities into the looping region, we found that the intrinsic flexibility of the looping DNA does not influence repression. DNA sequences shown to be flexible *in vitro*, including in our own tethered particle motion assays, do not lead to increased repression. We resolve the lack of *in vivo* sequence dependence by theoretically and experimentally exploring the role of the DNA-bending protein HU in loop formation. We found that after knocking out HU, sequence-dependent loop formation is restored *in vivo*, and use the models to suggest how the presence of DNA-bending proteins buffers away the influence of sequence-dependent mechanics on gene regulation.

97

#### **Heterogeneity in cell-matrix adhesion as an indicator of metastatic state.**

A. Fuhrmann<sup>1</sup>, T. D. Tlsty<sup>2</sup>, A. J. Engler<sup>1</sup>; <sup>1</sup>Bioengineering, University of California, San Diego, La Jolla, CA, <sup>2</sup>Pathology, University of California, San Francisco, San Francisco, CA

Cancer cells have great genetic diversity, which may be reflected in the variation in metastatic potential. As it has been difficult to determine a comprehensive set of genetic markers to define a metastasizing cell population, we propose to examine a common behavior, i.e. cell-matrix adhesion, that may be differentially regulated in metastasizing versus non-metastasizing cancer cells. To assess cell-matrix adhesion strength in a heterogeneous population of breast cancer cells, we employed a spinning disc device where cells adhering to matrix-coated substrates were exposed to radially-dependent shear. Within a cell population, those at the center or edge experience low or high matrix detachment forces, respectively. Exposure to acute shear for a highly metastatic cancer cell line, i.e. MDA-MB-231, resulted in a broadly distributed population of cells unlike the sigmoidal, homogeneous shear response observed from non-metastatic, non-malignant, or somatic cell lines, MCF7, MCF10A, NIH 3T3 fibroblasts, respectively. This suggests that adhesion strength differences may scale with cell state with the most metastatic cells coming from high shear regions. Magnesium and calcium concentration differences have been reported between stroma and tumors, which are also involved in regulating integrin activation. While there was an up to 2-fold increase in adhesion strength for MCF7 or MCF10A cells in the presence of 0.5 mM magnesium, MDA-MB-231 cells exhibited a 10-fold increase in adhesion strength and also developed a sigmoidal, homogeneous shear response when exposed to 0.5 mM magnesium and/or calcium. The average attachment strength as well as the restoration of attachment-homogeneity gradually increases with cation concentration with the most drastic increase occurring between 10 $\mu$ M to 0.5mM, which falls within the physiological range for both stroma and tumor. This observation indicates that variances in attachment

strength in the absence of cations may be dependent on cell state. Indeed, when selecting only strongly attaching cells (in the absence of exogenous cations), we found that those cells not only maintain their (strong) attachment phenotype over time (up to 48 hours tested so far), but also differ in cell behavior – the mitosis rate is nearly doubled compared to the bulk of cells. These findings suggest a potential mechanism to differentially regulate metastasizing cell adhesion, and also support using population-based adhesion assays to assess adhesion heterogeneity and select those cells that may have the highest metastatic potential.

98

### **Sensitive imaging of cellular processes using two-photon polarization microscopy (2PPM).**

*A. Bondar<sup>1</sup>, S. Timr<sup>2</sup>, J. Lazar<sup>1,3</sup>; <sup>1</sup>University of South Bohemia, Ceske Budejovice, Czech Republic, <sup>2</sup>Inst. of Organic Chemistry and Biochemistry, Prague, Czech Republic, <sup>3</sup>Cell Biology, Inst. of Nanobiology and Struct. Biology, Nove Hradky, Czech Republic*

Membrane proteins are difficult to study, due to their requirement of a lipid membrane for function. We have taken advantage of the cell membrane requirement for exceptionally sensitive functional imaging of membrane proteins, using two-photon polarization microscopy (2PPM). 2PPM can be used for imaging of G-protein activation, changes in intracellular calcium concentration, and other cellular processes, in living cells and organisms, with sensitivity comparable to, or even exceeding that of current FRET probes. Crucially, in contrast to FRET, polarization fluorescence microscopy only requires presence of a single fluorescent protein. Therefore, many existing constructs can be used as optical probes of molecular processes involving membrane proteins. Furthermore, polarization microscopy offers a clear path towards development of new genetically encoded optical probes of membrane protein function, including a usable genetically encoded optical sensor of cell membrane voltage. Our results indicate that in many biological applications, FRET is likely to be complemented or even replaced by 2PPM.

99

### **Opening windows into the cell: Focused ion beam micromachining of eukaryotic cells for cryoelectron tomography.**

*E. Villa<sup>1</sup>, M. Schaffer<sup>1</sup>, F. J. Bäuerlein<sup>1</sup>, A. Rigort<sup>1</sup>, J. Plitzko<sup>1</sup>, W. Baumeister<sup>1</sup>; <sup>1</sup>Max Planck Institute of Biochemistry, Martinsried, Germany*

Cryo-electron tomography (cryo-ET) provides unprecedented insights into the 3-D macromolecular organization of cells in their native state. However, the thickness of most cells makes them inaccessible to cryo-ET. I will show how focused ion beam (FIB) milling can be used to prepare 200-500 nm lamellae from intact cells, opening large windows into the cell's interior, exposing their landscapes at molecular resolution. Advanced computational analysis makes the identification of macromolecular complexes possible, yielding visual proteomes of cells. I will discuss the use of cryo-ET and FIB milling to study the structural dynamics of the nuclear pore complex, one of the largest macromolecular machines in the cell. It is composed of hundreds of proteins, selectively controlling all traffic between the nucleus and the cytoplasm. The architecture of the NPC is central to understanding nuclear transport. However, due to its sheer size, its local environment and its dynamic nature, determining its structure at molecular resolution remains a challenge for conventional techniques. Combining FIB milling, cryo-ET, and image processing enables the study of the NPC in its native environment, free of the distortions caused by purification. This approach has not only revealed the NPC architecture at unparalleled resolution, but also captured different conformational states in action. I will further illustrate the use of cryo-FIB/ET to study diverse cellular environments at molecular detail,

including actin networks, the architecture of cell division, and the distribution of macromolecular complexes within organelles such as mitochondria.

**Voltage imaging in vivo with a new generation of rhodopsin-based indicators.**

*A. Douglass<sup>1</sup>, J. Hou<sup>2</sup>, F. Engert<sup>1</sup>, A. Cohen<sup>2</sup>; <sup>1</sup>Molecular and Cellular Biology, Harvard University, Cambridge, MA, <sup>2</sup>Chemistry and Chemical Biology, Harvard University, Cambridge, MA*

Reliable, optical detection of single action potentials in an intact brain is one of the longest-standing challenges in neuroscience. We recently showed that a number of microbial rhodopsins exhibit intrinsic fluorescence that is sensitive to transmembrane potential. One class of indicator, derived from Archaerhodopsin-3 (Arch), responds to voltage transients with a speed and sensitivity that enable near-perfect identification of single APs in cultured neurons [Nat Methods. (2011). 9:90-5]. We extended the use of these indicators to an in vivo context through the application of advanced imaging techniques to the larval zebrafish. Using planar-illumination, spinning-disk confocal, and epifluorescence imaging modalities, we recorded electrical activity in a variety of structures, including the brain and heart, in a noninvasive manner. Transgenic lines expressing Arch variants in defined cells enable comprehensive measurements to be made from specific target populations. In parallel, we also extended the capabilities of our indicators by improving their multiphoton excitability and overall brightness. Microbial rhodopsin-based voltage indicators now enable optical interrogation of complex neural circuits, and electrophysiology in systems for which electrode-based techniques are challenging.

**Manipulating quorum sensing to control bacterial pathogenicity.***B. Bassler<sup>1</sup>; <sup>1</sup>Molecular Biology, HHMI and Princeton, Princeton, NJ*

Cell-cell communication in bacteria involves the production, release, and subsequent detection of chemical signaling molecules called autoinducers. This process, called quorum sensing, allows bacteria to regulate gene expression on a population-wide scale. Processes controlled by quorum sensing are usually ones that are unproductive when undertaken by an individual bacterium but become effective when undertaken by the group. For example, quorum sensing controls bioluminescence, secretion of virulence factors, biofilm formation, sporulation, and the exchange of DNA. Thus, quorum sensing allows bacteria to function as multi-cellular organisms. Bacteria make, detect, and integrate information from multiple autoinducers, some of which are used exclusively for intra-species communication while others enable inter-species communication. New studies show that interfering with quorum sensing can be used to control bacterial virulence in globally important pathogens. These findings suggest an alternative to traditional antibiotics.

102

**Immune defense of the intestinal epithelial surface.***L. Hooper<sup>1,2</sup>; <sup>1</sup>Department of Immunology, The University of Texas Southwestern Medical Center, Dallas, TX, <sup>2</sup>Howard Hughes Medical Institute, Dallas, TX*

The mammalian intestine is home to ~100 trillion bacteria that perform important metabolic functions for their hosts. The proximity of vast numbers of bacteria to host intestinal tissues raises the question of how symbiotic host-bacterial relationships are maintained without eliciting potentially harmful immune responses. We discovered that resident intestinal bacteria trigger epithelial cell expression of RegIIIgamma, a member of the C-type lectin family of carbohydrate binding proteins. RegIIIgamma directly kills Gram-positive bacteria and thus represents a novel class of antibacterial proteins. We have elucidated the mechanistic basis for RegIIIgamma bactericidal activity by showing that it kills bacteria by forming an oligomeric pore in the bacterial inner membrane. Using cryoelectron microscopy, we determined the structure of the hexameric pore assembly at subnanometer resolution. *In vivo* studies have revealed that RegIIIgamma is essential for maintaining a ~50 micron zone that physically separates the microbiota from the small intestinal epithelial surface. Loss of host-bacterial segregation in *RegIIIgamma*<sup>-/-</sup> mice is coupled to increased bacterial colonization of the intestinal epithelial surface and enhanced activation of intestinal adaptive immune responses by the microbiota. Together, our findings reveal that RegIIIgamma is a fundamental immune mechanism that promotes host-bacterial mutualism by regulating the spatial relationships between microbiota and host.

103

**Exploring the cell biology of 2-methyl hopanoids, an ancient class of microbial lipids.**

*D. K. Newman<sup>1,2</sup>, D. Doughty<sup>1,2</sup>, C-H. Wu<sup>1</sup>, G. Kulkarni<sup>1,2</sup>, J. Ricci<sup>1</sup>, C. Neubauer<sup>1</sup>, E. Cowley<sup>1,2</sup>, N. Shikuma<sup>1</sup>; <sup>1</sup>California Institute of Technology, Pasadena, CA, <sup>2</sup>Howard Hughes Medical Institute, Pasadena, CA*

Efforts to understand the roles of lipids in various aspects of microbial cell biology have gained momentum in recent years in recognition that the lipid composition of bacterial membranes, much like their eukaryotic counterparts, is exquisitely ordered at small spatial scales and may impact protein localization and activity. Hopanoids--steroid analogs in bacteria--are a fascinating class of lipids whose biological functions are poorly understood. Today, they are made by over 200 bacterial species, including some pathogens. Yet hopanoids are ancient: their molecular fossils can confidently be extracted from sedimentary rocks that are billions of years old. One such hopanoid fossil, 2-methyl hopane, has been used as a biomarker to date the rise of oxygenic photosynthesis because cyanobacteria were thought to be the dominant 2-methylhopanoid (2-MeBHP) producers in nature. However, over the past few years, our laboratory has challenged this interpretation by demonstrating that other bacteria can produce 2-MeBHPs in significant quantities under strictly anaerobic conditions. Using two photosynthetic bacteria (*Rhodospseudomonas palustris*, an anoxygenic phototroph and *Nostoc punctiforme*, an oxygenic phototroph) as model hopanoid-producing organisms, we elucidated the hopanoid biosynthetic and transportation machinery, investigated the regulation of 2-MeBHP production in particular, explored the phenotypes of hopanoid-deficient mutants, determined hopanoid subcellular localization and probed the ecological distribution of 2-MeBHP producers in various environments. We are currently using biochemical and biophysical methods to gain a more mechanistic understanding of hopanoid functions. Our data show that 2-MeBHPs are not linked to the process of oxygenic photosynthesis; rather, they suggest that 2-MeBHPs may facilitate certain types of symbiotic relationships between bacteria and plants/algae. Exploring the cell biology of hopanoids in modern bacteria not only provides an opportunity to gain insight into ancient microbial communities, but affords the chance to explore the processing and function of steroid analogs in living systems where they are not essential.

**Positive feedback in the  $\beta$ -catenin destruction complex promotes reliable cell fate decisions of intestinal cells.**

*C. A. Thorne<sup>1,2</sup>, J. Ravi<sup>3</sup>, K. C. Chen<sup>3</sup>, L. F. Wu<sup>1</sup>, S. J. Altschuler<sup>1</sup>, J. J. Tyson<sup>3</sup>, E. Lee<sup>2</sup>; <sup>1</sup>Green Center for Systems Biology, University of Texas Southwestern Medical Center, Dallas, TX, <sup>2</sup>Cell and Developmental Biology, Vanderbilt University Medical Center, Nashville, TN, <sup>3</sup>Biological Sciences, Virginia Polytechnic Institute and State University, Blacksburg, VA*

Homeostasis is the maintenance of a constant condition by feedback control. Tissues that self-renew and regenerate after exposure to environmental perturbation require layers of control to maintain homeostasis. The epithelial lining of the intestine, a prime example of a homeostatic system, completely renews itself every ~5 days. Amazingly, in response to continuous mechanical, chemical and pathogen-derived wounding, intestinal stem cells produce multiple cell types at just the right ratio throughout the entire life of the organism. Wnt signal transduction, through  $\beta$ -catenin-regulated transcription, controls intestinal tissue homeostasis and is dysregulated in many cancers. Typically,  $\beta$ -catenin levels are kept low in non-renewing

tissues by the  $\beta$ -catenin destruction complex, consisting of the scaffold protein Axin, Glycogen Synthase Kinase 3 (GSK3), Casein Kinase 1 (CK1), and Adenomatous Polyposis Coli (APC). Mechanisms underlying activation and inactivation of this complex remain poorly understood. Using high-content imaging of intestinal cells, we evaluated the response of single cells to Wnt signaling. We found cells respond in an “all-or-none” binary fashion without intermediates. To identify feedback control responsible for binary behavior, we performed biochemical studies in *Xenopus* egg extracts and uncovered positive feedback between Axin and GSK3. Mathematical modeling of this feedback loop predicts bistability in the activity of the  $\beta$ -catenin destruction complex as a whole. We are validating our model by pharmacologically and genetically perturbing the positive feedback between Axin and GSK3. Our findings elucidate molecular design features that convert a graded morphogen, such as Wnt, into discrete binary cell fate decisions and provide a mechanism for cellular memory of Wnt stimulation when the stem cell microenvironment is disrupted. This behavior has important consequences in the intestinal stem cell niche, where stem cell number must be tightly maintained to prevent loss or overgrowth of the epithelium.

105

### Role of Mob1 in regeneration of a single cell.

M. M. Slabodnick<sup>1</sup>, W. Marshall<sup>1</sup>; <sup>1</sup>Biochemistry, University of California, San Francisco, San Francisco, CA

Understanding the processes behind the regeneration of cells and tissues is an important cell biological question. Cells need to identify and react to specific damages in and around them, and in order to understand these processes at a basic level we need a model that exhibits a similar regeneration of specialized structures in the context of a single cell. Perhaps the most classical system for studying regeneration in single cells, pioneered by Thomas Hunt Morgan, F.R. Lillie, Vance Tartar and others, is *Stentor coeruleus*, a large ciliate, ~1mm long, with a highly patterned cell cortex and the ability to regenerate and reorganize after surgical or chemical manipulations. Its large size and complex organization rival those of metazoan organisms and the ease of surgical manipulations gives *Stentor* significant advantages over other ciliate models. Using the traditional surgical techniques unique to *Stentor* as well as modern RNA interference (RNAi) methods, visualization techniques, and genomic sequencing I will revive *Stentor* as a model for studying the regeneration of cell polarity and organization. We have partially sequenced *Stentor*'s macronuclear genome and shown that RNAi machinery is functional in *Stentor*. Using an RNAi approach we have begun a systematic investigation of the molecular basis of single-cell regeneration. Mob1 is a highly conserved kinase regulator and is known to interact with NDR/LATS kinases. It plays a role in a variety of functions including apoptosis, mitosis, morphogenesis, and cell proliferation. Recent work in *Tetrahymena thermophila* suggests that Mob1 also performs important roles in ciliates. Results for RNAi of Alpha-Tubulin and Mob1 in *Stentor* result in dramatic changes in cell polarity and organization of the cortex, showing that we can analyze single-celled regeneration in *Stentor* at a molecular level. Knocking down Alpha-Tubulin, a key structural component in the cortex, results in cortical defects and problems with cell regeneration. This is very different from the Mob1 knockdown, which results in the drastic elongation of cells, cortical aberrations, and an apparent loss of proper cell proportions. Using RNAi in conjunction with the unique microsurgical methods available in *Stentor*, it should be possible to restore this classical system to its previous status as a central model for understanding the basic principles of cell polarity, biological pattern formation, and cellular regeneration.

106

**Self-renewal and fate specification of skin stem cells.**T. Chen<sup>1</sup>, E. Fuchs<sup>1</sup>; <sup>1</sup>Rockefeller University, New York, NY

Adult stem cells (SCs) sustain tissue maintenance and regeneration throughout the lifetime of an animal. They often reside in specific signaling niches that orchestrate the stem cell's balancing act between quiescence and cell cycle re-entry based upon demand for tissue regeneration. How SCs maintain their capacity to replenish themselves following tissue regeneration is still poorly understood. Here, we use RNA interference (RNAi)-based loss-of-function screening as a powerful approach to uncover transcriptional regulators governing SC self-renewal and regenerative potential. Hair follicle (HF) SCs provide an ideal paradigm. They've been purified and characterized from their native niche in vivo, and in contrast to their rapidly dividing progeny, they can be maintained and passaged long-term in vitro. Focusing on nuclear proteins/transcription factors enriched in SCs versus progenies, we screened ~2,000 shRNAs for their impact on long-term but not short-term self-renewal in vitro. To address the physiological relevance of our findings, we selected one candidate, Tbx1, surfacing in the screen. Expressed in many tissues, this transcription factor has not been studied in the context of SC biology. By conditionally ablating Tbx1 in vivo, we show that tissue regeneration during homeostasis occurs normally but is dramatically delayed. Devising an in vivo assay for SC replenishment, we then show that when challenged with repetitive bouts of regeneration, the Tbx1-deficient SC niche becomes progressively depleted. Addressing mechanism, we discover that Tbx1 acts as an intrinsic rheostat of BMP signalling, the gatekeeper governing the transition between SC quiescence and proliferation in HFs. Our results validate the RNAi screen and underscore its power in unearthing new players governing SC self-renewal and tissue-regenerative potential.

107

**Growth coordination during tissue regeneration requires nitric oxide signaling.**J. Jaszczak<sup>1</sup>, A. Dao<sup>1</sup>, A. Halme<sup>1</sup>; <sup>1</sup>Department of Cell Biology, University of Virginia School of Medicine, Charlottesville, VA

The regeneration of tissues is often tightly coupled to developmental progression. Our group has been using *Drosophila melanogaster* as a model system to understand how developmental signals impact the regenerative capacity of tissues, and in turn how regenerating tissues alter developmental signals. Using this system, we have previously described a developmental checkpoint that is activated by localized tissue damage and delays developmental progression to allow for regenerative repair of the damaged tissue. We and others have observed that activation of the developmental checkpoint performs another important function: to coordinate the growth of the regenerating tissue with the growth of other undamaged tissues. Recently, we have identified an important role for nitric oxide signaling in growth coordination during regeneration through mutation and mis-expression of the sole *Drosophila* nitric oxide synthase (*Nos*) gene. We have found that *Nos* activity is both necessary and sufficient for growth restriction in undamaged tissues during regenerative repair, and likely exerts its effects on growth through inhibiting signaling through the steroid hormone ecdysone. In support of this, we have shown that ecdysone signaling is necessary for the growth of undamaged imaginal discs, the up-regulation of *Nos* activity can block ecdysone signaling, and that *Nos*-dependent growth inhibition during delay can be overcome by the ectopic addition of ecdysone. Whereas recent published experiments have demonstrated that nitric oxide can promote ecdysone signaling during development, our observations suggest that there may be a separate pathway by which nitric oxide can inhibit ecdysone signaling in response to tissue damage, and that this pathway is critical for maintaining proper tissue proportion following damage. We are currently

examining how nitric oxide limits ecdysone signaling, the role of ecdysone in regulating tissue growth, and how regenerating tissues remain unaffected by systemic growth inhibition.

108

**The vasculature guides the collective migration of Schwann cells during peripheral nerve regeneration.**

A-L. Cattin<sup>1</sup>, L. Rosenberg<sup>1</sup>, V. Quereda<sup>1</sup>, J. Hooving<sup>1</sup>, L. Mc Laughlin<sup>1</sup>, I. Napoli<sup>1</sup>, S. Ribeiro<sup>1</sup>, S. Parrinello<sup>1</sup>, A. Lloyd<sup>1</sup>; <sup>1</sup>MRC Laboratory for Molecular Cell Biology and UCL Cancer Institute, London, UK

The peripheral nervous system (PNS) has remarkable regenerative capacities following injury including the ability to restore a fully cut nerve. This process requires axons to find their way across a bridge of new tissue, often several millimetres in length, which forms to reconnect the severed ends of the nerve. We have previously shown that Schwann cells migrate collectively to guide the regrowing axons across the 'bridge', in a process directed by fibroblasts at the nerve stumps (Parrinello et al., Cell 2010). In this study, we have addressed the molecular and cellular mechanisms that control the direction of Schwann cell migration to ensure the successful delivery of axons to the distal stump. We have found that polarised blood vessels form inside the bridge rapidly following injury and prior to Schwann cell migration. We find they form in response to an angiogenic signal from macrophages - which are the major cellular component of the bridge. Importantly, we show that the migrating cords of Schwann cells use the blood vessels *in vivo* as "tracks" to find their way across the bridge. Moreover, we can recapitulate this behaviour *in vitro* using 3D blood vessel models. Significantly, when we disrupt the correct polarisation of the blood vessels *in vivo*, the Schwann cell cords lose their directionality leading to defective nerve repair. This study provides further novel insights into the mechanisms important for promoting nerve repair following injury and further highlights the complexity of the multicellular response required for successful regeneration of an adult tissue.

109

**Identification of factors critical for planarian nervous system regeneration.**

R. H. Roberts-Galbraith<sup>1</sup>, N. P. James<sup>1</sup>, P. A. Newmark<sup>1</sup>; <sup>1</sup>Howard Hughes Medical Institute and Cell and Developmental Biology, University of Illinois, Urbana-Champaign, Urbana, IL

Planarians possess an extraordinary capacity for regeneration. While superficially simple, the planarian brain exhibits regional specialization and is composed of a wide variety of neural cell types. Importantly, as one of only a handful of animals with the ability to regenerate their central nervous systems *de novo*, these freshwater flatworms provide a unique opportunity to study regeneration of complex nervous tissues *in vivo*. Despite some progress in understanding regeneration of the planarian brain, several important, mechanistic questions remain: What extrinsic and intrinsic factors direct planarian stem cells to neural (or specialized neural) fates? How are newly regenerated neurons reconnected with existing neural or target tissues? How are neural connections reestablished faithfully to restore function after regeneration? To discover factors key to these processes, we used high throughput sequencing and identified hundreds of transcripts significantly upregulated or downregulated at key time points during head regeneration in the planarian *Schmidtea mediterranea*. The expression patterns of these genes suggest a variety of potential functions; while several genes are expressed in the nervous system (either ubiquitously or in a limited manner), others are expressed in stem cells, stem cell progeny, or other tissue types (intestine, etc.). We are currently evaluating the function of many of these genes in brain regeneration using RNA interference. Already, we have identified two conserved transcription factors with uncharacterized roles in planarian regeneration. One LIM domain protein, expressed medially in the nervous system, is required for connection of the two

lobes of the planarian brain during regeneration. Additionally, knockdown of a basic helix-loop-helix transcription factor results in fusion of the two photoreceptors at the midline. The mechanistic insight revealed by this study will illuminate the coordination of cellular events required for planarian nervous system regeneration, contributing to the broader goal of recapitulating the complex type of nervous system regeneration required for functional restoration in humans.

### Transition in the division mode of cortical neural stem cells.

A. Shitamukai<sup>1</sup>, D. Konno<sup>1</sup>, F. Matsuzaki<sup>1</sup>; <sup>1</sup>Cell Asymmetry, Riken Center for Developmental Biology, Kobe, Japan

In the developing mammalian neocortex, elongated neuroepithelial cells function as neural stem cells. These cells initially undergo symmetric divisions to proliferate and then later divide asymmetrically to continuously generate a self-renewing daughter (radial glia or apical progenitors) and a differentiating daughter cell (neurons and intermediate progenitors). In the neurogenic mode, self-renewing daughters of radial glial divisions retain their epithelial structures, including both apical and basal processes, therefore maintaining the pseudo-stratified brain organization. However, our recent live-imaging studies have revealed that, on occasion, these radial glia undergo oblique cleavages that split the cell into an apical and basal part. The apical daughters inherit only the apical membrane and differentiate. In contrast, the basal daughters, which inherit only the basal process, migrate out from the ventricular zone and become a different type of self-renewing progenitors that continue asymmetric neurogenic divisions. These progenitors closely resemble a major type of progenitors seen in the outer subventricular zone (OSVZ) of gyrencephalic animals, termed the basal or outer radial glia (Fietz et al., 2010; Hansen et al., 2010), indicating that the basal (outer) radial glia are also present in rodents, but as a minor cell population. Thus, it appears that this type of progenitor is commonly found during mammalian cerebral development, and the self-renewing progenitors in the developing mammalian cortex undergo two transitions in the division mode; first, from symmetric to asymmetric divisions of radial glia, and then later on, from radial glia to basal radial glia. The second transition can shift radial glia to a new niche (OSVZ), which might have a role in the brain size expansion during mammalian evolution. Mutant mice with defects in cleavage plane orientations generate a number of the basal radial glia, and using these mice will allow us to analyze the properties and genetic defects of basal radial glia.

### Asymmetric cell division in stem cells during CNS development.

M. P. Postiglione<sup>1</sup>, Y. Xie<sup>1</sup>, C. Jueschke<sup>1</sup>, J. A. Knoblich<sup>1</sup>; <sup>1</sup>IMBA- Institute of Molecular Biotechnology, Vienna, Austria

The mammalian brain develops from a layer of progenitor cells located on the apical side of a neuroepithelium. Initially, the progenitor pool expands by symmetric divisions. Later, progenitors divide asymmetrically and generate only one self-renewing daughter cell. The other daughter

cell either migrates towards the cortical plate to differentiate into a neuron (direct neurogenesis) or becomes an intermediate progenitor generating two neurons after one additional symmetric division (indirect neurogenesis). In symmetric progenitor cell divisions the mitotic spindle is always parallel to the neuroepithelial surface, but asymmetric divisions can also have vertical or oblique spindles. Whether this reorientation of the mitotic spindle is actually responsible for the establishment of asymmetry during those divisions is highly controversial and unclear.

We have addressed this question by generating conditional mutants and overexpression lines for the mouse *Inscuteable* (*mlnsc*) gene, the homolog of a key regulator of spindle orientation in *Drosophila*. We find that mutating *mlnsc* almost completely abolishes oblique and vertical mitotic spindles while *mlnsc* overexpression has the opposite effect. Surprisingly, our data indicate that spindle reorientation is not essential for the asymmetric outcome of the progenitor divisions but strongly influences the balance between direct and indirect neurogenesis. Thus, lineage decisions in the vertebrate brain are influenced by the orientation of progenitor divisions. As modified lineages and increased indirect neurogenesis are highly correlated with the expanded cortical size in primates, our data might be relevant for human brain evolution as well. By genome-wide RNAi screening in *Drosophila* neural stem cells, we have identified a large set of genes essential for lineage specification. We have started to analyze their mammalian homologs and will present results on their functional conservation.

112

### **Neural stem and progenitor cells and the evolution of the cerebral cortex.**

*W. B. Huttner*<sup>1</sup>; <sup>1</sup>*Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, Germany*

Our group studies the molecular and cellular mechanisms of neurogenesis in the developing neocortex in the context of mammalian brain evolution, specifically the various types of cortical stem and progenitor cells and their modes of division. In terms of their cell biology, two principal classes of cortical stem/progenitor cells can be distinguished. One class comprises stem/progenitor cells exhibiting bipolar morphology and apical-basal cell polarity that divide at the ventricular, i.e. apical, surface of the ventricular zone. These are the neuroepithelial cells and apical radial glial cells, which are collectively referred to as apical progenitors (APs). The other class comprises stem/progenitor cells dividing in a more basal, abventricular location, notably the subventricular zone, which are collectively referred to as basal progenitors (BPs). These fall into two subclasses (i) radial glia-related progenitors exhibiting monopolar morphology and basal, but not apical, cell polarity, referred to as basal radial glial cells (bRGCs); and (ii) progenitors exhibiting nonpolar morphology and lacking overt apical-basal cell polarity, which comprise transit-amplifying progenitors (TAPs) that undergo multiple rounds of cell division and intermediate progenitor cells (IPCs) that undergo only one round.

Our group has been studying the following issues related to these progenitor cells in the embryonic mouse, ferret, marmoset, macaque and human neocortex:

- (1) the various lineages from APs to BPs and neurons and their impact on neuron number;
- (2) the machinery underlying BP delamination, focusing on the primary cilium and centrosome;
- (3) the relationship between cell polarity and cleavage plane orientation in the context of symmetric versus asymmetric progenitor cell divisions;
- (4) the role of the microcephaly gene *Aspm*;
- (5) the cholesterol-binding apical membrane protein prominin-1/CD133;
- (6) prominin-1-bearing extracellular membrane particles released into the ventricular fluid from the midbody and primary cilium of APs, and their role in differentiation;

(7) the basal process of APs and bRGs and its role in extracellular matrix-dependent, integrin-mediated progenitor self-renewal;  
 (8) the role of cell cycle length in stem and progenitor cell proliferation versus differentiation;  
 (9) the comparative analysis of the transcriptomes of the various progenitor types in embryonic mouse and fetal human neocortex, and the cross-species transfer of transcriptomes by microinjection of single progenitors in organotypic slice culture.  
 Recent insights relevant for understanding the evolution of the neocortex will be presented.

113

**Shootin1 acts in concert with Kif20b to promote polarization of migrating neurons.**

*O. Reiner<sup>1</sup>, T. Sapir<sup>1</sup>; <sup>1</sup>Weizmann Institute of Science, Rehovot, Israel*

Shootin1 has been ascribed a role in regulating polarization of primary hippocampal neurons. We set investigating the role of Shootin1 in polarization of migrating neurons based on the proposed analogy with the process of polarization in primary hippocampal neurons. Shootin1 is highly expressed in the developing cortex, is detected in the microtubule associated proteins fraction, and its knockdown affects neuronal migration and polarization in vivo. Furthermore, a member of the kinesin superfamily, Kif20b, was identified as a novel Shootin1 interacting protein, and we mapped the binding domain to a fifty-seven amino acid sequence. The direct interaction and binding affinities between the minimal binding domain of Kif20b and Shootin1 were analyzed using surface plasmon resonance based technology. Furthermore, these proteins interacted in vivo, and in primary hippocampal neurons Kif20b knockdown reduced the mobilization of Shootin1 to the developing axon as evident by immunostaining and fluorescence recovery after photobleaching (FRAP) analysis, thus suggesting that Shootin1 is a novel Kif20b cargo. In the developing brain, either knockdown of Kif20b or expression of the minimal binding domain inhibited neuronal migration. Functional interaction between Shootin1 and Kif20b is suggested from migration assays in vivo. Collectively, our data demonstrate the importance of Shootin1 and its interaction with Kif20b to the dynamic process of neuronal polarization and migration.

114

**A role for cilia in dendrite extension.**

*C. Schouteden<sup>1</sup>, A. Dammermann<sup>1</sup>; <sup>1</sup>MFPL/University of Vienna, Vienna, Austria*

The cilium is a cellular organelle involved in motility and sensation. Non-motile primary cilia are found in many cells of the human body, including the nervous system. Previously considered to be mostly vestigial, there has been a resurgence of interest in primary cilia due to their link to a range of developmental and adult disorders in humans known as ciliopathies. Most ciliopathy-associated proteins are located at the base of the cilium in a complex structure called the ciliary transition zone.

In the nematode worm *C. elegans*, cilia are found exclusively at the tip of the dendrites of sensory neurons. Loss of cilia results in impaired perception of the external environment, but does not affect viability or fertility of the animal, making *C. elegans* an excellent model to study cilia and ciliopathy-associated proteins. In this study, we set out to characterize the *C. elegans* ortholog of CEP-290 (mutated in Meckel-Gruber and Bardet-Biedl syndromes, as well as Nephronophthisis) and its interactions with other previously described transition zone proteins associated with those disorders. Our work supports the existence of two functional modules at the transition zone, one comprising the nephrocystins NPHP-1 and NPHP-4, the other CEP-290, MKSR-2 and other Meckel syndrome proteins.

Co-deletion of any two components of these two modules results in short ciliated dendrites. In these mutants, dendrites fail to extend due to a lack of attachment of the dendritic tip during neuronal migration. Dendrites display correct numbers of properly formed cilia, but mispositioning results in impaired ciliary function. This adhesive function is restricted to the transition zone, since mutations in other ciliary structures do not affect dendrite extension.

In conclusion, our work describes a novel and unsuspected function for cilia in cellular architecture, maintaining dendritic tip attachment during neuronal migration.

### **Molecular and cellular mechanisms of dendrite remodeling in *Drosophila* sensory neurons.**

*K. Emoto<sup>1</sup>; <sup>1</sup>Department of Cell Biology, Osaka Bioscience Institute, Osaka, Japan*

Developmental dendrite pruning is a general mechanism that is required for maturation of neural circuits, yet how neurons can specifically eliminate unwanted branches remains elusive. During *Drosophila* metamorphosis, the larval-specific dendrites of class IV sensory neurons are once pruned and replaced by adult-specific processes, providing an ideal model to genetically dissect molecular mechanisms that control dendrite pruning. Using in vivo calcium imaging, we found localized calcium transients in dendritic branches during metamorphosis. Once the calcium transients happened in dendritic branches, the branches were pruned 3-4hr after continuous transients. The localized transients are mediated by calcium influx through voltage-gated calcium channels (VGCCs), and blockage of the VGCCs activities impaired dendrite pruning, suggesting that the localized calcium transients are required for elimination of the unwanted dendritic branches. Further genetic and biochemical studies indicated that the PKA signaling pathway likely functions downstream of the calcium transients in dendrites. Based on these observations, we propose a novel model in which the localized calcium transients act as a temporal and spatial cue to trigger dendrite pruning in class IV sensory neurons during metamorphosis. I will discuss how the calcium-dependent dendrite pruning in *Drosophila* neurons might relate to the axon/dendrite pruning observed in the mammalian nervous system during the critical period.

### **Tracking shallow chemical gradients by actin-driven wandering of the polarization site.**

*J. M. Dyer<sup>1</sup>, N. S. Savage<sup>1</sup>, M. Jin<sup>2</sup>, T. R. Zyla<sup>1</sup>, T. C. Elston<sup>3</sup>, D. J. Lew<sup>1</sup>; <sup>1</sup>Pharmacology & Cancer Biology, Duke University Medical Center, Durham, NC, <sup>2</sup>Department of Biochemistry and Biophysics, University of North Carolina, Chapel Hill, NC, <sup>3</sup>Department of Pharmacology, University of North Carolina, Chapel Hill, NC*

Many cells are remarkably proficient at tracking very shallow chemical gradients, despite considerable noise from stochastic receptor-ligand interactions. Motile cells appear to undergo a

biased random walk: spatial noise in receptor activity may determine the instantaneous direction, but because noise is spatially unbiased it is filtered out by time-averaging, resulting in net movement up-gradient. How non-motile cells might filter out noise is unknown. Using yeast chemotropic mating as a model, we demonstrate that a polarized patch of polarity regulators “wanders” along the cortex during gradient tracking. Computational and experimental findings suggest that actin-directed membrane traffic contributes to wandering by diluting local polarity factors. The pheromone gradient appears to bias wandering via interactions between receptor-activated G $\beta$  and polarity regulators. Artificially blocking patch wandering impairs gradient tracking. We propose that the polarity patch undergoes an intracellular biased random walk that enables noise filtering by time-averaging, allowing non-motile cells to track shallow gradients.

### **An optogenetic analysis of the minimal requirements for bud-site selection.**

*D. Strickland<sup>1</sup>, M. Glotzer<sup>1</sup>; <sup>1</sup>Molecular Genetics and Cell Biology, The University of Chicago, Chicago, IL*

An autocatalytic complex of four proteins (Cdc42, Cdc24, Bem1, PAK) is associated with the selection and maintenance of a single site of polarity in budding yeast, and positive feedback in this complex is required to amplify stochastic fluctuations in Cdc42 activity during symmetry-breaking polarization. However, the relevance of this feedback is not clear for situations where cells polarize towards an established spatial cue, and there has been no direct demonstration that artificially localized cues can be recognized and amplified solely through this mechanism. In order to experimentally manipulate signaling processes such as polarity establishment, we have created tunable, light-controlled interacting protein tags (TULIPs) based on genetic fusion with a photosensory LOV2 domain from plants and an engineered PDZ domain binding partner. These domains can be fused to cellular proteins of interest or localization motifs, thereby making their interaction light-regulated. We have shown that the tags function in yeast and mammalian cells and are readily adaptable to diverse signaling pathways. Here, we use TULIPs tags to confer light sensitivity to the activation of Cdc42 in yeast, thereby eliciting light-directed specification of the site of budding. We show that the multifunctional Cdc42 guanine nucleotide exchange factor (GEF), Cdc24, is sufficient to provide a spatial cue upon localized recruitment to the cortex, and that this artificial cue can override the endogenous cue. Furthermore, the polarity-specifying ability of Cdc24 is lost when either its GEF activity or its ability to interact with the scaffold Bem1 is ablated, even when a wild-type copy of Cdc24 is present. These results suggest that several different functionalities are required to trigger positive feedback and successfully specify the site of budding. Future experiments will explore the timing, cell-cycle dependence, and molecular requirements of light-directed polarity specification.

### **Cell polarity: Mechanochemical patterning.**

*S. W. Grill<sup>1</sup>; <sup>1</sup>MPI-CBG and MPI-PKS, Dresden, Germany*

Recent advances in our understanding of the coupling of mechanical and biochemical processes for the purpose of cellular polarization will be presented. I will focus on a particular example, polarization of the *C. elegans* zygote, a classic example for mechanochemical patterning. In this system actively generated flow of the actomyosin cell cortex triggers polarization in terms of the intracellular distribution of markers of polarity. I will present biophysical principles of actively generated cortical flow, and I will discuss the two-way feedback between mechanical and biochemical networks. This work provides insight into general mechanisms of biological patterning that go beyond spatial patterning in the framework of reaction-diffusion.

119

**Human bone-marrow mesenchymal stem cells regulate biased DNA segregation in response to cell adhesion asymmetry.**

*D. Freida<sup>1,2</sup>, S. Lecourts<sup>1</sup>, A. Cras<sup>1</sup>, V. Vanneaux<sup>1</sup>, X. Gidrol<sup>2</sup>, M. Thery<sup>2</sup>; <sup>1</sup>APHP, Paris, France, <sup>2</sup>iRTSV, CEA, Grenoble, France*

Biased DNA segregation is a mitotic figure in which the chromosomes carrying the original DNA strand and those carrying the copy do not segregate equally between the two daughter cells. It has been documented in various species ranging from bacteria to mammals. In mouse muscles, biased DNA segregation has been shown to occur in adult stem cells and to regulate asymmetric cell fate (Rocheteau et al., Cell, 2012). However the absence of DNA bias in asymmetric divisions of mouse hematopoietic stem cells (Kiel et al., Nature, 2007) but its occurrence in human tumour-derived cells (Pine et al., PNAS, 2010) feed the debate on the relationship between stemness, asymmetric division and biased DNA segregation. The parameters influencing this bias have not been identified yet. No clear conclusions could be firmly drawn owing to the low frequency of biased DNA segregation in all these conditions and to the difficulty to clearly identify daughter cells in situ. Here we used pulse-chased EdU DNA labelling and video-microscopy to monitor cell division and quantify DNA segregation bias in human bone marrow-derived mesenchymal stem cells. The low rate of division in these cells was overcome by following a thousand of cells in parallel for each donor sample. Thereby we clearly showed that biased DNA segregation does occur in human stem cells. To investigate the role of cell adhesion to its micro-environment in the regulation of this event, cells were plated on micro-patterned extra-cellular matrices. We found that the rate of 10% of cells displaying biased DNA segregation observed in unconstrained cells or cells plated on symmetric micro-patterns increases to 50% on asymmetric micropatterns. To the best of our knowledge, it is by far the highest rate ever reported for this event which is no longer anecdotic. Importantly, this sensitivity of asymmetric extra-cellular cues was specific to stem cells, reproducible for all tested donor, and was not observed in human skin-derived fibroblasts used as a control of differentiated cells. These data demonstrate that stem cells have a unique capacity to feel and respond to the asymmetry of their adhesion pattern by increasing massively their capacity to segregate the chromosomes carrying the original strand in one of the daughter cells only.

120

**Bazooka forms a platform that integrates polarity and cell cycle progression in *Drosophila* male germline stem cells.**

*M. Inaba<sup>1</sup>, Y. M. Yamashita<sup>1,2,3</sup>; <sup>1</sup>Center for Stem Cell Biology, Life Sciences Institute, University of Michigan, Ann Arbor, MI, <sup>2</sup>Department of Cell and Developmental Biology, School of Medicine, University of Michigan, Ann Arbor, MI, <sup>3</sup>Cellular and Molecular Biology Program, University of Michigan, Ann Arbor, MI*

Many stem cells are known to divide asymmetrically to balance self-renewal and differentiation. In *Drosophila* male germline stem cells (GSCs), asymmetric division is achieved by spindle orientation, which is predetermined during interphase by stereotypical positioning of centrosomes. The correct centrosome orientation is further monitored by a checkpoint mechanism (the centrosome orientation checkpoint (COC) to ensure asymmetric division. Here we show that bazooka (Baz), a homolog of mammalian Par-3, is an integral component of the COC. In GSCs, Baz forms small foci at the hub-GSC interface, and orchestrates the subcellular localization of the centrosome and the spectrosome, a germline-specific ER-like organelle implicated in the COC. Par-1, a known component of the COC that localizes to the spectrosome, functions through the phosphorylation of Baz. We further show that the two opposing microtubule motors, dynein and kinesin, functions in the COC through their ability to

position the spectrosome and the centrosome, respectively. We propose that the Baz patch forms a platform to integrate the centrosome orientation status and cell cycle progression .

121

### **Mechanisms of SPB specification during spindle orientation in yeast.**

*Y. P. Barral<sup>1</sup>, M. Hotz<sup>1</sup>, J. Lengefeld<sup>1</sup>; <sup>1</sup>Institute of Biochemistry, ETH Zurich, Zurich, Switzerland*

In many asymmetrically dividing cells, the centrosomes are segregated in a non-random manner between the two daughter cells, with the centrosome containing the oldest centriole generally segregating to the renewing cell, and the younger one to the differentiating daughter. This phenomenon is conserved in budding yeast, where the mother cell and the bud inherit the two centrosome-equivalents, called the spindle pole bodies (SPBs), in a non-random manner. Indeed, budding yeast cells divide asymmetrically, producing a smaller and rejuvenated daughter cell at the surface of the bigger and slowly aging mother cell. Forming the poles of the mitotic spindle, the SPBs are produced through semi-conservative duplication, leading to the generation of a new SPB at the side of the old one. Remarkably, the new SPB segregates to the mother cell, and the old one to the bud, in more than 95% of mitosis. How the cell distinguishes the old from the new SPB is unknown. However, previous work has established that the microtubule and actin associated protein Kar9 is recruited virtually exclusively to the microtubules emanating from the old SPB and drives its orientation towards the bud. We are investigating the mechanisms specifying the fates of the SPBs. These studies revealed that the SPB components Nud1 and Cnm67 are absolutely essential for this function. In this process, the Nud1 protein functioned upstream of the mitotic exit network (MEN), a signaling cascade related to the Hippo pathway in metazoans and which mediated the establishment of Kar9 asymmetry towards the old SPB. MEN fulfills this function in conjunction with Cdk1 in metaphase, and at least in part through direct phosphorylation of Kar9 on S197, 332 and 429. Additional mutants interfering with proper specifications of the SPBs comprise kinases of the morphogenetic checkpoint, which control the timing of the metaphase-to-anaphase transition, as well as acetylation and deacetylation enzymes. Together, our data suggest a model in which SPB specification is linked to the SPB duplication cycle at bud emergence.

### **Aging, neurodegeneration and trinucleotide disease: Insight from *Drosophila*.**

*N. M. Bonini<sup>1</sup>; <sup>1</sup>Biology, University of Pennsylvania, Philadelphia, PA*

Human neurodegenerative diseases, like Huntington's disease and the spinocerebellar ataxias, are late-onset progressive neurodegenerative disorders for which few cures or treatments are available. To develop new approaches, we have been using the simple model organism *Drosophila* to provide insight that we then extend to the human disease. We use the human disease gene to recreate the disease toxicity in the fly, and then take advantage of powerful molecular genetic approaches in the fly to define pathways and mechanisms.

These studies have revealed multiple pathways involved in neurodegeneration, including toxicities due to RNA pathways. These processes include toxic activities of the mRNA encoding the disease proteins for repeat expansion diseases, RNA binding proteins and their altered activities, and modulation by miRNAs, including novel aspects of miRNA regulation such as 3'end trimming by the exonuclease Nibbler. A key miRNA we identified that links age-associated processes with long-term brain integrity is miR-34. Taken together, these findings emphasize

and highlight the diversity of ways in which altered RNA pathways and metabolism impacts brain integrity, and interplays with gene function in brain degenerative disease.

123

**Ubiquitin-dependent aggregation of misfolded proteins in the absence of HSP70 chaperones.**

*A. Shiber<sup>1</sup>, W. Breuer<sup>1</sup>, M. Brandeis<sup>2</sup>, T. Ravid<sup>1</sup>; <sup>1</sup>Biological Chemistry, Hebrew University of Jerusalem, Jerusalem, Israel, <sup>2</sup>Genetics, Hebrew University of Jerusalem, Jerusalem, Israel*

The heat shock protein-70 chaperone family is a key component of the cellular quality control system, mediating protein folding, refolding and preventing aggregation. The primary role of Hsp70 chaperones in ubiquitin-dependent degradation of misfolded proteins has been perceived to be the delivery of misfolded proteins to E3 ubiquitin-ligases for ubiquitylation.

In order to assess the precise role of Hsp70 chaperones in yeast protein quality control and degradation, we focused our study on substrates of the yeast E3 ligase, Doa10, which undergo ubiquitylation and subsequent degradation. We have previously identified a Doa10-recognized degradation signal (degron) at the C-terminal tail of the functionally conserved kinetochore protein, Ndc10. Degradation of protein substrates containing this degron requires the Hsp70 chaperones Ssa1 and Ssa2. Deletion of both SSA1 and SSA2 caused stabilization of an ER-localized substrate carrying an Ndc10-degron, but only slightly reduced its ubiquitylation levels. This implies that the function of Ssa1/2 is required downstream to ubiquitylation. Expression of the Ndc10 degron fused to GFP in DOA10-knockout cells led to its accumulation in the nucleus, in a soluble form. In contrast, deletion of SSA1/2 led to aggregation of the GFP-labeled degron, while the deletion of DOA10 together with the deletion of SSA1/2 significantly decreased aggregate formation. These results indicate that the aggregation of substrates containing the Ndc10 degron is strongly dependent on their ubiquitylation. Furthermore, the aggregates in SSA1/2-deficient cells were selectively retained in yeast mother cells undergoing budding, consistent with known asymmetric inheritance of deleterious proteins. As such, these cells could also provide a physiological paradigm for studying age-dependent accumulation of ubiquitylated protein aggregates.

We propose that the Hsp70 chaperones assist the degradation of misfolded proteins by two means: supporting substrate recognition by the ubiquitin-ligation apparatus and maintaining ubiquitylated proteins in a soluble form. This ensures safe delivery to the proteasome and protects cells from the possibly deleterious effects of misfolded protein aggregation.

124

**Systematic genetic interaction mapping of protein folding and stress response pathways in the human ER.**

*M. Kampmann<sup>1</sup>, J. Weissman<sup>1</sup>; <sup>1</sup>Cellular and Molecular Pharmacology, HHMI / UCSF, San Francisco, CA*

Systematic mapping of genetic interactions is a powerful approach to gaining a comprehensive mechanistic understanding of complex biological processes, and has successfully been applied to the yeast endoplasmic reticulum (ER) and other areas of biology in microorganisms. However, systematic genetic interaction mapping has thus far not been applied to mammalian cells. A genetic interaction map of the human ER would likely yield important insights into mammalian-specific ER functions.

We have now developed an RNA interference-based platform that allows us to conduct highly quantitative genetic screens and genetic interaction mapping in mammalian cells. To probe human ER function, we used the bacterial subtilase cytotoxin (SubAB), which kills cells by specifically cleaving BiP/GRP78, the Hsp70 chaperone of the ER, and thereby inducing the

unfolded protein response (UPR) and apoptosis. We have identified a large number of genes that modulate the response of human cells to SubAB: Host factors required for SubAB trafficking to the ER, many of which we also identified for other ER-trafficking toxins; factors contributing to protein load in the ER; a variety of chaperones and other protein folding factors; signaling components of the UPR; and previously uncharacterized factors. Surprisingly, factors implicated in other types of cellular stress responses also modulated sensitivity to subAB, hinting at possible cross-talk between different homeostatic and stress response pathways. We are now systematically mapping genetic interactions between these factors to understand how they interact in pathways, and in order to pinpoint putative functions for previously uncharacterized proteins.

125

### **H<sub>2</sub>S and fasting protect against hypoxia-induced disruption of proteostasis in *C. elegans*.**

N. N. Iranon<sup>1,2</sup>, E. M. Fawcett<sup>1,2</sup>, D. L. Miller<sup>1</sup>; <sup>1</sup>Biochemistry, University of Washington, Seattle, WA, <sup>2</sup>Graduate Program in Molecular and Cellular Biology, Seattle, WA

Cells and organisms must keep the proteome in a well-folded, functional state even in stressful conditions. Maintaining proteostasis requires the coordination of pathways that control protein translation, folding, and turnover. We are interested in the mechanisms by which animals integrate cellular stress responses with proteostasis networks. We have found specific hypoxic O<sub>2</sub> concentrations that disrupt proteostasis in *C. elegans*, as measured by aggregation and toxicity of polyglutamine-containing proteins. We demonstrate that H<sub>2</sub>S, an endogenous gaseous signaling molecule, can protect against and reverse the effects of hypoxia on proteostasis. H<sub>2</sub>S exposure activates the conserved hypoxia-inducible transcription factor, *hif-1*. However, we find that *hif-1* is necessary but not sufficient to protect proteostasis in hypoxia, suggesting that other factors are involved in the effects of H<sub>2</sub>S to improve proteostasis. In a screen to identify factors that coordinate the response to hypoxia with proteostasis network we identified the AMP-associated kinase (AMPK) subunit *aak-2*. The *aak-2* mutant animals do not show increased protein aggregation in hypoxia. In contrast, age-associated polyglutamine protein aggregation occurs normally in the *aak-2* mutant animals. In parallel studies we found that fasting protects animals against hypoxia-induced protein aggregation. AMPK has been shown to mediate some effects of increased lifespan by dietary restriction. Thus, we hypothesized that AMPK integrates the effects of food deprivation and hypoxia on proteostasis. Consistent with this model, *aak-2* mutant animals show increased protein aggregation in hypoxia after fasting. We propose that AMPK signaling regulates proteostasis to control allocation of resources in stressful hypoxic conditions. We are also testing the hypothesis that beneficial effects of H<sub>2</sub>S are mediated by AMPK.

126

### **The chaperome as a therapeutic space in aging and neurodegenerative diseases.**

C. Voisine<sup>1,2</sup>, M. Brehme<sup>3,4,5</sup>, T. Rolland<sup>4,5</sup>, S. Wachi<sup>3</sup>, K. Orton<sup>2</sup>, P. Reinhart<sup>3</sup>, M. Vidal<sup>4,5</sup>, R. Morimoto<sup>2</sup>, H. Ge<sup>3</sup>; <sup>1</sup>Biology, Northeastern Illinois University, Chicago, IL, <sup>2</sup>Molecular Biosciences, Northwestern University, Evanston, IL, <sup>3</sup>Proteostasis Therapeutics, Inc., Cambridge, MA, <sup>4</sup>Center for Cancer Systems Biology (CCSB) and Department of Cancer Biology, Dana-Farber Cancer Institute, Boston, MA, <sup>5</sup>Genetics, Harvard Medical School, Boston, MA

Chaperone networks act as regulators of proteostasis, safeguarding the proper folding of the proteome and preventing aggregation. While numerous chaperones and co-chaperones have been implicated in aging and disease using candidate gene approaches, our understanding of

chaperone connectivity and functional cooperativity at a systems level is incomplete. We utilized a series of comparative genomics and bioinformatics methodologies to identify the repertoires of 219 *C. elegans* and 332 human chaperone genes belonging to fifteen distinct protein families and specific subcellular compartments, collectively referred to as “chaperomes”. To establish the organizational properties of the chaperome, we combined physical protein-protein interactions (PPIs) and gene expression data from public databases and generated integrated *C. elegans* and human chaperome networks. We hypothesized that the chaperome network would reveal specificity when challenged to respond to the dynamics of aging or aggregation prone client proteins implicated in human neurodegenerative diseases such as Alzheimer’s, Huntington’s and Parkinson’s disease. Examination of expression patterns of chaperome genes during aging revealed distinct network communities of activation and repression that included representatives from all chaperone families. Strikingly, the subsets of chaperones that are activated or repressed during aging showed similar accelerated changes in brain tissue from AD, HD and PD patients. Following chaperome-wide perturbation studies in *C. elegans*, we validated and refined a functional chaperome subnetwork, which includes 16 specific members from the Hsp90, Hsp70, Hsp60 (chaperonin), Hsp40, and TPR families, and new candidate genes that have not been linked directly to proteostasis. Our studies define a core chaperome as a conserved modifier of proteostasis, in aging and disease, revealing potential targets for therapeutic intervention.

127

### Humoral control of proteostasis.

A. Dillin<sup>1</sup>; <sup>1</sup>MCB, UC Berkeley, Berkeley, CA

As an organism ages, its proteins face an increasing severity in the challenges they receive from extrinsic and intrinsic environmental perturbations. Chaperones become dysregulated, while the degradation machineries stop working properly. The protein accumulates damage and starts to misfold. At this point, the cell needs to mount a response to restore its homeostasis; however, the stress response machinery that it typically relies upon when faced with such challenges has lost its capacity to function.

This breakdown, however, does not lead to complete disorder. As the organism ages, it exhibits a degree of correlated, recognizable, and predictable changes to its physiology over time. These changes can occur synchronously across multiple tissues and organs. The phenotypic changes of aging occur in a type of concert, rather than in isolation, suggesting the residual participation of the endocrine system in the onset of age-related phenotypes. The demise of the cell thus most often occurs within the context of the simultaneous demise of the whole organism.

Our lab focuses on the questions of why an aging organism begins to lose control over the integrity of its proteome, and how this loss is communicated across its various tissues. We have taken the unique approach of breaking down a cell into its small and canonically-autonomous parts – its suborganelles and subcompartments – such that we can take a larger step back to ask how those smaller portions can communicate both with each other and with the organism as a whole. Our approaches have required us to diversify the contexts in which we ask questions: we work on model systems ranging from stem cells and nematodes to mice. We have developed and applied techniques that allow us to manipulate signaling pathways or proteins within a single tissue, cell, or an organelle within a single cell so that we can observe how that small perturbation might reverberate and effect the physiology of the whole of the organism.

## Minisymposium 20: Micro- and Coding RNA

128

### A subset of microRNAs and messenger RNAs in the nucleolus.

P. Reyes-Gutierrez<sup>1</sup>, T. Pederson<sup>1</sup>; <sup>1</sup>Biochemistry and Molecular Pharmacology, U. Mass. Medical School, Worcester, MA

During studies of myogenic differentiation with rat L6 myoblasts we found that a small set of microRNAs localizes in the nucleoli of these cells. Since these microRNAs are also present in the cytoplasm we considered their nucleolar localization to reflect a transit. This led us to ask whether they might be combining with messenger RNAs that also traffic through the nucleolus. Microarray analysis of RNA from highly purified nucleoli revealed the presence of a subset of the messenger RNAs expressed in these cells. Prevalent among these nucleolus-localized mRNAs are ones that encode connexin-like proteins involved in the cell fusion events of myogenesis taking place two days later. Target sites for two of the nucleolus-localized microRNAs were found in the 3' UTR of one of the nucleolus-localized mRNAs suggesting a docking of microRNAs on nucleolus-trafficking mRNAs prior to export in a translationally suppressed state, this suppression to be relieved later in myogenic differentiation. This is a strikingly different concept relative to the standard model of microRNA action in the cytoplasm and yet is not at variance with any prior results in the microRNA field.

129

### Crosslinking reveals unexpected roles for the yeast SR protein Npl3 in ncRNA metabolism.

R. K. Holmes<sup>1</sup>, S. Granneman<sup>2</sup>, S. Clauder-Munster<sup>3</sup>, C. Zhu<sup>3</sup>, L. Steinmetz<sup>3</sup>, C. Guthrie<sup>4</sup>, D. Tollervey<sup>1</sup>; <sup>1</sup>Wellcome Trust Centre for Cell Biology, University of Edinburgh, Edinburgh, United Kingdom, <sup>2</sup>Institute for Structural and Molecular Biology, Centre for Synthetic and Systems Biology (SynthSys), University of Edinburgh, Edinburgh, United Kingdom, <sup>3</sup>Genome Biology Unit, European Molecular Biology Laboratories, Heidelberg, Germany, <sup>4</sup>Biochemistry and Biophysics, University of California San Francisco, San Francisco, CA

From the onset of transcription, nascent RNA transcripts are coated with a complement of RNA binding proteins (RBPs). This array of proteins mediates a complex series of mRNA processing events, leading to the production of a mature functional RNA. Many processing events are highly inter-dependent and, in consequence, disruption of individual RBPs can result in numerous deleterious effects. In higher eukaryotes, this is further complicated by functional redundancies between paralogous genes. The determination of direct molecular functions for these RBPs thus remains a significant challenge.

The SR proteins are a large family of RBPs in metazoans with diverse functions in pre-mRNA processing. The budding yeast genome encodes a single SR protein, Npl3, to which a multitude of roles in pre-mRNA processing have been attributed, including transcription elongation, splicing and 3' end processing. To gain insights into the direct functions and targets of this protein, we employed an *in vivo* crosslinking and sequencing approach to elucidate which transcripts it associates with and where in the RNA it binds. We found Npl3 to bind diverse RNA species, including mRNAs and non-protein coding RNAs (ncRNAs), many of which were oligo-adenylated at non-canonical sites. Non-templated adenosine stretches are hallmarks of RNA molecules destined for turnover, suggesting a role for Npl3 in targeting RNAs for degradation. To determine whether specific RNA species are enriched in the absence of Npl3, we used strand-specific tiling arrays to look for expression changes when *NPL3* is deleted. We found that

CUTs, a class of unstable ncRNAs, were enriched in the mutant strain, and the transcription units of many snoRNAs were greatly extended. The increased abundance and/or length of these different ncRNAs had dramatic effects on the expression of surrounding genes. These data suggest that although deletion of *NPL3* results in many altered mRNA processing phenotypes, these may largely be downstream of a direct function in the transcription termination and/or turnover of ncRNAs. We are currently assessing whether Npl3 functions directly in the termination of ncRNAs, or in targeting aberrant RNAs for turnover, and how it interacts with other components of these pathways.

130

**Cyanobacterial DEAD-box RNA helicase: Autoregulation, RNA maturation and sRNA metabolism.**

A. R. Rosana<sup>1</sup>, D. Chamot<sup>1</sup>, J. Georg<sup>2</sup>, W. Hess<sup>2</sup>, G. Espie<sup>3</sup>, G. Owtrim<sup>1</sup>; <sup>1</sup>Department of Biological Sciences, University of Alberta, Edmonton, AB, Canada, <sup>2</sup>Faculty of Biology, University of Freiburg, Freiburg, Germany, <sup>3</sup>Department of Biology, University of Toronto, Mississauga, ON, Canada

DEAD-box RNA helicases are ubiquitous enzymes found in all domains of life that rearrange RNA secondary structure. They function in every aspect of RNA metabolism, frequently in response to abiotic stress. In the cyanobacterium *Synechocystis* sp. PCC 6803, expression of the cyanobacterial RNA helicase gene, *crhR*, is regulated in response to temperature fluctuation. Physiologically, CrhR inactivation dramatically affected the photosynthetic capacity and morphology of the mutant cells in response to temperature downshift. Analysis of the expression profile of the *crhR* dicistronic operon in wild type and  $\Delta$ *crhR* cells indicated that CrhR autoregulates its own expression through a combination of transcript processing and temperature-dependent mRNA and protein stabilization mediated by dramatic temperature- and mutant-induced alteration of half-life. *crhR* inactivation resulted in unregulated accumulation of both transcript and protein while multiple transcripts detected in the mutant suggested defects in RNA processing and/or degradation. 5' RACE-RCA and immunoprecipitation analysis are ongoing to establish processing sites and potential RNases (RNase II/R, E, J) involved in transcript turnover and maturation. Furthermore, tiling arrays revealed that CrhR controls expression of a subset of small RNAs in *Synechocystis*. A model integrating the ability of CrhR in unwinding and annealing RNA with a role in gene regulation during environmental acclimation involving autoregulatory pathways and small regulatory RNAs will be presented.

131

**The role of core RNA splicing factors in spindle assembly.**

M. Strzelecka<sup>1</sup>, R. Heald<sup>1</sup>; <sup>1</sup>Department of Molecular and Cell Biology, University of California, Berkeley, Berkeley, CA

The mitotic spindle is a complex macromolecular structure responsible for the faithful distribution of genetic material to daughter cells. Our lab has shown that the spindle is not a purely protein-based machine, since an RNA component is essential for its integrity. Furthermore, RNA splicing factors have been implicated by a number of genome-wide screens as important for cell cycle progression and mitosis. Lastly, a spindle assembly factor, TPX2, has been observed to co-purify with active spliceosomes. In order to investigate whether RNA splicing factors play a direct role in mitosis we are utilizing transcriptionally silent *Xenopus laevis* and *Xenopus tropicalis* egg extracts to reconstitute spindle assembly in vitro and isolate mitotically functioning RNAs. Interestingly, we have found that a small molecule inhibitor of spliceosome assembly, isoginkgetin, as well as antibodies with known splicing inhibitory

potential, caused defects in spindle integrity in a concentration-dependent manner. We observed similar phenotypes when we immunodepleted small nuclear ribonucleoproteins (snRNPs) with antibodies against an epitope shared by four spliceosomal snRNPs. One expectation of splicing involvement in mitosis is that introns are present in mitotic RNAs. We performed next generation sequencing on non-ribosomal RNAs from *X. tropicalis* egg extract as well as on RNAs co-immunoprecipitated with spliceosomal snRNPs. Strikingly, even though transcription had ceased in mature oocytes long before the eggs were harvested, we observed that approximately 2-4% of introns were retained. These introns represent a number of gene ontology terms with a strong enrichment of genes involved in regulation of transcription and protein phosphorylation; cell cycle, mitotic and microtubule-related terms are also represented. Of all retained introns 79% contained premature stop codons that must therefore be removed to allow for translation. Our data support the direct involvement of RNA splicing factors in mitosis and suggest the tantalizing possibility that RNA processing plays a regulatory role in cell division.

### **Assembling liquid droplets of cytoplasmic RNA and protein.**

*C. P. Brangwynne<sup>1</sup>; <sup>1</sup>Chemical & Biological Engineering, Princeton University, Princeton, NJ*

Ribonucleoprotein (RNP) granules are non membrane bound macromolecular assemblies that form from the dynamic interactions of RNA and protein. They play a central role in cell growth, embryonic development, and many other fundamental biological processes. Among dozens of examples include germ granules and processing bodies in the cytoplasm, and Cajal bodies and nucleoli in the nucleus. We show that these structures behave as liquid droplets, which assemble from soluble cytoplasmic/nucleoplasmic RNA and protein by a type of phase transition, whose set-point is biologically controlled in space and time. The size and shape of these structures is controlled by their liquid like material properties, and the mechanical and geometric constraints of their local environment. These findings shed light on both the self-assembly of RNP granules, and their function as fluid-phase micro-reactors that facilitate RNA metabolism.

133

### **Understanding co-transcriptional pre-mRNA splicing and the dynamic rearrangements at the heart of the spliceosome.**

*E. Merkhofer<sup>1</sup>, S. Pradhan<sup>1</sup>, T. L. Johnson<sup>1</sup>; <sup>1</sup>Division of Biological Sciences, Molecular Biology Section, University of California, San Diego, La Jolla, CA*

Eukaryotic gene expression is tightly controlled to maintain proper cellular function. Eukaryotic genes are transcribed by RNA polymerase II to generate fully-processed (capped, polyadenylated, and spliced), mature messenger RNA molecules. Although the cellular machineries that carry out these reactions (RNA synthesis and RNA processing) have typically been studied as biochemically distinct reactions, they are, in fact, temporally and spatially organized to coordinately orchestrate the proper production of a fully-processed mRNA. One of the outstanding challenges has been to identify specific factors that coordinate pre-mRNA splicing with transcription, particularly within the context of a chromatin template. We have previously shown that Gcn5, which encodes the HAT activity of the co-activator SAGA complex, mediates co-transcriptional recruitment of the U2 snRNP to pre-mRNA. As further evidence of a role for SAGA in mediating ATP-dependent rearrangement of the U2 snRNP, we have identified interactions between the DEXH/D box protein Prp5, which hydrolyzes ATP to remodel the U2 snRNP and facilitate branchpoint recognition, and components of SAGA. A mutation in PRP5

that decreases ATP-binding is suppressed when components of the SAGA complex are mutated, thereby for the first time linking SAGA with a catalytic activity that drives spliceosomal rearrangements. These results have led us to further analyze how histone acetylation contributes to U2 snRNP recruitment. We find that chromatin remodeling complexes that associate with acetylated histones physically and functionally interact with the U2 snRNP and contribute to spliceosome assembly. These data support a model whereby co-transcriptional spliceosome assembly is intimately coordinated with histone acetylation and chromatin remodeling.

### SUMOylation regulates mammalian septin functions.

*D. Ribet<sup>1,2,3</sup>, S. Mostowy<sup>1,2,3,4</sup>, P. Cossart<sup>1,2,3</sup>; <sup>1</sup>Unité des Interactions Bactéries-Cellules, Institut Pasteur, Paris, France, <sup>2</sup>Inserm U604, Paris, France, <sup>3</sup>Inra USC2020, Paris, France, <sup>4</sup>Centre for Molecular Microbiology and Infection, Section of Microbiology, Imperial College London, London, United Kingdom*

Septins are cytoskeletal proteins that assemble into non-polar filaments and higher-order structures such as rings and hourglasses. By acting as scaffolds for protein recruitment and as diffusion barriers for subcellular compartmentalization, septins play key roles in diverse cellular functions such as cytokinesis and ciliogenesis. In addition, septins play a crucial role in bacterial infection, by entrapping intracytoplasmic bacteria into cage-like structures and impairing their cell-cell spreading capacity. Yeast septins were among the first proteins reported to be modified by SUMOylation, a ubiquitin-like post-translational modification. However, whether mammalian septins could be modified by SUMO, and what roles this modification may have in septin functions remain unknown. We found that different members of the human septin family can be SUMOylated. We show that non SUMOylatable mutants of septins are impaired in their ability to form cages around intracytosolic bacteria. We also demonstrate that SUMOylation of septins is critical for mammalian cytokinesis. Together, our results reveal that SUMOylation is a key modification regulating mammalian septin functions.

### Dendritic network remodeling in *Listeria monocytogenes* protrusions.

*A. Talman<sup>1</sup>, R. Chong<sup>2</sup>, H. Agaisse<sup>1</sup>; <sup>1</sup>Yale University, New Haven, CT, <sup>2</sup>Genentech, South San Francisco, CA*

Several intracellular pathogens, including *Listeria monocytogenes*, display actin-based motility in the cytosol of infected cells and spread from cell to cell through membrane protrusion formation at the cell cortex. Seminal studies have revealed how these intracellular pathogens exploit the actin assembly machinery and display cytosolic motility. In contrast, the mechanisms supporting membrane protrusion formation at the cell cortex, and therefore pathogen dissemination, are still poorly understood. To bridge this gap in knowledge, we have developed large-scale RNAi treatment procedures, high-throughput fluorescence microscopy and computer-assisted image analyses to screen for cellular factors supporting *L. monocytogenes* dissemination in human epithelial cells. In addition to expected components of the actin assembly machinery, such as the ARP2/3 complex and capping proteins, we identified Actin Interacting Protein 1 (AIP1), a component of the Cofilin-dependent actin disassembly machinery. Cytosolic motility was indistinguishable from wild-type in AIP1-depleted cells.

However, AIP1 depletion resulted in a striking accumulation of membrane protrusions at the cell cortex. Using time-lapse video microscopy, we uncovered that, unlike the situation observed upon formation of actin tails in the cytosol, the ARP2/3-containing network formed at the bacterial pole was quickly remodeled into an ARP2/3-devoid network in protrusions. We used photo-activation of GFP-tagged proteins to demonstrate that this AIP1-dependent process in fact recycles actin molecules (and ARP2/3) from the actin network formed in protrusions. This recycling process is essential to fuel continuous ARP2/3-dependent actin nucleation at the bacterial pole, as protrusions elongate. To identify potential AIP1 partners, we screened for cellular factors whose depletion enhanced the cell-to-cell spreading defects observed in AIP1-depleted cells. As previously described in lamellipodia, we identified Cofilin as a central component of the AIP1-dependent remodeling machinery in protrusions. In addition, we uncovered a previously unappreciated role for the actin-depolymerizing factor homology (ADF-H) domain proteins GMF and Twinfilin 2. Thus, *L. monocytogenes* spread from cell to cell relies on the coordinated activity of machineries supporting assembly and disassembly of dendritic network in protrusions, which provides a powerful framework to investigate the mechanisms supporting actin network remodeling in cellular structures such as lamellipodia.

136

**Influence of host cell behavior on the invasion and cell-to-cell spread of *Listeria monocytogenes* in endothelial sheets.**

M. Rengarajan<sup>1</sup>, J. A. Theriot<sup>1,2</sup>; <sup>1</sup>Biochemistry, Stanford University, Stanford, CA, <sup>2</sup>Microbiology and Immunology, Stanford, Stanford, CA

The facultative intracellular bacterial pathogen *Listeria monocytogenes* harnesses the actin machinery of its host cell to move within individual cells and from one cell to another, without exposure to the extracellular space. Mounting evidence suggests that such actin-based motility and cell-to-cell spread contribute to systemic spread of *L. monocytogenes*, whereby the bacterium spreads from the initial site of infection in the mammalian gut epithelium to subvert cellular barriers and infect distal sites, such as the placenta or the central nervous system. However, the molecular details of cell-to-cell spread remain largely uncharacterized. We are studying the ability of *L. monocytogenes* to subvert the vascular endothelium, a single layer of cells that lines blood vessels and represents a significant barrier to systemic bacterial spread. In tissue culture experiments, we have demonstrated that *L. monocytogenes* in infected macrophages can robustly infect monolayers of uninfected human umbilical vein endothelial cells (HUVEC) via direct heterotypic cell-to-cell spread, and that this spread depends on both bacterial motility and macrophage-endothelial adhesion. Additionally, we have confirmed that *L. monocytogenes* can directly invade a monolayer of HUVEC; in these latter experiments, a substantial fraction of infected cells in a sheet are infected by cell-to-cell spread from the much smaller number of initially invaded cells. Using time-lapse microscopy of infected cells, we determined that infected HUVEC exhibit surprisingly normal bulk division rate and individual cell motility, suggesting that these and other normal host processes may contribute to bacterial spread. To identify specific host factors that modulate bacterial invasion and spread in HUVEC, we conducted a quantitative, image-based siRNA screen. We have identified a number of host genes that appear to specifically regulate bacterial invasion, cell-to-cell spread or both. We are currently using time-lapse fluorescence microscopy and flow cytometry to determine whether these factors directly affect bacterial infection or instead alter infection indirectly, e.g. by altering host cell motility, cytoskeletal dynamics, or cell-cell interactions. We are particularly interested in the role of host proteins associated with adherens junctions, which have been well-characterized in *L. monocytogenes* invasion of epithelial cells but have not been clearly implicated in endothelial cell invasion or in cell-to-cell spread.

137

**Unique requirement for the exocyst complex in the repair of large plasma membrane wounds and host cell invasion by *Trypanosoma cruzi*.**

M. C. Fernandes<sup>1</sup>, D. C. Miguel<sup>1</sup>, C. Tam<sup>1</sup>, N. W. Andrews<sup>1</sup>; <sup>1</sup>Department of Cell Biology and Molecular Genetics, University of Maryland, College Park, MD

Host cell entry by *T. cruzi* shares mechanistic elements with plasma membrane injury and repair. Both processes require Ca<sup>2+</sup>-triggered exocytosis of lysosomes<sup>1,2</sup>, delivery of the lysosomal enzyme acid sphingomyelinase to the outer leaflet of the plasma membrane<sup>3,4</sup>, and a rapid form of endocytosis that mediates internalization of small membrane lesions such as those caused by pore forming toxins<sup>4,5</sup>. *T. cruzi* trypomastigotes transiently wound host cells and enhance endocytosis, taking advantage of the ubiquitous plasma membrane repair pathway to gain access to the intracellular milieu and form a parasitophorous vacuole enriched in ceramide<sup>3</sup>. However, trypomastigotes are large (10-15 µm long) parasites that preferentially invade cells at specific peripheral sites, and it is unclear how generation of small sphingomyelinase/ceramide-dependent endosomes facilitates their internalization. Because *T. cruzi* invasion involves highly polarized mobilization of intracellular membranes<sup>1,3</sup>, we investigated a possible role of the exocyst tethering complex. *T. cruzi* invasion was significantly decreased in HeLa cells deficient in Exo70 or Sec8, and both exocyst proteins were recruited to the *T. cruzi* parasitophorous vacuole during early steps of invasion. Strikingly, depletion of Exo70 or Sec8 also inhibited Ca<sup>2+</sup>-dependent repair of large mechanical wounds, while not affecting the cell's ability to reseal after injury with small SLO pores. Thus, the exocyst complex appears to be uniquely required for the repair of large mechanical wounds and for *T. cruzi* internalization, two processes that require substantial trafficking and fusion of intracellular vesicles at specific plasma membrane sites.

**The role of Bst-2/Tetherin in HIV transmission from primary human macrophages.**

S. Giese<sup>1</sup>, M. Marsh<sup>1</sup>; <sup>1</sup>MRC Laboratory for Molecular Cell Biology, University College London, London, United Kingdom

Bst-2/Tetherin is a cellular protein that restricts HIV release and is antagonized by the viral protein U (Vpu). The restriction factor is thought to physically link budded virions to the host cell surface, preventing their release and cell-free transmission. Although Tetherin has been extensively studied in T cells and cell lines, little is known about its localization and functions in macrophages, and its role in the direct cell-cell transmission of HIV remains controversial.

Here we show that upon interferon treatment of primary monocyte-derived macrophages (MDM), Tetherin is highly up-regulated on both the mRNA and protein levels. Immunostaining shows that in IFN-treated MDM, Tetherin localizes to the cell surface as well as to an intracellular compartment positive for a marker of the trans-Golgi network. MDM infected with Vpu-deficient HIV show increased overall and cell surface levels of Tetherin, higher levels of cell-associated virus and decreased HIV release into the culture supernatant, suggesting that Tetherin restricts the release and cell-free transmission of HIV in these cells.

Direct cell-cell transmission of HIV is thought to be more efficient than cell-free propagation. One of the key structures mediating cell-cell transmission is the so-called virological synapse,

which is characterised by the accumulation of viral proteins and cellular receptors at the interface of the infected and the target cell. To investigate the role of Tetherin in cell-cell transmission of HIV from macrophages to T cells, we co-cultured infected MDM with autologous CD4<sup>+</sup> T cells. We find that T cells associate with MDM within minutes, while the formation of virological synapses takes at least half an hour. qPCR experiments show that in our system cell-cell transmission of HIV from MDM to T cells is about ten fold more efficient than cell-free infection of the T cells. Using Western Blot analysis to detect HIV protein in the T cells early (24 h) after the co-culture with infected MDM, we find that T cell infection is greatly diminished in the absence of the Tetherin antagonist Vpu. Depleting MDM of Tetherin by RNAi rescues the infection of the T cells.

In conclusion we find that Tetherin efficiently inhibits the release of cell-free HIV from primary macrophages and also inhibits cell-cell transmission of HIV from macrophages to autologous CD4<sup>+</sup> T cells. These results support the notion of high evolutionary pressure on HIV and related viruses to antagonize Tetherin.

**A novel role for cell polarity proteins in innate immunity to *Pseudomonas aeruginosa* infection.**

Y. Eran<sup>1</sup>, C. Tran<sup>1</sup>, D. Bryant<sup>1</sup>, A. Datta<sup>1</sup>, A. Kierbef<sup>2</sup>, R. Metzger<sup>1</sup>, T. Ruch<sup>1</sup>, T. Wittmann<sup>1</sup>, K. Mostov<sup>1</sup>, J. Engel<sup>1</sup>; <sup>1</sup>UCSF, San Francisco, CA, <sup>2</sup>University of Montevideo, Montevideo, Uruguay

The mucosal epithelium consists of polarized epithelial cells with distinct basolateral (BL) and apical (AP) membranes that serve as a barrier to the outside world. The ability of pathogens to modulate such barrier function through manipulation of cell polarity is an emerging theme in microbial pathogenesis. *Pseudomonas aeruginosa* is a gram negative pathogen that is an important cause of nosocomial infections. In the setting of epithelial cell injury and immunocompromise, *P. aeruginosa* can unleash its potent arsenal of virulence factors to cause devastating disease. We have previously reported the novel observation that aggregates of *P. aeruginosa* can bind to the AP surface of polarized cells, often near cell-cell junctions, where, within the first 30 to 60 minutes of infection, they transform a small patch of AP membrane into one with BL characteristics. This spatial and temporal inversion of cell polarity involves the production of a host membrane protrusion that is enriched for phosphatidylinositol 3,4,5-trisphosphate (PIP3), phosphoinositol-3-kinase (PI3K), actin, and BL proteins but that excludes AP proteins. Importantly, TJs are not disrupted during the initial stages of protrusion formation, suggesting that protrusions result from localized rearrangement rather than overt loss of cell polarity. The mechanism that induces these profound polarity changes and the role that membrane protrusions with inverted polarity play in infection remains largely unexplored. In this study, we examined the molecular pathways of protrusion formation and their biological consequences. We demonstrate that protrusion formation is dependent on recruitment of a Par3/PI3K/Rac module at the site of aggregate binding, leading to de novo formation of a primordial AJ and localized activation of NFκB. We identify two bacterial virulence factors critical for these events, including the flagella and the Type-III secretion system translocation apparatus. These data reveal an unanticipated function for spatial changes in polarity in activation of core innate immune pathways in response to challenge with *P. aeruginosa* and may represent a novel mechanism by which the host senses and distinguishes between pathogens and commensals.

### Extended-Synaptotagmins are endoplasmic reticulum (ER) proteins that function as tethers at ER-plasma membrane contact sites.

*F. Giordano<sup>1,2</sup>, Y. Saheki<sup>1,2</sup>, O. Idevall-Hagren<sup>2</sup>, N. Borgese<sup>3</sup>, P. De Camilli<sup>2</sup>; <sup>1</sup>Francesca Giordano and Yasunori Saheki equally contributed to this work (See also abstract by Saheki, Giordano et al.), New Haven, CT, <sup>2</sup>Department of Cell Biology, Howard Hughes Medical Institute, Program in Cellular Neuroscience, Neurodegeneration and Repair, Yale University School of Medicine, New Haven, CT, <sup>3</sup>CNR Institute of Neuroscience, University of Catanzaro, Milan, Italy*

The endoplasmic reticulum (ER) forms a complex network of cisternae and tubules that extends throughout the cell and participates in multiple contacts with virtually all other membranes, including the plasma membrane (PM). ER-PM contact sites in cells of higher eukaryotes have been primarily studied in the context of Ca<sup>2+</sup> homeostasis. However, there is growing evidence that ER-PM contacts play more general roles in the functional cross-talks between these two membranes. The molecular mechanisms shared by all eukaryotic cells that mediate such contacts remain to a large extent unknown. We have identified a family of multiple C2 domain containing proteins, the Extended-Synaptotagmins (E-Syt1, E-Syt2 and E-Syt3) as mediators of ER-PM contacts. The E-Syts are closely related to the yeast tricalbins (See Toulmay and Prinz, *J. Cell Science* 125: 49-58, 2011 and Abstract by Manford et al.). Ultrastructural analysis by electron microscopy revealed that E-Syts are ER membrane proteins, that epitope-tagged E-Syt2 and E-Syt3 are localized at ER-PM contact sites via interactions mediated by their C-terminal C2 domain, and that the overexpression of these two E-Syts induces a striking increase of ER-PM contact sites with a massive formation of cortical ER. E-Syt1 localizes to cortical ER only in a complex with E-Syt2 and/or E-Syt3. E-Syts-dependent cortical ER marks sites where STIM1 is recruited upon ER Ca<sup>2+</sup> depletion. Our results, along with the results reported in the companion Abstract by Saheki, Giordano et al., demonstrate that E-Syts are molecular tethers that bridge the ER to the PM and provide new insights into the conserved molecular machinery controlling ER-PM cross-talks by direct contacts.

### Visualizing the dynamic architecture of the endocytic machinery by high resolution tracking of fluorescent proteins in yeast cells.

*A. Picco<sup>1</sup>, F. Nédélec<sup>1</sup>, M. Kaksonen<sup>1</sup>; <sup>1</sup>Cell Biology and Biophysics Unit, European Molecular Biology Laboratory, Heidelberg, Germany*

Budding of clathrin-coated endocytic vesicles is driven by a highly dynamic and complex machinery consisting of over 50 different proteins. Although individual proteins have been studied extensively, their function as parts of the endocytic machinery is not well understood. Especially, it is not known how most of the protein components are organized *in situ* during vesicle budding.

We have developed a live-cell particle tracking approach that measures average positions of fluorescently tagged endocytic proteins in relation to each other during the vesicle budding process with high spatial and temporal resolution. To reconstruct the dynamic organization of the endocytic machinery we combine this tracking data with estimates of numbers of molecules, and with available structural and correlative light and electron microscopy data.

We first investigated coat-associated proteins Sla2 and Sla1. The clathrin coat is structurally well studied but the organization of other coat-associated proteins is poorly understood. Our

results suggested that the elongated rod-shaped Sla2 protein is located at the central part of the endocytic coat. By using N- and C-terminal GFP tagging we were able to resolve that Sla2 is oriented perpendicular to the plasma membrane so that its lipid binding domain is at the membrane and the actin binding domain projects away into the cytoplasm. Sla1, in contrast to Sla2, is likely located in the peripheral part of the coat. Next we tracked actin and several actin binding proteins to study the polymerization dynamics of the endocytic actin network. Two opposite models have been proposed about the direction of actin polymerization in relation to the forming vesicle. Our tracking of actin cytoskeletal proteins combined with FRAP experiments supported a model where actin filaments polymerize at the base of the invagination, not at the vesicle surface. Finally, we analyzed the dynamics of a BAR domain protein Rvs161/167 that binds to the membrane at the neck of the invagination to regulate vesicle scission. Our results suggested that Rvs161/167 starts assembling just below the coated tip of the invagination and then extends toward the base as the invagination elongates, eventually covering most of the tubular part of the invagination. The Rvs161/167 assembly ends with a catastrophic disassembly that coincides with vesicle scission. In summary, our results reveal several new insights into the mechanisms of endocytosis and demonstrate that live-cell imaging can provide detailed information about the dynamic molecular architecture of the endocytic machinery.

142

### **The centrosome regulates the Rab11-dependent recycling endosome pathway at appendages of the mother centriole.**

*H. Hehnyl<sup>1</sup>, S. Doxsey<sup>1</sup>; <sup>1</sup>Molecular Medicine, University of Massachusetts Medical School, Worcester, MA*

The recycling endosome localizes to a pericentrosomal area through microtubule-dependent transport. The observation that the mother centriole appendage protein, centriolin, interacts with Sec15, an effector of the recycling endosome component, Rab11-GTPase, suggests an interaction between centrosomes and endosomes. For the first time we show that the recycling endosome associates with the centrosome, more precisely, with mother (older) centriole appendages. The mother centriole appendage proteins, centriolin and cenexin/ODF2, regulate the association of the endosome components Rab11, the Rab11 GTP-activating protein Evi5, and the exocyst at the mother centriole. We have developed an in vitro method for reconstituting endosome protein complexes onto isolated centrosomes. This in vitro method for reconstituting proteins has a number of applications from understanding the hierarchy of protein association at the centrosome to understanding microtubule nucleation. Our experiments illustrate that purified GTP-Rab11 but not GDP-Rab11 binds to mother centriole appendages in the absence of membranes. Furthermore, centriolin depletion displaces the centrosomal Rab11 GAP, Evi5, and increases mother-centriole-associated Rab11; depletion of Evi5 has the same effect on Rab11 localization. This suggests that centriolin localizes Evi5 to centriolar appendages to turn off centrosomal Rab11 activity. Depletion of centriolin or cenexin disrupts recycling endosome organization and function suggesting that mother centriole proteins can regulate Rab11 localization and activity at the mother centriole through Evi5 and the exocyst.

143

### **Cavins and caveolar coat complexes.**

*C. G. Hansen<sup>1</sup>, A. Ludwig<sup>1</sup>, E. Shvets<sup>1</sup>, G. Howard<sup>1</sup>, T. Deerinck<sup>2</sup>, M. Ellisman<sup>2</sup>, B. J. Nichols<sup>1</sup>; <sup>1</sup>MRC-LMB, Cambridge, United Kingdom, <sup>2</sup>UCSD, San Diego, CA*

Caveolae are flask-shaped invaginations of the plasma membrane. They are thought to pinch off from the membrane to form endocytic vesicles, and there is good evidence that they play key

roles in endothelial permeability and transcytosis. The remarkably uniform and characteristic morphology of caveolae suggests that they are generated by specific protein-protein and protein-membrane interactions, but the number, identity and structural properties of protein complexes involved in generating caveolae are not well defined. The cavin proteins are components of caveolae, and are expressed at varied amounts in different tissues. The cavins have been shown to interact with each other, and potentially with caveolin proteins, to form caveolae.

We have used several approaches to analyse the ultrastructural, biochemical and functional properties of cavin proteins within the caveolar coat. Our new data begin to delineate the role of stable protein complexes in shaping caveolar membranes. The data highlight the paradigmatic differences between caveolar morphogenesis and the dynamic, reversible association between coat proteins and membranes observed at clathrin-coated pits and other vesicle transport steps.

In complementary experiments, we have used knockout mice to test the hypothesis that expression of different complements of cavin proteins leads to differences in the biogenesis and biochemical properties of endothelial caveolae between tissues. We analysed caveolae in endothelium from caveolin 1 and cavin 1 null mice, and from cavin 2 and cavin 3 null mice generated as part of this study. Deletion of cavin 2 causes a profound loss of endothelial caveolae in lung and adipose tissue, but has no effect on the abundance of caveolae in other tissues. Cavin 3 is not required for making caveolae. The tissue-specific effects caused by deletion of cavin 2 on caveolar abundance are accompanied by changes in endothelial morphology. The requirement for cavin 2 in caveolar biogenesis specifically in some tissues is associated with an altered size of the hetero-oligomeric complexes into which cavin proteins assemble. These data reveal unsuspected heterogeneity between endothelial caveolae, and suggest a mechanism for caveolae to carry out varied molecular functions.

144

**Scyl1 functions as a scaffold for multiple components of the COPI machinery.**

*J. N. Hamlin<sup>1</sup>, H. Dokainish<sup>1</sup>, M. Fotouhi<sup>1</sup>, P. Melançon<sup>2</sup>, P. S. McPherson<sup>1</sup>; <sup>1</sup>Neurology and Neurosurgery, Montreal Neurological Institute, McGill University, Montreal, QC, Canada,*

*<sup>2</sup>Department of Cell Biology, University of Alberta, Edmonton, AB, Canada*

COPI-coated vesicles mediate retrograde trafficking from the Golgi apparatus and the endoplasmic reticulum-Golgi intermediate compartment (ERGIC) to the ER in the early secretory pathway. We recently demonstrated that Scyl1-like 1 (Scyl1), a member of the Scyl1-like family of catalytically inactive protein kinases binds COPI coat proteins and that loss of Scyl1 disrupts COPI trafficking. We now demonstrate that Scyl1 interacts with class II Arfs, most notably Arf4, but does not bind class I Arfs. Moreover, Scyl1 co-localizes with Arf4 at the ERGIC. Scyl1 interacts with membranes through a C-terminal helical domain that is distinct from its non-overlapping binding sites for COPI and Arf4, suggesting that Scyl1 couples Arf4 to COPI on ERGIC membranes. Additionally, gel filtration chromatography reveals that Scyl1 undergoes trimerization mediated by HEAT repeats found in the central region of the protein. HEAT-repeat assemblies generate binding sites for proteins and remarkably, through the HEAT repeats Scyl1 also binds to GBF1, a guanine-nucleotide exchange factor for class II Arfs. Thus, Scyl1 appears to be a scaffold for multiple components of COPI vesicle formation and consistently, over expression of Scyl1, which will disrupt the scaffold function leads to tubulation of the ERGIC. Our data reveal Scyl1 as the first known protein to interact specifically with class II Arfs and place Scyl1 as a key organizer of the COPI protein machinery.

145

### **A novel, conserved complex regulates the membrane association of AP-1 clathrin adaptors.**

M. Davey<sup>1</sup>, Y. Y. Tam<sup>1</sup>, F. D. Mast<sup>2</sup>, C. Schluter<sup>1</sup>, C. Choi<sup>1</sup>, R. Rachubinski<sup>2</sup>, E. Conibear<sup>1</sup>;

<sup>1</sup>CMMT, Medical Genetics, University of British Columbia, Vancouver, BC, Canada,

<sup>2</sup>Department of Cell Biology, University of Alberta, Edmonton, AB, Canada

Clathrin adaptor complexes recognize cargo proteins and recruit them into clathrin-coated vesicles. Whereas the plasma membrane-associated AP-2 adaptor complex has many known accessory factors, few regulators of the Golgi/endosome-localized AP-1 complex have been identified to date. We have used a fluorescence-based yeast genome-wide screen to systematically identify new AP-1 regulators that restore transport of the chitin synthase Chs3 to the surface of cells lacking the exomer component Chs6. Top-scoring mutants were subjected to genetic interaction mapping to find functionally-associated clusters. This analysis identified a cluster of proteins linked to AP-1 that contained known AP-1 regulators and binding partners, as well as several Golgi-localized proteins whose functions are not well understood. We discovered that two of these proteins form a complex. One subunit of this novel complex, Laa2 (Large Adaptin Associated 2), contains a canonical AP-1 binding motif that links it to the gamma-adaptin subunit of AP-1. Loss of Laa2, or mutation of its AP-1 binding site, reduces the fluorescence lifetime of AP-1 suggesting the Laa2 complex binds AP-1 to regulate its membrane association. Laa2 is related to mammalian Fez1, a Golgi-localized protein that facilitates the transport of secretory vesicles in axons. Fez1 associates with the small coiled-coil protein SCOCO, and we found Laa2 copurifies with the yeast SCOCO homolog, Slo1. Moreover, *slo1* mutants have a phenotype similar to that of *laa2* mutants, strongly suggesting Laa2/Slo1 are the yeast counterparts of the mammalian Fez1/SCOCO complex.

### **Hsp90 chaperone sculpting evolutionary change: a quantitative genetic and proteomic view.**

S. Lindquist<sup>1</sup>; <sup>1</sup>Whitehead Institute for Biomedical Research and the Massachusetts Institute of Technology/HHMI, Cambridge, MA

Heat shock proteins (Hsps) promote the correct folding and maturation of many other proteins in the cell. Hsp90 is an abundant and highly specialized molecular chaperone that works on a particularly interesting group of client proteins: metastable signal transducers that are key regulators of a broad spectrum of biological processes. The folding of Hsp90 clients is particularly sensitive to changes in the external and internal environment of the cell. Therefore, Hsp90 is uniquely positioned to couple environmental contingencies to the evolution of new traits. Our work has defined two mechanisms by which Hsp90 influences the acquisition of new phenotypes. First, Hsp90 can potentiate the effects of genetic variation, allowing new mutations to produce immediate phenotypes. Second, by robustly maintaining signaling pathways, Hsp90 can buffer the effects of mutations, allowing the storage of cryptic genetic variation and its subsequent release by stress. Genetic reassortment and recombination can enrich these variants in subsequent generations making them manifest even in the absence of stress. We discovered these powerful evolutionary mechanisms in fruit flies, mustard plants, and fungi, but expect them to operate in all eukaryotes.

Recently we have taken advantage of two different model systems to further address the function of Hsp90 at the organismal and molecular levels. In the budding yeast *Saccharomyces cerevisiae*, we have mapped hundreds of Hsp90-dependent traits in ecologically diverse strains. In human cells, we have systematically and quantitatively surveyed most human kinases, transcription factors and ubiquitin ligases for interaction with Hsp90 and its co-chaperone Cdc37. This analysis clarified the mechanism of Hsp90 client recognition as a two-step process: its co-chaperones provide specificity at the protein-fold level, whereas thermodynamic parameters determine client binding within a protein family. Our results in these distinct model systems provide a unified and quantitative framework for understanding the role of Hsp90 in the evolution of genomes and in shaping health and disease.

De La Cruz<sup>1</sup>; <sup>1</sup>MB&B, Yale University, New Haven, CT, <sup>2</sup>Département de Physique, ENS de Cachan, Cachan, France, <sup>3</sup>Chemistry & Biochemistry, UCLA, Los Angeles, CA*

The regulation of actin assembly and modulation of filament mechanical properties are critical for actin function. It is well established that physiological salt concentrations promote actin assembly and alter the overall bending mechanics of assembled filaments and networks. However, the molecular origins of these salt-dependent effects, particularly if they involve non-specific ionic strength effects or specific ion binding interactions, are unknown. Here, we demonstrate that specific cation binding at two discrete sites situated between adjacent subunits along the long-pitch helix drive actin polymerization and determine the filament bending rigidity. We classify the two sites as “polymerization” and “stiffness” sites based on the effects that mutations at the sites have on salt-dependent filament assembly and bending mechanics, respectively. Cofilin binding is coupled to dissociation of filament-associated cations, stiffness site reorganization and enhanced actin filament bending and twisting dynamics, consistent with displacement of stiffness site cations underlying the effects of cofilin on actin filament mechanics. The work presented reveals the molecular mechanism of salt-dependent actin assembly and cofilin-mediated changes in actin filament bending mechanics and severing.

**The formin INF2 severs actin filaments through a fundamentally different mechanism from cofilin: relating biochemical function to cellular activity.**

*P. S. Gurel<sup>1</sup>, H. N. Higgs<sup>1</sup>; <sup>1</sup>Biochemistry, Geisel School of Medicine at Dartmouth College, Hanover, NH*

Formins are a class of proteins that accelerate actin nucleation, then influence filament elongation rate by remaining at the barbed end. INF2 is a biochemically unique mammalian formin in that it accelerates both actin polymerization and depolymerization. Importantly, mutations in INF2 lead to the kidney disease focal and segmental glomerulosclerosis (FSGS) and the neurological disorder Charcot-Marie Tooth Disease (CMTD). I am elucidating the molecular mechanism of INF2's unique depolymerization activity, using TIRF microscopy and other biochemical assays of actin dynamics. Prior work in our lab has shown that depolymerization requires both the FH2 and WH2/DAD sequences, and occurs in two steps: a) a severing step, which requires phosphate release from the actin subunits; and b) a depolymerization step, which requires the WH2/DAD. My work reveals the following mechanistic features of INF2-mediated severing/depolymerization. First, rapid severing occurs throughout the length of the filament and not progressively from the barbed end. This suggests that INF2 binds filament sides prior to severing and accelerates phosphate release of filaments since it is capable of severing filament segments less than 50s after monomer addition. Second, INF2 can bind filament sides that are both phosphate-bound and phosphate-free, but with different stoichiometries. Additionally, INF2 can alter filament flexibility in the phosphate-free state. These results suggest that phosphate release causes a conformational change to

filament-bound INF2, allowing severing. Lastly, INF2 bound at the barbed end causes catastrophic disassembly of short filaments. Based on these results, I postulate that both filament side binding and barbed end binding by the FH2 domain changes filament architecture, which promotes severing and changes monomer dynamics at filament ends. I postulate further that the WH2/DAD enhances severing by insertional binding between actin subunits in the filament. These results contrast in several aspects with the severing mechanism employed by cofilin. This mechanistic investigation of INF2 severing/depolymerization activity gives insight on recent cellular results from our lab, which reveal a role for INF2-mediated actin dynamics in fission of both Golgi and mitochondria.

### **Srv2/CAP forms six-bladed throwing stars that directly catalyze actin filament severing and disassembly.**

*F. Chaudhry<sup>1</sup>, D. Breitsprecher<sup>1</sup>, K. Little<sup>1</sup>, O. Sokolova<sup>2</sup>, B. L. Goode<sup>1</sup>; <sup>1</sup>Biology, Brandeis University, Waltham, MA, <sup>2</sup>Moscow State University, Moscow, Russia*

Actin filament severing is a critical step in the dynamic turnover of cellular actin networks. Cofilin is sufficient to sever filaments, but it has long been thought that additional factors may be required to enhance severing and account for very high rates of filament turnover observed in vivo. Srv2/CAP (cyclase-associated protein) is a conserved and widely expressed regulator of the actin cytoskeleton that until now has been proposed to function exclusively in binding and recycling actin monomers. Further, these functions have been ascribed to domains found in its C-terminal half (C-Srv2). Here, we have unveiled a new and unanticipated role for Srv2/CAP in directly catalyzing cofilin-mediated severing of actin filaments. This function is mediated by N-Srv2, and is physically and genetically separable from C-Srv2 function in actin monomer recycling. Using dual-color TIRF microscopy, we observed that N-Srv2 promotes filament disassembly by increasing the frequency of cofilin-mediated severing without affecting cofilin binding to filaments. To address the structural basis of these effects, we used electron microscopy and single particle analysis, which revealed that N-Srv2 forms novel hexameric structures resembling ninja throwing stars. An N-terminal truncation that disrupts Srv2 oligomerization severely impaired enhanced severing activity, and led to striking defects in cellular actin organization and cell polarity. In addition, genetic analysis revealed that the activities of N-Srv2 but not C-Srv2 are essential in vivo in combination with those of another cofilin co-factor, Aip1. Together, our results define a new cellular role for Srv2/CAP in directly stimulating filament severing and disassembly, and demonstrate that the activity of cofilin alone, while essential, is not sufficient for cell viability, and that additional severing co-factors are critical.

### **The mechanobiochemistry of dendritic actin network assembly.**

*P. Bieling<sup>1,2</sup>, T-D. Li<sup>2</sup>, R. D. Mullins<sup>1</sup>, D. A. Fletcher<sup>2</sup>; <sup>1</sup>Department of Cellular and Molecular Pharmacology, University of California, San Francisco, San Francisco, CA, <sup>2</sup>Department of Bioengineering, University of California, Berkeley, Berkeley, CA*

Branched actin networks generate protrusive forces required for cell motility and movement of sub-cellular structures. Despite advances in our biochemical knowledge of dendritic actin network assembly, very little is known about how dynamic networks of close-to-physiological architecture respond to mechanical stimuli at the molecular level. We combined micropatterning with atomic force microscopy (AFM) and multi-color TIRF imaging to visualize the active, force-generating region of in vitro reconstituted actin networks in a biochemically and mechanically

defined environment. Our measurements demonstrate that Arp2/3-generated actin networks are highly sensitive to load, particularly at low forces. The network growth velocity decreases exponentially with counteracting forces, while the actin density in the force-generating region of the network increases strongly with elevated loads. This shows that net actin polymerization decreases less drastically than the growth velocity. In addition, the levels of network-associated capping protein increase in proportion to the amount of actin polymer in the network, indicating that average filament length is determined solely by the kinetics of capping protein association and is insensitive to applied force. Our AFM-TIRF measurements provide new insight into the role of capping, branching, and filament elongation in force-dependent changes in dendritic actin network assembly.

### **Enabled negatively regulates diaphanous-driven actin dynamics.**

C. G. Bilancia<sup>1</sup>, J. D. Winkelman<sup>2</sup>, S. H. Nowotarski<sup>1</sup>, D. Tsygankov<sup>3</sup>, J. A. Sees<sup>2</sup>, T. Elston<sup>3</sup>, D. R. Kova<sup>2</sup>, M. Peifer<sup>1</sup>; <sup>1</sup>Biology, University of North Carolina at Chapel Hill, Chapel Hill, NC, <sup>2</sup>Molecular Genetics and Cell Biology, The University of Chicago, Chicago, IL, <sup>3</sup>Pharmacology, University of North Carolina at Chapel Hill, Chapel Hill, NC

Cell protrusions are an essential component of dynamic cell movement during development and disease. Actin regulatory proteins control the architecture and dynamics of cell protrusions, forming branched actin networks for lamellipodia or unbranched actin bundles for filopodia. While many actin regulators have been identified and characterized, it remains unclear why cells need multiple actin regulators with similar functions and how this network of proteins works together to create the diverse cell protrusions seen in normal development. Enabled (Ena) and Diaphanous (Dia) provide a superb model, as both can act at the barbed end of actin filaments to promote polymerization of unbranched filaments. We previously found that Ena and Dia form a protein complex, and discovered they act in complex, non-additive ways to shape the balance of lamellipodia and filopodia in migrating epidermal cells. We hypothesized that Ena and Dia directly bind each other and this binding regulates their activity. Through yeast two-hybrid and GST pull-downs, we found that Ena's EVH1 domain binds to Dia's proline-rich FH1 domain. To test how this Dia:Ena binding interaction affects cell protrusions, we are using three parallel model systems: in vitro actin assembly assays, *Drosophila* D16 cells, and *Drosophila* embryos. To compare protrusive behavior, we developed a software program to measure cell protrusion dynamics, including filopodia number, length, and stability, and lamellipodial protrusion. Our data reveal that while both Dia and Ena drive ectopic filopodia, these have distinct properties and dynamics. Consistent with our earlier in vivo experiments, together they act in non-additive ways. The EVH1 domain is sufficient to reduce the number of ectopic filopodia driven by activated Dia, suggesting that Dia:Ena binding is a negative regulatory mechanism. To test this hypothesis, we performed pyrene-labeled actin assembly assays and found that EVH1 reduces actin assembly by Dia's FH1FH2 domains. We are now using SNAP-tagged versions of activated Dia and Ena in TIRF assays to visualize their interactions with actin filaments and each other to understand their mechanism of controlling actin dynamics. We also are testing this hypothesis by examining the functional interactions of Ena EVH1 mutants and Dia FH1 mutants that block Dia:Ena interactions, to address whether this negative regulatory mechanism requires direct binding. Together, these assays will provide insight into how similar actin regulators interact to tune cell behavior.

152

**Anillin regulates junctional integrity and RhoA activation at cell-cell junctions in the intact epithelium.**

C. C. Reyes<sup>1</sup>, M. Jin<sup>2</sup>, A. L. Miller<sup>1,2</sup>; <sup>1</sup>Graduate Program in Cellular and Molecular Biology, University of Michigan, Ann Arbor, MI, <sup>2</sup>Department of Molecular, Cellular, and Developmental Biology, University of Michigan, Ann Arbor, MI

My lab is focused on studying the molecular mechanisms by which Rho family small GTPases regulate cytokinesis in the context of the intact epithelium. Understanding this process is important because successful cytokinesis is essential for proper development, and cytokinesis failure can contribute to tumor formation. Anillin is a contractile ring component that is required for cytokinesis in several model organisms. Anillin can link multiple components of the contractile ring including F-actin, Myosin-2, and Septins with the plasma membrane, and it scaffolds a number of other proteins including the small GTPase RhoA and the RhoA regulator MgcRacGAP. While Anillin is important for stable furrow positioning in isolated cultured cells, little is known about Anillin's function during cytokinesis in multicellular organisms *in vivo* or whether it plays functional roles outside of cytokinesis. Here, we used *Xenopus laevis* embryos as a model system to examine the role of Anillin in regulating cytokinesis in the intact epithelium. We find that a population of Anillin is localized at cell-cell junctions throughout the cell cycle and is particularly enriched at cell-cell junctions of dividing cells. Anillin functionally regulates cell-cell junctions; both tight junctions and adherens junctions are disrupted in Anillin knock down embryos. Additionally, we observe increased intercellular spaces between cells in Anillin knock down embryos. When control embryos are mounted in fluorescent dextran, the dextran cannot penetrate into intercellular spaces. However, in Anillin knock down embryos, dextran can penetrate, indicating that the epithelial barrier function is compromised. Because Anillin is reported to interact with both RhoA and MgcRacGAP, we tested the effect of knocking down Anillin on RhoA activity at cell-cell junctions. Surprisingly, Anillin knock down results in increased spontaneous flares of RhoA activity at cell-cell junctions. These RhoA activity flares are prominent at cell-cell junctions in both dividing cells and non-dividing regions of the epithelium. These results reveal a novel role for Anillin in regulating cell-cell junctions likely via RhoA. We propose that Anillin is required to properly distribute cortical tension and RhoA activity in order to maintain cell-cell junctions. This function is particularly important during the process of cytokinesis in an epithelial context when the dividing cell must maintain and remodel cell-cell junctions with neighboring cells as well as manage the contractile forces and shape changes associated with cytokinesis.

**Feed-forward regulation ensures stability and rapid reversibility of a cellular state.**

A. Doncic<sup>1</sup>, J. Skotheim<sup>1</sup>; <sup>1</sup>Biology, Stanford University, Stanford, CA

Cellular transitions are important for all life. Such transitions, including cell fate decisions, often employ positive feedback regulation to establish and stabilize the new cellular state. However, positive feedback is unlikely to underlie stable cell cycle arrest in yeast exposed to mating pheromone because the signaling pathway is linear, rather than bistable, over a broad range of extracellular pheromone concentration. We show that the stability of the pheromone arrested state results from coherent feed-forward regulation of the cell cycle inhibitor Far1, which is activated both by phosphorylation and transcription. Fast regulation by phosphorylation allows

rapid cell cycle arrest and reentry, whereas slow Far1 synthesis reinforces arrest. Importantly, feed-forward regulation achieves a stable arrest without altering signaling pathway output throughout the reversible transition. Since feed-forward regulation achieves the ostensibly conflicting aims of arrest stability and rapid reversibility without loss of signaling information, we expect its frequent implementation at reversible cellular transitions.

154

### **Evolution and conservation of G1/S regulation in fungi and beyond.**

*N. E. Buchler<sup>1</sup>; <sup>1</sup>Biology and Physics, Duke University, Durham, NC*

Cyclins are central regulators of cell cycle progression and form a large super-family, with multiple members in most eukaryotes. Recent work shows that the G1–S regulatory network (cyclins and transcription factors) and its associated dynamic properties in budding yeast and mammals are conserved, despite lack of sequence homology between many regulators. In particular, the origin of fungal G1 and B-type cyclins has remained enigmatic. To address this question, I have constructed a phylogeny of the cyclin superfamily in Fungi and beyond, anchored on *Saccharomyces cerevisiae* G1/S-type cyclins (CLN) and B-type cyclins (CLB). When compared to cyclins across the eukaryotic kingdom, the fungal CLB/CLN cyclins cluster closest to B-type cyclins found in plants and animals. In the fungal lineage leading to *S. cerevisiae*, the molecular phylogeny of G1/S-type cyclins (CLN) suggests they are derivatives of an ancient B-type cyclin (CLB) duplication that occurred in an early fungal ancestor. Evidence suggests that a fungal ancestor downsized and simplified its repertoire of cyclins. The zygomycetes contain only a single B-type cyclin (CLB) and no G1 cyclins (CLN), which may represent persistence of an ancestral state. The de novo evolution of fungal G1/S cyclins (CLN) from B-type cyclins (CLB) stands in stark contrast to the strong conservation of G1-S regulatory network between budding yeast and mammals. I also examine the phylogeny of fungal G1/S transcription factors (SWI6/SWI4/MBP1) and animal G1/S transcription factors (E2F/DP). Similar to cyclin phylogeny, early Fungi are characterized by the emergence of novel SWI6/SWI4/MBP1 transcription factors and the disappearance of the original E2F/DP transcription factors. These results suggest rapid evolution of the fungal cell cycle through which novel B-type cyclins and transcription factors are able to acquire and maintain the function and dynamics of G1-S regulatory network.

155

### **Insertion of spindle pole bodies into the nuclear envelope.**

*J. Chen<sup>1</sup>, C. J. Smoyer<sup>1</sup>, J. R. Unruh<sup>1</sup>, B. D. Slaughter<sup>1</sup>, S. L. Jaspersen<sup>1,2</sup>; <sup>1</sup>Stowers Institute for Medical Research, Kansas City, MO, <sup>2</sup>Department of Molecular & Integrative Physiology, University of Kansas Medical Center, Kansas City, KS*

The defining feature of eukaryotic cells is the double lipid bilayer of the nuclear envelope (NE) that serves as a physical barrier separating the genome from the cytosol. Nuclear pore complexes (NPCs) are embedded in the NE to facilitate transport of proteins and other macromolecules into and out of the nucleus. In *Saccharomyces cerevisiae* where the NE does not completely breakdown during mitosis, the microtubule-organizing center, known as the spindle pole body (SPB), must also be inserted into the NE to facilitate organization of the mitotic spindle. Although most aspects of this process are unknown or unproven at a molecular level, it is thought that remodeling of NE lipids and stabilization of the resulting highly conserved pore membrane structure are involved in the formation of insertion sites for both the NPC and SPB.

Using a combination of genetics, live cell imaging and biochemistry we have analyzed the process of SPB insertion in order to better understand the functional role of membrane proteins in NE remodeling, such as the pore membrane proteins Pom34 and Pom152 that are required for NPC assembly, the shared NPC and SPB component Ndc1 and the yeast ortholog of the conserved SUN family of inner nuclear membrane proteins Mps3. Our results suggest that the NPC and SPB compete for a shared insertion factor that we propose to be Ndc1. Levels of Ndc1 at the NPC and SPB are regulated by its interactions with Pom152-Pom34 and with Mps3, respectively. A competition model between the NPC and SPB for a shared insertion factor could be a mechanism to restrict SPB duplication to G1 phase of the cell cycle and may explain why mutation of many SPB components results in diploidization.

156

**Molecular mechanism for proteasomal recognition of ubiquitinated substrates described by CryoEM.**

G. C. Lander<sup>1</sup>, M. E. Matyskiela<sup>2</sup>, A. Martin<sup>2</sup>, E. Nogales<sup>1</sup>; <sup>1</sup>Life Sciences Division, Lawrence Berkeley National Lab, Berkeley, CA, <sup>2</sup>Molecular and Cellular Biology, UC Berkeley, Berkeley, CA

The proteasome is the major ATP-dependent protease in eukaryotic cells, degrading unwanted cellular proteins through recognition of covalently attached polyubiquitin chains. Highly discriminate recognition of ubiquitin chains by this multicatalytic complex is crucial to cellular function. Recent studies by cryo-electron microscopy (cryoEM) offer insight into the molecular organization of the regulatory particle, which is involved in substrate recognition, unfolding, and translocation, but the structural context by which the proteasome recognizes polyubiquitin chains remains poorly understood. Using cryoEM to visualize proteasome mutants lacking one or more of the ubiquitin receptors, we now have a detailed model for polyubiquitin reception by the proteasome. Upon receptor binding of a polyubiquitin chain, the proteasome regulatory particle undergoes a conformational reorganization in which portions of the lid serve as hinged attachment points to the core particle, while the remainder of the lid repositions the ATPases for substrate delivery to the proteolytic chamber. This offers an explanation for the proteasome's dependence on the lid for efficient substrate degradation.

157

**Cell cycle coupled structural oscillation of centromeric nucleosomes and kinetochores in yeast.**

M. Shivaraju<sup>1,2</sup>, J. R. Unruh<sup>1</sup>, B. Slaughter<sup>1</sup>, M. Mattingly<sup>1</sup>, J. Berman<sup>3</sup>, J. Gerton<sup>1,4</sup>; <sup>1</sup>Stowers Institute for Medical Research, Kansas city, MO, <sup>2</sup>The Open University, Milton Keynes, United Kingdom, <sup>3</sup>Department of Genetics, Cell Biology and Development, University of Minnesota, Minneapolis, MN, <sup>4</sup>Department of Biochemistry and Molecular Biology, University of Kansas Medical Center, Kansas city, KS

The centromere is a specialized chromosomal structure that regulates chromosome segregation. Centromeres are marked by a histone H3 variant. In budding yeast, the histone H3 variant Cse4 is present in a single centromeric nucleosome. Experimental evidence supports several different models for the structure of centromeric nucleosomes. To investigate Cse4 copy number in live yeast we developed a new method coupling fluorescence correlation spectroscopy and calibrated imaging. We find that centromeric nucleosomes have one copy of Cse4 during most of the cell cycle, whereas two copies are detected at anaphase. The proposal of an anaphase coupled structural change is supported by Cse4-Cse4 interactions, incorporation of Cse4, and the absence of Scm3 in anaphase. Nucleosome reconstitution and

ChIP suggests both Cse4 structures contain H2A/H2B. The increase in Cse4 intensity and deposition at anaphase is also observed in *Candida albicans*. Using the same calibrated imaging approach for kinetochore proteins, we find that some components are dynamic in anaphase. Our experimental evidence supports a cell cycle coupled oscillation of centromeric nucleosome and kinetochore structure in yeast.

158

**Geometric control of cell division in fission yeast: one kinase – one substrate – two effects.**

*P. Bhatia*<sup>1</sup>, *O. Hachet*<sup>1</sup>, *S. A. Rincon*<sup>2</sup>, *M. Berthelot-Grosjean*<sup>1</sup>, *C. Bicho*<sup>3</sup>, *K. E. Sawin*<sup>3</sup>, *A. Paoletti*<sup>2</sup>, *S. G. Martin*<sup>1</sup>; <sup>1</sup>*Department of Fundamental Microbiology, University of Lausanne, Lausanne, Switzerland,* <sup>2</sup>*Institut Curie, Paris, France,* <sup>3</sup>*Wellcome Trust Centre for Cell Biology, University of Edinburgh, Edinburgh, United Kingdom*

Spatial and temporal controls of cell division are essential to coordinate cell growth with division. In rod-shaped fission yeast cells, the DYRK-family Pom1 kinase couples cell size to cell cycle progression by forming plasma membrane-associated gradients emanating from the cell tips, which negatively regulate the medially localized SAD-family kinase Cdr2. Cdr2 promotes mitotic entry by inhibiting Wee1 and specifies the division plane at the cell middle by interaction with the anillin-like protein Mid1. While Cdr2 is a substrate for Pom1, the molecular mechanism underlying the negative regulation of Cdr2 by Pom1 remains elusive. In particular, *pom1* deletion affects both the localization and the output of Cdr2, but the relationship between the two effects is unclear. In agreement with this, by quantitative analysis of Pom1 and Cdr2 cortical distributions, we observe that, as cells grow, Cdr2 levels increase at the cell middle, within a widening window of basal-level Pom1.

Using an analog-sensitive *pom1-as* allele, we find that Pom1 effects on Cdr2 activity and localization are separable. Similarly, we identified a separation-of-function *pom1* allele, *pom1-305*, which produces short cells but shows only minor effect on Cdr2 localization. Conversely, an active *pom1* allele that lacks few autophosphorylation sites and spreads along cell sides, *pom1-2A*, produces long cells again with minor effects on Cdr2 localization. This suggests a differential threshold of Pom1-dependent phosphorylations on Cdr2 that separates the regulation of kinase activity from localization. We identified Pom1 phosphorylation sites on Cdr2 by SILAC and generated multiple phosphosite mutants spanning the entire Cdr2. Our experiments suggest that Pom1 regulates Cdr2 localization to the medial cortical region and its activity through phosphorylation of distinct domains. We show that Cdr2 membrane anchoring depends on a KA-1 domain, involved in phospholipid binding, and a polybasic motif, which is directly phosphorylated by Pom1. Ongoing work suggests other phosphosite mutants may specifically affect Cdr2 activity. These studies illustrate how one kinase may have two distinct effects on the same substrate to control timing and positioning of cell division.

**Cell and tissue mechanics in zebrafish gastrulation.**

*C-P. Heisenberg*<sup>1</sup>; <sup>1</sup>*IST Austria, Klosterneuburg, Austria*

Tissue morphogenesis during embryonic development is brought about by mechanical forces which are generated by the specific biophysical and motility properties of its constituent cells. It

has also been suggested that embryonic tissues behave like immiscible liquids with a given surface tension and that differences in surface tension between tissues determine their spatial configuration during embryogenesis. To understand how single cell biophysical and motility properties regulate tissue surface tension and how tissue surface tension controls tissue organization in development, we are studying the specific function of germ layer progenitor cell adhesion, cell cortex tension and motility in determining germ layer organization during zebrafish gastrulation. We found that the combinatorial activity of progenitor cell adhesion, cortex tension and motility determines germ layer tissue surface tension and that differences in germ layer tissue surface tension influence germ layer organization during gastrulation. We will discuss these findings in the light of different hypotheses explaining how single cell biophysical properties determine tissue morphogenesis in development.

160

**Dynamic interactions between PAR proteins modulate the cycling of actomyosin networks during *Drosophila* apical constriction.**

D. J. David<sup>1</sup>, T. J. Harris<sup>1</sup>; <sup>1</sup>Cell & Systems Biology, University of Toronto, Toronto, ON, Canada

Apical constriction is a major mechanism underlying morphogenesis. Previously thought to be mediated by contractile actomyosin belts anchored to cell junctions, recent studies including ours have shown that many cell types apically constrict via cyclical pulses of dynamic apical actomyosin networks. What governs the cycling of these networks *in vivo* remains unclear. Using *Drosophila* amnioserosa cells during dorsal closure as a model to study apical constriction, we previously found that amnioserosa contractility is based on cyclic assembly and disassembly of apical actomyosin networks. We also found that the PAR complex, composed of the apical polarity regulators Bazooka (Baz, *Drosophila* PAR-3), PAR-6, and atypical protein kinase C (aPKC) regulate distinct phases of the actomyosin cycles: Baz enhances network duration whereas PAR-6/aPKC promote the lull time between pulses. We hypothesized that Baz may enhance actomyosin network durations by inhibiting PAR-6/aPKC and that dynamic interactions between PAR proteins may be coupled to the cycling of the actomyosin networks. A later change in the actomyosin networks allowed us to test this hypothesized mechanism. During later dorsal closure, the actomyosin networks have decreased cycling and increased persistence; a change that occurs concomitantly with a shift in PAR proteins away from cell junctions and towards the apical surface. This shift appears to involve a rebalancing of mechanisms influencing junctional and apical surface PAR localization, with the latter being more closely linked to the apical actomyosin networks. To test whether increasing apical surface Baz attenuates aPKC-mediated inhibition of the actomyosin networks, we overexpressed mutant forms of Baz which either abolish or mimic its aPKC phosphorylation site (S980A and S980E, respectively). BazS980A is known to have increased affinity for aPKC whereas BazS980E has decreased affinity for aPKC. Overexpressed BazS980A precociously localized to the apical surface, stabilized and colocalized with apical surface aPKC, and promoted precocious apical constriction. In contrast, BazS980E had no such effects despite higher expression levels. We propose that the normal apical shift of the PAR proteins leads to increased Baz-aPKC interaction and to increased competitive inhibition of aPKC kinase activity towards its other substrates. This increased Baz-aPKC interaction may relieve aPKC-mediated inhibition of the actomyosin cytoskeleton leading to reduced cycling, more persistent networks, and greater apical constriction.

161

**Cellular mechanisms and evolution of morphogenesis in *Volvox* and related algae.**I. Nishii<sup>1</sup>; <sup>1</sup>*Temasek Life Sciences Laboratory, Singapore, Singapore*

Most metazoa first build a hollow sphere through successive cell cleavages and then this spherical multicellular sheet repeatedly folds - invaginate and protrude - to form unique shapes of organs and individual. How did such supercellular morphogenetic processes arise during the evolution of multicellular organisms from their unicellular ancestors? *Volvox* and their close relatives serve as a good model for investigating such issue. This group ranges from unicellular *Chlamydomonas*, through several related species increasing cell numbers, to *Volvox* with thousands of cells. The key morphogenetic process in *Volvox* development is called inversion, in which the spherical embryo turns inside out. The pre-inversion embryo is a cellular monolayer in which neighboring cells are linked to one another at the mid-level of their cell bodies by cytoplasmic bridges. The single place where such linkages are missing is across the opening where the inversion movement will start. In onset, the cells become flask shaped by extending long, thin stalks from their outermost ends, showing analogy with a characteristic cell shape seen in metazoan morphogenesis such as gastrulation. Next, cells near the opening migrate relative to their cytoplasmic bridges until they are linked to their neighbors only at the outermost tips of their stalks, which causes the cell sheet to turn outward. Transposon-tagged inversionless mutants were isolated and five different loci were characterized. Intriguingly, these genes were involved in cell shape changes and cell migration in inversion described above but also related to ECM. *invD* and *invE* genes, which encoded a novel phospho-protein and a MAP kinase, respectively, were required for cell elongation. Phosphorylated InvE proteins were abundant before inversion but they were rapidly dephosphorylated after inversion. In addition, phosphorylation of InvD was dependent on InvE. Next, *invA* encoded a kinesin motor protein that was localized near the cytoplasmic bridges (Nishii et al. 2003) and required for the cell migration. Furthermore, *invB* and *invC* encoded a sugar nucleotide transporter and a glycosyl transferase, respectively, both have roles in processing of glycoproteins involved in the size control of ECM surrounding embryo (Ueki & Nishii 2008, 2009). Finally, regarding evolution, all five homologous genes in *C. reinhardtii* were found. Intriguingly, *invD* and its ortholog were quite divergent in sequence compared to other pairs, suggesting that the evolution of InvD from an ancestral protein might have been an important role for elongated flask-shaped cell formation. We also discuss tracing such cellular basis in inversion and localization of InvA in related species from evolutionary aspects.

162

**Titration of histones sets the DNA threshold for activating transcription at the mid-blastula transition in *Xenopus*.**A. Amodeo<sup>1</sup>, A. Straight<sup>2</sup>, J. Skotheim<sup>1</sup>; <sup>1</sup>*Biology, Stanford University, Stanford, CA,*  
<sup>2</sup>*Biochemistry, Stanford University, Stanford, CA*

In many species, the early post-fertilization divisions occur rapidly and synchronously without growth phases, cell cycle checkpoints, or transcription. These early embryos are almost entirely transcriptionally inactive and rely on maternally supplied RNAs. At the Mid-blastula Transition (MBT), embryos initiate large-scale transcription from the zygotic genome (also known as the Maternal to Zygotic Transition or MZT), add growth phases, and gain checkpoints. Previous work suggested that the MBT is initiated by the increased DNA-to-cytoplasmic ratio resulting from repeated rounds of DNA replication and cell division without cell growth. This led to the hypothesis that the progressive titration of an inhibitory factor present in the embryo allows the initiation of zygotic transcription. However, the molecular identity of the titratable factor remained unknown. To determine the inhibitory molecule, and thus prove the titratable factor hypothesis,

we have developed a cell-free system in which to study the MBT. We found that *Xenopus* egg extracts initiate transcription at threshold DNA concentrations similar to those present at the MBT in intact embryos. Using this cell free system we have biochemically isolated histones H3 and/or H4 as the proteins responsible for inhibiting transcription in response to the DNA-to-cytoplasmic ratio. We have demonstrated that exogenous, bacterially produced, H3/H4 tetramers can increase the DNA threshold for transcriptional onset in a dose dependant manner. The identification of an abundant, high affinity DNA binding molecule that can inhibit transcription in a dose dependant manner strongly supports the titration model for MBT initiation. In addition, these findings suggest a molecular mechanism in which titrating out histones progressively opens chromatin structure to allow transcription.

163

#### **Asymmetric inheritance of primary ciliary membrane in dividing neural progenitors.**

*J. T. Paridaen<sup>1</sup>, M. Wilsch-Bräuninger<sup>1</sup>, W. B. Huttner<sup>1</sup>; <sup>1</sup>Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, Germany*

The primary cilium is a microtubule-based protrusion of the cell surface that is involved in mediating extracellular signals, such as Sonic Hedgehog (Shh). The primary cilium is nucleated by the centrosome containing the eldest centriole (mother centriole). Prior to mitosis, the primary cilium is assumed to be disassembled in order for the centrosomes to be free to serve as the poles of the mitotic spindle.

Recent findings show that asymmetric inheritance of the centrosome containing the mother centriole is related to cell fate decisions during mammalian neurogenesis. However, it is unknown whether centrosome-associated structures such as the primary cilium are involved in this asymmetrical regulation of cell fate. Therefore, we set out to investigate the fate of the primary cilium upon cell division of developing neural progenitors and the possible involvement of the primary cilium in subsequent cell fate decisions in the developing mouse neocortex.

We find that in mitotic neural progenitors and cultured cell lines, a membrane structure containing the ciliary small GTPase Arl13b is associated with the centrosome that contains the mother centriole. By surface biotinylation of the apical membrane in explanted mouse telencephalic hemispheres, we show that this structure contains ciliary membrane and is derived from the primary cilium that was present at the cell surface prior to mitosis. Using live imaging, we find that upon completion of mitosis, this centrosome-associated ciliary membrane is asymmetrically inherited by one of the daughter cells. Furthermore, we show that inheritance of the ciliary membrane causes earlier reestablishment of the primary cilium on the cell surface after division. Interestingly, the association of the ciliary membrane with one centrosome in mitotic neural progenitors decreases as neurogenesis proceeds.

We hypothesize that the observed asymmetry in primary cilium reassembly after mitosis might differentially expose daughter cells to extracellular signals, such as Shh. Therefore, we speculate that inheritance of the ciliary membrane affects cell fate decisions during mammalian neurogenesis.

#### **Contact-mediated long distance signaling by *Drosophila* cytonemes.**

*S. Roy<sup>1</sup>, T. B. Kornberg<sup>1</sup>; <sup>1</sup>Cardiovascular Research Institute, University of California, San Francisco, CA*

How cells communicate with each other at long distances is key to understanding how cells cooperate to form organized tissues during development and why cells in various disease states lose or escape normal controls. Although much progress has been made identifying signaling molecules that mediate these communications – proteins such as Hedgehog, Wingless,

Decapentaplegic (Dpp, a BMP homolog), Fibroblast Growth Factor and Epidermal Growth Factor – the mechanism by which these proteins move with target specificity and in regulated amount through and across tissues remains unproven. Several proposed models postulate that some form of diffusion moves these signaling proteins through extracellular spaces. My work has investigated a different “direct delivery” mechanism whereby specialized filopodia (cytonemes) transfer signaling proteins between cells at sites of direct contact (Roy and Kornberg, *Sci Signal.* 2011; 4:pt8). Cytonemes are types of filopodia first identified in the *Drosophila* wing imaginal disc that were proposed to be involved in long distance signaling during development. My work shows that same group of cells emanate different types of cytonemes that can be distinguished by their specific response to different signaling ligands depending on the presence or absence of different protein receptors in them (Roy et al. *Science.* 2011; 332:354-358). I then show, using the GRASP GFP reconstitution method, that cytonemes from epithelial cells make direct contact with distal target cells, and also show that contacting cytonemes exchange, receive and transport ligands from source cells to recipient cells in receptor dependent manner. Finally, I show that genetic conditions that reduce cytonemes also reduce signal transduction. These findings establish that even non-neuronal cells can make direct long distance contacts for target specific and regulated signal exchange and strongly support the model of cytoneme-based movement of signaling proteins as a novel and essential mechanism for cell-cell communication.

### Internalization of near infrared labeled transferrin into breast cancer cells using FRET tomography imaging.

K. Abe<sup>1</sup>, L. Zhao<sup>2</sup>, V. Venugopal<sup>2,3</sup>, X. Intes<sup>2</sup>, M. Barroso<sup>1</sup>; <sup>1</sup>Cardiovascular Sciences, Albany Medical College, Albany, NY, <sup>2</sup>Biomedical Engineering, Rensselaer Polytechnic Institute, Troy, NY, <sup>3</sup>Center for Molecular Imaging, Harvard Medical School, Boston, MA

Transferrin (Tfn) is an iron-binding protein used to transport iron via cell surface Tfn receptors (TFR) into the cytoplasm. The dimeric nature of TFR allows the use of Förster Resonance Energy Transfer (FRET) based detection methods to identify receptor-bound, fluorophore labeled Tfn donor and acceptor pairs from unbound Tfn. We report the use of near infrared (NIR)-FRET tomographic imaging to detect internalization of Tfn based on the reduction of donor fluorophore lifetime using a multispectral time resolved fluorescence molecular tomography (FMT) imaging system. Our main goal is to distinguish breast cancer cells (T47D) from normal cells (HMEC) via quantification of cellular Tfn uptake within live mice, due to the wide use of Tfn as a carrier for anti-cancer drug delivery systems. T47D and other cancer cells show higher TFR expression and more rapidly internalize Tfn compared to HMECs in which Tfn is co-localized to early endosome 1 (EEA1) positive markers, thus validating specific cellular internalization of Tfn. In support, we demonstrate increased % FRET efficiency (E%) at higher intensity thresholds of acceptor molecules in breast cancer cells compared to controls using confocal FRET analysis. To establish *in vivo* conditions, we tested temporal lifetime measurements of several donor NIR fluorophore candidates using our time-resolved imaging platform with data fitted into a bi-exponential decay function to estimate non-FRETing donor lifetimes. NIR FRET donor-acceptor AF700-Tfn and AF750-Tfn pair was selected as the optimal FRET pair under our imaging conditions due to the longer donor lifetime and higher quantum yield of AF700. Alexafluor NIR fluorophores AF700 and AF750 conjugated to Tfn molecules (AF700-Tfn/AF750-Tfn) were used for uptake studies into T47D and HMECs. Cells were

imaged using a time-resolved wide-field illumination strategy, with whole-body functional and fluorescence tomographic data sets at high-spatial and high-spectral densities (690nm-1020nm spectral range), and acquired using a 300ps time gate and a 40ps time delay to obtain time point spread function (TPSF) over a 4.6ns time window (116 gates). Co-internalization of AF700-Tfn and AF750-Tfn into T47D cells show a positive increase in fractional amplitude of FRETing donor Tfn molecules as A:D ratios increased from 1:4 to 4:1, as expected using fluorescence lifetime based FRET tomographic imaging. In support, mean photon counts show FRET-induced quenching at 4:1 compared to the 1:4 A:D ratio. We demonstrate a detection of Tfn internalization based on FRET events in cancer cells at a threshold of approximately  $1 \times 10^4$  cells, a number well below current clinical detection capabilities. We thus show proof-of-principle detection of NIR FRET in breast cancer cells in which these signals could be a powerful and non-invasive tool to identify the presence of tumors *in vivo* and to optimize targeted delivery systems based on Tfn-TFR mediated uptake into cancer cells.

### Direct imaging of sterol-enriched micro-domains that segregate vacuolar membrane proteins.

A. Toulmay<sup>1</sup>, W. Prinz<sup>1</sup>; <sup>1</sup>NIDDK, NIH, Bethesda, MD

The self-organization of lipids in membranes has been proposed to drive membrane domain formation. The most well studied lipid domains are sterol-sphingolipid enriched micro-domains (rafts) that are liquid ordered and coexist with liquid disordered portions of membranes. Rafts have been suggested to mediate the segregation of proteins and to be critical for processes such as endocytosis, viral budding, protein stability, immune receptor trafficking, and signaling. Large, stable liquid ordered rafts have been seen in model membranes. However, *in vivo* rafts have proven difficult to observe in live cells without invasive methods and seem to be much smaller and shorter-lived than those in artificial membranes, leading many to doubt whether rafts exist or play significant roles in cells. Here we show that large, stable sterol-enriched domains, which are strikingly similar to those observed in model membranes, form in the yeast vacuole membrane in response to nutrient deprivation or other stresses such as weak acid stress. All vacuolar membrane proteins tested segregate to one of two domains when cells starve. These two domains coalesce into several remarkable patterns on the vacuole surface, including a quasi-symmetrical pattern. Sterols are enriched in one of the two domains, are required for domain formation, and the sterol-enriched domain is liquid ordered. In addition, we demonstrate that liquid-ordered phases are present on vacuoles even when domains are not visible by microscopy, suggesting that the domains are present all the time but coalesce into large domains only in starvation or other stress conditions. We found that mutants lacking genes involved in lipid metabolism, vesicular trafficking, and regulating cellular entrance into quiescence lacked vacuolar lipid domains. Remarkably, these mutants were not able to recover from quiescence when treated with the TORC1-inhibitor rapamycin, suggesting that vacuolar lipid domains are required to exit the quiescence. This is the first demonstration that sterol-enriched raft-like liquid ordered domains similar to those observed in artificial membranes form in living cells and play an important role in the cellular response to stress.

**TLR4 signaling regulates a novel form of endocytosis.**

A. S. Haka<sup>1</sup>, R. K. Singh<sup>1</sup>, H. F. Chin<sup>1</sup>, I. Grosheva<sup>1</sup>, F. R. Maxfield<sup>1</sup>; <sup>1</sup>Biochemistry, Weill Cornell Medical College, New York, NY

We have characterized a novel form of endocytosis in which cells create an extracellular, acidic, hydrolytic compartment (a lysosomal synapse). The lysosomal synapse allows rapid catabolism of large species or moieties tightly linked to the extracellular matrix that cannot be internalized even by phagocytosis. These species are typically involved in disease states that are coupled to an inflammatory response. Consistent with this, we find that Toll-like receptor 4 signaling is necessary for lysosomal synapse formation. Thus far, we have examined this mechanism of uptake in macrophages and dendritic cells. These cells use the lysosomal synapse to degrade aggregated lipoproteins thereby transforming them into foam cells, a key pathological feature of atherosclerotic plaques.

We find that compartment formation is dependent on local F-actin polymerization and that targeted lysosomal exocytosis provides the hydrolases necessary for extracellular catabolism. Acidification of the lysosomal synapse allows hydrolase activity. Data indicate that after partial catabolism outside the cell, remnants can be internalized and digested in lysosomes. Thus, the formation of a lysosomal synapse requires extensive rearrangement of the actin cytoskeleton, formation of a nearly sealed extracellular compartment, and targeted secretion of lysosomal contents. All of these activities require carefully coordinated signal transduction processes. Recent work has focused on the receptors and signal transduction pathways involved in the formation and function of the lysosomal synapse. Data show that one arm of the signaling is associated with Toll-like receptor 4 via the downstream adapter protein myeloid differentiation primary response protein 88. Downstream signaling also involves phosphoinositide 3-kinase, protein kinase B (Akt), Bruton's tyrosine kinase, phospholipase C, protein kinase C and calcium mobilization as important events leading to lysosomal synapse formation and function.

Akin to phagocytosis, uptake via the lysosomal synapse occurs in specialized cells. Efforts are currently underway to examine the relevance of this pathway to several other diseases, such as Alzheimer's, diabetes and cancer. Identification of the specific molecular pathways involved in this process will not only contribute to the basic understanding of endocytic mechanisms but may also provide molecular targets for the ultimate development of therapies related to a number of diseases.

168

**Micropatterning of plasma membranes of differentiated vertebrate cells.**

P. M. Jenkins<sup>1</sup>, K. Nilsson<sup>2</sup>, C. Vasavda<sup>1</sup>, V. Bennett<sup>1</sup>; <sup>1</sup>Biochemistry, HHMI/Duke University, Durham, NC, <sup>2</sup>Department of Medicine, Duke University, Durham, NC

Vertebrate membranes are patterned into discrete domains necessary for critical physiological functions in multi-cellular organisms. This patterning not only involves proper delivery of proteins and lipids to different compartments (i.e. epithelial apical/basolateral membranes), but also lateral segregation of proteins within the membrane. Recently, it has been shown that yeast membrane proteins are distributed in non-homogenous patterns throughout the membrane, and that this patterning is necessary for proper protein function [1]. Here we show that the intracellular adaptor molecule ankyrin G (AnkG) is localized to discrete microdomains within mammalian cell membranes both in vitro and in vivo, including epithelial lateral membranes, axon initial segments, and cardiac T-tubules. Previous studies have shown that AnkG binds to

band 3 in erythrocytes with a low stoichiometry [2, 3], suggesting a close apposition of ankyrin to its binding partners. Surprisingly, using high resolution fluorescence microscopy, we find that AnkG and its partners are in distinct domains with only modest colocalization. These domains are independent of fixation as they can be seen in living cells. In addition, cysteine 70 of AnkG, which is palmitoylated, is necessary for the association of AnkG with these microdomains suggesting that lipid modifications may play a role in microdomain patterning. Finally, using fluorescence recovery after photobleaching, we show that AnkG binding partners may be restricted within their respective domains through tethering to the spectrin-based membrane skeleton. This is based on an increased E-cadherin mobile fraction, but no change in recovery rate, within the epithelial lateral membrane upon expression of an inducible dominant-negative consisting of the AnkG binding site from beta 2 spectrin.

### **TRIM9 coordinates membrane trafficking and cytoskeletal dynamics during neuronal development.**

*C. Bott<sup>1</sup>, L. McClein<sup>2</sup>, J. Valtschanoff<sup>1</sup>, C. Winkle<sup>1</sup>, F. Gertler<sup>2</sup>, S. L. Gupton<sup>1</sup>; <sup>1</sup>Cell and Developmental Biology, UNC-Chapel Hill, Chapel Hill, NC, <sup>2</sup>Koch Institute, MIT, Cambridge, MA*

During the establishment of neuronal circuitry, axons and their collateral branches are guided by attractive and repulsive cues to postsynaptic targets. While many guidance receptors have been identified, how they trigger the cytoskeletal dynamics and vesicle fusion with the plasma membrane required for guidance and branching is unclear. Here we identify TRIM9, an E3 ubiquitin ligase with restricted expression in the nervous system, as a critical component at the interface of netrin signaling to the cytoskeleton and membrane trafficking in the mammalian nervous system. The TRIM9 orthologue in *c. elegans* and *drosophila* has previously been implicated in netrin-dependent axon guidance. We will present evidence that vertebrate TRIM9 functions in two critical stages of neuronal development: axonal branching, which increases the number of synaptic partners, and axonal guidance, which underlies innervation of proper targets. Vertebrate TRIM9 interacts with the netrin receptor DCC, actin regulatory Ena/VASP and MRL proteins, the exocytic t-SNARE, SNAP25, and the nonconventional myosin motor that targets DCC to the membrane, Myo 10. Inhibition of TRIM9 ligase activity in cortical neurons alters filopodia formation and their invasion by microtubules. We also observe that genetic loss of TRIM9 results in increased VAMP2-mediated exocytosis and exuberant collateral axon branching in vitro in the absence of netrin. Interestingly, without TRIM9, cortical neurons lose the ability to respond to netrin. Culturing cortical explants from wildtype and TRIM9<sup>-/-</sup> brains indicates TRIM9 function is critical for asymmetric neurite outgrowth toward a netrin source. This suggests TRIM9 is involved in netrin-mediated axonal guidance, which we are currently investigating. Ongoing characterization of these mice has identified neuroanatomical defects caused by genetic loss of TRIM9, suggesting the functions of TRIM9 found in vitro are critical in vivo as well. The position of TRIM9 at the interface of netrin signaling to both the cytoskeleton

and membrane trafficking provides an exquisite regulation of these subcellular machines that power neuronal morphology changes in response to netrin.

170

**Dynamic regulation of endoplasmic reticulum-plasma membrane junctions monitored by a genetically-encoded fluorescent marker.**

*C-L. Chang<sup>1</sup>, J. Liou<sup>1</sup>; <sup>1</sup>UT Southwestern Medical Center at Dallas, Dallas, TX*

Many cellular functions, including secretion, cell migration and differentiation, depend on store-operated calcium entry (SOCE). A decrease of endoplasmic reticulum (ER) calcium and the subsequent activation of an ER calcium sensor, STIM1, initiate SOCE. Reduced ER calcium induces STIM1 to oligomerize and translocate to the ER-plasma membrane (PM) junctions where the two membranes are closely apposed to each other within 20nm. The calcium channel Orai1 in the PM is then activated, which enables SOCE. Although ER-PM junctions have been observed by electron microscopy (EM) in many cell types, little is known about their formation and regulation. To help understand the dynamic regulation of ER-PM junctions, we first generated a genetically-encoded fluorescent marker of ER-PM junctions based on the translocation mechanism of STIM1. We have confirmed that this marker selectively localized to ER-PM junctions using confocal microscopy and EM, and that it did not perturb STIM1 and Orai1 translocation to the junctions nor disrupt SOCE. This marker has enabled us to visualize and track ER-PM junctions using live-cell total internal reflection fluorescence (TIRF) microscopy. We found that approximately two hundred stable ER-PM junctions exist in the adhesion surface of a single HeLa cell at resting state. During SOCE, a significant up-regulation of ER-PM junctions was observed. We further employed a cytosolic calcium chelator and a cytosolic caged-calcium reagent to demonstrate that the up-regulation of ER-PM junctions required an increase of cytosolic calcium but not a decrease of ER calcium. In summary, we have generated a marker enabling us to track the dynamic change of single ER-PM junctions in live cells and discovered cytosolic calcium-dependent regulation of ER-PM junctions.

**The nuclear pore protein Nup98 plays a conserved role in transcriptional memory.**

*W. Light<sup>1</sup>, A. Thompson<sup>1</sup>, J. Freaney<sup>1</sup>, C. Horvath<sup>1</sup>, J. H. Brickner<sup>1</sup>; <sup>1</sup>Molecular Biosciences, Northwestern University, Evanston, IL*

The interaction of nuclear pore proteins (Nups) with genes can function to regulate transcription. In yeast, targeting of genes to the nuclear pore complex (NPC) promotes stronger transcription. For some inducible genes, interaction with the NPC is maintained for several generations after repression and serves to prime them for future reactivation, a phenomenon called transcriptional memory. We have found that a mechanistically similar phenomenon occurs in human cells. A subset of interferon  $\gamma$ -inducible genes are much more strongly induced in cells that have previously been exposed to IFN $\gamma$ . As in yeast, this type of transcriptional memory involves a physical interaction with Nups, binding of a poised form of RNA polymerase II to the promoter and changes in chromatin structure. However, unlike yeast, the interaction of these genes with Nups occurs in the nucleoplasm. Finally, in cells transiently knocked down for Nup98, memory is lost; RNA polymerase II does not remain associated with IFN $\gamma$ -inducible promoters and the rate of reactivation is dramatically reduced. These results suggest that Nup98 (Nup100 in yeast) plays a conserved role in promoting epigenetic transcriptional memory.

172

***In vivo* three-dimensional characterization of mRNA export through the nuclear pore complex.***W. Yang*<sup>1</sup>; <sup>1</sup>*Temple University, Philadelphia, PA*

Protein-receptor-facilitated nuclear export of messenger RNAs (mRNAs) through the nuclear pore complexes (NPCs) is a key step for the flow of genetic information in eukaryotic cells. However, the transport kinetics, the three-dimensional (3D) pathway and the export selectivity mechanism of mRNA-protein complexes through the NPCs remain poorly understood, although they are of fundamental interest. Here we employed a super-resolution microscopy imaging approach to three-dimensionally characterize mRNAs exporting through individual NPCs in living human cells. With a spatiotemporal resolution of 2 ms and 8 nm, the fundamental features of mRNA export through the NPCs, escaped from previous measurements of electron microscopy and single-molecule fluorescence microscopy, have been obtained: 1) mRNA complexes were decelerated and then selected at the narrowest waist of the NPC as they entered the NPC from the nucleus. Approximately one third of these incoming complexes successfully arrived at the cytoplasm, and the others aborted their export and returned back to the nucleus; 2) either the successful or the abortive mRNA export events took approximately 12 ms to interact with the NPCs; 3) In a 3D view, mRNA complexes primarily paved their passageways through the periphery around a rarely occupied central axial conduit on the nucleoplasmic side and in the central channel of the NPC, then dissociated on the cytoplasmic side of the NPC, and finally passively diffused into the cytoplasm.

173

***In vivo* visualization of chromosome synapsis in *C. elegans*.***O. Rog*<sup>1</sup>, *A. F. Dernburg*<sup>1</sup>; <sup>1</sup>*University of California, Berkeley; and Howard Hughes Medical Institute, Department of Molecular and Cell Biology and California Institute for Quantitative Biosciences (QB3), Berkeley, CA*

Meiosis is the special cell division process that enables the production of haploid gametes. During meiotic prophase, chromosomes form linkages with their homologous partners to enable reductional segregation during the first meiotic division. Essential to this process is the pairwise alignment of homologous chromosomes along their entire lengths. In most eukaryotes this alignment is reinforced through synapsis, the polymerization of a structurally conserved structure called the synaptonemal complex (SC), which links homologous chromosomes. The SC promotes genetic exchanges (crossovers) between homologs, and likely regulates their number and location. Synapsis is a dynamic process, the details of which are difficult to infer from images of fixed cells or tissues. Our goal has been to better understand this process through analysis in living nematodes, using fluorescently tagged SC components and high-resolution time-lapse microscopy. Our observations have revealed that synapsis is rapid and highly processive. Individual chromosomes achieve full synapsis in 20-30 minutes, at a rate of ~170nm per minute. We find that initiation of synapsis is a relatively infrequent event that is rate-limiting for completion of synapsis, consistent with evidence that initiation is subject to strict regulation. Initiation occurs asynchronously on each chromosome, resulting in staggered synapsis of different chromosomes. In *C. elegans*, synapsis is accompanied by rapid chromosome motions driven by dynein, which is coupled through the nuclear envelope to one end of each chromosome. Under conditions where this motion is severely abrogated, synapsis remains processive but is ~5-fold slower. This suggests that chromosome motion promotes

homolog alignment, enabling synapsis to proceed more rapidly. Moreover, it reveals a novel function for the rapid chromosome motions that have been observed in diverse organisms during meiotic prophase.

174

**Assembly, dynamics and function of the synaptonemal complex (SC) in meiotic prophase nuclei.**

*W. Zhang<sup>1</sup>, D. Libuda<sup>1</sup>, S. Mlynarczyk-Evans<sup>1</sup>, D. Pattabiraman<sup>1</sup>, G. Chen<sup>1</sup>, M. Presler<sup>1</sup>, A. M. Villeneuve<sup>1</sup>; <sup>1</sup>Stanford University, Stanford, CA*

The SC is a highly ordered proteinaceous structure that assembles at the interface between paired and aligned homologous chromosomes during meiotic prophase. The SC has long been recognized as a hallmark feature of the meiotic program and has at least two conserved functions, in stabilizing tight associations along the lengths of homologs and in promoting maturation of recombination intermediates into crossovers. Recent work has shown that the SC also plays a role in inhibiting crossover formation during *C. elegans* meiosis, thereby limiting crossover number. Further, SC structures undergo patterned disassembly that creates an organization crucial for directing the pattern of chromosome segregation during the meiotic divisions. In addition, several lines of evidence suggest that SC assembly is part of a feedback mechanism that regulates prophase progression to assure a successful meiotic outcome.

While substantial progress has been made in identifying SC components and defining its biological roles, the SC has remained enigmatic in many ways. Although the SC normally assembles only between aligned homologous chromosomes, the SC structure itself is indifferent to homology. Moreover, SC assembly appears to be cooperative and processive, indicating a requirement for tight coordination of homolog pairing and synapsis. Further, the zipper-like appearance of the SC in EM images belies a growing realization that the SC structure is likely much more dynamic than previously appreciated. We will discuss mechanisms that regulate assembly of the SC to ensure that it only occurs in a productive manner, i.e., linking the axes of correctly paired and aligned homologous chromosomes. We will show that reducing the pool of specific SC subunits results in attenuated crossover interference, reflected in an increase in the number of cytologically-differentiated crossover sites, implying a requirement for appropriate stoichiometry to confer normal SC function. Further, we will present evidence from FRAP analysis that the "fully assembled" SC structure is indeed dynamic, undermining the view of the SC as a static scaffold.

175

**Corralling the microtubule tip: Nanoscale kinetochore architecture suggests an integrative model for its bidirectional motility.**

*P. Aravamudhan<sup>1</sup>, A. P. Joglekar<sup>2</sup>; <sup>1</sup>Biophysics, University of Michigan, Ann Arbor, MI, <sup>2</sup>Cell & Developmental Biology, University of Michigan Medical School, Ann Arbor, MI*

The kinetochore is a macromolecular machine that drives chromosome movement and segregation during cell division. The molecular mechanism underlying this unique, bidirectional motor depends as much on its nanoscale protein architecture as the structures and biochemical properties of individual proteins. Yet, the *in vivo* kinetochore architecture, and more specifically, the nanoscale distribution of individual microtubule (MT) binding protein molecules around and along the microtubule tip remains unknown. To define this architecture, we have developed a systematic FRET quantification technique in live cells. Our analysis reveals two microtubule-binding domains within the budding yeast (*Saccharomyces cerevisiae*) kinetochore. The first unit in this bipartite arrangement consists of Ndc80 and Dam1. The MT-binding domains of

these complexes work in close spatial proximity (< 10 nm), suggesting a functional integration of these molecules. We propose that this force generating unit is mainly responsible for MT depolymerization coupled movement. The MT-associated, plus-end tracking protein Stu2p (XMAP215) makes up the second unit. The C-terminus of this large protein situated ~ 35 nm behind Ndc80-Dam1. This multi-function protein likely participates in polymerization-coupled motility. We propose that it contributes either tip-tracking ability or destabilizes the growing tip. Thus, our reconstructed kinetochore architecture, when considered in the context of the unique structural and MT-binding properties of each individual protein, suggests an integrative model explaining bidirectional kinetochore movement that is tightly coupled with MT polymerization and depolymerization. This scheme of corralling the dynamic MT tip is likely conserved in all eukaryotes, even if organisms freely substitute proteins with analogous activities (with the exception of the Ndc80 complex) to fine-tune chromosome motility.

176

### **The structure and function of a chromatin spring in mitosis.**

*K. S. Bloom<sup>1</sup>, A. Stephens<sup>1</sup>, J. Verdaasdonk<sup>1</sup>, J. Haase<sup>1</sup>, E. Yeh<sup>1</sup>; <sup>1</sup>Biology, University of North Carolina at Chapel Hill, Chapel Hill, NC*

The physical properties of a long-chain polymer such as DNA and its organization inside the cell contribute in fundamental ways to replication, repair, transcription and chromosome segregation. DNA and the unique chromatin organization at the centromere function as a mechanical spring in mitosis. We apply principles of polymer physics to understand how chromatin architecture (such as DNA wrapping around nucleosomes, looping and catenation) contributes to faithful chromosome segregation. Cohesin and condensin together with pericentric chromatin constitute the spring that functions as a restoring force counterbalancing the microtubule extensional force in metaphase of mitosis. The spring exhibits asymmetric stretching, inconsistent with a simple linear spring model. We present experimental and modeling evidence for a threshold extension in the spring to switch between cohesin-condensin rich versus depleted spring constants, that accurately recapitulates in vivo chromatin and spindle dynamics.

### **De Novo synthesis of the cell wall in *E. coli*: Reversion of L-Forms.**

*G. H. Billings<sup>1</sup>, K. C. Huang<sup>2</sup>; <sup>1</sup>Department of Physics, Stanford University, Stanford, CA, <sup>2</sup>Department of Bioengineering, Stanford University, Stanford, CA*

Bacterial morphology is crucial to a wide variety of cell functions, including motility, adhesion, pathogenesis. The shape of nearly all bacterial cells is determined by a rigid cell wall made of peptidoglycan. A rod-shaped cell such as *E. coli* thus faces the challenge of coordinating the nanoscale proteins responsible for peptidoglycan synthesis to construct a micron-scale sacculus. What are the principles that allow cell wall synthesis proteins to establish order over a range of length scales spanning nearly three orders of magnitude? We approached this question by examining the re-growth of the sacculus in cell wall-deficient 'L-forms' of *E. coli*, in which cell wall synthesis has been transiently disrupted by beta-lactam antibiotics. An L-form undergoing reversion begins in a spherical shape without an intact cell wall. When cell wall synthesis inhibiting antibiotics are removed, the cell generates new rod-shaped protrusions, which eventually undergo septation and adopt the normal rod morphology of *E. coli*. The

reversion of L-forms thus provides an opportunity to study morphogenesis in bacteria lacking an intact cell wall, and to study the activity of cell wall synthesis enzymes independently of their interaction with the cell wall. We used automated image analysis to quantify the morphological trajectories of reverting L-forms as they transition from rod to sphere, and to track the activity of cell wall synthesis enzymes. In particular, we examined the localization of bacterial cytoskeletal elements MreB and FtsZ, both of which are involved in cell wall growth and morphogenesis, and correlated their localization patterns with changes in cell shape. We also probed the effect of different mutants of MreB on the dynamics of the reversion process. We found that MreB determines the size of early rod-shaped protrusions in reverting L-forms, demonstrating that MreB regulates cell shape even in the absence of an intact cell wall.

178

### **MinCD cell division proteins form alternating co-polymeric filaments.**

*D. Ghosal<sup>1</sup>, L. A. Amos<sup>1</sup>, J. Löwe<sup>1</sup>; <sup>1</sup>Structural Studies Division, MRC Laboratory of Molecular Biology, Cambridge, United Kingdom*

Most bacteria form a dynamic ring-like structure at the division site, containing the tubulin-like protein FtsZ, which constricts to produce two daughter cells. The Min proteins play an important role in the precise positioning of Z ring at the division site by oscillating between the poles in most organisms.

In *E. coli*, the three proteins MinC, MinD and MinE, encode the Min system. MinC and MinD are widely conserved in bacteria and they act together to inhibit Z ring assembly. MinD binds to the membrane in dimeric form in the presence of ATP through an amphipathic helix and also binds to MinC. MinC directly interacts with FtsZ and destabilises Z ring assembly. MinE stimulates the ATP hydrolysis of MinD and hence dissociates the MinCD complex from the membrane. So far it has been thought that a reaction/diffusion pattern-forming reaction based on MinD and MinE alone causes the oscillation of all three proteins.

Using light scattering and electron microscopy (EM) we show *in vitro* that MinC and MinD form nucleotide-dependent, alternating co-polymeric filaments, even in the absence of membrane. To better understand the interaction between MinC and MinD in the filament, we have solved the crystal structure of the MinC-MinD complex at 2.7 Å resolution. A hybrid model of the MinCD filaments, built using the MinCD and MinD dimer crystal structures correlates well with the appearance of MinCD filaments as observed in EM. Our structural analysis also identifies residues important for the MinCD interaction and helps to explain how MinE competes with MinC for the overlapping binding site on MinD.

We propose that the MinCD filament belongs to a new class of cytomotive, nucleotide-regulated filaments, adding to actin and tubulin-like systems present in many bacteria.

179

### **How to segregate DNA without dynamic instability: Bundling of the bacterial actin-like filament AlfA is regulated by an accessory factor, AlfB.**

*J. K. Polka<sup>1</sup>, R. D. Mullins<sup>1</sup>; <sup>1</sup>UCSF, San Francisco, CA*

AlfA is a filament-forming actin-like protein in *Bacillus subtilis* that functions to actively partition the large, low copy number plasmid by which it is encoded. Previous *in vivo* and *in vitro* observations of filament dynamics have revealed a set of kinetic and structural properties (namely constitutive bundling and lack of dynamic instability) that are inconsistent with previously established models for actin-like plasmid segregating proteins such as ParM. To

understand the mechanism of AlfA-driven plasmid segregation, we imaged AlfA and its downstream DNA-binding protein, AlfB, interacting with plasmids *in vivo* and *in vitro*. Our live cell microscopy reveals that plasmids can move along existing AlfA structures or track the ends of growing ones, consistent with the idea that the AlfA polymer seen *in vivo* is actually a bundle of multiple filaments. Furthermore, these polymers can form between plasmids to push them apart, prompting us to ask how plasmids alter filament dynamics to generate this specific assembly. To address this question, we purified AlfB and found that it dramatically alters the kinetics and structure of AlfA. AlfB binds to AlfA monomers and polymers, not only increasing the critical concentration of assembly, but also preventing the otherwise very robust bundling of AlfA. The 100bp centromeric DNA region to which AlfB binds, however, rescues bundling and promotes polymerization. These observations lead us to a model of AlfA-driven plasmid segregation wherein bundles of AlfA form specifically in association with AlfB-DNA complexes. We propose that the intrinsic bundling property of the polymer, normally inhibited by a high concentration of free AlfB in the cytoplasm, functions as a capture mechanism to specifically join DNA-bound filaments to one another. Polymerization in opposite directions, driven by antiparallel bundling, would cause plasmids to be segregated from one another, ensuring their maintenance through cell division.

#### **Spatial regulation of protein distribution in bacterial cells.**

S. Schlimpert<sup>1,2</sup>, E. A. Klein<sup>3</sup>, A. Briegel<sup>4</sup>, V. Hughes<sup>5</sup>, J. Kahn<sup>6</sup>, K. Bolte<sup>2</sup>, U. G. Maier<sup>7</sup>, Y. V. Brun<sup>5</sup>, G. J. Jensen<sup>4,8</sup>, Z. Gitai<sup>3</sup>, M. Thanbichler<sup>1,2</sup>; <sup>1</sup>Max Planck Institute for Terrestrial Microbiology, Marburg, Germany, <sup>2</sup>Faculty of Biology, Philipps-Universität, Marburg, Germany, <sup>3</sup>Department of Molecular Biology, Princeton University, Princeton, NY, <sup>4</sup>Division of Biology, California Institute of Technology, Pasadena, CA, <sup>5</sup>Department of Biology, Indiana University, Bloomington, IN, <sup>6</sup>Department of Ecophysiology, Max Planck Institute for Terrestrial Microbiology, Marburg, Germany, <sup>7</sup>Department of Biology, Philipps-Universität, Marburg, Germany, <sup>8</sup>Howard Hughes Medical Institute, Pasadena, CA

The formation of specialized cellular architectures often requires the establishment and maintenance of subcellular domains with a distinct lipid and protein composition. We report the identification of a novel mechanism that determines the distribution of proteins within cells of the stalked model bacterium *Caulobacter crescentus*. It depends on the establishment of a macromolecular protein complex forming at the junction between the cell body and the stalk appendage. Mutants with defects in the assembly or integrity of this structure show aberrant protein distribution patterns, which in turn lead to a significant decrease in cellular fitness. Collectively, our results demonstrate that eukaryotes and prokaryotes use similar molecular principles for the regulation of subcellular protein localization in order to ensure the proper function of cells.

#### **Time-resolved nanometer scale AFM imaging of antimicrobial peptide activity on live *Escherichia coli* cells.**

A. Slade<sup>1</sup>, J. H. Kindt<sup>1</sup>, S. C. Minne<sup>1</sup>; <sup>1</sup>Bruker Nano Inc., Santa Barbara, CA

Understanding drug-membrane interactions is crucial to drug research and development. Bacterial membranes have a much more complex structure than mammalian cell membranes. As such, knowledge of bacterial membrane composition and organization, as well as characterization of the molecular-level responses to drug interactions, is critical to the development and assessment of effective drug formulations. Cellular drug responses involve

highly dynamic processes. However, the ability to image live cells with nanometer resolution on timescales relevant to dynamic cellular events has proven challenging. The ability of atomic force microscopy (AFM) to obtain three-dimensional topography images of biological molecules with nanometer resolution and under near-physiological conditions remains unmatched by other imaging techniques. However, with traditional AFM systems, the typically longer image acquisition times required to obtain a single high-resolution image (~minutes) has limited the ability to investigate dynamic biological processes. While recent years have shown significant progress in the development of high-speed atomic force microscopy (HS-AFM), the nature of the instrumentation that has been developed has several drawbacks in specimen size, requiring small scan sizes and flat sample surfaces. As such, the majority of biologically-related HS-AFM studies have concentrated on imaging single biomolecules with little focus on using HS-AFM to examine cellular processes. With the rapidly growing antibiotics crisis, antimicrobial peptides (AmP) are increasingly being investigated as therapeutic alternatives. Key to their success is an understanding of the mechanisms by which AmPs interact with the cell membrane and facilitate cellular death. Using HS-AFM, we have obtained the first high-resolution time sequence images of the native structure of a bacterial outer membrane, obtained directly on the surface of live *Escherichia coli* cells. The increased time resolution of HS-AFM allowed us to observe dynamic changes in the nanoscale structure of the outer membrane in direct response to the AmP CM15, at timescales relevant to the mechanism of AmP-induced cell death. The results of these HS-AFM studies have provided the first opportunity to resolve the dynamics of AmP-mediated cell death in a native cell membrane environment in real-time and with nanoscale resolution.

182

#### **Type 6 secretion dynamics within and between bacterial cells.**

*M. Basler<sup>1</sup>, B. Ho<sup>1</sup>, J. Mekalanos<sup>1</sup>; <sup>1</sup>Harvard Medical School, Boston, MA*

The bacterial Type VI secretion system (T6SS) corresponds to an organelle that is functionally analogous to a contractile bacteriophage tail and can power secretion of proteins between cells. The dynamics of this organelle can be readily visualized by time-lapse fluorescent microscopy using ClpV fusion proteins. This methodology has documented cell-cell interactions referred to as "T6SS dueling" that correspond to the location of protein translocation events between cells that signal assembly of new T6SS organelles. In order to characterize the contact-dependent signal that triggers T6SS dueling behavior, we have explored the ability of different bacterial species to prey upon T6SS-positive cells and T6SS-negative cells. Our results show that in the case of *Pseudomonas aeruginosa*, T6SS-dependent killing of *Vibrio cholerae* is greatly stimulated by T6SS activity occurring in those prey species. These results suggest that T6SS dueling activity occurs between heterologous species and is used to direct killing activity toward T6SS+ prey cells at the exact point of that prey cell's initial T6SS attack on the predator. In contrast, *V. cholerae* T6SS activity is repeatedly randomly distributed around the predator cell envelope. While *V. cholerae* can readily kill T6SS-negative *E. coli*, *P. aeruginosa* fail to kill this prey species efficiently suggesting that aiming of the "T6SS thrust" is essential for killing by this prey species. Imaging and quantification of prey viability further suggests that both T6SS effectors and the T6SS apparatus itself may be mediators of prey cell killing.

### Repressing and tethering chromosomes via molecular machines.

B. J. Meyer<sup>1</sup>; <sup>1</sup>HHMI and U.C. Berkeley, Berkeley, CA

Genome stability requires that chromosomes be properly replicated, tethered, recombined, segregated, and expressed. These processes are controlled, in part, by related protein complexes, the condensins and cohesins. The talk will focus on mechanisms by which these complexes control chromosome-wide gene expression and chromosome tethering and segregation. Gene expression in multi-cellular organisms is controlled by regulatory mechanisms that function over dramatically different distances: across large chromosomal territories or along individual genes. X-chromosome dosage compensation is exemplary for dissecting gene regulation over vast distances and the role of chromosome structure in that regulation. Dosage compensation ensures that males (XO or XY) and females (XX) express equal levels of X-chromosome gene products, despite the difference in X-chromosome dose. In the worm *C. elegans*, the dosage compensation complex (DCC) is targeted to both X chromosomes of hermaphrodites to repress transcript levels across the entire X by half. The DCC resembles condensin, a protein complex required for the compaction, resolution, and segregation of mitotic and meiotic chromosomes. The DCC shares all but one subunit with two other condensin complexes in the worm, and DCC subunits also participate in other aspects of chromosome dynamics, including chromosome segregation and the regulation of crossovers between homologous chromosomes during meiosis. Emphasis will be given to the mechanisms by which the DCC recognizes and binds X chromosomes in somatic cells and the mode of DCC action, including its effects on chromosome structure and transcription. Protein complexes structurally related to condensin (the cohesin complexes) mediate the reduction of genome copy number during meiosis that is required for the production of haploid sperm and eggs. Yeast studies showed that the meiotic pattern of chromosome segregation requires that the "kleisin" subunit of mitotic cohesin be replaced by a meiosis-specific paralog. Unlike budding yeast, *C. elegans* has three meiosis-specific kleisin subunits and three distinct meiotic cohesin complexes. Work presented will show that kleisin identity dictates the biological role of the cohesin complex during meiosis, how cohesin is loaded onto chromosomes, how cohesin is triggered to become cohesive, and when, where, and how cohesin is removed from chromosomes to achieve the two successive rounds of chromosome segregation essential for the reduction in genome copy number. An important generality from our studies is that reshuffling of interchangeable molecular parts can create independent molecular machines with similar architectures but very different functions.

184

### How do cells establish and maintain sister chromatid cohesion?

K. Nasmyth<sup>1</sup>; <sup>1</sup>University of Oxford, Oxford, United Kingdom

Sister chromatid cohesion is mediated by a multi-subunit complex called cohesin whose Smc1 and Smc3 form rod shaped proteins with ABC-like ATPase domains at one end and "hinge" dimerization domains at the other, through which they form V-shaped heterodimers that are converted to tripartite rings through association of Smc3 and Smc1's ATPase domains with the N- and C-terminal domains of cohesin's kleisin subunit respectively. Though the structures of Smc1/3 and Smc1/kleisin interfaces have been known for several years and are conserved among all Smc/kleisin complexes, that of the Smc3/kleisin interface has proved more elusive. Through a collaboration with Stephan Gruber (Max Planck, MPI), we show that N-terminal

kleisin domains bind to Smc3 ATPase heads in manner similar to that of equivalent bacterial proteins and through a mechanism that is completely different to that of the Smc1/kleisin interface. These structural insights have enabled us to cross-link chemically all three interfaces using pairs of cysteine insertions and thereby test whether cohesin rings entrap sister DNAs. Because these experiments have now confirmed the ring hypothesis, we need to understand how DNAs enter cohesin rings, what occurs to them during DNA replication, and how cohesin is prevented from releasing either DNA until separase cleaves rings open at the onset of anaphase. I will describe experiments suggesting that DNAs enter rings through Smc1/3 hinge interfaces but can subsequently exit through their Smc3/kleisin interfaces. DNA exit through opening the Smc3/kleisin interface is responsible for cohesin's turnover on chromosomes in both yeast and *Drosophila* and is blocked by acetylation of Smc3 ATPase heads by Eco1. I will also discuss the key role of cohesin's Pds5 subunit which binds to sequences near Smc3's N-terminal Smc3 ATPase binding domain and together with Wapl, which binds to Pds5, and Scc3, which binds to a central domain within kleisin, catalyzes transient dissociation of Kleisin's N-terminal domain from Smc3 ATPase heads. This releasing activity is responsible for dissociation of cohesin from chromosome arms during prophase in animal cells. Remarkably, by facilitating acetylation of Smc3's ATPase heads by Eco1 during S phase and by blocking access of the Hos1 de-acetylase during G2, Pds5 also functions to block the releasing activity that would otherwise destroy cohesion after it has been generated at replication forks.

#### **Single molecule analysis of Myosin-1a membrane binding dynamics in cells.**

*J. N. Mazerik<sup>1</sup>, L. J. Kraff<sup>2</sup>, A. K. Kenworthy<sup>2</sup>, M. J. Tyska<sup>1</sup>; <sup>1</sup>Cell and Developmental Biology, Vanderbilt University Medical Center, Nashville, TN, <sup>2</sup>Molecular Physiology and Biophysics, Vanderbilt University Medical Center, Nashville, TN*

At the enterocyte apical surface, densely packed microvilli form a barrier called the brush border. The monomeric motor protein Myosin-1a (Myo1a) forms lateral cross bridges in microvilli by linking the core actin bundles to the plasma membrane. As the most abundant motor in the brush border, Myo1a plays a key role in physiological functions at the membrane/cytoskeletal interface, including maintaining microvillar structure and membrane tension, and regulating microvillar vesicle shedding. Myo1a performs these functions while membrane bound, yet it is unknown how this motor transduces force onto a fluid lipid bilayer. Previous studies from our lab have shown that Myo1a tail homology 1 (TH1) domain binds electrostatically to liposomes containing phosphatidylserine (PS), and that Myo1a membrane binding potential is distributed throughout TH1 rather than localized to a single motif. Structural prediction studies using I-TASSER further suggest the membrane binding regions may fold into independent motifs. Therefore, distribution of lipid binding potential may result in a multi-site interaction between TH1 and the lipid bilayer. Multiple points of contact not only increase affinity, but might also slow or immobilize the diffusion of a membrane bound protein. In the case of Myo1a, this could be beneficial for imparting force onto the membrane. To test this prediction in cells, we employed single molecule total internal reflection fluorescence microscopy in combination with single particle tracking and mean squared displacement analysis. We quantitatively compared the lateral mobility of Myo1a, TH1 and Lactadherin-C2, a protein that binds to PS and diffuses with velocities similar to the lipid alone. Preliminary results indicate that Lactadherin-C2 diffuses the fastest, followed by TH1 and then Myo1a. In addition to diffusing more slowly, many Myo1a molecules also exhibit near immobility. These results suggest that the motor/actin interaction may make an unexpected contribution to controlling the dynamics of Myo1a at the membrane/actin interface. Future experiments will focus on confirming these results and will examine how TH1 structure and membrane composition affect Myo1a mobility while bound to membrane.

#### **Myosin1B shapes Organelles and Plasma Membrane and pulls Membrane Tubules out of Giant Unilamellar Liposomes.**

*A. Yamada<sup>1</sup>, A. Mamane<sup>1</sup>, A. Di Cicco<sup>1</sup>, D. Lévy<sup>1</sup>, J-F. Joanny<sup>1</sup>, P. Bassereau<sup>1</sup>, E. Coudrier<sup>1</sup>; <sup>1</sup>Institut Curie/CNRS, Paris, France*

Microtubules and microtubule-associated motors (kinesins and dyneins) have a well-established role in controlling membrane shape of organelles. In contrast, the multiple roles played by the actin-associated motors (myosins) in the dynamics of intracellular membranes only begin to emerge. We have recently demonstrated that the motor activity of a myosin 1 (myosin 1b,

Myo1b) is required for the formation of tubular carriers at the Trans-Golgi Network (TGN) [1]. More recently using molecular biology, live cell imaging and biochemistry we observed that Myo1b motor activity controls filopodia formation at the plasma membrane upon EphB2 stimulation through the interaction with EphB2 receptor. Thus Myo1b may control membrane shape both in organelles and at plasma membrane. Myo1b is a vertebrate myosin-I isoform with a single-headed molecular motor. Its motor activity has been shown to display large force sensitivity [2], compatible with a control of the dynamic changes of membrane morphology by Myo1b. To further elucidate the mechanism by which Myo1b controls the membrane tubule formation, we develop an in vitro model membrane system composed of purified Myo1b bound to giant unilamellar vesicles (GUVs) containing phosphatidylinositol -4,5- biphosphate (PIP2), and actin-fascin bundles immobilized on a glass substrate. We demonstrate for the first time that Myo1b alone is able to pull membrane tubules out from a GUV along actin bundles, even though they are single-headed and non-processive. We successfully observe the dynamics of tubule elongation and estimate Myo1b density along membrane tubules. Additionally, Cryo-EM observations provide the first direct evidence at molecular resolution of the direct binding of Myo1b to PIP2 containing lipid bilayers. Based on our experimental observations and the known biophysical properties of the motor [2], we propose a physical model explaining myosin-induced membrane tubulation.

**Myosin 1b is required for amino acid transport in renal proximal tubule cells.**

S. Komaba<sup>1</sup>, A. Hishiya<sup>1</sup>, L. Coluccio<sup>1</sup>; <sup>1</sup>Boston Biomedical Research Institute, Watertown, MA

In the kidneys amino acids in the blood are filtered in glomeruli and reabsorbed by amino acid transporters in the microvilli-rich brush border membrane of proximal tubule (PT) epithelial cells. Recent studies demonstrated that renal amino acid transport is critically dependent on the membrane protein collectrin, which is homologous to the membrane anchor region of angiotensin-converting enzyme 2. In mice collectrin knock out decreases expression of multiple amino acid transporters including the SLC proteins B<sup>0</sup>AT1, SIT1, XT2 (B<sup>0</sup>AT3) and XT3, a family of sodium-dependent neutral amino acid transporters, and causes severe aminoaciduria. Myo1b is an actin- and membrane-associated molecular motor protein found in membrane protrusions such as lamellipodia, filopodia and ruffles and associated with intracellular organelles. In this study, we show that myo1b is localized in brush border membrane of PTs in murine kidney. Myo1b colocalizes with collectrin and B<sup>0</sup>AT1 in the apical microvilli of cultured PT cells. Localization of myo1b at the apical membrane requires both motor activity and phosphoinositide binding. Knock down of myo1b decreases collectrin and B<sup>0</sup>AT1 expression and reduces leucine transport mediated by collectrin-dependent B<sup>0</sup>AT1 in PT cells, while phosphate transport does not change. These results suggest that myo1b is critical for the association of collectrin and/or B<sup>0</sup>AT1 to the brush border membrane in PT cells.

**Characterization of myosin 1e function in maintaining cell junction integrity in the kidney.**

J. Bi<sup>1</sup>, S. E. Chase<sup>1</sup>, C. D. Pellenz<sup>1</sup>, A. S. Fanning<sup>2</sup>, M. Krendel<sup>1</sup>; <sup>1</sup>Cell and Developmental Biology, SUNY Upstate Medical University, Syracuse, NY, <sup>2</sup>Cell Biology and Physiology, University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC

Focal segmental glomerulosclerosis (FSGS) is a renal disorder that results in massive proteinuria and often progresses to end-stage kidney disease. Kidney visceral epithelial cells, also known as podocytes, are critical both to normal kidney function and the development of FSGS. Podocyte actin cytoskeleton and their highly specialized cell-cell junctions (also called slit diaphragm complexes) play key roles in controlling glomerular filtration.

Myosin 1e (myo1e) is an actin-based molecular motor that is expressed in renal glomeruli. Previous studies have identified two mutations in the MYO1E gene that are associated with childhood familial FSGS in humans (Mele et al., NEJM, 2011, and Sanna-Cherchi et al., Kidney Int., 2011). Our lab has also shown that disruption of the Myo1e gene in mice promotes podocyte injury and results in loss of the integrity of the glomerular filtration barrier (Chase et al., AJP Renal Physiol., 2012). Here we have used biochemical and microscopic approaches to characterize myo1e localization and protein-protein interactions in glomerular podocytes. Myo1e was consistently enriched in the slit diaphragm fraction during subcellular fractionation of renal glomeruli. Protein pulldown assays indicated that myo1e interacted with ZO-1, a tight junction protein and a component of the slit diaphragm, in vitro. Myo1e and ZO-1 were present in the areas of cell-cell contact in cultured kidney podocytes. Live cell imaging studies showed that myo1e was recruited to newly formed cell-cell junctions, where it colocalized with the actin filament bundles supporting nascent contacts. These findings suggest that myo1e represents a component of the slit diaphragm complex and may contribute to regulating junctional integrity in kidney podocytes.

189

**Functional role of specific regions of the tail domain of Myosin IIIA in actin bundle based motility.**

J. Gallagher<sup>1</sup>, O. Quintero<sup>2</sup>, M. Raval<sup>3</sup>, W. Unrath<sup>3</sup>, C. Yengo<sup>3</sup>; <sup>1</sup>Biology, Lincoln University, Lincoln University, PA, <sup>2</sup>University of Richmond, Richmond, VA, <sup>3</sup>Cellular and Molecular Physiology, Penn State College of Medicine, Hershey, PA

Myosin IIIA (MYO3A) is proposed to function as a transporter in parallel actin-bundle based structures such as the stereocilia of inner ear hair cells and calycal processes of photoreceptors. Interestingly, the tail region of MYO3A binds Espin 1, allowing for the transport of Espin 1 to the tips of actin protrusions. Since Espin 1 contains WH2 activity which is capable of enhancing filament elongation, the ability of MYO3A to transport and concentrate Espin 1 at the tips causes elongation of the actin protrusions. In the current study we focused on the regions of the tail domain of MYO3A that are important for its ability to move to the tips and generate actin protrusions in the absence of Espin 1. The domain structure of the MYO3A tail can be separated into 6 exons (30-35). Exon 35 contains the tail actin binding site which has been found to be critical for localization of MYO3A to the actin bundle protrusion tips. To determine if any other exon(s) (30-34) are necessary for allowing MYO3A to move to the tips of actin protrusions, we generated exon deletion constructs of GFP-tagged MYO3A and transfected them into COS7 cells. Removal of either exon 30 or 34 reduced but did not abolish MYO3A localization to filopodial tips. Interestingly, exon 30 contains a proposed calmodulin-binding IQ motif of unknown function. There are two other IQ motifs in MYO3A known to bind calmodulin and likely serve as the traditional lever arm in MYO3A. Therefore the IQ motif in

exon 30 and other regions of the tail may play a role in MYO3A based motility. Studies are ongoing examining density and length of filopodia to assess the role of specific MYO3A tail regions in generating and elongating actin protrusions.

190

**Protein Kinase A triggers Myosin Va-dependent melanosome transport.**

A. Oberhofer<sup>1</sup>, D. Zimmermann<sup>1</sup>, M. Schliwa<sup>2</sup>, Z. Ökten<sup>1</sup>; <sup>1</sup>Physik-Department E22, Technische Universität München, Garching, Germany, <sup>2</sup>Institut für Anatomie und Zellbiologie, Ludwig-Maximilians-Universität, München, Germany

Pigment-containing melanosomes are reversibly distributed throughout the cytoplasm of melanophores in lower vertebrates. During dispersion, melanosomes are transported via kinesin-2 towards the cell periphery, where Myosin Va takes over to finalize the delivery across the actin-meshwork. During aggregation, cytoplasmic dynein moves melanosomes back towards the cell center, a process during which Myosin Va function is dispensable. However, the molecular mechanisms of regulated employment of Myosin Va during melanosome transport are still unknown. To identify factors that directly regulate and control Myosin Va function, we reconstituted melanosome transport on actin filaments *in vitro*. Consistent with the *in vivo* observations, melanosomes purified from the aggregated cell state are largely dormant, while melanosomes from the dispersed cell state exhibit directed movement on actin filaments. We rescued this 'inactivity' of Myosin Va observed in aggregated melanophores either by adding cell extract from dispersed cells or exogenous Protein Kinase A (PKA) to the isolation procedure. A PKA-specific inhibitor prevented this rescue. Conversely, the addition of cell extract from aggregated cells significantly reduced the activity of melanosomes isolated from the dispersed state. These results point towards a regulation mechanism via activation and inactivation of Myosin Va with PKA acting as the master switch. Consistent with this notion, the protein content of the melanosome-associated beta-isoform of PKA (catalytic subunit) hardly differed between the aggregated and dispersed state. Thus, PKA is ideally suited to reversibly regulate the Myosin Va activity during dispersion and aggregation.

191

**Class V Myosins - The Promiscuous Actin Motors and their Rab Partners.**

A. J. Lindsay<sup>1,2</sup>, M. W. McCaffrey<sup>2</sup>, B. Goud<sup>1</sup>; <sup>1</sup>UMR144, Institut Curie, Paris, France, <sup>2</sup>Biochemistry, University College Cork, Cork, Ireland

Class V myosins are highly processive actin motors. Mammals have three isoforms that have been implicated in the transport of a diverse range of cargoes including mRNA, viruses, organelles, and cell surface receptors. How they are recruited to specific cargo is unclear, however it is emerging that Rab GTPases are likely to be involved. To date each myosin V isoform has been found to interact with Rab8, Rab10, and Rab11. However, to our knowledge, no class V myosin has been tested in a systematic screen of the entire Rab GTPase family. To this end we used a high throughput yeast two-hybrid "living chip" assay to test myosin Va for interactions with all human Rab GTPases. In addition to the previously identified partners, we observed interactions with several other Rabs that function in overlapping endocytic and secretory transport pathways. These interactions have been confirmed biochemically and we demonstrate that myosin Va has three distinct Rab binding domains. Using site-directed mutagenesis we generated mutants that abolish individual Rab interactions and we show that, depending on the splice-isoform, Rab10 or Rab11 recruits calcium-activated myosin Va to membranes. A pool of myosin Va associates with each Rab-positive compartment. We provide evidence that in non-specialised cells myosin Va is unlikely to play a role in the trafficking of bulk cargoes, but rather acts as a dynamic tether. Our results indicate that myosin Va is a major

regulator of the topology of membrane compartments belonging to the endocytic recycling and post-Golgi secretory systems.

192

**A mitotic checkpoint protein regulates the dissociation of myosin V from its cargo.**

R. G. Yau<sup>1</sup>, Y. Peng<sup>2</sup>, R. Valiathan<sup>3</sup>, S. Birkeland<sup>4</sup>, T. E. Wilson<sup>4</sup>, L. S. Weisman<sup>5</sup>; <sup>1</sup>Cellular and Molecular Biology, University of Michigan- Ann Arbor, Ann Arbor, MI, <sup>2</sup>Department of Molecular & Cell Biology, University of California- Berkeley, Berkeley, CA, <sup>3</sup>Department of Pathology, Wayne State University, Detroit, MI, <sup>4</sup>Department of Pathology, University of Michigan- Ann Arbor, Ann Arbor, MI, <sup>5</sup>Life Sciences Institute, University of Michigan- Ann Arbor, Ann Arbor, MI

Myosin V motors, present in virtually all eukaryotic organisms, are critical for cellular differentiation, organization and function. Myosin V based transport initiates with the regulated attachment of myosin V to its cargo via cargo specific adaptors. After transport, the regulated detachment from myosin V deposits cargoes at their destinations. Insight into the regulated detachment of cargoes was revealed in studies of *Xenopus laevis* melanophores where in coordination with the cell cycle, phosphorylation of myosin V triggers the detachment of melanosomes<sup>1</sup>.

In *Saccharomyces cerevisiae*, in coordination with the cell cycle, the myosin V motor, Myo2, transports the vacuole. Transport terminates after the vacuole reaches the bud. Vac17, the vacuole specific adaptor for Myo2, contains a PEST sequence that is required for the degradation of Vac17 and the termination of vacuole transport<sup>2</sup>. We sought to determine the mechanisms that regulate the detachment of the vacuole from Myo2.

In random mutagenesis and alanine screens, we identified specific Vac17 residues critical for the detachment of the vacuole from Myo2. Notably, all residues identified were within the PEST sequence. Using phospho-specific antibodies, we show that one of these residues, Thr240, is phosphorylated *in vivo*. In an EMS mutagenesis screen we identified the spindle position checkpoint/E3 ubiquitin ligase Dma1 as a novel regulator of the detachment of the vacuole from Myo2. Interestingly, Dma1 binds directly to Vac17-phospho-Thr240 but not to *vac17-T240A*. Moreover, Dma1 colocalizes with Vac17 at the bud tip, the site where vacuole transport terminates. We generated an enzymatically inactive mutant, *dma1-I329R*, and found that Dma1 dependent ubiquitylation is required for the detachment of the vacuole from Myo2 and for the subsequent degradation of Vac17 via the proteasome.

Regulated Vac17 phosphorylation likely ensures that Dma1 recruitment and thus the termination of vacuole transport does not occur until the vacuole reaches its destination. As a checkpoint protein, Dma1 regulates mitotic exit and cytokinesis; thus, it is tempting to speculate that Dma1 terminates vacuole movement in coordination with other events that occur late in the cell cycle.

**Autophagy-receptors link myosin VI to autophagosomes to mediate Tom1-dependent autophagosome maturation and fusion with the lysosome.**

D. A. Tumbarello<sup>1</sup>, B. J. Waxse<sup>1</sup>, S. D. Arden<sup>1</sup>, N. A. Bright<sup>1</sup>, J. Kendrick-Jones<sup>2</sup>, F. Buss<sup>1</sup>;

<sup>1</sup>Cambridge Institute for Medical Research, University of Cambridge, Cambridge, England,

<sup>2</sup>Laboratory of Molecular Biology, Cambridge, England

Autophagy is both a crucial regulator of cell homeostasis during times of starvation and a specialised pathway for the targeted degradation of protein aggregates, damaged organelles, and pathogens. During selective autophagy, ubiquitinated cargo is recognized by autophagy receptors. These receptors contain both ubiquitin recognition motifs and interaction domains for the autophagy-related protein, LC3, thus linking autophagic membranes to ubiquitinated cargo in order to form autophagosomes. Following biogenesis, maturation leaves autophagosomes competent for fusion with the lysosome, thus facilitating subsequent cargo degradation and recycling. We have found that the unique minus-end directed motor protein, myosin VI, is required for autophagosome maturation and fusion with the lysosome. The disparate cellular functions of myosin VI are mediated by interactions with distinct binding partners that recruit myosin VI to different intracellular compartments. The ESCRT-0 protein Tom1 is a novel myosin VI adaptor protein in mammalian cells that is involved in targeting of myosin VI to early endosomes. The loss of either myosin VI or Tom1 reduces delivery of endocytic cargo to autophagosomes, thereby preventing autophagosome maturation and autophagosome-lysosome fusion. Indeed, without myosin VI, ubiquitinated protein aggregates – such as mutant huntingtin protein containing a pathological polyQ expansion – are not properly degraded and instead accumulate. Myosin VI targets to autophagosomes via the RRL motif in its cargo-binding tail domain, which is known to mediate direct interaction with the autophagy receptors T6BP, NDP52, and optineurin. Therefore, we postulate that myosin VI and Tom1 are required for endosome delivery to autophagosomes via docking to optineurin, NDP52 or T6BP. Thus our data provides insights into the mechanisms and proteins required for autophagosome maturation and their fusion with the lysosome. These studies contribute to a further understanding of the unique functions of the minus-end directed myosin VI.

194

**Myosin 7a Binding Protein.**

V. Siththanandan<sup>1</sup>, Y. Yang<sup>1</sup>, F. Zhang<sup>1</sup>, A. Hong<sup>1</sup>, N. Billington<sup>1</sup>, X. Wu<sup>1</sup>, J. R. Sellers<sup>1</sup>; <sup>1</sup>NHLBI, NIH, Bethesda, MD

*Drosophila* myosin 7a (Dm7a) is an unconventional myosin that is essential for the maintenance of bristle structure in Johnston's organ (the auditory center in *Drosophila*) as well as the morphology of the fly's thorax bristles. Dm7a has previously been shown to auto-regulate its ATPase activity via a MyTH7 domain, present at the C-terminus of the myosin tail. A yeast-2-hybrid screen, using the MyTH7 as bait, yielded positive colonies for a protein we call M7BP (myosin 7a binding protein). The N-terminus of M7BP (residues 1~160) is a potential Rab-binding domain, and the C-terminus (residues 550~938), termed the myosin-binding domain (MBD), interacts with Dm7a via the MyTH7 at the C-terminus. M7BP activated the ATPase of Dm7a at low actin concentration, and the approximate affinity between the two proteins was 0.8  $\mu$ M. While purified M7BP is monomeric (based on cross-linking, analytical-centrifugation, and EM studies), when mCherry-M7BP is transfected into S2 cells along with GFP-Dm7a, it appears to facilitate oligomerization of the myosin inferred from the co-localized migration of the two fluorescent proteins to the tips of filopodia. Filopodia were observed in approximately half of the

cells co-transfected with mCherry-M7BP and GFP-Dm7a, which is similar to the effect seen with transfections using artificially zippered GFP-HMM constructs of Dm7a. Conversely, single transfections of either GFP-Dm7a or mCherry-M7BP alone do not cause filopodial formation, and transfections using truncated GFP-Dm7a (i.e. missing the C-terminal MyTH7) or truncated mCherry-M7BP (i.e. only the MBD) yields a small population (>20%) of cells with filopodia. In the latter cases we believe the myosin is activated, but still unable to oligomerize. IP experiments from fly lysates show M7BP binds at least four different Rabs (4, 5, 8, 11), and therefore in vivo oligomerization of Dm7a likely involves endogenous Rabs in S2 cells that induce a tripartite protein formation. To investigate the role of Dm7a in the fly, we over-expressed GFP-Dm7a in the *Drosophila* larval hemocytes using the UAS/GAL4 system and show that it induces the formation of filopodia in the hemocytes. Dm7a is localized to the tips of the filopodia. The hemocytes of Dm7a mutant flies show defective phagocytosis of *E. Coli*. Additionally, we conducted a lethality assay by challenging the larvae with bacteria and show that 21% of wild-type larvae eclosed into adult flies and less than 10% of Dm7a mutant larvae eclosed. This suggests that the failure of Dm7a hemocytes to phagocytose invading pathogens compromised the defense mechanism of the flies.

195

#### **Characterization of *Drosophila* myosin 7a and M7BP in the eyes.**

A. Hong<sup>1</sup>, J. R. Sellers<sup>1</sup>; <sup>1</sup>Laboratory of Molecular Physiology, NHLBI, National Institutes of Health, Bethesda, MD

Mutations in crinkled (*ck*), the *Drosophila* ortholog of myosin 7a (Dm7a) caused deafness in flies due to a disorganization of Johnston's organ, which is its auditory system and abnormal bristle structures on the thorax. Both of these structures are formed by bundled arrays of actin. We have identified a binding partner of Dm7a using the MyTH7 as a bait in a yeast two hybrid system and it is named Myosin 7a Binding Protein (M7BP). M7BP protein has a potential Rab-binding domain in the N-terminus and immunoprecipitation experiments using M7BP antibody pulled down some *Drosophila* Rab proteins (Rab 4, 5, 8 and 11). We show that Dm7a, M7BP and Rab11 are expressed in the larval eye disc in the lens-secreting cone cells. Electron microscopy sections of the adult eyes of Dm7a mutants showed missing pigment granules around the primary pigment cells and at the base of the rhabdomeres of the photoreceptor cells. Scanning electron microscopy displayed abnormal bristles in the adult eyes. We are presently characterizing a P-element insertion line of M7BP. These flies also showed anomalies in the bristles in the adult eyes. We are performing excision mutagenesis to isolate more M7BP mutants.

196

#### **Loss of Myosin VIIA alters epidermal actin protrusions in developing *Drosophila* embryos.**

J. L. Sallee<sup>1</sup>, D. P. Kiehart<sup>1</sup>; <sup>1</sup>Biology, Duke University, Durham, NC

Myosin VIIA (MyoVIIA) is an actin based motor protein conserved in mammals and flies, and mutations in both species cause hearing loss due to defects in stereocilia or the Johnston's organ, respectively. In *Drosophila melanogaster* severe mutations in MyoVIIA are lethal or "semi-lethal" with only a very small percentage of flies surviving to adulthood. Those that survive show defects related to actin bundling in hair and bristle morphology, are deaf, and do not survive for long. In this study, we examined the function of crinkled (*ck*), the fly homolog of MyoVIIA, in embryogenesis. All embryos lacking maternal and zygotic *ck/MyoVIIA* display defects in denticle formation, the hair like growths on the ventral epidermal cells. The mutant denticle rows are disorganized with denticles displaying a variety of phenotypes including loss of

polarity, a smaller than normal size, and a branched morphology, apparently due to a failure of actin filament bundling. We used *ck/MyoVIIA* C-terminal tail truncation mutants to investigate which of its domain(s) contribute to denticle formation (Singh 2012 Duke University Ph.D Diss.) and the data suggest that the Myth4FERM domains are important for proper denticle morphology. In addition, we investigated genetic interactions of MyoVIIA with the family of ZPD proteins, another family of proteins known to affect denticle morphology. This study suggests *ck/MyoVIIA* is necessary for actin appendage formation in developing embryos, but the detailed molecular mechanisms which produce this biological effect are not yet clear (Supported by GM33830 and DC007673 to DPK and GM093592 to JLS).

#### **Mechanistic study of myosin X for filopodial formation.**

Q. Lu<sup>1</sup>, J. Yan<sup>1</sup>, Z. Wei<sup>1</sup>, J. Yu<sup>1</sup>, F. Ye<sup>1</sup>, M. Zhang<sup>1</sup>;

<sup>1</sup>Division of Life Science, Hong Kong University of Science and Technology, Hong Kong, China

Myosin X, as an unconventional myosin, is best known for its filopodial tip localization and filopodia induction activity. Myosin X is involved in a series of physiology process, including cell migration, cell adhesion, phagocytosis and even essential for developmental procedures with neuronal axon guidance and blood vessel formation. A lot of studies were done but it is still vague that how myosin X promote filopodia formation through several potential mechanisms, including regulating motor activity, inducing dimerization, transporting filopodial-formation related proteins or activated by extracellular signaling. Here through structural and biochemical study, at the cellular level, we provide crucial evidence to reveal the detailed mechanism about how different domains of myosin X contribute to its filopodia tip localization and induction activity. We show that coiled coil region of myosin X folds into a novel antiparallel structure and essential for its walking along filopodia. And myosin X split PH1-PH2 tandem at the tail region function as a specific and acute cellular PI(3,4,5)P3 sensor. The C-terminal MyTH4-FERM tandem can form complex with the DCC P3 domain and is required for filopodia induction. Here we proposed a model that, after activation by the guidance cues, myosin X is recruited to membrane and restricted to the filopodia tip by its different tail regions interacting distinctly with membrane receptor and specific lipid components.

198

#### **Evolution of MyTH/FERM Myosins.**

H. V. Goodson<sup>1</sup>, M. A. Titus<sup>2</sup>; <sup>1</sup>Chemistry and Biochemistry, U. Notre Dame, Notre Dame, IN,

<sup>2</sup>Genetics, Cell Biology & Development, U. Minnesota, Minneapolis, MN

Myosins are a highly diverse family of actin-based motors present in almost every eukaryote. A subgroup of these myosins is characterized by the presence of one or two adjacent MyTH (myosin tail homology 4)/FERM (band 4.1, ezrin, radixin, moesin) domains in their C-terminal tail regions. A M7-like MF myosin is also present in Amoebozoa but it was initially designated as an orphan and then subsequently as M22 (Kollmar & Odronitz, 2007; CyMoBase.org). The Metazoan class 7, 10 and 15 MF myosins have roles in regulating the growth of parallel actin bundles such as filopodia (M10) and stereocilia (M7, M15), as does the *Dictyostelium* M7-like MF myosin that is essential for filopod extension. These common functions of amoeboid and metazoan MF myosins as well as the availability of additional amoeboid MF myosin sequences prompted a comprehensive phylogenetic analysis of the MF myosins to reinvestigate the classification of amoeboid MF myosins and gain better insight into the evolutionary relationship between known MF myosins.

A complete collection of MF myosin sequences from a set of diverse organisms was obtained from CyMoBase.org (Odrionitz & Kollmar, 2007), aligned using MUSCLE and/or PROMALS 3D. The motor and C-terminal MF domain sequences were extracted, re-aligned and then separate phylogenetic trees generated for both domains using a variety of programs including ClustalX, FastTree and MrBayes. The initial analysis suggests that the last common ancestor of Amoebozoa and Metazoa had an M7-like MF myosin with a tail domain containing two MF domains separated by an SH3 domain. The family of M7-related proteins then underwent a dramatic expansion in the lineage leading to animals, with early gene duplications generating an M22/M10 branch as well as an M15/12/35 branch. The existence of an M22-like protein in some basal fungi, e.g. *Gonapodya*, suggests that the earliest of the gene duplications resulted in the M22 subfamily. This analysis reveals that the MF-containing myosins could be considered collectively as an M7 supergroup, perhaps analogous to M1 class that contains several divergent subgroups.

*This work was supported by grants from the NSF (HVG, MAT) and NIH (MAT). Many thanks to the CyMoBase team for generating and maintaining their superb sequence database.*

199

**Characterization of full-length mammalian myosin-18A.**

*N. Billington<sup>1</sup>, S. Guzik-Lendrum<sup>1</sup>, S. Heissler<sup>1</sup>, Y. Takagi<sup>1</sup>, Y. Yang<sup>1</sup>, E. Homsher<sup>2</sup>, P. J. Knight<sup>3</sup>, J. R. Sellers<sup>1</sup>; <sup>1</sup>NHLBI, NIH, Bethesda, MD, <sup>2</sup>CHS, UCLA, Los Angeles, CA, <sup>3</sup>University of Leeds, Leeds, United Kingdom*

Class 18 myosins share a close phylogenetic relationship with the well-characterized class 2 myosins. They have been demonstrated to play roles in cytoskeletal maintenance, control of Golgi morphology and stromal cell differentiation. We purified recombinant full-length, HMM, and S1-like mammalian myosin-18A using baculoviral/Sf9 expression. Expressed myosin-18A heavy chain was shown to bind co-expressed Essential light chain (ELC) and Regulatory light chain (RLC), similar to the behavior of conventional class 2 myosins. EM and analytical ultracentrifugation of full-length myosin-18A reveal a two-headed structure at high salt, reminiscent of myosin-2, and a four-headed antiparallel structure at physiological salt concentrations. Despite the presence of a long coiled-coil and in contrast to the class 2 myosins, myosin-18A did not form filaments, even at very low ionic strength or when the RLC was phosphorylated. Binding of myosin-18A to actin was shown to be weak in both the absence and presence of ATP. Myosin-18A bound ATP and ADP weakly and did not show any activation of its very low basal ATPase rate by actin even when the RLC was phosphorylated. Homology modelling of its structure is consistent with this myosin lacking conserved amino acids known to participate in the catalysis of ATP hydrolysis. Myosin-18A was unable to translocate actin filaments in actin gliding assays and no powerstroke was observed in single molecule optical trapping experiments. An interaction with nonmuscle myosin-2 was demonstrated in vitro suggesting a possible means by which a myosin with little or no inherent motor activity may play a role in modulating cytoskeletal morphology.

**Emergent behavior in nano-patterned groups of myosin motors.**

R. F. Hariadi<sup>1</sup>, M. Cale<sup>2</sup>, S. Sivaramakrishnan<sup>1,2,3</sup>; <sup>1</sup>Cell and Developmental Biology, University of Michigan, Ann Arbor, MI, <sup>2</sup>Biophysics, University of Michigan, Ann Arbor, MI, <sup>3</sup>Dept of Biomedical Engineering, University of Michigan, Ann Arbor, MI

Unconventional myosin function in a cellular process emerges from the interaction of multiple myosins on an organelle scaffold with several spatially patterned actin filaments. Currently, the role of myosins in a cellular process is inferred from the effects of disruption of myosin function using chemical or genetic approaches. In contrast, single molecule studies over the last decade have focused almost exclusively on understanding single actin-myosin interactions. To bridge this gap between single molecule and cellular function, modular well-defined assays are necessary, wherein the number, type and spatial distribution of actin-myosin interactions can be engineered. We have developed an assay platform that combines the polarized actin network derived from a fish epidermal keratocyte with DNA nano-structures engineered with precise number and spatial configuration of myosins. Here, we report on the emergent behavior of nano-structures patterned with myosin V and VI. Nano-structures with myosin V move towards the cell periphery whereas those with myosin VI moves towards the cell center. Run length increases with motor number to spans the width of the keratocytes ( $n \geq 4$ ). Movement speed for nano-structures with multiple myosins of the same type does not depend on motor number. Surprisingly, while most myosin VI trajectories (~ 90%) are linear, a substantial fraction (~ 35%) of myosin V trajectories are highly skewed with fraction of skewed trajectories increasing with motor number. Therefore, myosin VI appears well suited to bring about linear-directed endocytic transport, whereas myosin V is tuned for dispersion of exocytic vesicles. For nano-structures with equal number of myosin V and VI, both directions of movement are equally favored (53% myosin V, 47% myosin VI). The run length of the nano-structures increases with motor number, regardless of motor type. Our results differ from findings for single filaments (79% myosin V), emphasizing the importance of actin architecture in myosin behavior. For nano-structures with both myosin V and VI, majority (> 95%) of trajectories are unidirectional, unlike bi-directional movement driven by a combination of kinesin and dynein. In an assembly with asymmetric motor composition, the net flux of trajectories is highly sensitive to the relative number of myosin V and myosin VI. This sensitivity represents a potential avenue for regulating net flux of vesicle movement *in vivo*. To understand the molecular basis for emergent behavior, we performed sensitivity analyses in stochastic simulations of nano-structure movement. Current efforts are focused on manipulating emergent behavior in our assays, based on key parameters identified from simulations, in order to extend our insights into myosin function *in vivo*.

**Kinesins**

201

**A spatial sensor of kinesin activity reveals conformational changes in KIF17 induced by EB1.**

C. Espenel<sup>1</sup>, G. Kreitzer<sup>1</sup>; <sup>1</sup>Cell and Developmental Biology, Weill Medical College of Cornell University, New York, NY

Kinesin family motors (KIFs) are versatile microtubule stimulated ATPases that perform functions contributing to establishment and maintenance of cell architecture, cell motility and cell division. To act appropriately during these processes, kinesin activity must be regulated in space and time. Little is known about how regulation is achieved but members of kinesin 1, 2, 3

and 7 families are known to adopt compact and extended conformations that reflect autoinhibited and active states, respectively. We designed intramolecular conformation sensors encoding kinesins tagged with fluorescent proteins at their N- and C-termini. We used Förster resonance energy transfer and fluorescence lifetime imaging microscopy to directly monitor biosensors in compact and extended conformations in single cells with minimal experimental manipulation. Lifetime data was mapped on a simple graphical polar plot (the “phasor” plot) allowing us to resolve the positions and relative populations of active and inactive motors in fixed or live cells. In addition to enhanced spatial resolution garnered by this method, FRET-FLIM is also advantageous in that large data sets can be analyzed rapidly, accurately and reproducibly. We validate this approach in MDCK epithelial cells expressing biosensors of KIF17, a homodimeric kinesin-2 family member involved in MT stabilization in epithelial cells. Expression of the KIF17 biosensors resulted in MT stabilization, demonstrating they function as expected. At steady state ~30% of KIF17 is in an extended, active conformation in cells. The majority of active KIF17 localizes near the cell cortex and resides on nocodazole-resistant, stable MTs. Co-expression of EB1, which interacts with the KIF17 motor domain, induces a MT-dependent increase of KIF17 in the extended, active conformation in cells. Unexpectedly, we found EB1 was not necessary for MT stabilization by KIF17. Together, our data suggest a model in which EB1 helps maintain KIF17 in an active conformation at MT plus-ends, possibly to direct local MT stabilization.

#### **A role for kinesin-1 in phagosome transport in the RPE.**

*M. Jiang<sup>1</sup>, T. Diemer<sup>1</sup>, V. Lopes<sup>1</sup>, D. S. Williams<sup>1</sup>; <sup>1</sup>Departments of Ophthalmology and Neurobiology, Jules Stein Eye Institute, Los Angeles, CA*

Retinal pigment epithelial (RPE) cells are professional phagocytes. Each day they phagocytose the tips of the photoreceptor outer segments, as part of the turnover of these phototransductive disk membranes. Phagosomes are then transported towards the basal region of the RPE cells, where they are degraded, following fusion with lysosomes. We have been studying the roles of molecular motors in delivering RPE phagosomes to lysosomes. Here, we report our findings on the role of conventional kinesin, kinesin-1, and its coordination with the unconventional myosin, myosin-7a. First, we observed that myosin-7a and kinesin-1 associated with phagosomes, with preferences towards less mature and more mature phagosomes, respectively. These associations were observed in fixed cells and by live-cell tracking of phagosomes in cells expressing fluorescently-tagged motors. Second, using RPE cells from mutant mice, we found that normal phagosome motility and digestion is impaired in cells lacking kinesin-1 function. Our results support a relay model whereby kinesin-1 takes delivery of phagosomes from myosin-7a, in the apical RPE, and then transports them in a basal direction towards the primary lysosomes.

203

#### **Motility by the chromokinesin NOD contributes to production of the polar ejection force.**

*A. A. Ye<sup>1,2</sup>, S. Cane<sup>1,2</sup>, S. J. Luxs-Morgan<sup>1</sup>, T. J. Maresca<sup>1,2</sup>; <sup>1</sup>Biology Department, University of Massachusetts, Amherst, MA, <sup>2</sup>Molecular and Cellular Biology Graduate Program, University of Massachusetts, Amherst, MA*

Polar ejection forces (PEFs), which push chromosomes away from spindle poles, are primarily generated by kinesin-10 family chromokinesins. Vertebrate kinesin-10 motors produce PEFs by walking chromosomes towards the spindle equator via plus-end directed motility. Although PEFs are also present in *D. melanogaster*, it is uncertain how the *Drosophila* kinesin-10 motor NOD produces force. NOD is classified as a non-motile kinesin and is believed to generate

PEFs by end-tracking on polymerizing microtubules. Here we demonstrate that two types of chromosome-microtubule interactions contribute to PEF production by NOD. Elevated PEFs stretched NOD-coated mitotic chromatin through both lateral and end-on interactions with microtubules. NOD mutants engineered to have either plus-end directed motility or tip-tracking activity generated PEFs albeit with less efficiency than the wild-type protein, suggesting that NOD could possess both activities. Remarkably, NOD exhibited motility in microtubule gliding assays. Our findings support the hypothesis that NOD end-tracks and demonstrate, for the first time, that NOD is a motile kinesin.

204

**Molecular Motor Kid Plays a Role in Focal Adhesion Localization and Protein Synthesis.**

*L. Xu<sup>1</sup>, K. Bartolf<sup>2</sup>, W. Saunders<sup>1</sup>; <sup>1</sup>Department of Biological Sciences, University of Pittsburgh, Pittsburgh, PA, <sup>2</sup>Department of Biology, Massachusetts Institute of Technology, Cambridge, MA*

During mitosis in eukaryotes, the microtubule-based spindle assembles with the aid of the kinesin superfamily proteins (also known as KIFs). A typical KIF contains a motor domain, which binds to the microtubule, and a stalk and tail domain, which uses energy from ATP hydrolysis to drive conformational changes that generate the motile force used for cargo transport.

The two motor proteins we focus on in our lab are Eg5/KIF11/Kinesin-5 and Kid/KIF22/Kinesin-10. They both interact with microtubules and play critical roles in spindle assembly and chromosome alignment during mitosis. Eg5 is a plus-end-directed motor which helps slide anti-parallel microtubules apart. Kid is a plus-end-directed chromokinesin (chromosome arm-localization kinesin) which binds to both the chromosome and the microtubule. It contributes to the polar ejection force that pushes chromosomes away from the spindle pole. Previous studies focused on the roles of Eg5 and Kid in mitosis. However, our lab recently identified an unexpected role Eg5 plays during interphase. Loss of Eg5 led to a decrease in new protein synthesis and an increase in free ribosomes, suggesting that Eg5 may have a function facilitating protein synthesis.

On the other hand, our preliminary data for Kid suggested a potential role for Kid as an inhibitor for protein synthesis. Like Eg5, Kid was also shown to associate with ribosomes, but loss of Kid led to a general increase in protein translation. More specifically, Kid might be involved in regulating localized translation at sites of focal adhesions. First, Kid colocalized with focal adhesions by immunofluorescence. Secondly, knockdown of Kid resulted in a change in the number and distribution of focal adhesions. After knockdown of Kid in HeLa or NIH-3T3 cells, the number of focal adhesions increased and the sites of focal adhesions became more scattered throughout the cytoplasm. Finally, such changes in the distribution of focal adhesions appear to have an effect on cell adhesion as cells became less adherent. Altogether, these results suggest that Kid might play a novel role in translational regulation at focal adhesions.

205

**Eg5 functions as a brake during anaphase B pole-pole separation in mammalian cells.**

*E. S. Collins<sup>1</sup>, W-L. Lee<sup>1</sup>, P. Wadsworth<sup>1</sup>; <sup>1</sup>Biology, UMass-Amherst, Amherst, MA*

Our previous work showed that mitotic spindles in LLC-Pk1 epithelial cells frequently move along the long axis of the cell resulting in displacement of the metaphase spindle away from the geometrical center of the cell. Differential pole movement in anaphase B corrects spindle mispositioning, resulting in approximately equal sized daughter cells. The minus end-directed motor, dynein and its activator, dynactin, are localized to the cell cortex during anaphase and

are required for pole-pole separation during anaphase B. Here, we examine the role of the plus-end directed kinesin-5, Eg5, in spindle pole separation. Eg5, which is required for centrosome separation during spindle formation, is localized to the spindle throughout mitosis, but its role in spindle pole separation in mammalian cells remains unclear. To address this, we first verified that inter-polar microtubules overlap in the spindle midzone, using cells expressing EB1-GFP to track dynamic plus-ends. We next characterized the localization of Eg5 during anaphase in cells expressing localization and affinity purification (LAP)-tagged Eg5 from a bacterial artificial chromosome under the control of the endogenous promoter. LAP-Eg5 localized to midzone microtubules throughout anaphase, and was lost from the midzone upon treatment with the Eg5 inhibitor, S-Trityl-L-cysteine (STLC). To determine the contribution of Eg5 to anaphase B, we tracked pole movements in cells expressing GFP- $\gamma$ -tubulin using multidimensional motion analysis. We show that spindle pole separation in anaphase B is characterized by an initial rapid separation followed by a secondary slow phase of separation. Addition of STLC prior to anaphase onset resulted in a faster initial pole-pole separation (from 0.03  $\mu\text{m}/\text{min}$  to 0.06  $\mu\text{m}/\text{min}$ ). This is consistent with Eg5 having a role as a “brake” during spindle pole separation during anaphase in mammalian cells.

206

**Heterotrimeric kinesin 2-dependent transport localizes odor receptors to the ciliary outer segment in adult *Drosophila*.**

A. Jain<sup>1</sup>, S. C. Jana<sup>1</sup>, K. Bobra<sup>1</sup>, K. Ray<sup>1</sup>; <sup>1</sup>Dept of biological sciences, Tata Institute of Fundamental research, Mumbai, India

Sensilla on the third antennal segment of *Drosophila* are innervated with three different types of odor sensing neurons (OSNs), expressing three morphologically distinct cilia. Each of them displays a specific set of olfactory receptors (ORs). How these ORs reach the ciliary outer segment is unclear. We have earlier shown that the *Drosophila* olfactory cilia are formed during the pupal stages and this process requires the heterotrimeric kinesin-2, comprising the motor subunits, KLP64D and KLP68D, and a non-motor accessory protein, DmKAP. Here, we present the results of an extensive genetic and developmental analysis of OR localization to the ciliary outer segments in pupae and adults. We found that the ciliary entry of a recombinant odor coreceptor, OR83::GFP, is developmentally restricted. In addition, increasing amounts of the OR83b::GFP and OR47b::GFP accumulates in the cilia with aging. A set of viable Klp64D mutants, which are found to affect the kinesin-2 entry into the cilia, selectively in adult stages, reduce the OR::GFP localizations in the adult cilia. The olfactory cilia, however, grow to the standard sizes and both the membrane and tubulin contents of the cilia remain unaltered in these mutants. Together, these observations indicate that a separate olfactory receptor transport by the heterotrimeric kinesin-2 maintains the sensory function in the adult, and provide a paradigm for future exploration of the mechanism of sensory maturation and plasticity.

207

**StARD9 is a Novel Transmembrane Kinesin Implicated in the Dynamics of Lysosomal Membranes Containing NPC1 and Cholesterol.**

A. M. Brumfield<sup>1</sup>, K. L. Huegel<sup>1</sup>, P. S. Vaughan<sup>1</sup>, K. T. Vaughan<sup>1</sup>; <sup>1</sup>Biological Sciences, University of Notre Dame, Notre Dame, IN

Niemann Pick-Type C (NPC) is a rare neurodegenerative disease induced by mutations in either the NPC1 or NPC2 genes. 95% of NPC patients suffer from mutations in NPC1, a multi-pass transmembrane protein shown recently to bind cholesterol (Infante et al., 2010). While defects in cholesterol transport are recognized in NPC disease, the contributions of NPC1

cholesterol binding is not understood completely. Live-cell imaging of membranes containing NPC1 reveals that, in contrast to wild-type NPC1, mutant NPC1 membranes fail to project dynamic tubular NPC1 membranes. This suggests that membrane tubulation is a critical aspect of cholesterol transport and proteins responsible for tubulation are targets for therapeutic intervention. Mass spectrometry analysis of wild-type NPC1 and mutant NPC1 membranes isolated from the NPC24 human patient cell line was used to identify protein composition differences. The novel protein StARD9 was present in wild type membranes but absent in NPC1 mutant membranes. Sequence analysis of StARD9 reveals that the 4700 amino acid protein contains a N-terminal kinesin-like motor domain, a C-terminal START lipid binding domain, and transmembrane segments. These features suggest STARD9 is a membrane protein with cytoplasmic microtubule motor activity. Upon shRNA depletion of StARD9 activity, a five-fold decrease in membrane tubulation from NPC1 lysosomal membranes relative to untransfected cells was observed. Additionally, accumulations of cholesterol that mimic NPC disease are observed when StARD9 is depleted. These preliminary studies suggest that STARD9 is an essential membrane-associated motor protein required for tubulation of lysosomal membranes, allowing for stimulation of cholesterol efflux. To analyze full and partial length StARD9 constructs, we completed cDNA cloning of the full 4700 amino acid protein. The N-terminal kinesin motor domain, but not a p-loop motor domain mutant, labeled microtubules consistent with other kinesins. Intermediate constructs encoding the motor domain and initial transmembrane segments displayed punctate microtubule labeling, which became more robust as the C-terminus was further extended. The full length construct displayed labeling of both membranous organelles and microtubules. Membranes containing full length StARD9 and stained with LysoTracker confirmed an accumulation in lysosomes. These findings suggest StARD9 is a lysosomal transmembrane protein containing an N-terminal kinesin motor domain. We propose that StARD9 is a membrane protein responsible for driving dynamics of membranes containing NPC1.

208

#### **Modulation of ERRA Nuclear Localization and Function by KIF17.**

*P. Seneviratne<sup>1</sup>, Z. Turan<sup>1</sup>, F. Jaulin<sup>1</sup>, A. Lemant<sup>2</sup>, P. Lecine<sup>2</sup>, G. Kreitzer<sup>1</sup>; <sup>1</sup>Department of Cell and Developmental Biology, Weill Medical College, Cornell University, New York, NY, <sup>2</sup>Centre de Recherche en Cancérologie de Marseille, Inserm, Marseille, France*

Kinesins are microtubule stimulated ATPases that transport a variety of cellular cargoes. Among the kinesins, KIF17 belongs to the kinesin 2 family and is a plus-end directed motor that participates in MT stabilization and polarization of epithelial cells. In a yeast-2-hybrid screen for additional factors that might contribute to its role in MT stabilization, we identified estrogen related receptor alpha (ERRA) as a novel KIF17 interacting protein. ERRA is a ligand-independent, orphan nuclear receptor that modulates cellular responses to estrogen by competing with estrogen receptor for binding to regulatory cofactors and estrogen response elements (ERRE) on target DNA. The testis-specific KIF17 isoform was shown previously to play a role in nucleo-cytoplasmic shuttling of ACT (activator of CREM mediated transcription). As such, we hypothesized that in epithelial cells, KIF17 could modulate ERRA activity by controlling its sub-cellular distribution and interaction with promoter elements on target genes. Therefore, after confirming KIF17 and ERRA interact in cells, we tested if KIF17 plays a role in regulating the localization and function of ERRA in breast epithelial cells. To do this, we injected cells with cDNAs encoding GFP-ERRA and monitored the localization of newly synthesized ERRA by time-lapse microscopy. In control cells, GFP-ERRA accumulated in nuclei by 4h after cDNA injection. Interestingly, in cells co-expressing the KIF17-tail domain, translocation of ERRA from the cytoplasm to the nucleus was attenuated 40%. We then tested whether

inhibition of ERRA nuclear localization by the KIF17 mutant also affected ERRA activity in cells. In luciferase reporter assays, expression of mutant KIF17 reduced binding of ERRA to ERRE suggesting inhibition of ERRA nuclear transport by KIF17 can alter transcriptional activity of this orphan receptor in breast epithelial cells. Collectively, these data show that KIF17 interacts with ERRA and can modulate ERRA localization and activity in epithelial cells. These results also suggest that targeted inhibition of ERRA localization could serve as a novel strategy for breast cancer treatment.

209

**Molecular motor KIF5A is essential for GABA<sub>A</sub> receptor transport to the neuronal surface and is involved in inhibitory neural transmission.**

*K. Nakajima<sup>1</sup>, X. Yin<sup>1</sup>, Y. Takei<sup>1</sup>, D-H. Seog<sup>2</sup>, N. Homma<sup>1</sup>, N. Hirokawa<sup>1,3</sup>; <sup>1</sup>University of Tokyo, Hongo, Tokyo, Japan, <sup>2</sup>Inje University, Busan, Korea, <sup>3</sup>King Abdulaziz University, Jeddah, Saudi Arabia*

KIF5 (also known as kinesin-1) family members, consisting of KIF5A, 5B and 5C, are microtubule-dependent molecular motors important for neuronal function. Among the KIF5s, KIF5A is neuron-specific and highly expressed in the central nervous system. However, specific roles of KIF5A remain unknown. Here, we established conditional KIF5A-knockout mice, in which KIF5A protein expression was postnatally suppressed in neurons. Epileptic phenotypes were observed with electroencephalogram (EEG) abnormalities in knockout mice due to impaired GABA<sub>A</sub> receptor (GABA<sub>A</sub>R)-mediated synaptic transmission. We further identified reduced cell surface expression of GABA<sub>A</sub>R in knockout neurons. Importantly, we identified that KIF5A specifically interacts with GABA<sub>A</sub>R-associated protein (GABARAP) that is known to be involved in GABA<sub>A</sub>R trafficking. It was shown that KIF5A regulated neuronal surface expression of GABA<sub>A</sub>Rs via interaction with GABARAP. These results provide a new insight into the molecular mechanisms of KIF5A, which regulate inhibitory neural transmission.

**Kinetochore kinesin CENP-E is a processive tracker of dynamic microtubule tips.**

*N. Gudimchuk<sup>1,2</sup>, B. Vitre<sup>3</sup>, Y. Kim<sup>3,4</sup>, D. W. Cleveland<sup>3</sup>, F. I. Ataullakhanov<sup>2,5</sup>, E. L. Grishchuk<sup>1</sup>; <sup>1</sup>Physiology Department, University of Pennsylvania, Philadelphia, PA, <sup>2</sup>Center for Theoretical Problems of Physicochemical Pharmacology, Moscow, Russia, <sup>3</sup>Ludwig Institute for Cancer Research and Department of Cellular and Molecular Medicine, University of California, San Diego, La Jolla, CA, <sup>4</sup>Department of Molecular and Cell Biology, University of California, Berkeley, CA, <sup>5</sup>Federal Research and Clinical Centre of Pediatric Hematology, Oncology and Immunology, Moscow, Russia*

Member of kinesin-7 family CENP-E is a kinetochore-associated plus-end-directed motor, which is important for faithful chromosome segregation in mitosis. CENP-E has been implicated in chromosome transport to the spindle midzone, where the microtubule (MT) plus ends are located. Here we report that once reaching the dynamic MT ends in vitro, CENP-E converts from a lateral transporter into a MT tip-tracker, stably associating with the tips of both assembling and disassembling MTs. We show that the binding between kinetochores and dynamic MT ends is destabilized in live cells when CENP-E function is perturbed via an inhibition or RNAi depletion, implying that the tip-associated CENP-E plays an important mitotic role. To determine the molecular mechanism of CENP-E tip-tracking, we characterized two purified recombinant fragments: the motor & neck domain and the C-terminal tail, harboring a MT binding site. The motor & neck domain walked on the MT wall in essentially the same manner as the full length CENP-E, while the C-terminal tail exhibited rapid diffusion along the

MT. Neither of these mutant proteins showed tip-tracking, however, this activity could be recapitulated by artificially joining them with Qdots. We analyzed these results with a coarse grained molecular model of CENP-E motility. This model successfully describes the observed tip-tracking of CENP-E, which occurs via the repeated cycles of the plus-end-directed walking, tail-mediated diffusion of the MT wall-tethered motor heads and their speedy re-association with the MT wall in the vicinity of the MT tip. This novel “tethered motor” mechanism of tip-tracking does not rely on the specific properties of the assembling or disassembling MT tips, explaining why this kinesin can tip-track bi-directionally. Together, these results establish the requirement for CENP-E in stably linking the kinetochores to dynamic MT tips, and provide a detailed molecular explanation about how CENP-E can achieve this function.

**Illuminating the intraflagellar transport machinery in the chemosensory cilia of *Caenorhabditis elegans*.**

B. Prevo<sup>1</sup>, P. Mangeol<sup>1</sup>, F. Oswald<sup>1</sup>, J. Scholey<sup>2</sup>, E. Peterman<sup>1</sup>; <sup>1</sup>Department of Physics and Astronomy, VU University Amsterdam, Amsterdam, Netherlands, <sup>2</sup>Department of Molecular & Cellular Biology, University of California, Davis, Davis, CA

In the chemosensory cilia of *Caenorhabditis elegans* two kinesin-2-family motors, heterotrimeric kinesin-II and homodimeric OSM-3-kinesin, act together in a process called intraflagellar transport (IFT). Along the middle segment these two kinesins cooperate, however OSM-3-kinesin alone maintains the distal segment. How the interplay between these motors in IFT is regulated is unknown. Using ultrasensitive, quantitative fluorescence microscopy we are able to track both motors at endogenous expression levels deep inside the living organism. We find that initially the two motors form an IFT-train together, but while moving along the middle segment kinesin-II gradually undocks, allowing the OSM-3-kinesin train to reach terminal velocity already at the middle segment. Our results provide new insight into IFT and motor-driven processes in general.

**Polarized motor activity moves myonuclei in vivo.**

E. S. Folker<sup>1</sup>, V. K. Schulman<sup>2</sup>, M. K. Baylies<sup>1</sup>; <sup>1</sup>Developmental Biology, Sloan-Kettering Institute, New York, NY, <sup>2</sup>Weill Cornell Medical College, New York, NY

Proper positioning of the nucleus is essential for cellular and tissue functions ranging from the proper segregation of DNA, to the polarization of the cytoskeleton, to the contraction of muscle. Microtubule motors provide the force to move nuclei in many systems, yet how Dynein and Kinesin are coordinated to move nuclei is poorly understood. To address these questions we examined nuclear movement in the muscles of live, developing *Drosophila* embryos. These experiments revealed that translocating nuclei are polarized with Kinesin acting at the leading edge of the nucleus and Dynein acting at the trailing edge of the nucleus. These conclusions are supported by multiple lines of evidence that suggest at least two functions for polarized Kinesin and Dynein activity. First, the movement of nuclei is unidirectional toward the muscle pole with fewer than 2% of nuclei changing directions. However, when nuclei do change direction, the leading edge of the nucleus becomes reoriented in the new direction of movement. Moreover, translocating nuclei undergo dynamic shape changes alternating between elongated and spherical shapes. These shape changes are the result of the leading edge of the nucleus being moved forward before the trailing edge of the nucleus is moved. In Kinesin and Dynein mutant embryos, nuclear movement is slow compared to controls and the changes in nuclear shape are absent. The nuclei in Kinesin mutants retain a spherical shape

with an aspect ratio of approximately one, whereas the nuclei in Dynein mutants are in a persistently elongated shape with an aspect ratio of approximately three. That the nuclei cannot elongate in Kinesin mutants suggests that Kinesin is required to extend the leading edge of the nucleus. Similarly, that the nuclei are persistently elongated in Dynein mutants, indicates that Dynein is required to contract or release the trailing edge of the nucleus to complete a step in translocation. Together these data indicate that the activities of the microtubule motors Kinesin and Dynein are polarized on the nucleus and that the benefits of this polarization are two-fold: Polarized activity provides a means to enhance the unidirectional aspect of movement, and more importantly, enables the nuclei to dynamically change shape, thus maximizing movement efficiency in the dense environment of the embryo within the time constraints of development.

**Nuclear positioning during skeletal muscle fibers formation implicates microtubule network, molecular motors and MAPs and is essential for muscle function.**

V. Gache<sup>1</sup>, B. Cadot<sup>1</sup>, T. Metzger<sup>2</sup>, M. Xu<sup>2</sup>, S. Falcone<sup>1</sup>, E. Folker<sup>2</sup>, B. Richardson<sup>2</sup>, M. Baylies<sup>2</sup>, E. R. Gomes<sup>1</sup>; <sup>1</sup>Inserm U787, Paris, France, <sup>2</sup>Program in Developmental Biology, Sloan-Kettering Institute, New York, NY

The basic unit of skeletal muscle in all metazoans is the multinucleate myofiber, within which individual nuclei are regularly positioned. The molecular machinery responsible for myonuclear positioning is not known. Improperly positioned nuclei are a hallmark of numerous muscle diseases, including centronuclear myopathies, but it is unclear whether correct nuclear positioning is necessary for muscle function.

We performed an in vitro time-lapse video microscopy on myotubes to measure nuclei velocity and localization in early myotubes. Using a cytoskeleton targeting drugs approach and a siRNA screen on molecular motors, we identified two distinct microtubules dependent nuclei movements in myotubes. The first movement occurs just after fusion: entering nucleus of the myoblast moved towards the center of the myotube. This nuclear movement is driven by dynein/dynactin complex and regulated by Cdc42, Par6 and Par3. We also provide evidence for a role of Par6 and Par3 on myotube growth. The second movement occurs inside the myotube and is responsible for the alignment of nuclei. This nuclear movement is driven by the interaction between the kinesin Kif5b and the Microtubule Associated Protein Map7. This complex maintains an anti-parallel network of microtubules in myotubes and allows nuclei to correctly align within the myotube. We demonstrate that myonuclear positionings is physiologically important. Drosophila mutant larvae for the ortholog of Map7 display decreased locomotion and incorrect myonuclear positioning, and these phenotypes are rescued by muscle specific expression of Map7.

Our results show for the first time that the ability to correctly position myonuclei correlates with better muscle growth and function. Correcting nuclear positioning defects in patients with muscle diseases might benefit muscle strength and improve muscle function.

**Understanding Kinesin-Mediated Cell Wall Assembly Using Genetic and Single-Molecule Studies.**

C. Zhu<sup>1</sup>, R. Dixit<sup>1</sup>; <sup>1</sup>Biology Department, Washington University, St. Louis, MO

The microtubule cytoskeleton at the cortex of plant cells guides the oriented deposition of cell wall material which determines cell shape and the overall growth and stature of plants. It is hypothesized that the Arabidopsis FRA1 kinesin, a member of the kinesin-4 family, plays a major role in this process by mediating the directional movement of cell wall-related cargo along cortical microtubules. We have characterized a T-DNA-induced knockout mutant, called

fra1(SALK), which has shorter, fatter and weaker stems as compared to wild-type controls. These phenotypes correlate with shorter pith cells and thinner walls in fiber cells. Cell wall composition analysis revealed that fra1(SALK) has 60% less glucose than wild-type controls, indicating that FRA1 mediates the synthesis and/or secretion of cellulose and/or hemicelluloses, which together make up the bulk of the plant cell wall. To study the mechanism of FRA1 function, we stably introduced a FRA1-3GFP fusion construct into our fra1(SALK) mutant. The FRA1-3GFP construct complements the fra1(SALK) mutant, indicating that the fusion protein is functional. We used highly inclined and laminated optical sheet (HILO) microscopy for single-molecule imaging of FRA1-3GFP in living Arabidopsis seedlings. FRA1-3GFP appears as discrete puncta at the cell cortex and photobleaching analysis revealed that these puncta primarily consist of FRA1 dimers. The FRA1-3GFP dimers were found to move long distances on cortical microtubules, making FRA1 well-suited for transporting cell wall-related cargo along cortical microtubule tracks. The velocity of FRA1 is about 60x faster than the velocity of the plasma-membrane-embedded cellulose synthase complexes, which synthesize and extrude cellulose microfibrils in the extracellular space. In addition, pharmacological experiments showed that FRA1 motility is unaffected by drugs that either deplete or immobilize cellulose synthase complexes at the plasma membrane. These data indicate that FRA1 is unlikely to direct the movement of plasma-membrane-embedded cellulose synthase complexes along cortical microtubules. Instead, FRA1 likely facilitates delivery of secretory vesicles containing cellulose synthase complexes and/or hemicelluloses to sites of exocytosis along cortical microtubules. We have screened for FRA1-interacting proteins using yeast 2-hybrid and identified proteins that are associated with vesicle trafficking. Together, our data provide new insights into how the FRA1 kinesin regulates plant cell wall assembly. This work is supported by NSF grant MCB-1121287.

## Actin and Actin-Associated Proteins I

### Fission yeast tropomyosin promotes directed transport in cells by converting myosin-V into a processive motor.

J. Clayton<sup>1</sup>, L. W. Pollard<sup>1</sup>, C. Bookwalter<sup>1</sup>, A. Hodges<sup>1</sup>, K. Trybus<sup>1</sup>, M. Lord<sup>1</sup>; <sup>1</sup>The University of Vermont, Burlington, VT

Most class-V myosins studied to date are dimeric motors that walk along actin filaments as single molecules. This processivity relies on a high-duty ratio in which motors spend the majority of their ATPase cycle time in the strong actin-bound ADP state. However, recent studies have shown that a sub-population of myosin-Vs are low duty ratio, non-processive motors. Here we employed a low duty ratio fission yeast myosin-V (Myo52p) to investigate the role of tropomyosin on motor function and transport. Decoration of actin filaments with fission yeast tropomyosin (Cdc8p) converts Myo52p into a processive motor. Similarly, Cdc8p-decoration activated the movement of beads coated with small numbers of Myo52p molecules (that mimic in vivo distributions). This regulation was not unique to Cdc8p because budding yeast tropomyosins and two out of three mammalian tropomyosins tested also activated Myo52p processivity. Our findings reveal a novel mechanism of regulation that facilitates sorting of myosin transport to specific actin tracks within the cell.

**Effect of mutations in the tropomyosin-binding sites on assembly of tropomodulin isoforms in skeletal myocytes..**

S. Novak<sup>1</sup>, M. Colpan<sup>2</sup>, N. Moroz<sup>2</sup>, C. C. Gregorio<sup>1</sup>, A. S. Kostyukova<sup>2</sup>; <sup>1</sup>Department of Cellular and Molecular Medicine and Molecular Cardiovascular Research Program, University of Arizona, Tucson, AZ, <sup>2</sup>Voiland School of Chemical Engineering & Bioengineering, Washington State University, Pullman, WA

Tropomodulins (Tmod 1-4) cap the pointed end of the actin filament in a tropomyosin (TM)-dependent manner. Tmod/TM interactions are isoform-specific and the affinity of Tmod1 for skeletal striated  $\alpha$ TM (stTM) is higher than that of Tmod3 and Tmod4. Earlier we showed that mutations R11K, D12N and Q144K in both TM-binding sites of Tmod1 decreased the affinity of Tmod1 to stTM making it similar to that of Tmod3 and Tmod4. The actin filament-capping ability of the Tmod1 mutants in the presence of stTM also decreased. GFP-Tmod1 WT, GFP-Tmod1 Q144K (single mutant), GFP-Tmod1 D12N/Q144K (double mutant) and GFP-Tmod1 R11K/D12N/Q144K (triple mutant) were expressed in primary chicken skeletal myocytes. CFP-Tmod3 and ChFP-Tmod4 were co-expressed with GFP-Tmod1, WT and mutants, to compare the propensity for them to assemble at thin filament pointed ends. Single, double and triple mutations in Tmod1 decreased its assembly at the pointed ends, correlating with our *in vitro* data. Surprisingly, assembly of the Tmod1 mutants was enhanced by the co-expression of Tmod3. Moreover, assembly of Tmod3 was increased in the presence of Tmod1WT in comparison to when it is expressed alone. Our data suggest that Tmod1 and Tmod3 mutually promote localization of each other at the pointed ends. Co-expression of Tmod4 with Tmod1 led to a drastic reduction of assembly for both molecules, potentially due to competition mechanism. We hypothesize that cooperation and competition in function of Tmod isoforms are influenced by their TM-binding properties. Supported by NIH grants to ASK and CCG.

**A nemaline myopathy-linked tropomyosin mutation reduces thin filament length and disrupts actomyosin crossbridge formation.**

D. S. Gokhin<sup>1</sup>, J. Ochala<sup>2</sup>, V. M. Fowler<sup>1</sup>; <sup>1</sup>Cell Biology, The Scripps Research Institute, La Jolla, CA, <sup>2</sup>Neuroscience, Uppsala University, Uppsala, Sweden

Nemaline myopathy (NM) is the most common nonprogressive hereditary myopathy, with an incidence of 1 in 50,000 live births. NM results in muscle weakness, delayed motor development, slow fiber predominance, and appearance of actin-containing aggregates ("nemaline bodies") in muscle tissue. NM is caused by mutations in genes that encode the structural components of the sarcomeric actin (thin) filaments, which, in addition to actin, include tropomyosin, troponin, and nebulin. Previous studies have identified the mechanism for muscle weakness in NM as either thin filament length dysregulation or impaired actomyosin crossbridge activity. In this study, we examined the basis for thin filament pathogenesis in tropomyosin-based NM by testing the hypothesis that thin filament instability leads to actin depolymerization from the pointed end and resultant thin filament shortening. Using tissue from human NM patients with three different NM-causing tropomyosin mutations (*TPM2*-null, *TPM3*-R167H and *TPM2*-E181K) as well as healthy controls, we found that skeletal muscle harboring the *TPM3*-R167H mutation displays a lower thin filament length ( $1.03 \pm 0.08 \mu\text{m}$ ) than skeletal muscle with the *TPM2*-null and *TPM2*-E181K mutations ( $1.30 \pm 0.08 \mu\text{m}$  and  $1.33 \pm 0.06 \mu\text{m}$ , respectively) as well as healthy control muscle (ranging from  $1.26 \pm 0.05 \mu\text{m}$  to  $1.38 \pm 0.07 \mu\text{m}$ ). Thin filament shortening in *TPM3*-R167H muscle was not accompanied by changes in the distance of the N-terminus of nebulin from the Z-line, indicating that the observed shortening specifically affected the nebulin-free pointed-end extension of the thin filament. The *TPM3*-R167H mutation also

decreased cooperative thin filament activation in combination with reductions in myosin crossbridge number and active force production. This study is the first to demonstrate simultaneous thin filament length misregulation and inhibited actomyosin crossbridge formation in tropomyosin-based NM, suggesting crosstalk between these pathogenic mechanisms for NM. The results presented here have broad relevance to the development of future therapeutic approaches for tropomyosin-based NM as well as other NMs.

**The actin regulatory protein Tropomyosin 5NM1 regulates glucose uptake and GLUT4 trafficking in the mouse.**

A. J. Kee<sup>1</sup>, C. A. Lucas<sup>1</sup>, L. Yang<sup>1</sup>, R. C. Szokolai<sup>1</sup>, N. Martel<sup>2</sup>, G. M. Leong<sup>2</sup>, G. E. Muscat<sup>2</sup>, W. Hughes<sup>3</sup>, G. Cooney<sup>3</sup>, D. E. James<sup>3</sup>, P. W. Gunning<sup>4</sup>, E. C. Hardeman<sup>1</sup>; <sup>1</sup>Neuromuscular and Regenerative Medicine Unit, School of Medical Sciences, University of New South Wales, Sydney, Australia, <sup>2</sup>Institute for Molecular Biosciences, University of Queensland, Brisbane, Australia, <sup>3</sup>Diabetes and Obesity Program, Garvan Institute of Medical Research, Sydney, Australia, <sup>4</sup>Oncology Research Unit, School of Medical Sciences, University of New South Wales, Sydney, Australia

A primary defect in Type 2 diabetes is alterations to glucose uptake in skeletal muscle and adipose tissue. Insulin-stimulated glucose uptake requires the trafficking of GLUT4-containing vesicles from intracellular stores to the cell surface. We have identified a novel population of actin filaments defined by the cytoskeletal tropomyosin (Tm) isoform Tm5NM1. Analysis of Tm5NM1 transgenic (Tg) mice suggests these filaments play a role in glucose uptake. In Tm5NM1 Tg mice, whole body glucose clearance and insulin-stimulated glucose uptake into white adipose tissue (WAT), skeletal muscle and heart was increased. This was specific to Tm5NM1, as glucose clearance was unaltered in mice expressing an alternative Tm, Tm3. Gene expression profiling (Illumina microarray), quantitative RT-PCR and Western blot analysis of WAT from the Tm5NM1 Tg mice detected an increase in genes involved in actin filament turnover and GLUT4 trafficking, including myosin motors (Myo1c,  $P < 0.05$ ) and components of the exocyst complex (Sec8,  $P < 0.005$ ). In keeping with Tm5NM1's reported role in stabilising actin filaments, there was a 30% increase ( $P = 0.019$ ) in filamentous actin (detected by phalloidin staining) in Tg WAT. In 3T3L1 adipocytes, insulin-stimulation resulted in a shift in Tm5NM1 localisation to the plasma membrane, consistent with a role in GLUT4 trafficking. This effect was specific to Tm5NM1 and not other Tm isoforms. Finally, in 3T3-L1 adipocytes stably expressing Tm5NM1, there was an increase in insulin-stimulated GLUT4 movement to the plasma membrane compared to vector control cells. We propose that Tm5NM1 actin filaments promote recruitment of GLUT4 trafficking machinery that in turn results in enhanced insulin-stimulated GLUT4 translocation to the plasma membrane and glucose uptake.

### Regulation of cell proliferation mediated by the actin filament stabilizing protein, Tropomyosin 5NM1.

G. Schevzov<sup>1</sup>, J. Coombes<sup>1,2</sup>, J. Hook<sup>1</sup>, B. Wang<sup>1</sup>, A. Kee<sup>3</sup>, C. Lucas<sup>3</sup>, R. Szokolai<sup>3</sup>, V. Sequeira<sup>1</sup>, J. Stehn<sup>1</sup>, E. Musgrove<sup>4,5</sup>, E. Hardeman<sup>3</sup>, P. Gunning<sup>1</sup>; <sup>1</sup>Pharmacology, The University of NSW, Sydney, Australia, <sup>2</sup>Sydney Medical School, The University of Sydney, Sydney, Australia, <sup>3</sup>Anatomy, The University of NSW, Sydney, Australia, <sup>4</sup>Garvan Institute of Medical Research, Sydney, Australia, <sup>5</sup>St Vincent's Clinical School, Faculty of Medicine, University of NSW, Sydney, Australia

The actin cytoskeleton has long been known to link signalling pathways with cellular proliferation, although the molecular mechanism(s) by which actin filaments participate in cell cycle progression are not very well understood. Tropomyosins (Tms), integral components of microfilaments, can regulate the dynamics and structural properties of actin filaments by controlling the interaction of filaments with actin binding proteins. In this study we demonstrate that a specific population of actin filaments composed of Tm5NM1 play a critical role in regulating cell proliferation. An increase in proliferation was evident in B35 cells and primary mouse embryonic fibroblast (MEFs) overexpressing Tm5NM1. In contrast, Tm5NM1 knock-down in SHEP cells or in knock-out (KO) MEFs significantly reduced proliferation. In Tm5NM1 transgenic mice, we convincingly show that the predominant phenotype seen is an increase in total fat mass due to an increase in the number of adipocytes without changes in fat cell size. Conversely, mice null for Tm5NM1 have reduced fat mass content. In order to elucidate the potential signalling pathway(s) most likely influenced by Tm5NM1, we employed the use of an antibody microarray featuring 500 pan-specific and 300 phospho-site specific antibodies to components from the major established signalling pathways. The array revealed the significant upregulation of components of the MAPK/ERK pathway including EGFR, KSR1 scaffolding protein, MEK 1 and pERK1/2 in the KO MEFs compared to WT MEFs. Whilst phosphatases, PP2A and MKP-1, known to regulate the duration of ERK signalling, were significantly downregulated. Initial western blots have indeed confirmed elevated expression of pERK1/2 seen in the KO MEFs relative to WT MEFs. More over, specific signalling pathway inhibitors demonstrate that proliferation via the PI3K pathway is Tm5NM1 independent but MAPK/ERK2 dependent. This was demonstrated using an ERK2 specific inhibitor that has no effect on the poor proliferation of the KO MEFs whilst significantly reducing that of the WT MEFs. Taken together our data strongly proposes that a specific population of actin filaments consisting of Tm5NM1 mediates cell proliferation via the MAPK/ERK2 pathway.

220

### Functional Analysis of Conserved Residues in Fission Yeast Tropomyosin.

M. C. Pamula<sup>1</sup>, J. Wang<sup>2</sup>, S. Cranz-Mileva<sup>2</sup>, N. Walworth<sup>3</sup>, S. E. Hitchcock-DeGregor<sup>2</sup>; <sup>1</sup>Department of Molecular Biology and Biochemistry, Rutgers University, Piscataway, NJ, <sup>2</sup>Department of Pathology and Laboratory Medicine, Robert Wood Johnson Medical School, Piscataway, NJ, <sup>3</sup>Department of Pharmacology, Robert Wood Johnson Medical School, Piscataway, NJ

Tropomyosin (Tm) is a global regulator of actin filament function through stabilizing filaments and interacting with actin binding proteins including myosins and formins. We have taken a bioinformatics approach in a structure-function analysis of this protein in *Schizosaccharomyces pombe* (fission yeast). *S. pombe* has a single, essential Tm gene (*cdc8*) that is required for growth, formation of actin cables and the contractile ring, transport of actin patches, and conjugation. Our goal is to identify critical residues for these and other potential functions of Tm in the cell. We previously overexpressed 16 Ala/Ser mutants to screen 21 evolutionarily-

conserved surface residues for their ability to rescue growth of a *cdc8-ts* mutant (*cdc8-27*) at the restrictive temperature (35 °C). Whereas all rescued growth, three that exhibited abnormal growth or morphological characteristics were selected for further analysis: (D16A/K30A), (V114S/ E117A/H118A) and (R121A/D131A/E138A). To analyze Tm's universal function, actin binding, we expressed recombinant Tm in *E. coli* with a N-terminal AlaSer to enhance actin affinity. Whereas D16A/K30A had near-wildtype actin affinity (by cosedimentation), the binding of V114S/ E117A/H118A and R121A/D131A/E138A was too weak to measure. For cellular analysis, we created *cdc8* mutant strains using a marker gene replacement strategy in which the endogenous gene is replaced using homologous recombination; recombinants were selected using nutritional markers (Tang et al., 2011). Following selection, the recombinants were backcrossed against parental strains, and the presence of mutations was confirmed by genomic DNA sequencing. We note that the V114S/ E117A/H118A and R121A/D131A/E138A strains are genetically unstable; the backcrosses yielded colonies with phenotypes that differ from that of either parent, in addition to the expected parental phenotypes. The strains were analyzed for nuclear number (DAPI), cell and septum morphology (Calcofluor), and the actin cytoskeleton (phalloidin). All contained one or two nuclei with normal localizations, indicating that cells complete nuclear and cell division. The D16A/K30A cells contained actin cables, but the actin patches were not well-polarized, often found throughout the cell rather than being localized at the poles. Contractile rings formed but were often irregular. V114S/ E117A/H118A showed actin cables and a normal distribution of actin patches. However, the contractile ring was irregular. R121A/D131A/E138A exhibited the most severe phenotype. Actin cables were present, but the actin patches were found at the poles and throughout the cells. Often cells with two nuclei had dual diffuse contractile rings and septa that resulted in two "cell" divisions with two daughter cells and a piece of cell without a nucleus in between. We conclude that the conserved residues mutated in these strains have crucial but distinct functions in actin patch localization and contractile ring assembly that depend on interactions with other actin binding proteins, as well as actin. Supported by NIH-RO1-GM093065 and The Aresty Research Center for Undergraduates at Rutgers University.

### Multi-domain model structures of $\alpha$ -actinin-4 explain how external cues can regulate actin binding.

T. Travers<sup>1</sup>, H. Shao<sup>2</sup>, A. Wells<sup>2</sup>, C. J. Camacho<sup>1</sup>; <sup>1</sup>Computational and Systems Biology, University of Pittsburgh, Pittsburgh, PA, <sup>2</sup>Pathology, University of Pittsburgh, Pittsburgh, PA

In eukaryotic non-muscle cells, the regulation of the homodimeric actin-crosslinking protein alpha-actinin-4 (ACTN4) during cell migration involves signaling receptors with intrinsic tyrosine kinase activity, yet the underlying molecular mechanisms are poorly understood. Here we develop structural models for human ACTN4 and three of its phosphorylation states, both in the presence and absence of Ca<sup>2+</sup> ions, revealing the complex network of interactions responsible for the regulation of this protein. The core structure corresponds to a complex between the C-terminal CaM-like domain of one monomer, and the N-terminal actin-binding domain of the opposite antiparallel monomer. Mutagenesis experiments validate our predictions of distinct Ca<sup>2+</sup>-independent phenotypes for phosphorylated Y265 and Y4/Y31 that upregulate and downregulate actin binding, respectively. A kinetic model of the predicted network that entails eight combinations of multi-domain complex structures reconciles a broad set of semi-quantitative in vitro binding data. Collectively, these studies provide insight pertinent to the molecular basis of actin crosslinking by ACTN4, while revealing a framework for understanding how post-translational modifications can result in robust signals by assembling and disassembling multi-domain complexes.

**WASH-dependent Actin Recruitment to the Maturing Phagosome.**

V. Szeto<sup>1</sup>, M. Bohdanowicz<sup>1</sup>, J. T. Piotrowski<sup>2,3</sup>, R. Flannagan<sup>1</sup>, J. Kay<sup>1</sup>, D. D. Billadeau<sup>2,3</sup>, S. Grinstein<sup>1</sup>; <sup>1</sup>Cell Biology Program, The Hospital for Sick Children, Toronto, ON, Canada, <sup>2</sup>Departments of Immunology, Mayo Clinic, Rochester, MN, <sup>3</sup>Division of Oncology Research, Mayo Clinic, Rochester, MN

Phagocytosis is a receptor-mediated process whereby professional phagocytes engulf foreign particles into a membrane-bound organelle termed the phagosome. Through a coordinated series of membrane fission and fusion events the nascent phagosome matures into the highly microbicidal phagolysosome. Despite the multiple rounds of vesicular fusion, the size of the maturing phagosome remains constant, suggesting that in addition to membrane fusion membrane fission also occurs. Through these fission events, the phagocyte presumably retrieves biologically important molecules to be recycled; however, the molecular mechanisms regulating membrane fission at the phagosome remain elusive. We investigated early phagosome membrane fission by monitoring the fate of glycosylphosphatidylinositol (GPI)-anchored proteins using fluorescent membrane tracers. Our data show that membranous tubules emanate from the maturing phagosome; actin puncta, revealed by phalloidin staining, were found near the base of these tubules. We therefore speculated that actin-containing structures might be involved in driving membrane fission and cargo retrieval from the phagosome. Recent evidence has shown that the WASP and SCAR homologue (WASH) activates the actin-nucleating complex Arp2/3 on endosomes, where it participates in membrane remodeling and receptor trafficking. Expression of WASH-GFP, as well as immunolocalization of endogenous WASH showed that this protein co-localizes with the actin puncta of early phagosomes. Moreover, the sorting nexins SNX1 and 2 also co-localize with WASH-positive structures on maturing phagosomes, suggesting the involvement of retromer in WASH recruitment. Importantly, WASH-deficient primary macrophages failed to recruit actin to early phagosomes, implying that actin association with early phagosomes is WASH-dependent. These data are consistent with a model where WASH induces actin polymerization, which promotes membrane fission and efficient remodeling of the maturing phagosome. To verify this model, comparative measurements of the rate and extent of phagosome maturation in wild-type and WASH-deficient macrophages are currently underway.

223

**Processive acceleration of actin barbed end assembly by N-WASP.**

N. Khanduja<sup>1</sup>, J. R. Kuhn<sup>1</sup>; <sup>1</sup>Biological Sciences, Virginia Tech, Blacksburg, VA

Motile cells direct the force of actin barbed end polymerization towards the leading edge of the membrane. WASP family nucleation promoting factors (NPFs) bind to the membrane at the leading edge and activate arp2/3 to generate a dendritic actin network. WASP family proteins also bind to actin filament barbed ends, and we recently showed that neuronal WASP (N-WASP) can remain processively attached to bundled barbed ends in an *in vitro* motility assay (Hu and Kuhn, 2012, PLoS ONE 7(2): e31385). We used total internal reflection fluorescence (TIRF) microscopy of individual actin filaments to determine whether N-WASP acts as a true processive actin barbed end assembler in the absence of arp2/3 complex. N-WASP PP-WWCA coated nanofibers were incubated with *de novo* nucleated actin filaments in chambers coated with rigor myosin. When N-WASP nanofibers captured individual barbed ends, barbed ends either continued to grow along the nanofiber at the diffusion-limited rate or, when oriented perpendicular to the nanofiber, grew at a substantially reduced rate. However, when filament densities increased to the point of substantial filament overlap, a subset of nanofiber-attached barbed ends formed prominent buckles or loops between their nanofiber tethers and myosin

attachment points. Buckling filament barbed ends showed substantial parallel association with neighboring filaments. Measurement of elongation rates showed that buckling filament barbed ends grew 3.4-fold faster than the diffusion-limited rate of unattached barbed ends in the same field. We found similar barbed end rate enhancements in N-WASP constructs with and without the native poly-proline (PP) region. We found that increasing polycationic  $Mg^{2+}$  concentrations to 10 mM did not alter barbed end acceleration rates. However, increasing  $Mg^{2+}$  from 1 to 10 mM increased the frequency of buckle formation 2.6 to 3.0 fold, consistent with a requirement of accelerated assembly on barbed end bundling. Filament bundling by divalent cation  $Mg^{2+}$  confers multimerization of barbed ends that allows their cooperative, processive binding to dense, tethered WCA-domains. Acceleration of barbed ends beyond their natural diffusion limited rate shows that, like formin and VASP, tethered N-WASP can act as a processive barbed-end assembly motor in the absence of arp2/3 complex.

#### **Molecular details of drebrin-cofilin cross-talk.**

*E. E. Grintsevich<sup>1</sup>, E. Reisler<sup>1,2</sup>; <sup>1</sup>Department of Chemistry & Biochemistry, University of California, Los Angeles, CA, <sup>2</sup>Molecular Biology Institute, University of California, Los Angeles, CA*

The competition between drebrin and cofilin is believed to be a part of the pathway leading to synaptic dysfunction in Alzheimer's disease and epilepsy. However, up to date the cross-talk between cofilin and drebrin is poorly understood. TIRF microscopy revealed that saturating concentrations of drebrin, either full length or of its actin binding core (a.a. 1-300), inhibit but do not abolish cofilin-induced severing of actin filaments. The dependence of cofilin binding on fractional saturation of actin filaments with drebrin suggests direct competition between these two proteins. Decoration of F-actin with both cofilin and drebrin can yield a total combined binding density of 100%. This implies that these two proteins can either overcome or reverse the allosteric changes in F-actin induced by the competitor's binding. Pre-steady state kinetic experiments revealed that the binding of drebrin to actin filaments was over two orders of magnitude faster than the cooperative binding of cofilin (as evaluated by the nearest-neighbor approach; Cao W et al, 2006, JMB, 361; P:257-267). However, drebrin dissociation rate from the filaments was also faster (~10 fold) than that reported for cofilin. Despite its higher affinity for F-actin, drebrin can be displaced from the filaments by high concentrations of cofilin. This is explained by a decrease in the availability of segments of five actin protomers (unoccupied by cofilin), which constitute the drebrin binding site on F-actin. Our results contribute to a molecular understanding of the cross-talk between drebrin and cofilin.

225

#### **Regulation of axonal filopodia and collateral branches by the actin filament binding protein drebrin.**

*A. Ketschek<sup>1,2</sup>, M. Spillane<sup>1,2</sup>, X-P. Dun<sup>3</sup>, J. Chilton<sup>3</sup>, G. Gallo<sup>1,2</sup>; <sup>1</sup>Shriners Hospitals Pediatric Research Center, Temple University School of Medicine, Philadelphia, PA, <sup>2</sup>Neurobiology & Anatomy, Drexel University College of Medicine, Philadelphia, PA, <sup>3</sup>Institute of Biomedical and Clinical Science, University of Exeter, Peninsula Medical School, Plymouth, United Kingdom*

Axon collateral branches underlie the ability of individual neurons to make connections with multiple targets. Collateral branches arise from the maturation of transient axonal filopodia, which in turn, emerge from axonal patches of actin filaments. In this study we investigated the role of the actin filament binding protein drebrin in the formation of axonal filopodia and branches by chicken sensory neurons. Live imaging of RFP-drebrin E1 and eYFP-actin in vitro revealed that drebrin is present throughout the axon shaft and is recruited to actin patches,

persisting throughout the lifespan of the actin patch. Furthermore, over-expression of drebrin increased the probability that an actin patch will give rise to a filopodium, while conversely shRNA-mediated depletion of drebrin decreased the probability that an actin patch gives rise to a filopodium. Endogenous drebrin was detected in the proximal portion of established filopodia and in the shafts of nascent branches. Over-expression of drebrin increased the number of axonal filopodia and branches *in vitro* and *in ovo*, while conversely depletion of drebrin decreased the number of axonal filopodia and collateral branches. Furthermore, expression of drebrin increased the length and branching of individual axonal filopodia, while depletion of drebrin decreased the length and branching of filopodia. *In vitro*, over-expression of drebrin increased the percentage of axonal filopodia invaded by GFP-EB3, a microtubule plus end binding protein. Furthermore, filopodia of drebrin over-expressing axons were remarkably stable, although capable of bouts of tip elongation and retraction. Collectively, the data suggest that drebrin is involved in the formation of axonal filopodia and collateral branches by regulating the emergence of filopodia from axonal actin patches and the stability of axonal filopodia. Furthermore, the data suggest that drebrin assists the entry of microtubules into axonal filopodia thereby promoting the maturation of axonal filopodia into branches.

**Cryo-electron tomography and subvolume analysis of MSP filaments derived from the amoeboid sperm of *Ascaris suum*.**

A. Malowney<sup>1</sup>, T. M. Roberts<sup>1</sup>, K. A. Taylor<sup>1</sup>; <sup>1</sup>Biological Science, Florida State University, Tallahassee, FL

Locomotion of nematode sperm is remarkably similar to that of most other crawling cells but is powered by a system of filaments composed of major sperm protein (MSP) instead of the actin-myosin machinery typically associated with amoeboid motility. The MSP motility apparatus has been reconstituted *in vitro*, and individual MSP filaments can be generated by the addition of ATP to detergent-treated *Ascaris* sperm cytosol. Filaments formed in this way have been examined using electron cryo-tomography of both frozen-hydrated and negatively-stained samples. Together, these have allowed for the structural analysis of filaments formed in the presence of MSP accessory proteins. Filaments within complex MSP meshworks have been averaged using subvolume alignment by classification, and the resulting physiological models have been compared to tomographic reconstructions of purified MSP polymerized in ethanol as well as earlier models derived using both Fourier synthesis (King et al. 1992. JCS 101:847) and X-ray crystallography (Bullock et al. 1998. NSB 5:184). There are currently six *Ascaris* sperm proteins known to modulate MSP filament dynamics in sperm; these same proteins are absent from filaments prepared using purified MSP but may be present and bound to filaments prepared from cytosol. Model comparisons provide us with a greater understanding of how these accessory proteins effect MSP filament dynamics and influence motility. Supported by NIH Grant R37 GM29994 and by the American Heart Assoc.

**Direct binding of BAR-domain protein FAP52 to F-actin.**

A. A. Orlova<sup>1</sup>, A. Solodukhin<sup>1</sup>, J. Kostan<sup>2</sup>, U. Salzer<sup>2</sup>, C. Shreiner<sup>2</sup>, K. Carugo<sup>2</sup>, E. H. Egelman<sup>1</sup>; <sup>1</sup>Dept. of Biochemistry and Molecular Genetics, University of Virginia, Charlottesville, VA, <sup>2</sup>Dept. of Structural and Computational Biology, University of Vienna, Vienna, Austria

BAR domain proteins have been extensively studied for their roles in membrane-binding and shaping. These domains have characteristic curved shapes, and it has been shown that they can induce this curvature in the membrane to which they bind. This has emerged as an important element in membrane remodeling, including vesiculation and tabulation. More

recently, many links have been found between membrane remodeling and the actin cytoskeleton. In a number of cases it has been assumed that BAR domain proteins interact with the actin cytoskeleton via actin-binding proteins. We can now show that Focal Adhesion Protein (FAP52), a multidomain adaptor protein of 448 amino acids containing a BAR domain and characterized as an abundant component of focal adhesions, directly binds to F-actin. FAP52 binds to F-actin in a similar manner to tropomyosin, and we have used cryo-EM to generate three-dimensional reconstructions of this complex using the BAR domain fragment of FAP52. Strikingly, the curvature of FAP52 on the actin filament is very similar to the curvature previously shown for F-BAR domains binding to membranes. These results suggest that, at least for this BAR domain protein, the interactions with the membrane and with F-actin both can be accomplished by the same protein.

228

**Possible link between copine A and the actin cytoskeleton.**

*M. Han<sup>1</sup>, H. Mao<sup>1</sup>, P. Steimle<sup>2</sup>, T. A. Haystead<sup>3</sup>, C. K. Damer<sup>1</sup>; <sup>1</sup>Biology, Central Michigan University, Mount Pleasant, MI, <sup>2</sup>Biology, University of North Carolina at Greensboro, Greensboro, NC, <sup>3</sup>Pharmacology, Duke University Medical Center, Durham, NC*

Copines make up a multigene family of calcium-dependent, phospholipid-binding proteins. Copine proteins consists of two C2 domains at the N terminus followed by an "A domain" similar to the von Willebrand A domain found in integrins. The C2 domain is a calcium-dependent membrane-binding motif, while the A domain is thought to be a protein-binding domain. We are studying copine protein function in the model organism, *Dictyostelium discoideum*, which has six copine genes, *cpnA*-*cpnF*. Previous research showed that *cpnA*- cells exhibited a cytokinesis defect, a developmental defect, and a defect in contractile vacuole function. To fully understand the role of CpnA in these cellular processes, we used several methods to identify proteins that interact with CpnA. We first used column chromatography and mass spectrometry to isolate proteins that bound to a CpnA-linked agarose column. One of the proteins that eluted from the CpnA-linked column and not the control column was actin. We also carried out immunoprecipitations in the absence of calcium using a polyclonal antibody to GFP with *Dictyostelium* cells expressing GFP, GFP-CpnA, or GFP-fused to the VWA domain of CpnA (GFP-Ado). Actin co-precipitated with GFP-Ado, but not GFP or GFP-CpnA. In addition, we treated cells with Triton X-100 and spun down the insoluble cytoskeletal fraction. GFP-Ado was found in the cytoskeletal pellet in the presence or absence of calcium, while GFP-CpnA was found in the cytoskeletal pellet only in the presence of calcium. GFP alone was not found in the cytoskeletal pellet. This data suggests that the VWA domain of CpnA is able to interact with the cytoskeleton in a calcium-independent manner, while full length CpnA interacts with the cytoskeleton in a calcium-dependent manner. We have also expressed a GST-tagged version of CpnA in *Dictyostelium* and have purified GST-CpnA using glutathione chromatography. We are currently carrying out experiments to test whether CpnA is able to bind directly to actin and is able to regulate actin polymerization in vitro. In addition, we are using GST-pull down assays to explore whether other candidate binding proteins are able to bind directly to CpnA in vitro.

229

**Coronin Effects on Actin Filaments.**

*M. A. Mikati<sup>1</sup>, Z. A. Oztug Durer<sup>1</sup>, E. Reisler<sup>1</sup>; <sup>1</sup>Chemistry and Biochemistry, UCLA, Los Angeles, CA*

Coronin is one of the conserved actin-binding proteins and its different isoforms have been identified in many eukaryotic organisms. Coronin's mode of influencing actin dynamics in the

cell is not well understood yet. In vitro, coronin was found to regulate cofilin's severing of actin filaments in a nucleotide state dependent manner. Here, the structural effects of coronin on F-actin were examined by microscopy and in solution. Electron microscopy (EM) images show shortening of actin filaments in the presence of coronin alone. This effect varies with the nucleotide state of actin. AMP-PNP bound F-actin appears completely shredded in the presence of Crn $\beta$ ;CC. Coronin's recognition of the nucleotide binding site on actin is indicated by a decrease in fluorescence emission and an increase in the accessibility of etheno-ADP to collisional quenchers in the presence of Crn $\beta$ ;CC. The effect of coronin on interprotomer contacts in F-actin was explored by monitoring its impact on disulfide crosslinking reactions. We found that Crn $\beta$ ;CC decreased the inter-strand disulfide cross-linking between Cys265 (H-loop) and Cys374 (C-terminal) in F-actin but increased the cross-linking rates between Cys41(DNase I binding-loop) and Cys374. Our data suggest that coronin binding has an effect on the major structural elements and the interprotomer contact regions of the actin filament.

230

**SPIN90, a novel actin binding protein, induces fibroblasts differentiation depending on substrate rigidity.**

*E. You<sup>1</sup>, D. Kim<sup>1</sup>, P. Ko<sup>1</sup>, W. Song<sup>2</sup>, S. Rhee<sup>1</sup>; <sup>1</sup>Department of Life Science, Chung-Ang University, Seoul, Korea, <sup>2</sup>Bio-Imaging and Cell Dynamics Center, Gwangju Institute of Science and Technology (GIST), Gwangju, Korea*

Mechanical environment has been proposed to alter various cellular processes including cell motility and differentiation. However, the molecular basis for how mechanical signaling is converted into biochemical reaction for cellular events is largely unknown. In this study, we demonstrated that SPIN90 (Nck-interacting protein with SH3 domain), an F-actin binding protein, controls myofibroblast differentiation depending on substrate rigidity. Mouse embryonic fibroblast (MEF) isolated from SPIN90 null mouse protruded profound dendritic extensions in the 3D collagen matrices responding to serum, as compared with control MEFs. Interestingly, SPIN90<sup>-/-</sup> MEFs tended to be able to maintain the protrusion of dendritic extensions even in 3D collagen culture at low cell densities. In addition, SPIN90<sup>-/-</sup> MEFs displayed prominent development of stress fibers with enlargement of vinculin positive focal adhesions and increased the 3D collagen matrix contraction, suggesting a critical role of SPIN90 in cellular contractility. When cells were grown on collagen coated soft polyacrylamide gel on which the tension state of cell-matrix interaction is reduced, SPIN90<sup>-/-</sup> MEFs showed both faster spreading than normal MEFs and focal adhesion kinase (FAK) activation, suggesting that SPIN90<sup>-/-</sup> MEFs seemed to turn on the contractile machineries independent of mechanical and biochemical signaling. Finally, SPIN90<sup>-/-</sup> MEFs can be highly expressed alpha-smooth muscle (alpha-SMA), a marker for myofibroblast, in the soft acrylamide gel without agonist stimulation. The newly expressed alpha-SMA is completely inhibited by Rho kinase inhibitor. In conclusion, our results suggest that SPIN90 could play important roles in regulating the cellular contractility via regulation of FAK/Rho kinase signaling when cells were in the low-tension environments, which in turn contribute to regulating myofibroblast differentiation.

231

**Regulation of endogenous septin scaffolds and the role of p53 and p63.**

*L. V. Hinds<sup>1</sup>, S. S. McDade<sup>1</sup>, D. J. McCance<sup>1</sup>, J. Price<sup>2</sup>, H. Russell<sup>3</sup>, P. A. Hall<sup>3</sup>; <sup>1</sup>Centre for Cancer Research and Cell Biology (CCRCB), Queen's University Belfast, Belfast, United Kingdom, <sup>2</sup>Obstetrics and Gynaecology, Belfast City Hospital, Belfast, United Kingdom, <sup>3</sup>King Faisal Specialist Hospital and Research Centre., Riyadh, Saudi Arabia*

Septins are a conserved family of genes encoding proteins involved in a variety of cellular processes including cytokinesis, polarity, actin and microtubule dynamics, membrane events and apoptosis. These GTP binding proteins are increasingly recognized as a novel part of the cytoskeleton and are now known to form hetero-oligomeric complexes and higher order structures, such as filaments and rings. The human SEPT9 gene has a complex genomic architecture with 18 different transcripts generated through shuffling of six 5' ends and three 3' ends. Two transcripts with unique 5' ends (SEPT9\_v4 and SEPT9\_v4\*) encode the same protein. Five different amino termini isoforms are recognized (SEPT9\_i1-i5) with \_i4 and \_i5 truncated versions of the larger isoforms. In neoplasia the relative ratio of transcripts changes and in particular there is upregulation of SEPT9\_v4\* mRNA, a transcript that is translated with enhanced efficiency leading to increased SEPT9\_i4 protein. We have examined the effect of overexpression of the individual SEPT9 isoforms on endogenous SEPT9 and endogenous SEPT6 scaffolds. We find that SEPT9\_i2, SEPT9\_i4 and SEPT9\_i5 over-expression in two different cell lines induces dramatic actin and cytoskeletal reorganization with the formation of filopodia around the cell periphery when compared to other isoforms. In addition, SEPT9\_i4 and SEPT9\_i5 expression causes disruption of both endogenous SEPT6 and SEPT9 containing filaments with granular staining visible or shorter filaments within the cytoplasm of transfected overexpressing cells. We next examined how one of these small isoforms might be regulated. Using a combination of sequence analysis and CHIP-seq we identified putative p53 and p63 binding sites upstream of the first exon of SEPT9\_v4\*. Using a luciferase reporter gene construct we demonstrate that at least one of these sites is regulated by wild type but not mutant p53 and by all of the TAp63 isoforms ( $\alpha$ ,  $\beta$ ,  $\gamma$ ) and two of the  $\Delta$ Np63 isoforms ( $\alpha$ ,  $\beta$ ). Similarly, the induction of p53 in a p53 wild type background by doxorubicin also led to the upregulation of SEPT9\_v4\*. This upregulation was dependent on p53 since it was lost when p53 was knocked down by siRNA. Conversely, knocking down total p63 caused upregulation of SEPT9\_v4\* in a background of wild-type p53 in HFK cells. Taken together this data suggests that the truncated isoforms of SEPT9 may regulate septin scaffolds and that p53 and p63 both have a role in the regulation of at least one of these isoforms.

**Self-organization in Reconstituted Bundles of Actin and Skeletal Muscle Myosin II.**

*M. R. Stachowiak<sup>1</sup>, P. M. McCall<sup>2</sup>, T. Thoresen<sup>2</sup>, H. E. Balcioglu<sup>1</sup>, L. Kasiewicz<sup>1</sup>, M. L. Garde<sup>2</sup>, B. O'Shaughnessy<sup>1</sup>; <sup>1</sup>Columbia University, New York, NY, <sup>2</sup>University of Chicago, Chicago, IL*

Actomyosin bundles such as muscle myofibrils, stress fibers and cytokinetic rings are used by cells to exert force, contribute to the cell's structural integrity and accomplish morphological change. While these linear structures exhibit varied architecture, two common organizational themes are a punctate distribution of myosin II and distinct patterns of actin polarity. The mechanisms that cells use to assemble and maintain these organizational features are poorly understood. To investigate the mechanisms of organization, we combined mathematical modeling with in vitro reconstitution of actomyosin bundles that contained only actin filaments and skeletal muscle myosin II thick filaments. In the presence of ADP, actin and myosin formed a loose network of stable (>1 hour) bundles ~5-50  $\mu$ m long anchored between polystyrene beads. Upon addition of ATP, the bundles contracted and became taut over 2-8 s. Over a longer

timescale of ~30 s skeletal muscle myosin II, initially distributed uniformly along the bundles, self-organized by translating along the bundle into distinct puncta reminiscent of those in the actomyosin cytoskeleton of living cells. To understand myosin II self-organization quantitatively, we developed a mathematical model in which the motions of myosin thick filaments depend on the local actin polarity. Owing to the random bundle assembly process, actin filaments have random positions and orientations, resulting in local deviations of actin polarity that follow a random walk along the bundle axis. The actin-myosin interaction propels myosins in the direction of local actin polarity, resulting in aggregation of myosin filaments at those locations where the net bundle polarity vanishes. With no fitting parameters, our model successfully reproduces the broad distribution of distances  $d$  between neighboring myosin puncta observed in our experiments. In particular, our prediction that the distribution follows a power law decay  $\sim d^{3/2}$  on intermediate scales less than the filament length is in remarkably close agreement with our measurements. Thus, our results show that the local pattern of actin filament orientation is an important regulator of the larger scale organization of actomyosin structures, and that a minimal bundle of actin and myosin has the inherent capacity to self-organize into a heterogeneous banded structure without an organizing template or accessory proteins.

233

**Plectin contributes to the mechanical stability of keratinocytes and myoblasts.**

A. Schilling<sup>1</sup>, N. Bonakdar<sup>1</sup>, G. Walko<sup>2</sup>, A. Mainka<sup>1</sup>, M. Kuhn<sup>1</sup>, P. Lennert<sup>1</sup>, W. H. Goldmann<sup>1</sup>, G. Wiche<sup>2</sup>, B. Fabry<sup>1</sup>; <sup>1</sup>*Biophysics, University of Erlangen-Nuremberg, Erlangen, Germany*, <sup>2</sup>*Biochemistry and Cell Biology, University of Vienna, Vienna, Austria*

Plectin and its isoforms are promiscuous crosslinkers of actin filaments, microtubules and intermediate filaments (IF). Plectin is expressed in a wide variety of cell types. In epithelial cells and keratinocytes, it is also found in hemidesmosomes that link the laminin receptor  $\alpha 6 \beta 4$  with the keratin IFs. Mutations in the plectin gene cause a skin blistering disorder (epidermolysis bullosa) that is also associated with a late-onset of muscular dystrophy. In both disorders, mechanical alterations of the keratinocytes and the myoblasts, respectively, are thought to be ultimately responsible for the pathological manifestation. To test this hypothesis, we measured the mechanical properties (stiffness, contractility, adhesiveness, and motility) of plectin knockout and plectin-expressing mouse keratinocytes and myoblasts. Cell stiffness was measured by pulling superparamagnetic fibronectin or laminin1-coated beads with a force of 10 nN. The magnetic force was then ramped up to 80 nN, and the cell-bead rupture force was recorded as a measure of adhesive strength. Contraction (only in myoblasts) was measured by polyacrylamide-based traction microscopy, and cell migration was determined over a time course of 5 h. In plectin-deficient myoblasts, stiffness, tractions, and adhesive strength were ~2-fold reduced, indicating that plectin is important for the mechanical stability of these cells. Plectin-deficient keratinocytes assessed under similar conditions were found not to show such effects. Confocal immunofluorescence images of laminin1-coated magnetic beads attached to keratinocytes demonstrated prominent association of the beads with the actin cytoskeleton, but not with keratin intermediate filament-linked hemidesmosomal components. This suggested that the contribution of keratin intermediate filaments to the overall mechanical stability of keratinocytes could not be assessed by this particular (bead-based) type of force measurements. Taken together, our results demonstrate that human diseases associated with plectin mutations have a cell mechanical origin, and that plectin affects the cytoskeleton in different cell types in distinct ways.

234

**ZASP mutations trigger disassembly of F-actin bundles in myofibrillar myopathy.**

X. Lin<sup>1</sup>, J. Ruiz<sup>1</sup>, I. Bajraktari<sup>1</sup>, S. Banerjee<sup>1</sup>, J. Robertson<sup>2</sup>, K. Gribble<sup>1</sup>, R. C. Griggs<sup>3</sup>, K. H. Fischbeck<sup>1</sup>, A. Mankodi<sup>1</sup>; <sup>1</sup>Neurogenetics Branch, NINDS/NIH, Bethesda, MD, <sup>2</sup>Semiconductor Electronics Division, National Institute of Standards and Technology, Gaithersburg, MD, <sup>3</sup>Neurology, University of Rochester, Rochester, NY

Myofibrillar myopathies (MFM) are characterized by a degenerative process that primarily affects the actin myofibrils at the Z-disc in skeletal muscle. In this report we explore the underlying mechanisms of the myofibrillar degeneration in zaspopathy, a prototype MFM. Zaspopathy is caused by heterozygous mutations in the Z-band alternatively spliced PDZ-motif protein (ZASP). The A165V and the A147T mutations are in or near a highly conserved motif that is expressed in skeletal muscle (sZM). We have identified the sZM as a skeletal  $\alpha$ -actin (ACTA1) binding region of ZASP. Both wild type and mutant ZASP bind to actin filaments in vitro, but only the mutant proteins cause disassembly of F-actin bundles induced by  $\alpha$ -actinin 2. To examine the effects of the sZM mutation on skeletal  $\alpha$ -actin in vivo, we electroporated plasmids encoding either ZASP-GFP or ZASPA165V-GFP into the tibialis anterior muscles of wild type mice (n=4). Both GFP-tagged wild type and mutant ZASP co-localized with  $\alpha$ -actinin 2, a marker for the skeletal muscle Z-disc. By 4 weeks after the electroporation, there was streaming of GFP fluorescence from the Z-disc into the sarcoplasm accompanied by a patchy loss of the  $\alpha$ -actinin 2 staining in the muscle fibers expressing mutant ZASP. Phalloidin staining of the same muscles showed focal accumulations of actin filaments that co-localized with ZASPA165V-GFP in the sarcoplasm. Focal accumulations of phalloidin-actin co-localized with ZASP were also seen in biopsied skeletal muscle sections from a patient with zaspopathy. Electron microscopic images of mouse muscle expressing mutant ZASP showed discrete disruption of Z-discs, loss of the normal actin filament pattern, and the presence of cellular debris, including membranous whorls reminiscent of the findings reported in the human disease. These findings were not observed in muscle fibers expressing wild type ZASP. Our observations support a gain-of-function mechanism for ZASP mutations in the pathogenesis of MFM.

235

**Characterization of ZASP-skeletal actin interaction and its role in a myofibrillar myopathy.**

J. Ruiz<sup>1</sup>, X. Lin<sup>1</sup>, I. Bajraktari<sup>1</sup>, S. Banerjee<sup>1</sup>, J. Robertson<sup>2</sup>, K. H. Fischbeck<sup>1</sup>, A. Mankodi<sup>1</sup>; <sup>1</sup>Neurogenetics Branch, NINDS/NIH, Bethesda, MD, <sup>2</sup>Semiconductor Electronics Division, National Institute of Standards and Technology, Gaithersburg, MD

Myofibrillar myopathies (MFM's) are a group of muscular dystrophies characterized by disruption of actin cytoskeleton in skeletal muscle. Zaspopathy, a prototype MFM, is caused by heterozygous mutations in the Z-band alternatively spliced PDZ motif protein (ZASP). The disease-causing mutations A147T and A165V are near or within an evolutionarily conserved 26 amino acid motif expressed in skeletal muscle sZM. The function of sZM and the mechanism by which mutations lead to disease are not yet known. To identify the proteins interacting with the sZM region, we performed yeast two-hybrid (Y2H) screen of human skeletal muscle cDNA library using the 132 amino acids encoded by exons 5-6-7 of ZASP (sZM<sub>132aa</sub>±A165V) as bait. The most frequent prey clones (n=8 for each bait) encoded the 131 C-terminal amino acid residues of skeletal muscle  $\alpha$ -actin 1 protein (ACTA1<sub>247-377</sub>). Pair wise Y2H assays using different regions of ZASP as bait against skeletal actin validated the sZM<sub>132aa</sub> as an actin-binding region of ZASP. Deletion analysis of ACTA1 in Y2H assays showed that the amino

acids 304-325 of skeletal  $\alpha$ -actin are essential for binding to the sZM<sub>132aa</sub> region in ZASP. The interaction between ZASP and skeletal actin was validated by co-immunoprecipitation (co-IP) of these two proteins from mouse muscle lysates as well as transfected Cos7 and HEK293 cell lysates. Presence of either A147T or A165V mutation did not affect ZASP interaction with skeletal actin. ZASP-actin interaction was abolished by deletion of sZM from ZASP in Y2H and co-IP assays. Direct binding of ZASP to skeletal actin filaments was examined by a co-sedimentation assay using purified proteins. After a high speed centrifugation GST remained in supernatant, whereas GST-tagged ZASP proteins sedimented with skeletal actin filaments in pellet. We are performing surface plasmon resonance assays to assess binding affinity of WT and mutant ZASP proteins to skeletal actin. Whereas both WT and mutant ZASP bound to skeletal actin, only the mutant proteins caused disassembly of  $\alpha$ -actinin 2-crosslinked F-actin bundles in vitro and accumulation of F-actin in sarcoplasm in electroporated mouse muscle fibers (ASCB submission # 858). These results suggest that ZASP is a novel skeletal actin binding protein and that sZM is essential for this interaction. F-actin destabilizing properties of mutant ZASP point to a gain-of-function disease mechanism in MFM.

## Regulation of Actin Dynamics I

236

### RhoA and Rac1 GTPases contribute independently to actin regulation during particle engulfment by retinal pigment epithelial cells.

Y. Mao<sup>1</sup>, S. C. Finnemann<sup>1</sup>; <sup>1</sup>Biological Science, Fordham University, Bronx, NY

Mammalian rod photoreceptors renew their outer segments by shedding their distal, aged tips diurnally. These aged photoreceptor outer segment particles (POS) are removed by adjacent retinal pigment epithelial (RPE) cells through an  $\alpha\beta 5$  integrin dependent phagocytosis mechanism that resembles the clearance phagocytosis of apoptotic cells. Particle engulfment during RPE phagocytosis requires actin-rich phagocytic cup formation at the site of bound particles. Rho GTPase family members are the primary regulators of F-actin distribution. We hypothesized that RPE cells utilize Rho GTPases to control phagocytic cup formation during particle engulfment. To determine contributions of individual Rho GTPases to particle engulfment, we investigated the phagocytic activity and F-actin distribution of immortalized or primary rat RPE cells in culture in response to POS particles isolated from pig eyes. We found that expression of a dominant-negative form of Rac1 decreased POS internalization as well as abolished formation of phagocytic cups. In contrast, inhibition of RhoA or its downstream effector Rho kinase (ROCK) increased the particle internalization rate, while activation of RhoA decreased internalization and abolished phagocytic cup formation. Treating RPE cells with the ROCK inhibitory agent Y-27632 reversed the inhibitory effect of RhoA activation on phagocytosis. However, ROCK inhibitor treatment failed to rescue phagocytic cup formation in RPE cells expressing dominant-negative Rac1. Moreover, expression of a constitutively active form of Rac1 did not restore phagocytic cup formation in cells also treated with RhoA activator. Taken together, these results indicate that activation of Rac1 and inhibition of RhoA-ROCK are independently required for phagocytic cup formation during POS engulfment by RPE cells.

237

**Dynamin2 orchestrates Actomyosin assembly and dynamics in non-muscle cells.**

M. Menon<sup>1</sup>, D. A. Schafer<sup>1,2</sup>; <sup>1</sup>Department of Biology, University of Virginia, Charlottesville, VA, <sup>2</sup>Department of Cell Biology, University of Virginia, Charlottesville, VA

Actin networks in non-muscle cells exist in two major architectures: a sheet-like network of branched actin filaments in lamellipodia and parallel, bundled actin filaments which, together with myosin II, comprise actomyosin of contractile stress fibers of lamellae. A current model for formation of one type of stress fiber (transverse arcs) suggests that crosslinked lamellipodial actin filaments co-assemble with myosin assemblies forming actomyosin of lamellae. Our work and that of others have implicated the large GTPase dynamin2 in influencing actomyosin of transverse arcs. To determine dynamin2's function in actomyosin assembly, we used time-lapse microscopy of live U2OS cells expressing two probes of actomyosin: GFP-myosin light chain 2 (MLC2) and mCherry-alpha-actinin. In control cells, nascent myosin assemblies first appeared within the lamellipodia then flowed rearward and coalesced with alpha-actinin-decorated actin filaments forming distinct, striated cables of actomyosin near the lamellipod-lamellum interface. In cells depleted of dynamin2, nascent myosin assemblies appeared more frequently within lamellipodia and their integration with alpha-actinin-decorated actin filaments was irregular; transverse arcs also flowed rearward more rapidly than in control cells. Since dynamin2 localized to the distal edge of lamellipodial actin networks, but not with nascent myosin assemblies, we suggest that dynamin2 orchestrated the transition of a subset of lamellipodial actin filaments into crosslinked filaments optimized for co-assembly with myosin. To test this hypothesis, we examined the spatial and temporal distribution of alpha-actinin within lamellipodia. In control cells, alpha-actinin was discontinuous, with some regions of the network enriched with alpha-actinin compared to other regions. In dynamin2-depleted cells, alpha-actinin was homogeneously distributed within the network. Thus, dynamin2 influences the spatial and temporal distribution of alpha-actinin-decorated actin filaments of lamellipodia. Dynamin2-R399A, a mutant defective in self-assembly but with basal level of GTPase activity, restored the dynamic distribution of alpha-actinin within lamellipodial F-actin and partially restored the retrograde flow of transverse arcs. Surprisingly, dynamin2-T141A, which exhibits increased GTP hydrolysis, did not restore either phenotype in dynamin2-depleted cells. Importantly, the effects of depleting dynamin2 on actomyosin did not result from perturbations in endocytosis, since internalization of either integrin  $\beta$ 1 or transferrin receptor were not significantly perturbed in cells depleted of 80-90% of endogenous dynamin2. Hence, we conclude that dynamin2 regulates actomyosin assembly and dynamics in non-muscle cells, most likely through its actions on lamellipodial actin filaments.

**Early cell spreading depends on actin polymerisation from integrin clusters by FHOD1.**

T. Iskratsch<sup>1</sup>, C-H. Yu<sup>2</sup>, A. Mathur<sup>3</sup>, J. Hone<sup>3</sup>, M. Sheetz<sup>1,2</sup>; <sup>1</sup>Biological Sciences, Columbia University, New York, NY, <sup>2</sup>Mechanobiology Institute, National University of Singapore, Singapore, Singapore, <sup>3</sup>Department of Mechanical Engineering, Columbia University, New York, NY

Matrix adhesions are critical for cell growth and differentiation, and actin network assembly at adhesion sites dynamically regulates various downstream cellular signals. The formation of adhesions depends upon a number of steps that follow integrin binding to matrix ligands and clustering that include actin polymerisation by an unknown mechanism. Actin nucleation and polymerization factors are grouped into several classes, such as the ARP2/3 complex or the formin family proteins. Here we demonstrate that formins are critical for adhesion formation. Furthermore, one of the major formins in mouse fibroblasts, FHOD1, is activated during early

cell adhesion. FHOD1 is also recruited to early integrin clusters in an Src family kinase dependent fashion, concomitantly with outward polymerisation of actin and its knockdown impairs spreading. Other major fibroblast formins on the other hand, such as mDia1 and mDia2 are activated only after the initial fast spreading phase. By showing a sequential involvement of distinct formins in cell spreading with FHOD1 as early regulator of spreading and rigidity sensing, our findings provide novel insights into the mechanisms of cell migration with implications for development and disease.

### **Src Regulation of Actin Dynamics in Growth Cone Filopodia and Lamellipodia.**

Y. He<sup>1</sup>, B. Wu<sup>1</sup>, D. M. Suter<sup>1</sup>; <sup>1</sup>Department of Biological Sciences, Purdue University, West Lafayette, IN

Axonal growth and pathfinding is fundamental to development and regeneration of the nervous system. Src tyrosine kinase has been implicated in axonal growth and pathfinding; however, how exactly it affects the underlying cytoskeleton has remained elusive. Here, we have used quantitative fluorescent speckle microscopy to determine which specific aspects of actin and protrusion dynamics are controlled by Src activity in neuronal growth cone filopodia and lamellipodia. We manipulated and determined protein levels and activities of *Aplysia* Src2 tyrosine kinase by expressing various mutant constructs in cultured *Aplysia* neurons in a controlled manner. Our results show that the expression of constitutively active (CA) Src2 increases density and lateral movements of filopodia compared with controls, while the expression of dominant negative (DN) Src2 has opposite effects, suggesting a positive role of Src2 in filopodia formation and integration within the lamellipodial actin network. On the other hand, analysis of actin dynamics revealed that CA Src2 expression only slightly increases filopodial actin assembly rate and protrusion time, while DN Src2 expression slightly decreases actin assembly rate, suggesting a minor role of Src2 in filopodial elongation. CA Src2-expressing growth cones also spend more time in leading edge protrusion and thereby have wider lamellipodia compared with control growth cones, while DN Src2-expressing growth cones have narrower lamellipodia, suggesting that Src2 activity enhances actin assembly in growth cone lamellipodia rather than filopodia. These findings support our hypothesis that Src activity promotes actin assembly and branching in growth cone lamellipodia in an Arp2/3 complex-dependent manner, a hypothesis that will be tested in future experiments.

### **The role of actin polymerization in regulating endothelial cell barrier function.**

L. B. Case<sup>1,2</sup>, N. Gutierrez<sup>1,3</sup>, C. Higgins<sup>1,4</sup>, L. Gao<sup>1,5</sup>, C. M. Waterman<sup>1,2</sup>; <sup>1</sup>Physiology Course, MBL, Woods Hole, MA, <sup>2</sup>NIH, Bethesda, MD, <sup>3</sup>Rutgers University, Newark, NJ, <sup>4</sup>University of North Carolina, Chapel Hill, NC, <sup>5</sup>HHMI Janelia Farm, Ashburn, VA

Endothelial cells form a selectively permeable barrier in blood vessels and arteries. Endothelial cells are exposed to a variety of extracellular stimuli including shear force, pulsatile stretching, soluble factors such as growth factors and chemokines, as well as leukocyte adhesion and transmigration. Since the endothelial cytoskeleton is known to play a role in regulating vascular permeability, we sought to test the hypothesis that different stimuli may compromise barrier function via specific effects on the actin cytoskeleton of endothelial cells. In this study, we examine how the endothelial actin cytoskeleton and cell-ECM adhesions change in response to growth factors and chemokines known to induce vascular permeability as well as to membrane rupture induced by physical perturbation. We expressed a fluorescently-labeled F-actin marker with fluorescently labeled paxillin in primary human umbilical cord endothelial cells (HUVECs)

and imaged cells by total internal reflection fluorescence microscopy (TIRF). We found that endothelial cells have small (3-5 $\mu$ m) semicircular dynamic actin structures that propagate along the ventral ECM-attached surface of the cell. These adhesive F-actin waves contain paxillin and integrin, but do not degrade fluorescently labeled-gelatin. Adhesive F-actin waves are sensitive to VEGF, Thrombin and TNF $\alpha$ . To determine how HUVECs responded to physical disruption, we used a 440nm dye-laser to ablate small (~1-2 $\mu$ m) holes in the ventral plasma membrane and cell cortex. The wounds formed by laser ablation were consistently healed by a burst of Arp2/3-mediated actin polymerization, and myosin II contractility was not required for wound closure. We conclude that dynamic actin polymerization contributes to endothelial response to growth factors and is essential for proper closure of plasma membrane wounds.

241

### **Regulating the Actin Cytoskeleton During Transendothelial Migration.**

*O. L. Mooren<sup>1</sup>, J. Li<sup>1</sup>, J. A. Cooper<sup>1</sup>; <sup>1</sup>Washington University, St. Louis, St. Louis, MO*

Transendothelial migration (TEM), or diapedesis, is a vital physiological process by which leukocytes cross from the bloodstream into the underlying tissue. During migration to the site of an infection or tissue damage, the leukocyte must cross the endothelium. Two routes are taken by the leukocyte: either a paracellular route, which is between two adjacent endothelial cells, or a transcellular route, which is directly through one endothelial cell. Leukocytes and endothelial cells actively participate in this process by signaling to one another, and by regulation of their respective actin cytoskeletons. Much research has revealed key players within the lymphocytes during TEM, however much less is known about the mechanisms that govern regulation in the endothelial cells.

Since actin regulation via various Rho GTPases within endothelial cells is important for transendothelial migration, we hypothesized that the Arp2/3 complex regulators would play key roles during TEM. Using RNAi, we examined the role of N-WASP, WAVE2, and cortactin in TEM. Using a transwell assay we observed reduced TEM of lymphocytes through N-WASP, WAVE2 and cortactin knockdown endothelial cells. Interestingly, counting the number of transmigration events by immunofluorescence revealed a reduction in both the paracellular and transcellular routes of transmigration of lymphocytes in cortactin and N-WASP knockdown cells. However, there was no change observed for paracellular transmigration of lymphocytes in WAVE2 knockdown cells, but a decrease in the number of transcellular events. Arp2/3, WAVE2, N-WASP and cortactin are all recruited to form rings around anti-ICAM-1 coated beads, which cluster ICAM-1, form a docking structure, and initiate downstream signaling important for TEM.

In resting endothelium, WAVE2 and cortactin localize to junctions, while there is little to no localization of Arp2/3 or N-WASP at junctions. All these proteins can be strongly recruited to junctions following S1P treatment, indicating a potential role in the maintenance of the endothelial barrier. Indeed, the permeability and transendothelial resistance of the monolayers are altered following knockdown of Arp2/3 regulators, suggesting a role for each in maintaining the integrity of the monolayer. The contribution of Arp2/3 regulators to barrier integrity influences transmigration.

242

**Mobile Actin Densities in the Axons of Rat Sensory Neurons.**

J. Chetta<sup>1</sup>, S. Shah<sup>2</sup>; <sup>1</sup>University of Maryland, College Park, MD, <sup>2</sup>University of California, San Diego, La Jolla, CA

Local and long-distance transport of cytoskeletal proteins is vital to the maintenance and growth of the axon in neurons. Though recent progress has provided insight into the movement of microtubules and neurofilaments, mechanisms underlying the movement of actin remain elusive, in large part due to rapid transition between its filament states and its diverse cellular localization and function. In this work we have undertaken the first quantitative, high-resolution characterization of actin movement in individual axons of rat sensory neurons during unimpeded growth. Cells were transfected with GFP-actin and seeded on laminin coated glass coverslips. Transient GFP-actin densities that moved bidirectionally were observed along the length of the axon. These densities were composed of filamentous actin, which our data suggest were created through bundling of actin filaments rather than through polymerization or de novo synthesis in the axon. Further, kymographic analysis was used to show quantitative and qualitative differences in the dynamics of these densities compared to other soluble proteins in the axon. Although there were long-lived densities, many arose, moved in complex bidirectional paths, and then disappeared. Despite this complexity, there was an anterograde bias in the net movement of all densities in an axon. This net displacement was consistent with rates of slow component B transport (8.5mm/day). These results suggest a novel form of actin transport. In order to test this, cells were exposed to either latrunculin or nocodazole to test the effect of altered structural integrity in the actin and microtubule cytoskeletal networks. We show that increased stability of either microtubules or actin inhibits the movement of these densities. Similarly, EHNA and BDM were used to inhibit the motor proteins dynein and myosin. Surprisingly, dynein is not responsible for the retrograde movement of actin and myosin appears to be not involved. Taken together, these results suggest a novel mechanism in which actin, unlike other proteins, is not transported along microtubule tracks. It is unclear if actin piggybacks onto short mobile microtubules or if another mechanism is at work. Regardless, this represents the first comprehensive quantitative analysis of actin movement in the axon. We have identified key players in actin transport and raise specific testable hypotheses for future study.

243

***Rickettsia* motility occurs in two temporally and mechanistically distinct phases mediated by different actin nucleators.**

S. C. Reed<sup>1,2</sup>, R. L. Lamason<sup>1</sup>, V. I. Risca<sup>3</sup>, E. Abernathy<sup>2</sup>, M. D. Welch<sup>1</sup>; <sup>1</sup>Molecular and Cell Biology, University of California, Berkeley, Berkeley, CA, <sup>2</sup>Microbiology Graduate Group, University of California, Berkeley, Berkeley, CA, <sup>3</sup>Department of Genetics, Stanford University School of Medicine, Stanford, CA

Spotted fever group *Rickettsia* hijack the host actin cytoskeleton to invade, move within, and spread between host cells during their obligate intracellular life cycle. *Rickettsia parkeri* express two bacterial proteins that can activate host actin polymerization: RickA activates the host actin-nucleating Arp2/3 complex while Sca2 directly nucleates actin filaments by mimicking host formins. We sought to determine how each protein contributes to bacterial actin based-motility and actin comet tail formation. Over the timecourse of infection of cultured endothelial cells, we observed that *Rickettsia* form actin comet tails immediately after invasion (early actin tails), followed by a decrease in tail formation after 2 h post-infection, and an increase as actin tails again become numerous at 24-48 h post-infection (late actin tails). Late actin tails, as previously described, were long, composed of helical bundles of actin, and associated with polar localization of Sca2. Late tail formation was insensitive to treatment with Arp2/3 inhibitors, and

the Arp2/3 complex was not recruited to late tails. Time-lapse microscopy indicated that late actin-based movement was more rapid and followed a straighter path when compared to either early *Rickettsia* motility or *Listeria monocytogenes* actin-based motility in the same cell type. In contrast with late tails, early tails were formed only between 15 and 60 min after infection, had a distinctive short and curved appearance, and were associated with polar localization of RickA. Early tails were decorated with the Arp2/3 complex proteins Arp3 and ARPC5, and treatment with Arp2/3 inhibitors blocked early tail formation. Finally, early actin-based motility was slower and paths of movement were more curved compared to late motility. Interestingly, the parameters of early *Rickettsia* motility resemble those of *Listeria* motility, also an Arp2/3 complex-dependent process. We conclude that RickA activates the Arp2/3 complex during early actin-based motility, while Sca2 independently nucleates actin during late motility. Thus *Rickettsia* are unusual in their ability to promote two temporally and mechanistically distinct phases of actin-based motility during infection, possibly performing unique functions during the bacterial life cycle.

244

#### **Diverse strategies of actin-based motility within the *Burkholderia* genus.**

E. L. Benanti<sup>1</sup>, C. M. Nguyen<sup>1</sup>, M. D. Welch<sup>1</sup>; <sup>1</sup>Molecular and Cell Biology, University of California, Berkeley, Berkeley, CA

The pseudomallei group of *Burkholderia* spp. are Gram-negative facultative intracellular pathogens that use actin-based motility to facilitate their spread from one host cell to another. Previous studies identified the bacterial protein BimA as a factor that is required for actin-based motility. However, BimA sequence differences among three species from this group (*B. pseudomallei* (Bp), *B. mallei* (Bm) and *B. thailandensis* (Bt)) and previous biochemical studies of two of the three BimA proteins suggest that each ortholog mediates actin nucleation by a distinct mechanism. We sought to determine if the actin tails formed by bacteria expressing different BimA orthologs display distinct filament architectures. To enable the analysis of BimA from select agent strains (Bp and Bm), we engineered non-infectious Bt strains that lack endogenous *bimA* and instead contain *bimA* from Bp or Bm. Confocal and structured illumination microscopy of mammalian cells infected with bacteria that express BpBimA, BmBimA or BtBimA revealed actin tail morphologies unique to each ortholog. Both BpBimA- and BmBimA-expressing strains generate tails consisting of helical actin bundles similar to those observed for *Rickettsia* spp. In contrast, the BtBimA-expressing strain generated tails that were more densely packed with actin, reminiscent of *Listeria monocytogenes* actin tails. The expression of distinct BimA orthologs also resulted in different motility rates in infected mammalian cells, as well as in *Xenopus laevis* egg extract. These results support the idea that BimA from different *Burkholderia* spp. mediates actin nucleation by distinct mechanisms, and suggest that differences in polymerization mechanism and tail architecture have functional consequences for actin-based motility.

245

#### **Actin dynamics in the sea urchin egg.**

A. Ellis<sup>1</sup>, C. B. Shuster<sup>1</sup>; <sup>1</sup>Department of Biology, New Mexico State University, Las Cruces, NM

The actin cytoskeleton of the early sea urchin embryo is organized into a thin, isotropic cortex with many interspersed microvilli. And while much is known regarding the upstream and proximal regulators of actin polymerization during cell migration, it is unclear how these regulators contribute to actin organization early in development or how these regulators are themselves modulated by the cell cycle. In an effort to understand actin organization and function during the embryonic cell cycle, we employed GFP-Lifeact to follow actin filament

dynamics during the first embryonic cell division. In addition to the contractile ring, we were able to identify four distinct populations of actin filaments in sea urchin eggs, all of which were subject to changes in CDK1 activity. Upon entry into mitosis, microvilli were found to be short and dense leading up to mitotic exit, at which time they elongated at a rate of approximately 340 nm/minute. A thin submembranous population of actin filaments could also be detected that underwent a transient thinning upon anaphase onset, only to recover shortly before cytokinesis. A bright ring of nuclear actin was observed that collapsed approximately 2-3 minutes prior to nuclear envelope breakdown. Lastly, GFP-Lifeact revealed an explosive elaboration of cytoplasmic actin occurring just prior to the metaphase-anaphase transition. The polymerization of cytoplasmic actin appeared to initiate at the cell surface, moving in wave towards the cell center. However, kymograph analysis suggested that these filaments were not being transported inward, but were instead stationary, disassembling during cytokinesis. Our current efforts are focused on identifying the proximal regulators of these different actin populations, but injection of C3 transferase ablated all actin-based structures, implicating RhoA-dependent actin modulators as likely candidates.

246

**Pulsed accumulation of RHO-1 drives focal contractility in the early *C. elegans* embryo.**

J. Michaux<sup>1</sup>, E. Munro<sup>1</sup>; <sup>1</sup>University of Chicago, Chicago, IL

Actomyosin contractility is a key force generator for a diverse range of developmental processes including cell polarization, cell division, cell migration and tissue morphogenesis. We are using the early *C. elegans* embryo as a model system to study a mode of contractility known as pulsed contractility, in which cycles of actomyosin assembly, contraction, and disassembly produce transient local deformations of the cell surface. Pulsed contractions occur in a variety of contexts including polarity establishment in *C. elegans*, dorsal closure in *Drosophila*, and convergent extension in *Xenopus*, but despite their widespread occurrence and apparent importance, the mechanisms that underlie their initiation and termination are poorly understood. Pulsed contractions likely represent an excitable event initiated by positive feedback, and terminated via delayed negative feedback. As a first step towards identifying key feedback mechanisms, we used dual-color near-TIRF microscopy to measure the kinetics and recruitment order of four known regulators of pulsed contractility: RHO-1 and its downstream targets ANI-1 (Anillin), F-actin and NMY-2 (non-muscle myosin II). We found that ANI-1, F-actin and NMY-2 accumulate and dissipate with nearly identical timing during pulsed contractions both in the polarizing zygote P0 and in the non-polarized AB blastomere. In contrast, a biosensor for active RHO-1 accumulates and dissipates *before* its targets in AB and *with* its targets in P0. These data suggest that pulsed contractions are driven by transient activation of RHO-1. Hypothesizing that one or more of RHO-1's downstream targets feedback to promote its further activation/accumulation, we depleted embryos of each target and measured RHO-1 dynamics. NMY-2 depletion/inactivation had no effect on RHO-1 pulses. Depletion of ANI-1 had little effect on RHO-1 or NMY-2 pulses in AB, but shortened pulse duration and increased the delay between RHO-1 and NMY-2 appearance/disappearance in P0. This suggests that neither ANI-1 nor NMY-2 are required for RHO-1 pulses, but that ANI-1 may act during polarization to more strongly couple RHO-1 and NMY-2 during individual pulses. In contrast, depolymerizing F-actin abolished RHO-1 pulses, instead producing stable co-accumulations of RHO-1, ANI-1 and NMY-2. This suggests that either F-actin assembly participates in a positive feedback loop that drives RHO-1 activation/accumulation or F-actin forms a scaffold that is required for such a feedback loop to operate. Finally, inhibiting F-actin disassembly caused an increase in RHO-1 pulse duration, suggesting that filament disassembly may be involved in pulse termination.

247

**Calcium influx contributes to cytoskeletal remodeling and positioning of CRAC channels at the immune synapse.**

C. Hartzell<sup>1</sup>, R. S. Lewis<sup>1</sup>; <sup>1</sup>Dept. of Molecular and Cellular Physiology, Stanford University, Stanford, CA

Calcium influx through Ca<sup>2+</sup> release-activated Ca<sup>2+</sup> (CRAC) channels is an essential signal for T lymphocyte activation and immune function. Following antigen-induced depletion of Ca<sup>2+</sup> from the endoplasmic reticulum (ER), the ER Ca<sup>2+</sup> sensor STIM1 accumulates at ER-plasma membrane (PM) junctions where it traps and activates Orai1, the pore-forming subunit of the CRAC channel in the PM. STIM1 and Orai1 accumulate at the immune synapse (IS) that forms between the T cell and the antigen presenting cell, raising the question of how CRAC channels become localized to the IS and whether Ca<sup>2+</sup> influx through these channels influences IS formation or function. To address these questions, we stimulated Jurkat T cells on coverslips coated with anti-CD3 antibodies and monitored the organization of eGFP- or mCherry-tagged proteins at the IS using time-lapse TIRF microscopy. As T cells spread on the coverslip, actin and myosin accumulated in concentric rings around the center of the contact region, with myosin forming filamentous structures at the central boundary of the actin ring. Actin and myosin flowed continuously towards the center of the IS where they disassembled, leaving a cleared central region. ER tubules extended continuously from this central region towards the cell periphery on the tips of growing microtubules, while actin treadmilling appeared to push ER tubules back towards the center of the IS. Fluorescent puncta containing STIM1 and Orai1 accumulated in the central actin-poor region of the IS, suggesting that corraling of the ER restricts STIM1 to the center of the IS, where it can trap and activate Orai1. Interestingly, acute removal of extracellular Ca<sup>2+</sup> or addition of 2-APB, a CRAC channel blocker, evoked an increase in filamentous actin at the cell footprint, inhibited actin treadmilling, and caused myosin to become disordered, indicating that Ca<sup>2+</sup> influx through CRAC channels is required for cytoskeletal reorganization during IS formation. Based on these results, we hypothesize that open CRAC channels promote their own localization at the center of the IS through a feedback loop involving calcium influx, actomyosin dynamics, and ER positioning.

248

**GMF severs Arp2/3 complex-actin filament branches by a cofilin-like mechanism.**

C. A. Ydenberg<sup>1</sup>, S. B. Padrick<sup>2</sup>, M. Sweeney<sup>1</sup>, M. Gandhi<sup>3</sup>, B. L. Goode<sup>1</sup>; <sup>1</sup>Department of Biology, Brandeis University, Waltham, MA, <sup>2</sup>Department of Biochemistry, University of Texas, Southwestern Medical Center, Dallas, TX, <sup>3</sup>Myriant Technologies, LLC, Quincy, MA

Rapid actin assembly and disassembly are responsible for driving lamellipodial extension, propulsion of intracellular parasites, and internalization of endocytic patches. In all of these systems, actin filaments are nucleated from the sides of existing filaments by the Arp2/3 complex, a multimer consisting of two actin-related subunits and five unrelated subunits, together with a nucleation promoting factor (NPF) such as WASp. Arp2/3 complex remains bound to both the mother and daughter filaments after nucleation, creating a stable, 70°-angled, branch. ADF/cofilin plays a key role in the disassembly of all actin structures, where it contributes to disassembly by severing filaments. Previously, our group showed that GMF, a highly conserved cousin of ADF/cofilin, localizes to endocytic patches in yeast and, in vitro, binds to and inhibits nucleation by Arp2/3 complex. TIRF microscopy revealed that yeast GMF also dissociates daughter filaments from mothers, identifying GMF as the first dedicated “debranching factor”. Here, we show that these activities are conserved in murine GMF isoforms. Further, we identified functional surfaces on yeast GMF through scanning mutagenesis. From a collection of 19 mutant alleles, five compromised cell growth in a *cof1-22*

background. All 19 of the corresponding mutant proteins were purified and their activities compared. Three of the mutants defective *in vivo* also were impaired for nucleation inhibition and debranching *in vitro*. The surface defined by these mutants corresponds to a surface on ADF/cofilin that binds both G- and F-actin, the G/F-site. A fourth mutant was defective specifically in debranching, demonstrating that nucleation inhibition and debranching are separable activities. Interestingly, the debranching-specific mutant is located on a different surface of GMF, analogous to the F-site in ADF/cofilin. Chemical cross-linking suggested that GMF interacts with the Arp2, Arp3, and p40/ARPC1 subunits of Arp2/3 complex, and anisotropy revealed that GMF binds with high affinity to Arp2/3 complex ( $K_d = 7$  nM). Based on these data and structural modeling, we propose that the G/F-site of GMF interacts with the barbed ends of Arp2 and/or Arp3, and that the F-site may interact with the first actin subunit in the daughter filament. This mode of interaction is similar to ADF/cofilin binding to actin filaments, in which it uses its G/F- and F-sites to interact with two different actin subunits along the long-pitch of a filament. Thus, the actin severing mechanism of ADF/cofilin may have been adapted in GMF to specifically sever Arp2/3 complex generated branch junctions.

249

**Actin-regulated feedback loop based on Phactr4, PP1 and cofilin maintains the actin monomer pool.**

G. Huet<sup>1</sup>, E. Rajakylä<sup>1</sup>, T. Viita<sup>1</sup>, K-P. Skarp<sup>1</sup>, M. Crivaro<sup>1</sup>, M. Vartiainen<sup>1</sup>; <sup>1</sup>Institute of Biotechnology, Helsinki, Finland

Phactr proteins are actin binding proteins (ABPs) required for several key steps during multicellular development such as angiogenesis. The four members of this family vary in their expression pattern and little is known of their exact functions in cell biological context. Interestingly, they bind actin with their RPEL domain, which has previously been shown to regulate the nucleocytoplasmic transport of MRTF-A in response to actin dynamics. Our work describes an entirely new adaptation for the RPEL domain in Phactr4 in the regulation of actin monomer levels. The RPEL domain does not regulate the subcellular localization of Phactr4. We show that protein phosphatase 1 (PP1) and actin compete for binding to Phactr4 RPEL domain. Therefore, at low actin monomer levels Phactr4 can bind to and activate PP1, which will then dephosphorylate its downstream target cofilin, a small ABP. Cofilin then acts to restore actin monomer levels by severing and disassembling actin filaments. Consequently, this final step closes the self-regulating feedback loop, where actin monomers regulate their own number through coordinated action via Phactr4.

250

**Using Bio-Layer Interferometry to determine affinities between ADF and a family of putative ADF regulators.**

M. A. Emmanuel<sup>1</sup>, P. H. Grey<sup>1</sup>, D. G. Oppenheimer<sup>1,2,3</sup>; <sup>1</sup>Department of Biology, University of Florida, Gainesville, FL, <sup>2</sup>Plant Molecular & Cellular Biology Program, University of Florida, Gainesville, FL, <sup>3</sup>UF Genetics Institute, University of Florida, Gainesville, FL

The actin cytoskeleton is required by all eukaryotic cells to carry out key functions such as cellular motility and intracellular trafficking of cellular components. One of the most important actin-binding proteins responsible for actin remodeling is Actin Depolymerizing Factor/Cofilin (ADF). Higher plants have moderately-sized ADF families. The *Arabidopsis* genome encodes 11 ADF genes (*ADF1-ADF11*). Current work in our lab on ADF regulation in *Arabidopsis*, led to the identification of a novel regulator of ADF1 called Irregular Trichome Branch 3 (ITB3). In addition to *ITB3*, *Arabidopsis* has 21 additional *ITB3-Like* genes (*ITB3L1-ITB3L21*). The role of these ITB3 family proteins is still largely unknown. Based on our previous results, we suspect that the

remaining ITB3 family members also function in regulating ADF1 and/or other ADF family members. Here we will report the results of determining the binding affinities of ITB3 family members to the ADF family members. The central hypothesis being tested is that the ITB3 family members will show binding specificity with respect to specific ADF family members. We will use a label free assay called Bio-Layer Interferometry to determine if different ITB3 family members bind to specific ADF family members. In addition to testing the binding of one protein to another, Bio-Layer Interferometry will allow us to characterize binding affinity ( $K_d$ ), association rates ( $k_a$ ) and dissociation rates ( $k_d$ ) in real time. Initially, we will test four different ITB3 family proteins, ITB3, ITB3L-3, ITB3L-6, and ITBL-11 (representing all three ITB3 family clades) to ADF1. We will then extend our analysis to other ADF family members representing the four characterized ADF subclasses in Arabidopsis. The results of our analyses will help define a function for a large conserved gene family in plants, and extend our knowledge about the regulation of ADF.

251

**Cofilin regulation of actin realignment is essential for vascular endothelial barrier integrity during shear stress.**

*J. B. Slee<sup>1</sup>, L. J. Lowe-Krentz; <sup>1</sup>Biological Sciences, Lehigh University, Bethlehem, PA*

Fluid shear stress (FSS) induces vascular endothelial cell and actin microfilament realignment in the direction of FSS in vitro and in vivo, yet the molecular mechanisms underlying this process are not completely understood. At least one mechanosensing mechanism has been identified involving a complex of PECAM-1, VE-cadherin, and VEGFR2. While PECAM-1 and VEGFR2 are reported to be responsible for downstream signaling, VE-cadherin functions as an endothelial cell-specific component of adherens junctions which is essential for maintaining endothelial barrier integrity. The cytoplasmic domain of VE-cadherin is known to associate with p120-,  $\beta$ -,  $\gamma$ -, and  $\alpha$ -catenin to mediate connections to the actin cytoskeleton. Regulation of actin microfilament turnover depends in part upon the Actin Depolymerizing Factor (ADF) family of proteins, of which cofilin is a prominent player. We have determined that FSS induces p-cofilin accumulation in nuclei of vascular endothelial cells and decreased p-cofilin in the cytoplasm. Two cofilin mutants (S3A and S3D) both disrupt multiple stages of the actin realignment process indicating that continued modulation of cofilin phosphorylation is important for actin realignment. Vascular endothelial cells expressing either of the cofilin mutants were utilized to study the role of actin realignment during FSS in maintaining endothelial barrier integrity. Inhibition of dynamic changes in cofilin phosphorylation through cofilin mutants decreased barrier integrity as determined by immunofluorescent staining for VE-cadherin and  $\beta$ -catenin. In similar experiments, inhibition of stress kinases, JNK and p38, also interfered with actin realignment and maintenance of barrier structure. These results identify the importance of actin realignment in maintaining the endothelial barrier during FSS and the necessity of cofilin phospho-regulation in control of the actin realignment. Ongoing research in the lab is funded by NIH grant award HL54269 to LJK.

252

**Identification of novel nuclear actin regulating proteins using genome-wide RNAi screening.**

*J. Dopie<sup>1</sup>, T. Xie<sup>2</sup>, M. Vartiainen<sup>1</sup>; <sup>1</sup>Institute of Biotechnology, University of Helsinki, Helsinki, Finland, <sup>2</sup>ICCB-Longwood Screening facility, Harvard Medical School, Boston, MA*

Actin is an essential protein that functions in various cellular activities including cell motility and cytokinesis. Actin exists either as monomers or filaments and the regulated assembly and

disassembly of actin filaments is important in the numerous functions of actin in the cytoplasm. In the nucleus, actin is central in the gene expression machinery and serves as an essential component of many nuclear complexes including the chromatin remodelling, RNA polymerases and mRNA processing and export complexes. Recent data have shown an active nuclear export and import mechanism for actin. However the dynamic regulation of nuclear actin is unclear. For example, the relationship between actin monomers and filaments in the nucleus is not known. Moreover, the form of actin involved in these critical nuclear functions remains a subject of debate. In the cytoplasm, the functions of actin are highly regulated by actin-binding proteins most of which also localize to the nucleus but the relations between actin and actin-binding proteins in the nucleus have not been studied. Here we employ RNA interference in cultured *Drosophila* cells to identify novel nuclear actin regulators and to understand the regulatory mechanism of actin in this compartment. Results from our genome-wide screen reveal several novel pathways that impinge on nuclear import of actin.

253

### **Properties and dynamics of nuclear actin.**

*G. Huet<sup>1</sup>, M. Vartiainen<sup>1</sup>; <sup>1</sup>Institute of Biotechnology, Helsinki, Finland*

Historically described as cytoplasmic, actin is also a nuclear protein that plays important roles in various steps of gene expression. Chromosome movements, transcription by the three types of polymerases but also messenger RNA processing in the nucleus are now widely recognized as actin-dependent events. Several actin-regulating proteins are located in the nucleus and some nuclear effectors of actin have been described. These include MRTF-A, a coactivator of the transcription factor SRF. Of importance, the nuclear import and export mechanisms of actin were recently clarified. However, many questions remain open about the organization of actin in the nucleus. For instance, its polymerization state, the variety and organization of actin-containing protein complexes, or the dynamics of actin interactions at the level of chromatin during gene expression processes. We have used molecular biology techniques and confocal microscopy to study the localization and the dynamics of actin in the nucleus of mammalian cells. Through these approaches, we collect clues to assess the mobility properties of actin in the nucleus and to identify the precise steps in nuclear events that involve actin. These observations aim ultimately to understand how this versatile protein performs its nuclear functions at the molecular level.

### **RanGTP regulates the Arp2/3 complex to nucleate actin on chromosomes in starfish oocytes.**

*M. Mori<sup>1</sup>, H. Yokoyama<sup>1</sup>, K. Somogyi<sup>1</sup>, P. Lenart<sup>1</sup>; <sup>1</sup>European Molecular Biology Laboratory, Heidelberg, Germany*

Chromosome congression and segregation are known to be coordinated by the dynamic spindle microtubules in dividing cells. However, we recently showed that microtubules do not have sufficient length to capture all chromosomes scattered in the large nucleus of starfish oocytes. An actin-driven mechanism is therefore essential to deliver chromosomes to the “reaching distance” of spindle microtubules. Although this mechanism is essential to prevent aneuploidy of the egg and thus for the survival of the embryo, the underlying molecular mechanisms are completely unknown.

We tested actin nucleators that may be involved in this process, and we found the Arp2/3 complex to show a striking localization: right at nuclear envelope breakdown the Arp2/3 was recruited to the contact surface of chromosomes and nuclear envelope membranes. This

localization was confirmed by expressing a GFP-tagged Arp2/3 subunit, Arpc1-GFP, as well as by immunofluorescence using a starfish Arpc1 specific antibody. Concomitant with Arp2/3 recruitment we also observed the formation of large patches of F-actin that surrounded individual chromosomes. Treatment with an Arp2/3 inhibitor, CK-666 blocked the formation of the F-actin patches, evidencing that Arp2/3 complex nucleates these structures. In the contrary, Arp2/3 inhibition did not affect the overall structure of the F-actin the meshwork present in the cytoplasm. Therefore, we conclude that the Arp2/3 complex functions specifically to nucleate actin filaments on chromosomes and thereby forming a direct linkage between chromosomes and cytoplasmic actin filaments.

Next, we investigated how chromosomes may promote recruitment and activation of the Arp2/3 complex on their surface. The small GTPase Ran is known to form a RanGTP gradient around chromosomes during M-phase that serves as a positional marker to guide processes as such microtubule dynamics. Therefore, we tested whether RanGTP was also involved in regulating the Arp2/3 complex by injecting a large excess of the RanGTP binding protein, Importin-beta. In these oocytes Arp2/3 no longer localized around chromosomes and F-actin patches did not form. These results indicate that RanGTP generated on chromatin recruits and activates the Arp2/3 complex that nucleates dense F-actin patches directly linking chromosomes to the actin cytoskeleton. This also evidences that RanGTP not only regulates microtubule dynamics but also the actin cytoskeleton.

#### **CD2AP, Capping Protein and Cortactin Coordinate to Regulate Dynamic Actin Assembly at the Cell Periphery.**

*J. Zhao<sup>1</sup>, S. Bruck<sup>1</sup>, S. Cemerski<sup>1</sup>, L. Zhang<sup>1</sup>, B. Butler<sup>2</sup>, A. Dani<sup>1</sup>, J. A. Cooper<sup>2</sup>, A. S. Shaw<sup>1,3</sup>; <sup>1</sup>Department of Pathology and Immunology, Washington University, St. Louis, MO, <sup>2</sup>Department of Cell Biology and Physiology, Washington University, St. Louis, MO, <sup>3</sup>Howard Hughes Medical Institute, St. Louis, MO*

Understanding the physiology of complex relationships between components of signaling pathways and the actin cytoskeleton is an important challenge. CD2AP is a membrane scaffold protein implicated in a variety of physiological and disease processes. The physiological function of CD2AP is unclear, but its biochemical interactions suggest it may have a role in dynamic actin assembly. Here we report that a critical physiological function of CD2AP is to recruit actin capping protein (CP) to the cell periphery, and that this is necessary for formation of the short branched filaments that characterize lamellipodia formation and are required for cell migration. Furthermore, we discovered that recruitment of CD2AP to the cell periphery is mediated by cortactin which can stimulate actin assembly and Arp2/3 activity. We provide the first evidence of physiological relevance for the biochemical interaction between cortactin and CD2AP and the novel conclusion that recruitment of CD2AP is a key element of cortactin function in cells. These results demonstrate how the interplay between specialized actin regulatory molecules can shape the actin cytoskeleton.

#### **The Role of The Capping Protein – CARMIL-1 Interaction in Migrating Cells.**

*M. Edwards<sup>1</sup>, T. Kim<sup>1</sup>, Y. Liang<sup>1</sup>; <sup>1</sup>Washington Univ St Louis Sch of Med, St. Louis, MO*

Regulation of the creation and capping of actin filament barbed ends by Rho family GTPases, is central to the control of actin cytoskeletal architecture and cellular migration. Recent work in this area has revealed a class of proteins, which can generate free, barbed ends, by uncapping capped filaments. The CARMIL family, (Capping Protein, Arp2/3 and Myosin I Linker), falls into

this class of actin filament uncapping proteins. Knockdown of CARMIL-1 leads to a reduction of cell migration speed, impaired actin assembly at the leading edge, and a loss of fibronectin-induced Rac1 activation. Here we examined the function of the CARMIL-1- Capping Protein, CP, interaction in these regulatory functions of CARMIL-1. In these studies we employed the KR987/989AA CARMIL-1 mutant, which does not interact with CP. Our results indicate CARMIL-1 's role in leading edge actin assembly is dependent on its interaction with Capping Protein. In contrast, its role in Rac1 activation and cell migration is not dependent on the CARMIL-1-CP interaction. This finding is of particular interest given that the assembly of branched actin networks, impaired in the CARMIL-1 knockdown, is believed to play an integral role in generating force for cell migration. Future studies will focus on discovering CP independent mechanisms of cell migration regulation by CARMIL-1.

257

**A CARMIL and V-1/Myotrophin-Dependent Regulatory Cycle for Capping Protein May Potentiate Actin Polymerization at the Plasma Membrane: Cytosol Interface.**

I. Fujiwara<sup>1</sup>, K. Remmert<sup>1</sup>, G. Piszczek<sup>2</sup>, J. A. Hammer<sup>1</sup>; <sup>1</sup>LCB, NHLBI, NIH, Bethesda, MD, <sup>2</sup>Biochemistry & Biophysics Center, NHLBI, NIH, Bethesda, MD

Cells focus robust actin assembly at the interface between the plasma membrane and the cytoplasm and suppress assembly throughout the rest of the cytoplasm. Actin polymerization is focused at the plasma membrane: cytosol interface by the site-specific recruitment/activation at this interface of the major protein complexes that promote nucleation (i.e. Arp2/3, formins). Actin polymerization at this interface is also supported by the site-specific recruitment/activation of factors (e.g. VASP, formins) that promote filament elongation by antagonizing the action of the major cellular barbed end capper, Capping Protein (CP). Another leading edge elongation factor may be CARMIL, as it exhibits two robust anti-CP activities: weak barbed end capping by the CARMIL: CP complex and the ability to uncap CP-capped filaments. Finally, the cell may also use proteins that globally sequester CP in an inactive form to promote leading edge polymerization. One such sequestering protein may be V-1/myotrophin, an abundant (cellular concentration ~8  $\mu$ M, versus ~1  $\mu$ M for CP) protein that binds CP 1:1 with an affinity of about 20 nM, resulting in a complex that has no affinity for the barbed end. Here we have explored at the biochemical level the mechanism of an exchange reaction that drives the transfer of CP from its sequestered state (CP: V-1) to its weak barbed end binding state (CP: CARMIL). These efforts yielded direct evidence of a CP: CARMIL: V-1 ternary complex, as well as an estimate of the relative contributions of this ternary complex pathway and a competitive binding pathway to the overall exchange reaction. Using both bulk actin polymerization assays and single filament imaging, we then provide evidence for the conversion of CP from its sequestered state to its weak barbed end binding state following the addition of CARMIL to assays containing the CP: V-1 complex. Finally, we show that CARMIL is recruited to the plasma membrane: cytosol interface *in vivo* and only during periods of active polymerization/edge advance. Together, these results suggest that a CARMIL-driven exchange reaction funnels inactive CP sequestered in freely-diffusing, CP: V-1 complexes into weak barbed end capping CP: CARMIL complexes specifically at advancing edges. This mechanism, together with VASP, which shields the barbed end from CP at advancing edges, may serve to enhance the growth of newly-nucleated actin filaments in a narrow zone at the plasma membrane: cytosol interface.

258

**The Over Expression of Myotrophin/ V-1, a Negative Regulator of Capping Protein, Enhances Actin Polymerization and Filopodia Formation in *Dictyostelium*.**

G. Jung<sup>1</sup>, J. A. Hammer<sup>1</sup>; <sup>1</sup>Lab of Cell Biology, NHLBI, NIH, Bethesda, MD

Myotrophin/V-1 is a ubiquitously expressed, ~13 kDa, ankyrin-repeat protein that binds Capping Protein (CP) 1:1 with an affinity of ~20 nM, resulting in a complex that has no affinity for the barbed end. This “CP sequestering” activity may allow V-1 to play a major role in regulating the barbed end capping activity of CP in *Dictyostelium* (*Dd*), especially given our estimates of the cellular concentrations of CP and V-1 in *Dd* (1 μM and 8 μM, respectively). Consistent with biochemical studies of mouse V-1, endogenous *Dd* CP is pulled down by GST-tagged, wild type *Dd* V-1 (WT *Dd* V-1) and is co immunoprecipitated by Flag-tagged, WT *Dd* V-1. Moreover, these interactions are abrogated when using a version of *Dd* V-1 (FBM *Dd* V-1) containing four closely-spaced point mutations that in mouse V-1 greatly attenuate its interaction with CP. Consistent with V-1’s ability to inactivate CP, the major cellular terminator of actin assembly, the over expression of WT *Dd* V-1 results in a significant elevation in total cellular F-actin content. Moreover, this increase scales positively with the degree of V-1 over expression. As expected, the over expression of FBM *Dd* V-1 does not alter cellular F-actin levels. The over expression of WT *Dd* V-1 (but not FBM *Dd* V-1) also induces the formation of actin-rich, filopodial-like structures, and this effect once again scales positively with the degree of V-1 over expression. WT-*Dd* V-1 over expression leads not only to a significant increase in the number of filopodia, but also to a significant increase in their length. Moreover, time lapse images of cells co expressing a live-cell reporter for F-actin reveal that the filopodia in WT-*Dd* V-1 over-expressing cells are less dynamic than filopodia in control cells. Together, these over expression studies suggest that V-1 regulates actin polymerization and filopodial formation *in vivo* by buffering the level of active CP (where, in the case of V-1 over expression, actin polymerization and filopodia formation are enhanced because more cellular CP is sequestered). These results are consistent with previous studies showing that CP knockdown leads to the explosive formation of filopodia in both B16F1 melanocytes and *Dictyostelium*, and that V-1 over expression enhances actin polymerization and induces finger-like surface structures in PC12D cells. Efforts to create a *Dictyostelium* cell line that lacks V-1, which should provide further confirmation of the protein’s role in regulating CP *in vivo* (these KO cells are expected to exhibit a profound decrease in cellular F-actin content because the bulk of cellular CP will now be active) are underway.

**The effects of antigen mobility and actin dynamics on B cell signaling activation and BCR cluster movement.**

C. M. Ketchum<sup>1</sup>, H. Mille<sup>2</sup>, C. Liu<sup>2</sup>, W. Song<sup>2</sup>, A. Upadhyaya<sup>3</sup>; <sup>1</sup>Biophysics Program, University of Maryland, College Park, MD, <sup>2</sup>Department of Cell Biology & Molecular Genetics, University of Maryland, College Park, MD, <sup>3</sup>Department of Physics, University of Maryland, College Park, MD

B lymphocytes are an important part of the adaptive immune system and provide humoral immunity for an organism. Upon encountering a foreign antigen presented on the surface of an antigen presenting cell (APC), which demonstrates a sign of infection, the B cell rapidly spreads on the surface of the APC, binding and gathering antigen via the B cell receptor (BCR). This initiates the activation of the B cell, which then triggers changes in gene expression that enable the B lymphocyte to produce antibodies to fight infection. Although spreading is necessary for B cell activation, the mechanics of cell deformation during this process are poorly understood. It is clear that much of the change in morphology is driven by rapid rearrangement of the actin cytoskeleton, but many questions remain on how this is accomplished and how this process is dependent on the physical properties of antigen. Herein, we investigate the dependence of B

cell spreading and activation on the mobility of surface ligands. Specifically, we compare a ligand tethered to surfaces offering no lateral mobility (glass) with the same ligand tether to surfaces providing lateral mobility (planar lipid bilayers). We find that ligand lateral mobility modulates the spreading rates, the final areas, and the actin organization of spreading B cells. Spreading rates on the supported lipid bilayer are faster than on glass, however the final areas are significantly smaller. Furthermore, B cells spreading on ligand-tethered lipid bilayers exhibit more well-defined and persistent BCR clusters. This is concurrent with a much higher level of surface signaling, as assayed using phosphotyrosine staining as compared to cells spreading on antigen tethered glass surfaces. Finally, using simultaneous live cell imaging of actin and BCR during spreading, we find that the movements of BCR clusters and actin patches are highly correlated with each other during translocation of BCR clusters from the periphery towards the center of the B cell contact zone. Our results suggest that the lateral mobility of ligand regulates BCR signaling by modulating B cell spreading and BCR lateral movement and that actin dynamics play an active role in driving BCR cluster movement.

260

#### **The role of Mo25 for cytokinesis in *Dictyostelium discoideum*.**

C. H. Gallinger<sup>1</sup>, S. Köhler<sup>1</sup>, M. Rohlf<sup>2</sup>, M. Schleicher<sup>1</sup>; <sup>1</sup>Institute for Anatomy and Cellbiology, Ludwig-Maximilians-Universitaet, Munich, Germany, <sup>2</sup>Dr. von Hauner Children's Hospital, Ludwig-Maximilians-Universitaet, Munich, Germany

Mo25 (morula protein 25) is a highly conserved 40 kDa scaffolding protein with 60% identity from amoeba to man. It facilitates and activates a complex of a Ste20-like kinase with downstream kinases. In humans for example, Mo25 is part of a complex with STRAD (STE20-related adaptor protein) and the kinase LKB1. Disruption of this complex causes Peutz-Jeghers-syndrome (Boudeau et al., EMBO J. 22: 5102, 2003), an inherited disease with high disposition to develop cancer (Jansen et al., Physiol. Rev. 89: 777, 2009). We generated for the first time a stable Mo25-minus cell line, using the social amoeba *Dictyostelium discoideum*. The knockout of the *mo25* gene in *D. discoideum* results in very large, multinucleated cells unable to complete cytokinesis. Growth as well as development are severely delayed in the Mo25-minus strain. Furthermore, in phototaxis assays performed with multicellular aggregates, the Mo25-minus was unable to migrate towards the light source. These findings imply that Mo25 plays an important role in cytokinesis, growth and cell polarity. By using GFP-Trap resin we identified as a binding partner of Mo25 the Ste 20-like kinase Severin kinase (SvkA) (Eichinger et al., J Biol Chem. 273: 12952, 1998), a homolog of the human MST3, MST4 and YSK1 kinases. To further elucidate the interaction of Mo25 with SvkA and other possible interactors as well as their role in cytokinesis or polarity signaling, we generated a series of GFP-Mo25 rescue constructs with distinct point mutations in its interaction surfaces and transformed these into the Mo25-minus background. With these mutations in Mo25 we hope to reduce the complex multilayer phenotype to its basic modules and identify the different downstream signaling pathways that branch off from the Mo25/SvkA kinase complex.

#### **Analysis and Comparison of the Effects of the Deafness-Causing D51N Actin Mutation in Yeast and Human Gamma Actin.**

K. Kruth<sup>1</sup>, M. McKane<sup>1</sup>, K-K. Wen<sup>1</sup>, P. Rubenstein<sup>1</sup>; <sup>1</sup>Biochemistry, University of Iowa, Iowa City, IA

The beta and gamma nonmuscle actin isoforms differ by only four biochemically similar amino acids, making separation of the two isoforms for in vitro assays exceedingly difficult. Conventional protein purification methods, including affinity chromatography methods using

tagged proteins, are not possible, as any alteration to the actin monomer interferes with the protein's activity. To circumvent this difficulty, we have used budding yeast as a model from which to isolate pure mutant actins, as yeast contain only a single actin isoform and separation of multiple isoforms is not necessary. Nevertheless, although yeast actin is 89% identical to human gamma actin, the question remains as to how closely the yeast model system can reproduce the behavior of human gamma actin. To address this question, we have expressed and purified deafness-causing D51N mutant actin from both the yeast model system and insect cells expressing human gamma actin. In vitro analysis of both actins indicates that yeast actin very accurately represents the behavior of human gamma actin at a fraction of the cost and time of production. Furthermore, characterization of D51N mutant actin reveals that the mutation increases flexibility in actin subdomain 2, increases the rate of polymerization, and reduces the rate of ATP hydrolysis and subsequent nucleotide release. In yeast cells, the D51N mutation also causes mitochondrial defects, reduced cable formation, and depolarized actin patches, strongly suggesting that the mutation causes significant regulatory defects within an in vivo system in addition to directly affecting polymerization dynamics.

### **Quantitative Analysis of Approaches to Measuring the Cooperativity of Phosphate Release in Polymerized Actin.**

*M. M. Burnett<sup>1</sup>, A. E. Carlsson<sup>1</sup>; <sup>1</sup>Physics, Washington University in St Louis, St Louis, MO*

We use simulations of actin polymerization/depolymerization and phosphate cleavage/release to treat several experimental probes of actin dynamics that are affected by the cooperativity of phosphate release. The simulations treat both actin and phosphate dynamics stochastically using finite ensembles of filaments. The correlations between release on nearest-neighbor sites can be varied continuously between the random and vectorial limits. Using this model, we simulate phosphate release time-courses from polymerization and co-polymerization experiments of ATP- and ADP-actin, including the effects of variations in filament number concentration. We also treat single-filament depolymerization time-courses. For each value of the cooperativity parameter, we use rate constants which optimize the fit to experiment. We find that highly cooperative models are consistent with the experimental data. We also find that some types of experiments that are believed to provide strong constraints on the cooperativity of actin hydrolysis models provide much weaker constraints.

## **Microtubule Dynamics and Its Regulation I**

263

### **De novo centriole emergence does not initiate canonical interphase microtubule organisation in the mouse blastocyst.**

*K. Howe<sup>1</sup>, G. FitzHarris<sup>1</sup>; <sup>1</sup>Department of Cell and Developmental Biology, University College London, London, UK*

Centrioles form the central core of the centrosome, the major microtubule organising centre (MTOC) in most animal cells. In interphase, the centrosome organises a polarized microtubule (MT) array in which MT minus ends are proximal to the centrosome and plus ends are oriented towards the cell periphery. In contrast, oocytes of most species lack centrioles. In mouse embryos, new centrioles are generated by *de novo* formation during late pre-implantation development. How centriole emergence impacts MT organisation in this setting is not known.

Here we use a GFP-CETN2 transgenic mouse to study the dynamics of centriole emergence, and confirm that centrioles are first assembled *de novo* at the blastocyst stage in both the trophoectoderm, and the inner cell mass - the two major cell lineages of the blastocyst. Centriole biogenesis is preceded by the emergence of  $\gamma$ -tubulin foci at the morulae stage of embryogenesis.

To investigate the impact of centrosome and centriole emergence on MT organisation we performed detailed analyses of MT layout throughout embryogenesis. In early pre-implantation embryos, we find that MTs extend throughout the cytoplasm and are enriched at the cortex and around the nucleus. These early embryos do not possess an obvious dominant site of MT nucleation, which was expected given the absence of centrioles and centrosomes at this developmental stage. Unexpectedly however, later embryos also appear to lack a dominant MTOC, and MTs are similarly enriched at the cortex and nuclear membrane as opposed to at the centrioles. This arrangement is in stark contrast to the distinctive astral MT array which emanates from the centrioles in somatic cells.

To further analyse MT architecture in embryos we used EB1-GFP, which binds to growing MT plus ends and therefore allows MT growth trajectories to be visualised and mapped. Kymograph analysis revealed no difference in MT growth velocity between acentriolar and centriolar embryos. Furthermore, whereas EB1-GFP comets predominantly radiate from a single central focal point in cultured somatic cells, a dominant centre of MT organisation is not evident in embryos of any developmental stage, including centriole-containing blastocysts. Therefore, our experiments reveal that embryos adopt an atypical mode of MT organisation throughout pre-implantation development, despite the emergence of centrosomes and centrioles in morulae and blastocysts respectively. The mouse embryo is thus a rare example of a mammalian cell in which centrioles fail to serve as the dominant MTOC.

264

**Gamma-tubulin is required for *Drosophila* neuronal microtubule organization.**

M. M. Nguyen<sup>1</sup>, M. C. Stone<sup>2</sup>, M. M. Rollis<sup>1</sup>; <sup>1</sup>Biochemistry and Molecular Biology, The Pennsylvania State University, University Park, PA, <sup>2</sup>Genetics, The Pennsylvania State University, University Park, PA

The polarization of neurons into axons and dendrites is essential in building functional neuronal circuits. The arrangement of microtubules is an important factor in neuronal polarity, as microtubules are used for long-range trafficking of vesicles and other cargo, cytoskeletal structure, and synaptic growth. *Drosophila* provides a good model for the study of neuronal microtubule polarity due to its simple microtubule arrangement. In *Drosophila* neurons, microtubules have opposite orientation in axons and dendrites: axons have microtubules with plus ends distal to the soma, while dendrites have minus ends distal to the cell body. We have recently determined that the centrosome, an organelle that is the primary microtubule nucleator and organizer in dividing cells, does not contribute to neuronal microtubule organization in *Drosophila*, and are now looking at other factors that may be involved. A likely candidate is gamma-tubulin, as it is the core nucleation protein that is essential for acentrosomal microtubule nucleation. Thus, the objective of this study is to determine whether gamma-tubulin plays an integral role in establishing the differing microtubule orientations seen in axons and dendrites. To examine the function of gamma-tubulin, immunostaining and fluorescence localization experiments were performed, and microtubule dynamics were analyzed in gamma-tubulin mutants using the plus-end tracking protein EB1. Our preliminary studies indicate that gamma-tubulin is localized at dendrite branch points, which have previously been shown to house

proteins that affect microtubule polarity. Meanwhile, in axons, gamma-tubulin surprisingly showed distinct localization at the presynapse. Additionally, we saw that gamma-tubulin mutant animals had disrupted microtubule dynamics as well as altered microtubule orientation in axons and dendrites. In loss-of-function mutants, microtubule polarity became more mixed in dendrites, and the number of growing microtubules was decreased. In gain-of-function mutants, microtubule polarity was mixed in both axons and dendrites, and microtubule dynamics were increased in the axon. Based on these results, we predict that overactive gamma-tubulin contributes to the changes in microtubule orientation by nucleating extra microtubules in the wrong orientation. Also, dendrite microtubule polarity may require local microtubule nucleation, while axon microtubule polarity may require proper regulation of gamma-tubulin. We conclude that gamma-tubulin is a prime player in neuronal microtubule polarity, and that tight regulation of microtubule nucleation is crucial for correct neuronal microtubule polarity.

265

**Specific in vivo labeling of tyrosinated alpha-tubulin and measurement of microtubule dynamics using a GFP-tagged and cytoplasmically expressed recombinant antibody.**

*L. Cassimeris<sup>1</sup>, L. Gugliemi<sup>2</sup>, V. Denis<sup>2</sup>, C. Larroque<sup>2</sup>, P. Martineau<sup>2</sup>; <sup>1</sup>Biological Sciences, Lehigh University, Bethlehem, PA, <sup>2</sup>I.R.C.M., I.N.S.E.R.M., Montpellier, France*

GFP-tagged proteins are used extensively as biosensors for protein localization and function, but the size of GFP (27 kD) could interfere with protein-protein interactions within the cell. An alternative to direct protein labeling is to use intracellular expression of recombinant antibodies (scFvs), but these antibody fragments are typically insoluble in the reducing environment of the cytosol. We developed a large synthetic human scFv library that is optimized for stable recombinant antibody expression in mammalian cytosol (Philibert et al. 2007) and isolated an anti-tubulin scFv, 2G4, which is soluble when expressed as a GFP-fusion protein. Here we report the use of this GFP-tagged scFv to label microtubules (MTs) in living cells. GFP-alpha tubulin is a useful tracer for study of MT dynamics, allowing comparison between GFP-tubulin and 2G4-GFP as MT labels. We found that 2G4-GFP localized uniformly along the lengths of MTs and did not disrupt binding of EB1, a protein that binds MT ends and serves as a platform for binding by a complex of proteins regulating MT polymerization. MT dynamic instability, measured by tracking 2G4-GFP labeled MTs, was nearly identical to that measured previously in cells expressing GFP-tubulin or microinjected with rhodamine-tubulin (Rusan et al., 2001; Ringhoff and Cassimeris, 2009). Fluorescence recovery after photobleaching demonstrated that 2G4-GFP turns over rapidly on MTs ( $t_{1/2} \sim 4$  s), similar to the turnover of photobleached tau-GFP ( $t_{1/2} \sim 7$  s) and to turnover rates published previously for several other MT-associated proteins. These data indicate that 2G4-GFP binds relatively weakly to MTs, and this conclusion was confirmed in vitro. Purified 2G4 partially co-pelleted with MTs but a significant fraction remained in the soluble fraction, while a second anti-tubulin scFv, 2F12, was almost completely co-pelleted with MTs. In cells, 2G4-GFP localized to most MTs, but did not co-localize with MTs composed of detyrosinated alpha-tubulin, a post-translational modification associated with non-dynamic, more stable MTs. Immunoblots probing bacterially expressed tubulins confirmed that 2G4 recognized alpha-tubulin and required tubulin's C-terminal tyrosine residue for binding. Thus, a recombinant antibody with weak affinity for its substrate can be used as a specific intracellular tracer that can differentiate between unmodified and post-translationally modified forms of a protein.

266

**Mechanistic Significance of Phospho- $\alpha$ -tubulin in Microtubule Dynamics.**

S. De<sup>1</sup>, A. Tsiola<sup>2</sup>, S. A. Rotenberg<sup>3</sup>; <sup>1</sup>Chemistry & Biochemistry, Queens College and Graduate Center of C.U.N.Y., Flushing, NY, <sup>2</sup>Biology, Queens College of C.U.N.Y., Flushing, NY, <sup>3</sup>Chemistry & Biochemistry, Queens College of C.U.N.Y., Flushing, NY

Protein kinase C $\alpha$  (PKC $\alpha$ ) serves diverse biological functions through phosphorylation of its various cellular substrates. A role for PKC $\alpha$  in the etiology of breast cancer metastasis arises from elevated PKC activity that has been observed in some metastatic human breast tumors. Previous work from this laboratory showed that engineered over-expression of PKC $\alpha$  in non-tumorigenic, non-motile human breast epithelial MCF-10A cells resulted in aggressive cell movement. A recently discovered PKC $\alpha$  substrate in these cells,  $\alpha$ -tubulin, which is a structural component of microtubules (MTs), was shown to undergo intracellular phosphorylation by PKC $\alpha$  and consequently to engender cell motility. The present work addresses the impact of  $\alpha$ -tubulin phosphorylation on MT dynamics in MCF-10A cells. Live-cell imaging of cells expressing EGFP-EB1, a MT plus-end binding protein, showed a significant increase in the number of MT growing ends near the cell periphery following treatment with DAG-lactone, a cell-permeable PKC activator. Quantitative analysis of MT dynamic parameters in DAG-lactone-treated cells transfected with EGFP- $\alpha$ -tubulin showed a dramatically increased MT growth rate and duration of the growth phase, as well as increased frequency of rescued catastrophes, all indications of enhanced MT stability. Further analysis was conducted in MCF-10A cells expressing an  $\alpha$ 6-tubulin mutant in which the PKC phosphorylation site (Ser-165) was rendered as pseudo-phosphorylated (Ser $\rightarrow$ Asp) or phosphorylation-resistant (Ser $\rightarrow$ Asn). Analysis of MT dynamics in cells expressing the pseudo-phosphorylated mutant showed a significant increase in the average growth rate and dynamicity, similar to parental cells treated with DAG-lactone. However, MT dynamics recorded for cells expressing the phosphorylation-resistant mutant were similar to untreated parental cells. Immunocytochemistry performed with MCF-10A cells transfected with myc-tagged wildtype  $\alpha$ -tubulin and treated with DAG-lactone showed enhanced incorporation of the myc signal into MTs, especially near the cell periphery, as compared with untreated cells. This enhancement was reproduced in untreated cells expressing myc-tagged pseudo-phosphorylated  $\alpha$ 6-tubulin. These findings support a model in which PKC engenders motile behavior of human breast cells by phosphorylation of its substrate  $\alpha$ -tubulin, thereby leading to altered MT dynamics that favor MT elongation. This work provides a foundation for exploring phosphorylated  $\alpha$ -tubulin as a biomarker for metastatic breast disease and as a strategic target for chemotherapeutic intervention. [Funded by NIH CA125632].

**Regulation of microtubule mechanics by intraluminal acetylation.**

Z. Xu<sup>1</sup>, A. Aguilar<sup>1</sup>, M. V. Nachury<sup>1</sup>; <sup>1</sup>Stanford University School of Medicine, Stanford, CA

Nearly all studies of microtubules to date have focused on their outer surface. Currently, the only molecular event known to take place inside the microtubule lumen is acetylation of alpha-tubulin on lysine 40, a major post-translational modification with unknown biochemical consequences. In this context, our recent identification of the tubulin acetyltransferase TAT1 provides a molecular handle on the biology of the microtubule lumen. Interestingly, TAT1 is encoded by the mec-17 gene in nematodes and mec-17 mutants are defective for mechanosensation, thus linking intraluminal acetylation to the sensing of mechanical perturbations.

Surprisingly, we find that TAT1 can acetylate microtubules at any point along their length in vitro. Previously, Atomic Force Microscopy of unfixed microtubules had uncovered openings in bent but not straight microtubules. Bending may thus generate enough tensile stress on the

outer edge of the tube to overcome the rather weak lateral interactions between protofilaments and create an opening.

Intriguingly, long-lived microtubules in mammalian cells are both highly acetylated and highly bent. The very short radius of curvature found on long-lived microtubules is paradoxical when one considers the low flexural strength and high rigidity of pure microtubules. This disconnect suggests the existence of cellular mechanisms that locally decrease the flexural rigidity of long-lived microtubules. To address whether acetylation may be part of such a mechanism, we visualized long-lived microtubules in fibroblasts by treating them with nocodazole for 40 min. Surprisingly, nocodazole-resistant microtubules appeared highly fragmented in TAT1-depleted cells treated when compared to control-treated cells. Furthermore, time-resolved imaging of nocodazole-resistant microtubules shows that the frequency of microtubule breakage in TAT1-depleted cells is significantly elevated when compared to control-depleted cells. Based on these findings, we posit that intraluminal acetylation protects microtubules from breakage by locally decreasing flexural rigidity. In support of this model, physical or pharmacological release of cell tension leads to the recovery of long-lived microtubules in the absence of TAT1. Thus, acetylation may modify the mechanical properties of microtubules to prevent rupture under flexure.

We propose a two-step adaptive model for the mechanical stabilization of microtubules where bending triggers sidewall breathing to let TAT1 enter the lumen. Subsequent acetylation locally modifies the mechanical properties of the microtubule to protect it against flexural breakage.

268

### **Posttranslational Incorporation of 3-Formyltyrosine in $\alpha$ -Tubulin Inhibits Cell Proliferation without Altering Microtubule Morphology.**

*K. Mukherjee<sup>1</sup>, S. L. Bane<sup>1</sup>, D. L. Sackett<sup>2</sup>; <sup>1</sup>Chemistry, State University of New York at Binghamton, Binghamton, NY, <sup>2</sup>Laboratory of Integrative and Medical Biophysics Program in Physical Biology, Eunice Kennedy Shriver National Institute of Child Health and Human Development, NIH, Bethesda, MD*

The C-terminus of  $\alpha$ -tubulin undergoes a cyclic posttranslational modification of tyrosination/detyrosination. The genetically encoded C-terminal tyrosine is removed by a specific enzyme, tubulin tyrosine carboxypeptidase, and is reintroduced by another specific enzyme, tubulin tyrosine ligase. This cycle generates pools of tyrosinated and detyrosinated tubulin and regulates a number of microtubule functions. Here, we report that endogenous enzymes can reversibly incorporate a tyrosine derivative, 3-formyltyrosine (3fY), in the C-terminus of  $\alpha$ -tubulin instead of tyrosine. Cellular incorporation of 3fY is completely restricted to  $\alpha$ -tubulin even after extended periods of time. The reactivity of 3fY with hydrazine fluorophores then permits specific labeling of  $\alpha$ -tubulin. The present study explores the implications of this phenomenon in human prostate cancer (PC3) cells. We find that 3fY inhibits PC3 cell proliferation in a cell cycle independent manner. This inhibition can be partially reversed by withdrawal of 3fY from the culture medium. Interestingly, despite significant growth inhibitory effects, no alteration in the cell morphology or microtubule network was observed during cycles of 3fY ligation and removal. Thus, incorporation of 3fY permits the simple fluorescent labeling of  $\alpha$ -tubulin, but also interferes with some microtubule function essential for progression throughout the cell cycle. Identification of this microtubule function will be the focus of future experiments.

**Microtubule-associated proteins control microtubule nucleation from templates***M. Wieczorek<sup>1</sup>, S. Bechstedt<sup>1</sup>, G. Brouhard<sup>1</sup>; <sup>1</sup>Biology, McGill University, Montreal, QC, Canada*

Cells nucleate new microtubules continuously, but the kinetics of nucleation is arguably the least understood aspect of microtubule dynamics. While microtubules can form spontaneously in vitro,  $\gamma$ -tubulin ring complexes ( $\gamma$ -TURCs) serve as template structures for microtubule nucleation in cells. Many microtubule-associated proteins (MAPs) have also been implicated in microtubule nucleation, but their direct role in the templating process is unclear. To determine the role of MAPs in templated nucleation, we have developed a quantitative assay that allows us to study the kinetics of microtubule nucleation from centrosomes ( $\gamma$ -TURCs), axonemes, and single microtubule templates using purified components. We found that templated nucleation is highly cooperative and that this cooperativity is independent of the type of template used. Performing the assay in the presence of different MAPs indicates that both catastrophe frequencies and growth rates influence the ability of a template to nucleate microtubules. Certain MAPs also changed the strength of cooperativity in the nucleation process. We directly demonstrate that MAPs can both enhance and inhibit templated nucleation by distinct mechanisms. These findings provide a means by which cells can control the numbers and locations of their microtubules throughout development and the cell cycle.

270

**The importance of Augmin in microtubule generation beyond cell division.***J. W-C. Chen<sup>1</sup>, J. G. Wakefield<sup>1</sup>; <sup>1</sup>University of Exeter, Exeter, United Kingdom*

Augmin, a conserved hetero-octomeric microtubule (MT) associated protein complex originally characterized in *Drosophila*, has recently been shown to be at least as important as centrosomes in generating MTs that contribute to the mitotic spindle. The current model is that it does so by recruiting the MT nucleator  $\gamma$ -TuRC to pre-existing MTs, where it can facilitate the formation of additional MTs. However, whether Augmin has a role in generating MTs outside of cell division is currently unknown.

During *Drosophila* oogenesis, extensive MT networks are generated for inter- and intracellular transport of materials. It is with these networks that various maternal mRNA are transported to specific areas within the oocyte. Centrosomes, although playing a role in generating a portion of these MTs, have been shown to be dispensable. We hypothesized that Augmin, being a generator of MTs, has a role in facilitating the oocyte MT network. To test this, we have been analyzing MT organization in oocytes carrying a null mutation in the Augmin subunit, *Wac*.

At stage 6 of *Drosophila* development, the MT-dependent transport of *gurken* mRNA to the posterior pole, followed by its translation into Gurken protein, signals the destabilization of posterior MT organizing centres (MTOCs). The drastic re-organization of the MTs releases the anchored nucleus, facilitating its re-distribution to the dorsal-anterior corner. Consequently, during stage 8-9, the MT network is arranged to an anterior-posterior gradient. By stage 10, distinct MT bundles are formed.

We show that *wac* mutant oocytes fail to anchor, and properly localize Gurken protein at stage 6. Interestingly, the nucleus is still released from the posterior pole, and migrates to the anterior-dorsal corner by stage 8. Although MTs are present at stages 8 and 9, the gradient normally formed at this time is absent. However, those MTs present still show bundling at stage 10. One interpretation is that Augmin generates additional MTs during stages 6, 8, and 9, contributing to the overall MT network formed by other mechanisms. We are currently investigating this further by analyzing MT dynamics during oogenesis in  $\alpha$ -Tubulin-GFP expressing oocytes lacking Augmin, and those lacking both Augmin and other MT nucleators.

**Linker scanning mutagenesis of yeast microtubule nucleating proteins Spc97 and Spc98.**

K. Fong<sup>1</sup>, J. Tien<sup>1</sup>, C. Payen<sup>2</sup>, B. Graczyk<sup>1</sup>, A. Zelter<sup>1</sup>, M. Dunham<sup>2</sup>, T. Davis<sup>1</sup>; <sup>1</sup>Biochemistry, University of Washington, Seattle, WA, <sup>2</sup>Genome Sciences, University of Washington, Seattle, WA

The mitotic spindle is a large structure responsible for the regulation and organization of chromosome segregation. Microtubules are a major component of the mitotic spindle and play several key roles during mitosis—mediating chromosomal movements, stabilizing spindle structure, and positioning the spindle within the cell. It has been shown that  $\gamma$ -tubulin is highly conserved and essential for microtubule nucleation in all organisms. Characterization of  $\gamma$ -tubulin revealed that it is part of a larger complex. In yeast, the  $\gamma$ -tubulin small complex is sufficient for nucleation and is comprised of two  $\gamma$ -tubulin molecules and one copy each of Spc97 and Spc98. Both Spc97 and Spc98 are essential, suggesting they play supplementing roles to  $\gamma$ -tubulin during microtubule nucleation. Despite our advances in understanding microtubule function, dynamics and nucleation, purified  $\gamma$ -tubulin complexes fail to efficiently recapitulate nucleation *in vitro*, suggesting that additional regulatory processes activate the nucleating complex. The cryo-EM structure of the yeast  $\gamma$ -tubulin complex reveals 13  $\gamma$ -tubulins in a ring as expected for a template for the 13-protofilament microtubule found *in vivo*. However, the spacing between  $\gamma$ -tubulins is offset from a perfect template. We have performed a saturating linker-scanning mutagenesis to define the regions of Spc97 and Spc98 required for the small complex to function *in vivo* and promote the formation of a microtubule. *In vitro* transposition reactions generated a library of random 15 base pair insertions in each gene, with approximately 89% coverage. Approximately 60,000 transposition events were screened for function. For both Spc97 and Spc98, about 4% of the screened colonies contained lethal mutations and 0.02% contained temperature-sensitive mutations. Sites of lethal insertions were identified and mapped by high-throughput sequencing. Temperature sensitive mutants were inspected by fluorescence microscopy and *in vitro* nucleation assays to reveal several nucleation hyperactive and deficient mutants. When combined with high-throughput sequencing, linker-scanning mutagenesis was a powerful approach to identify essential regions of the  $\gamma$ -tubulin complex and provide novel temperature-sensitive mutants with specific defects in microtubule nucleation.

272

**Depletion of the  $\beta$ III-tubulin isotype increases the affinity and activity of <sup>3</sup>H-eribulin for brain tubulin and microtubules: a role for  $\beta$ III-tubulin in reduced neuropathy?**

L. Wilson<sup>1</sup>, H. P. Miller<sup>1</sup>, M. Lopus<sup>1</sup>, S. Riffle<sup>1</sup>, O. Azarenko<sup>1</sup>, M. Jordan<sup>1</sup>; <sup>1</sup>MCDB and The Neuroscience Res Inst, University of California, Santa Barbara, Santa Barbara, CA

To explore the role of  $\beta$ III-tubulin in the reduced incidence of peripheral neuropathy associated with eribulin mesylate as compared with other microtubule (MT) targeted drugs in mice, we analyzed <sup>3</sup>H-eribulin binding to purified unfractionated (~ 25%  $\beta$ III-tubulin), and  $\beta$ III-depleted bovine brain tubulin and to MTs composed of unfractionated and  $\beta$ III-depleted tubulin.  $\beta$ III tubulin was depleted to undetectable levels after passing unfractionated tubulin through a column of CNBr Sepharose 4B covalently coupled to anti- $\beta$ III tubulin antibody TuJ1. Eribulin binding was determined with <sup>3</sup>H-eribulin (0.5  $\mu$ M - 80  $\mu$ M, 25 min, 30 °C) after separation of bound from free drug by Zeba spin columns. The <sup>3</sup>H-eribulin bound to both unfractionated and to  $\beta$ III-depleted tubulin (1 mol eribulin/mol tubulin). However, the affinity of <sup>3</sup>H-eribulin for  $\beta$ III-depleted tubulin ( $K_D$ , 1.4  $\mu$ M) was ~ 2-fold stronger than its affinity for unfractionated tubulin ( $K_D$ , 2.5  $\mu$ M). The stoichiometry and affinity of <sup>3</sup>H-eribulin binding per MT to unfractionated MTs and

to  $\beta$ III-depleted MTs was determined by assembling MTs to steady state (30  $\mu$ M tubulin plus 3  $\mu$ M tau to stabilize the MTs, 35 °C, 30 min), incubating them with  $^3$ H-eribulin (0.1-14  $\mu$ M), and separating  $^3$ H-eribulin-bound MTs from unbound  $^3$ H-eribulin by sedimentation through 30% glycerol cushions (2h, 32 °C, 200,000 x g).  $^3$ H-eribulin bound to  $\beta$ III-depleted MTs ~ 2-fold more strongly ( $K_D = 1.5 \mu$ M; ~ 7 ( $\pm$ 6) molecules of eribulin/MT) than to MTs prepared from unfractionated tubulin ( $K_D = 3.9 \mu$ M, ~10 ( $\pm$ 5) molecules of eribulin/MT), indicating that the presence of  $\beta$ III-tubulin diminishes eribulin binding to brain MTs. In agreement with these results, eribulin suppressed the growth rate and dynamicity of unfractionated MTs, but did not appreciably affect any other dynamic instability parameter. However, eribulin more strongly suppressed growth of  $\beta$ III-depleted MTs as well as other parameters, including the shortening rate and the catastrophe/rescue frequencies. The reduced activity of eribulin on tubulin/MTs containing  $\beta$ III-tubulin supports a hypothesis that the normal presence of  $\beta$ III-tubulin in neuronal cells may play a role in the reduced peripheral neuropathy with eribulin as compared with other MT-targeted agents in mouse models. Supported by a grant from Eisai Inc.

### **TubZ filament morphology is regulated by nucleotide state.**

E. Montabana<sup>1</sup>, D. A. Agard<sup>2,3</sup>; <sup>1</sup>Graduate Group in Biophysics, UC, San Francisco, San Francisco, CA, <sup>2</sup>Howard Hughes Medical Institute, San Francisco, CA, <sup>3</sup>Biochemistry and Biophysics, UC, San Francisco, San Francisco, CA

Low copy number plasmids have developed complex systems to ensure that the plasmid DNA faithfully segregates during bacterial cell division, including the use of actin-like or tubulin-like cytoskeletal elements. Several bacterial tubulin homologs involved in plasmid segregation have been discovered through the aid of phylogenetic analysis. One such homolog, TubZ-Bt, is found on the pBtoxis virulence plasmid in *Bacillus thuringiensis*.

To gain insight into the mechanism by which TubZ-Bt is able to segregate plasmids, we sought to understand the impact of different nucleotide states on TubZ filament formation, structurally and kinetically, using electron microscopy and biochemistry.

*In vitro*, we observe that TubZ-GTP forms almost exclusively four-stranded filaments, whereas TubZ filaments formed with catalytically compromised protein or non-hydrolyzable GTP analogs are predominantly two-stranded. These results show that the filament conformation is linked to nucleotide state.

In order to further understand this morphological change, we have determined the cryo-EM structure of TubZ-GTP filaments to ~7Å resolution by iterative helical real space reconstruction (IHRSR), as well as the structure of TubZ-GTP $\gamma$ S 2-stranded filaments to ~15Å. Mutational analysis of interfacial residues suggested by these structures implicate that an early form of the two-stranded filaments are necessary for the formation of the four-stranded filaments.

Additionally, the extended C-terminal tail of TubZ-Bt appears to be necessary for the formation of both filament morphologies. This extended C-terminus has previously been shown to interaction with the TubRC complex which connects TubZ-Bt with the pBtoxis DNA (Ni, L., et al. PNAS 2010). This suggests that *in vivo* TubZ-Bt kinetics and morphology may be regulated by interaction with this complex.

### Mitotic motor CENP-E cooperates with PRC1 in temporal control of central spindle assembly.

X. Liu<sup>1</sup>, T. Zhu<sup>2</sup>, P. Yao<sup>1</sup>, Y. Huang<sup>1</sup>, J. Zhang<sup>2</sup>, Z. Dou<sup>2</sup>, X. Ding<sup>3</sup>, Z. Yang<sup>4</sup>, X. Yao<sup>2</sup>; <sup>1</sup>Georgia Cancer Coalition, Atlanta, GA, <sup>2</sup>Anhui Laboratory for Chemical Biology, Hefei, China, <sup>3</sup>Beijing University of Chinese Medicine, Beijing, China, <sup>4</sup>Drug Discovery, Proteomics Research Laboratory, Beijing, China

Mitotic motor CENP-E plays key roles in chromosome congression and spindle checkpoint satisfaction. We have recently identified and characterized syntelin, a novel selective CENP-E inhibitor (Ding et al., 2010. *Cell Res.* 20, 1386-1390). Cells treated with syntelin progress through interphase, enter mitosis normally with a bipolar spindle and lagging chromosomes around the poles. Syntelin is an allosteric inhibitor which tightens CENP-E-microtubule interaction by slowing inorganic phosphate release. To delineate the role of CENP-E in reorganization of interpolar microtubules into an organized central spindle, metaphase synchronized cells were exposed to syntelin and other mitotic motor inhibitors. Syntelin does not perturb interpolar microtubule assembly but abrogates the anti-parallel microtubule bundle formation. Real-time image shows that CENP-E inhibited cells undergo central spindle splitting and exhibit chromosome instability phenotypes. Interestingly, inhibition of CENP-E did not alter the interaction between CENP-E and PRC1 but perturbed temporal assembly of PRC1 to the midzone. Surprisingly, inhibition of CENP-E perturbs the temporal control of PRC1 dephosphorylation which led to a persistent phosphorylation of PRC1 and an inhibition of central spindle assembly. These findings reveal a previously uncharacterized role of CENP-E motor in temporal control of central spindle assembly.

275

### Knockdown of microtubule polymerase XMAP215 can increase microtubule polymerization in *Xenopus laevis* neuronal growth cones.

L. A. Lowery<sup>1</sup>, L. Ding<sup>1</sup>, M. Baird<sup>2</sup>, M. Davidson<sup>2</sup>, G. Danuser<sup>1</sup>, D. Van Vactor<sup>1</sup>; <sup>1</sup>Department of Cell Biology, Harvard Medical School, Boston, MA, <sup>2</sup>National High Magnetic Field Laboratory, Florida State University, Tallahassee, FL

Proper neural connections, essential to nervous system function, depend upon precise navigation by the neuronal growth cone. A fundamental problem in growth cone cell biology is how guidance pathways are integrated to coordinate cytoskeletal dynamics, thus driving accurate steering. To address this question, we focus on the plus-ends of microtubules (MTs), which explore the growth cone periphery and play a key role in growth cone steering. MT plus-end dynamics are regulated by a conserved family of proteins called 'plus-end-tracking proteins' (+TIPs). Yet, it is still unclear how +TIPs interact with each other and with plus-ends to control MT behavior, especially in the developing nervous system. Here, we address this question by investigating the function of the traditional MT polymerase, XMAP215, during neurite outgrowth. When XMAP215 function is reduced, neurite outgrowth is severely compromised. By using automated, quantitative imaging analysis following acquisition of high-resolution live-imaging data of tagged +TIPs within cultured *Xenopus laevis* growth cones, we were surprised to discover that partial knock-down of XMAP215 leads to a 30% increase in MT plus-end velocity. This is unexpected given that XMAP215 is known to have MT polymerase activity. There are at least two possible mechanisms by which this increase in MT plus-end velocity may occur in growth cones, either by affecting the polymerization/depolymerization rate directly, or by changing MT translocation rates through the regulation of MT interaction with other cellular structures. We have tested between these two models using quantitative fluorescence speckle

microscopy, and we find that MT translocation rates are indistinguishable between controls and XMAP215 knockdown. Thus, reducing the function of the traditional MT polymerase XMAP215 leads to increased rates of MT polymerization in cultured *Xenopus* growth cones. We are currently investigating the mechanism by which this occurs, as well as how these changes in growth cone MT polymerization correlate with the reduced axon outgrowth phenotype that we also observe.

**p150<sup>Glued</sup> regulates neuronal microtubule assembly through tandem tubulin-binding domains.**

J. E. Lazarus<sup>1</sup>, A. J. Moughamian<sup>1</sup>, M. K. Tokito<sup>1</sup>, E. L. Holzbaur<sup>1</sup>; <sup>1</sup>Department of Physiology, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA

Regulation of microtubule assembly is critical for cellular survival, particularly in large, post-mitotic cells such as neurons, where disruption of microtubule dynamics has been shown to contribute to neurodegenerative disease. We have previously suggested that the dynactin complex, best known as an activator of cytoplasmic dynein, may also participate in the regulation of microtubule dynamics through its p150<sup>Glued</sup> subunit. Here, using solution biochemistry and direct visualization of microtubule assembly dynamics with TIRF microscopy, we demonstrate *in vitro* that p150<sup>Glued</sup> promotes microtubule formation via multiple activities; it catalyzes nucleation, increases the microtubule polymerization rate, and inhibits catastrophe. We show that although either the N-terminal CAP-Gly or basic domains of p150<sup>Glued</sup> are sufficient for binding to microtubules, both are necessary in tandem to stably bind soluble tubulin dimers and promote assembly. Splicing of p150<sup>Glued</sup> is tissue-specific and only the longest p150<sup>Glued</sup> spliceform, expressed primarily in the nervous system, includes both the full CAP-Gly and basic domains. To test the hypothesis that this isoform modifies microtubule dynamics in cells, we first depleted p150<sup>Glued</sup> in a non-polarized cell line, and found no effect on microtubule dynamics. In contrast, knockdown of p150<sup>Glued</sup> in primary neurons leads to a dramatic increase in microtubule catastrophe. Strikingly, a single point mutation in p150<sup>Glued</sup>, causal for an early-onset Parkinson syndrome, is sufficient to completely abolish activity *in vitro* and in neurons. Together, our data reveal that dynactin plays a crucial role in promoting microtubule stability in neurons, and that disruption of this activity may lead to neurodegenerative disease.

277

**Kinesin 13s are key regulators of neuronal microtubule polarity.**

M. K. Long<sup>1</sup>, A. Marks<sup>1</sup>, M. Rolls<sup>1</sup>; <sup>1</sup>Pennsylvania State University, University Park, PA

Neurons are highly specialized cells that transmit information over long distances by way of polarized processes known as axons and dendrites. One of the major cell biological differences between axons and dendrites is the arrangement of microtubules. In *Drosophila* dendritic arborization (da) neurons, which are multipolar neurons with a single axon and many dendrites, dendritic microtubules are minus-end-out and axonal microtubules are plus-end-out. While microtubule polarity is likely to play a key role in all aspects of neuronal polarity, it is not known how a single cell can establish two compartments with completely different arrangements of microtubules. In a screen to identify regulators of microtubule polarity in da neurons, we identified Kinesin 13s, which are known to be important for spindle organization in mitosis, as regulators of neuronal microtubules.

Kinesin 13s are a family of microtubule-based motors that are known to be microtubule depolymerases in mitotic and interphase cells<sup>1</sup>; however, there have been very few studies of their roles in neurons. In *Drosophila* there are three Kinesin 13s, and we found that two of these,

Klp59C and Klp10A, play important roles in da neurons. Reduction of Klp59C caused severe mixing of microtubule polarity in dendrites as well as dendrite branching defects. Reduction of Klp10A had a comparably mild effect in dendrites, and instead showed the greatest phenotype in axons, changing both microtubule orientation and overall number of polymerizing microtubule plus ends. We therefore propose that Klp59C is a major regulator of dendritic microtubules and Klp10A is a major regulator of axonal microtubules. In keeping with this idea, antibodies that recognize Klp10A show more intense staining of axons than dendrites. We conclude that Klp59C and Klp10A act differentially on dendritic and axonal microtubules, and their localized function may be one mechanism that allows neurons to establish different arrangements of microtubules within axons and dendrites.

**Microtubule Length Regulation by the Kinesin-8 Motor Protein: Capping and Polymerizing Enzymes.**

*L. Reese<sup>1</sup>, A. Melbinger<sup>2</sup>, E. Frey<sup>1</sup>; <sup>1</sup>Arnold Sommerfeld Center for Theoretical Physics (ASC) and Center for NanoScience (CeNS), Ludwig-Maximilians-Universität München, Munich, Germany, <sup>2</sup>Institut Pasteur, Paris, France*

In the cell, size and dynamics of filaments are tightly controlled. One important player in microtubule length regulation is the microtubule depolymerizing motor protein kinesin-8. The accumulation of this protein along microtubules enables a differential regulation of microtubule length. Cellular mechanisms of length regulation however, are still obscure due to the complicated mechanochemical dynamics of microtubules and the presence of a multitude of microtubule associated proteins. We extend a simple mathematical model based on what is known for the microtubule depolymerizing motor kinesin-8, to account for microtubule growth factors, like the microtubule polymerizing enzyme XMAP215. We predict that microtubule polymerizing enzymes significantly enhance the range over which microtubule dynamics can be regulated. Further, our findings shed light on the functioning of microtubule depolymerization by kinesin-8. We show that depending on microscopic details of kinesin-8's depolymerization mechanism, it's length regulatory function is reminiscent of dynamic instability.

279

**The novel Joubert syndrome protein KIF7 is involved in the regulation of microtubular dynamics, cellular polarity and cell cycle progression.**

*C. Dafinger<sup>1</sup>, M. C. Liebau<sup>1,2</sup>, T. Benzing<sup>1,3</sup>, B. Schermer<sup>1,3</sup>; <sup>1</sup>Department II of Internal Medicine and Center of Molecular Medicine Cologne, University of Cologne, Cologne, Germany, <sup>2</sup>Department of Pediatrics, University of Cologne, Cologne, Germany, <sup>3</sup>University of Cologne, Cologne Excellence Cluster on Cellular Stress Responses in Aging-Associated Diseases, Cologne, Germany*

Joubert syndrome (JBTS) is a rare mostly autosomal recessively inherited developmental disorder characterized by a specific brain malformation with various additional pathologies. JBTS results from mutations in at least 17 different genes, all of which play a role in the formation or function of primary cilia. Primary cilia are essential for vertebrate development, and mutations affecting this organelle underlie a large group of diseases referred to as ciliopathies. We recently identified mutations in *KIF7* as a cause of JBTS in a consanguineous family. *KIF7* belongs to the family of kinesin motor proteins and is a known regulator of Sonic Hedgehog signaling. Knockdown of *KIF7* in retinal pigment epithelial (RPE) cells affects the structure of

cilia, centrosomes and the Golgi network, and is associated with alterations in cell shape, rendering the cells larger and no longer able to align in a parallel manner as wild type RPE cells do, suggesting defects in cell polarity. Consistently, KIF7 was found to interact with the polarity complex protein PAR3. We have now subsequently analyzed the cell biological function of KIF7 in more detail. In migration assays over 48 hours *KIF7* knockdown cells presented with impaired directed cellular growth likely due to a defect in cell cycle progression. FACS analysis revealed a considerable G2/M arrest in U2OS cells. Additionally, we found KIF7 to interact with the histone deacetylase HDAC6 and observed increased tubulin acetylation after knockdown of *KIF7*, which may impair correct transport of polarity complex proteins and could be causative for the additional cellular phenotypes observed in *KIF7* knockdown cells. Changes in microtubule stability might function as underlying disease mechanisms impacting ciliary function, cellular polarity and cell cycle progression.

280

#### **Effect of Laulimalide on Microtubule Dynamics during Cell Division.**

A. Mazumdar<sup>1</sup>, G. Chan<sup>1</sup>; <sup>1</sup>Experimental Oncology, Cross Cancer Institute, University of Alberta, Edmonton, AB, Canada

Small molecule inhibitors of microtubules are valuable both as tools for studying the biology of microtubules and in the development of anti-tumor agent. Laulimalide is one such recent molecule isolated from the sea-sponges and has taxol like properties. It inhibits cell-cycle proliferation and is highly effective in taxol resistant cells. In contrast to taxol, it binds to a different site at the exterior of  $\beta$ -tubulin near the charged c-terminal tail and stabilizes the microtubules in vitro. Cells treated with laulimalide show no evidence of microtubule bundling in interphase. Live cell analysis reveals that cells treated with laulimalide enter mitosis but chromosomes scatter from the metaphase plate. HeLa cells incubated with low dose of laulimalide have high mitotic index and lead to multiple ring shaped spindle poles along with defects in chromosome alignment and segregation. In order to understand the molecular pathways that are affected by laulimalide treatment, we did an extensive literature search looking for proteins, depletion of which creates multiple ring shaped spindle poles. We found that cells lacking microtubule associated proteins (MAPs), ch-TOG or HAUS, have multiple spindle poles that are ring-shaped. We found that ch-TOG and HAUS were both mislocalized in HeLa cells treated with laulimalide. This result implicates the involvement of ch-TOG and HAUS in the laulimalide phenotype. Immunofluorescence and RNAi studies reveal that these proteins are localized at the spindle poles and required for their maintenance. Also, we show that in cells treated with laulimalide, Eg5 kinesin motor protein is required to generate the multipolarity. Currently, we are using quantitative immunofluorescence and fluorescence recovery after photobleaching (FRAP) to study the differences in spindle microtubule organization caused by laulimalide versus taxol in interphase and mitotic PtK2 cells. This will allow us to understand the effect of laulimalide on microtubule dynamics in cells.

#### **New Insights into the Inhibition of Microtubule Dynamics and Spindle Formation by the Novel Microtubule Stabilizer Taccalonolide AJ.**

A. L. Risinger<sup>1</sup>, C. C. Rohena<sup>1</sup>, M. Lopus<sup>2</sup>, S. Riffle<sup>2</sup>, M. A. Jordan<sup>2</sup>, L. Wilson<sup>2</sup>, S. L. Mooberry<sup>1</sup>; <sup>1</sup>University of Texas Health Science Center at San Antonio, San Antonio, TX, <sup>2</sup>University of California at Santa Barbara, Santa Barbara, CA

Taccalonolide AJ causes cancer cells to arrest in mitosis due to the formation of abnormal, multipolar mitotic spindle asters. The morphology of these structures differs from those initiated

by paclitaxel. At the concentration that causes maximal G<sub>2</sub>/M accumulation, paclitaxel initiated the formation of 2-3 relatively large diffuse spindle asters, while 5-7 compact spindle asters were observed in taccalonolide AJ-treated cells. Studies were conducted to determine if the mechanism of aberrant spindle aster formation differed between taccalonolide AJ and paclitaxel. High-content live-cell microscopy was used to investigate the initial formation and the fate of cells entering mitosis after treatment with each microtubule stabilizer. Two distinct mechanisms of multipolar spindle formation were observed: the slow fragmentation of an initial bipolar spindle or the initial formation of multiple spindle asters that seem to be nucleated from the cell cortex. While paclitaxel and taccalonolide AJ shared similar patterns of initial aster formation, dramatic differences were observed in the fate of these asters. Paclitaxel-treated cells contained multiple asters that appeared to fuse into 2-3 larger more diffuse asters. This is possibly the cell's attempt to restore a bipolar spindle morphology. In contrast, taccalonolide AJ-treated cells contained multiple spindle asters that did not merge and instead persisted as more numerous and compact asters. Co-localization studies showed that while many microtubule associated proteins were eventually localized to mature taccalonolide AJ-induced asters, NuMa was unique in that it associated with microtubules very early in mitosis, even localizing to the asters nucleated at the cell cortex. Depletion experiments showed NuMa was not required for the cortical localization of microtubules, but that it may play an important role in aster maturation after drug treatment. Further mechanistic studies were conducted to determine whether taccalonolide AJ inhibited microtubule dynamics in a similar way to paclitaxel. These experiments demonstrated that sub-stoichiometric concentrations of taccalonolide AJ cause a dose-dependent suppression of microtubule dynamics. While taccalonolide AJ had no effect on the growth rate of microtubules, it significantly suppressed the shortening rates and catastrophe and rescue frequencies. We hypothesize that the ability of taccalonolide AJ to suppress microtubule dynamics is responsible for the aberrant spindle aster formation and resolution observed.

282

### **Neuropathic effects of eribulin, ixabepilone, paclitaxel, and vincristine on peripheral sensory neurons in vitro.**

J. A. Smith<sup>1</sup>, A. Rifkind<sup>1</sup>, G. Smiyun<sup>1</sup>, J. Meinert<sup>1</sup>, S. Feinstein<sup>1</sup>, L. Wilson<sup>1</sup>, M. Jordan<sup>1</sup>;

<sup>1</sup>University of California, Santa Barbara, Santa Barbara, CA

Peripheral neuropathy can be a serious dose-limiting toxicity associated with microtubule-targeting anticancer drug treatment. We examined the neuropathic effects of four microtubule-targeting drugs in vitro, eribulin mesylate (ERB), ixabepilone (IXA), paclitaxel (PAC), and vincristine (VCR) and using an immortalized rat peripheral sensory neuronal cell line, 50B11. The goal is to investigate a possible correlation between drug effects on microtubule assembly dynamics and neuronal cell damage. As an assay for cell viability we determined the ability of each drug to reduce total cellular ATP levels. We found that IXA, which suppresses microtubule dynamics and enhances microtubule polymer mass, was 20-fold weaker than PAC, which has a similar effect on microtubules (EC<sub>50</sub>, IXA, 6.7 nM; PAC, 0.33 nM). VCR and ERB, which suppress microtubule dynamics but decrease microtubule mass, induced cell death with EC<sub>50</sub> values of 0.36 nM and 0.82 nM, respectively. Thus, the order of potency for induction of 50B11 cell death is PAC=VCR>ERB>IXA. After 24 h incubation, the drugs induced a loss of neurites (neurite retraction) with potencies of: VCR>ERB>IXA> PAC. At 10 nM VCR, neurite number was reduced from 0.79 neurites/cell in control to 0.09 neurites/cell. Nearly complete neurite retraction occurred with ERB only at ≥ 100 nM (to 0.08 neurites/cell). Neither PAC nor IXA induced complete loss of neurites at ≤ 1000 nM. The microtubule-depolymerizing effects of VCR and ERB may be responsible for their stronger effects on neurite retraction. We measured drug effects on α-tubulin protein expression and tubulin acetylation by in-cell western.

Increased acetylation of  $\alpha$ -tubulin is a correlate of increased microtubule stability. VCR strongly reduced  $\alpha$ -tubulin protein levels, in agreement with Huff et al., 2010.  $\alpha$ -tubulin was reduced by 60% at 100 nM VCR and by 38% at 100 nM ERB. No reduction in  $\alpha$ -tubulin protein occurred with PAC or IXA, and at high concentrations both drugs increased tubulin expression, by 15% and 28% for 100 nM PAC and IXA, respectively. All four drugs increased the acetylation of tubulin at low nanomolar concentrations; at 4 nM, tubulin acetylation was increased by 107% for PAC, 75% for IXA, 70% for ERB and 61% for VCR. However, VCR uniquely reduced tubulin acetylation at high concentrations (by 88% at 100 nM, possibly due to microtubule destabilization). The relative effects on tubulin expression and acetylation by the four drugs correlate well with their relative potencies on neurite retraction, indicating that changes in microtubule stability may play a significant role in drug-induced neurite retraction. These results indicate that the specific functional perturbations of 50B11 sensory neurons by microtubule-targeting anticancer drugs vary substantially from one drug to another. Experiments to further assess effects of these drugs on sensory neuron damage in relation to their effects on microtubule assembly dynamics are underway. This work is funded by Eisai Inc.

**Novel method for examining the effects of beta tubulin mutations on drug resistance or sensitivity by creating isogenic U2OS cell lines expressing codon-customized mutant TUBB ORFs.**

*K. Sagane<sup>1</sup>, K. Ogawa-Mitsuhashi<sup>1</sup>, K. Takase<sup>1</sup>, K. Kubara<sup>1</sup>, K. L. Agarwala<sup>1</sup>, K. Tsukahara<sup>1</sup>;  
<sup>1</sup>Eisai Product Creation Systems, Eisai Co., Ltd., Tsukuba, Japan*

Tubulin is one of the oldest, most highly validated targets for cancer chemotherapy. A large number of mutations in tubulin genes have been identified from cancer patients. However, the effects of such mutations on drug susceptibility have not been adequately characterized. This is because there is no appropriate assay system, due to high expression levels and isoform complexity of endogenous tubulins. To overcome this problem, we have established a new method of tubulin mutation analysis. Our system is comprised of 3 parts, 1) a codon-customized synthetic type 1 beta-tubulin (TUBB) ORF, which is resistant to siRNA, 2) siRNA targeting of the endogenous TUBB sequence, and 3) integration of mutant TUBB ORF-expression cassettes into the specific genomic locus of the host cells using the Jump-In™ TI™ Gateway® Targeted Integration System (Invitrogen). Several drug-resistant mutations of the TUBB gene were tested in our system, and the effects of each TUBB mutation upon sensitivity to or resistance against tubulin inhibitors, such as paclitaxel, vinblastine, vincristine and eribulin, were successfully determined. In conclusion, our versatile assay system is useful for characterizing the effects of TUBB gene mutations on drug resistance or sensitivity.

284

**Effects of the Chemotherapeutic Agent Taxol at Nanomolar Concentrations Observed by TIRF Microscopy.**

*B. D. Charlebois<sup>1</sup>, S. M. McCubbin<sup>1</sup>; <sup>1</sup>Biomedical Engineering, University of Michigan, Ann Arbor, MI*

Microtubules are intracellular polymers that assemble from heterodimeric  $\alpha\beta$ -tubulin subunits. Polymerizing microtubules exhibit dynamic instability, a GTP-hydrolysis-driven phenomenon in which they alternate abruptly between phases of growth and relatively rapid shortening. The kinetics of tubulin subunit exchange at the microtubule tip, which are crucial to processes such

as mitosis, are affected by the chemotherapeutic drug taxol, but the precise mechanism of action at therapeutic concentrations remains unclear.

We observe microtubules polymerized at 4.5 micromolar tubulin and at 1-480 nanomolar taxol using total internal reflection fluorescence microscopy (TIRFM), achieving improvements in spatial and temporal resolution of, respectively, 1 and 2 orders of magnitude compared to previous taxol studies. We measure microtubule length changes to within 25 nm at 8 Hz, and we detect changes in the structure of the microtubule tip. We find that taxol potently affects microtubule growth at concentrations as low as 10 nM. At these concentrations we observed abrupt changes in the growth rate not observed under control conditions, with phases lasting on the order of 1 – 2 minutes, suggesting multiple tip states and kinetic rate constants. In many of these cases, microtubules switched between a state of normal growth and a “paused” state, where the net growth rate is small or negligible. Further, we have found that 10 nM taxol almost completely suppresses rapid shortening, and beginning at 100 nM taxol, the tubulin on and off rates gradually decrease, though the microtubule net growth rate (excluding pauses in taxol-microtubules) remains constant.

285

#### **Fluorescent Probes for Carbonyl-Containing Proteins.**

*O. Dilek<sup>1</sup>, K. Mukherjee<sup>1</sup>, S. Bane<sup>1</sup>; <sup>1</sup>Chemistry, State University of New York at Binghamton, Binghamton, NY*

Carbonyl groups can be introduced into proteins deliberately for bioorthogonal labeling or by endogenous processes such as oxidative stress. Chemical probes for detection and labeling protein aldehydes are primarily hydrazides or 2,4-dinitrophenylhydrazine, but the kinetics of the labeling reactions are slow at neutral pH. Aromatic hydrazines and amines are better candidates for performing the labeling reactions under biocompatible conditions. We have synthesized fluorophores that possess aromatic amino and hydrazinyl groups and studied their reactive and photochemical properties with a model aldehyde-containing protein. Of particular interest are fluorescein, rosamine and BODIPY-based fluorophores in which the nitrogen is bonded to the pendant aromatic ring. In most cases, the parent amine or hydrazine is weakly fluorescent due to intramolecular photoinduced electron transfer from the nitrogen. Imine or hydrazone formation can remove the intramolecular quenching, and therefore the fluorescence can “turn on” as a result of covalent bond formation. The reversible imine bond can be hydrolyzed to regenerate the carbonyl or reduced to form a stable covalent bond. Applications of these fluorophores to protein and cell biochemistry vary with the specific fluorophore. For example, cell impermeable fluorophores can label oxidized proteins on the cell surface, while cell permeable probes can react with proteins on the interior of the cell. Some of these reactions occur specifically in live cells.

## Centrosomes I

286

### How Flies Build a Mitotic Centrosome

*P. T. Conduit<sup>1</sup>, M. Pratt<sup>1</sup>, J. Baumbach<sup>1</sup>, J. W. Raff<sup>1</sup>; <sup>1</sup>Sir William Dunn School of Pathology, University of Oxford, Oxford, United Kingdom*

Centrosomes are the main microtubule organising centres in many cells. They comprise a pair of centrioles, which can recruit a large number of proteins collectively known as the Pericentriolar Material (PCM). The PCM harbours the complexes that facilitate microtubule nucleation and large amounts of PCM are recruited during mitosis in a process known as centrosome maturation. Several proteins have been implicated in this process, but a clear understanding of how the mitotic PCM is assembled has remained elusive. Here we show that two PCM components, Cnn and DSpd-2, are constantly recruited into a zone of PCM immediately surrounding the centrioles by the centriolar protein Asl, and then move outwards to fill the rest of the PCM. Thus, they exhibit a 'central to peripheral flow'. In contrast, all of the other PCM components we have analysed are recruited evenly throughout the PCM, suggesting that they bind to a preformed PCM 'scaffold'. Mutant analysis in somatic cells shows that centrosomes can partially mature and nucleate MTs in the absence of either Cnn or DSpd-2. In the absence of both proteins, however, centrosome maturation and MT nucleation is completely abolished. We propose that Asl, Cnn and DSpd-2 cooperate to form a PCM scaffold around the centrioles onto which other PCM components can bind. Without this scaffold, other PCM components are unable to accumulate around the centrioles and the centrosomes cannot function to nucleate microtubules.

287

### Quantitative Mass Spectrometry-based Proteomics of Human Centrosomes after Cullin-RING E3 ligase and Proteasome Inactivation.

*K. Vanselow<sup>1</sup>, K. M. Larsen<sup>1</sup>, L. Jakobsen<sup>1</sup>, J. M. Schrøder<sup>1</sup>, K. B. Schou<sup>1</sup>, E. Lundberg<sup>2</sup>, J. S. Andersen<sup>1</sup>; <sup>1</sup>Department of Biochemistry and Molecular Biology, University of Southern Denmark, Odense, Denmark, <sup>2</sup>School of Biotechnology, Alba Nova University Center, Royal Institute of Technology, Stockholm, Sweden*

Ubiquitin-ligases are key regulators of centrosome function during the cell cycle. The identity and substrates of these regulators are, however, not well established. To identify novel ubiquitin-ligases and substrates with a role in centrosome biology, we applied mass spectrometry-based proteomics to quantify proteins differentially associated with the centrosome before and after treatment of cells with the proteasome inhibitor bortezomib and the NEDD8-activating enzyme inhibitor MLN4924. Upon proteasome inhibition, we observed that a large number of proteins accumulate at the centrosome. This is consistent with previous reports where fluorescence microscopy experiments have revealed that proteins accumulate at the centrosome, most likely due to a failure of degrading poly-ubiquitylated proteins. We were able to quantify those changes for the majority of known centrosomal proteins and observed major differences in the degree of accumulation of proteins involved in distinct processes such as centriole duplication, elongation and cohesion. Inactivation of Cullin-RING E3 ligases by the NEDD8-activating enzyme inhibitor MLN4924 followed by quantitative proteomic analysis revealed more subtle and selective changes in stabilization of proteins at the centrosome. To identify novel proteins associated with centrosomes after proteasome inhibition, we applied our PCP-SILAC method (Jakobsen, EMBO J., 2011) to measure enrichment profiles of proteins in fractions collected after sucrose gradient centrifugation of centrosomes. Cluster analysis of

profiles for 3822 proteins revealed a distinct cluster with 150 known centrosomal proteins and 60 additional components representing novel candidate proteins and possibly ubiquitylated substrates associated with the centrosome. This group of proteins comprised several E3 ligases of interest for further analysis. Initial immunostaining experiments confirmed centrosome localization for 12 proteins not previously shown to be associated with the centrosome. Changes in the localization patterns indicated cell cycle dependent function for these proteins.

288

**Dissecting the interactions of the centrosome.**

*B. J. Galletta<sup>1</sup>, C. J. Fagerstrom<sup>1</sup>, R. X. Guillen<sup>1</sup>, K. C. Slep<sup>2</sup>, N. M. Rusan<sup>1</sup>; <sup>1</sup>Cell Biology and Physiology Center, National Institutes of Health, Bethesda, MD, <sup>2</sup>Biology, University of North Carolina, Chapel Hill, NC*

The major microtubule-organizing (MTOC) center of many eukaryotic cells is the centrosome, a non-membrane bound organelle that consists of the centriole and surrounding peri-centriolar material (PCM). As cells enter mitosis, centrosomes accumulate PCM and become highly active MTOCs, nucleating and/or anchoring microtubules. Proteomics have identified the constituent parts of the centrosome and RNAi screens have identified proteins critical for centrosome function and maintenance. However, understanding how specific proteins function in the construction, maturation and function of centrosomes has been hindered by the fact that knockdown of many centrosomal proteins can cause a failure in centrosome duplication or in its structural integrity. As a result, how the many proteins of the centrosome interact and function together remains unclear. A critical next step is to understand the relationships among the proteins within the centrosome, and how these relationships change as the centrosome becomes active. To identify the specific interactions between centrosomal proteins, we have carried out a yeast two-hybrid screen to identify all of the interactions among 34 centrosomal proteins including proteins in the centriole and PCM, as well as proteins with the potential to regulate centrosome function. By analyzing known and predicted protein structures, we divided many of these proteins into smaller fragments representing likely functional domains. In total we analyzed all of the possible interactions among 88 polypeptides. This analysis has revealed a multitude of connections between centrosomal proteins, perhaps providing insight into why loss of a single protein is so detrimental to the entire organelle. We have now expanded this analysis to include 42 additional proteins that proteomics and RNAi have suggested may play a role at the centrosome. To begin understanding the significance of these interactions, we are now generating mutations to disrupt specific interactions within the centrosome. Our goal is to identify mutations that perturb aspects of centrosome maturation and function, but do not affect the overall stability or maintenance of structure. The effect of mutations that disrupt specific interactions will be analyzed in S2 cells and in live *Drosophila* neural stem cells to determine their effect on the recruitment of PCM, the MTOC capacity of centrosomes and asymmetric cell division. This system allows us not only to determine the consequence of these mutations at the cellular level, but also how these small perturbations in centrosome function affect the larger tissue's architecture. We have started this type of analysis with Asterless, which we found had 23 interactions with 14 centrosomal proteins.

289

**Centrosome maturation starts at centrioles: Implications from a clear cytoplasmic separation of key players of centrosome maturation in *C. elegans*.**

O. Wueseke<sup>1</sup>, J. Bunkenborg<sup>2</sup>, J. S. Andersen<sup>2</sup>, T. Hyman<sup>1</sup>; <sup>1</sup>Max Planck Institute for Molecular Cell Biology and Genetics, Dresden, Germany, <sup>2</sup>Department of Biochemistry and Molecular Biology, University of Southern Denmark, Odense M, Denmark

Centrosomes are the major microtubule organizing centers of the cell. Mature centrosomes consist of a two centrioles, surrounded by a proteinaceous matrix called pericentriolar material (PCM). Prior to mitosis centrosomes grow by accumulating PCM, a process called centrosome maturation. In *C. elegans* we know that SPD-2, SPD-5, AIR-1 and PLK-1 are essential for this process. Existing yeast-two-hybrid data suggests a direct interaction between SPD-5 and SPD-2 as well as AIR-1. Other data shows that the interaction between SPD-2 and PLK-1 is essential for proper centrosome growth. It was shown in *D. melanogaster* that centrosome proteins form pre-assembled cytoplasmic complexes that are tethered to the centrosome via SAS-4. Even though we know the key proteins and their molecular interactions the exact steps required for PCM accumulation in *C. elegans* remain unknown. Do pre-assembled complexes also exist in *C. elegans* or does the PCM accumulate in a step-wise manner? To differentiate between the two scenarios we ask the question whether SPD-5, SPD-2, AIR-1 and PLK-1 form pre-assembled complexes in the cytoplasm.

By using a combined approach of single molecule microscopy and proteomics on the cytoplasmic level we analyzed interactors that associate with SPD-2 and SPD-5 inside the cytoplasm of *C. elegans* embryos. We find that SPD-5 forms a complex with PP2A related proteins RSA-1 and RSA-2 but without AIR-1. Our analysis of SPD-2 indicates that it exists freely in the cytoplasm and does neither interact with SPD-5 nor with PLK-1.

With the use of Fluorescence correlation spectroscopy(FCS) we then measured the diffusion of the SPD-5 complex and the free SPD-2 in a spatial and cell cycle dependent manner. We report that the diffusion for both proteins stays constant throughout the cell cycle and is independent of the cytoplasmic location inside the embryo.

Here we show that SPD-2 and SPD-5 move separately throughout the cytoplasm in a localization and cell cycle independent manner. Combined with the absence of an interaction with AIR-1 and PLK-1 these results suggest that PCM assembly is initiated at the centrioles rather than in the cytoplasm.

290

**Quantitative Mass Spectrometry-based Proteomics and Electron Microscopy Reveals Cep128 as a Core Component of the Subdistal Appendages.**

J. M. Schroder<sup>1</sup>, L. Jakobsen<sup>1</sup>, M. Rogowski<sup>2</sup>, K. Vanselow<sup>1</sup>, E. Lundberg<sup>3</sup>, L. B. Pedersen<sup>4</sup>, S. Geimer<sup>2</sup>, J. S. Andersen<sup>1</sup>; <sup>1</sup>Department of Biochemistry and Molecular Biology, University of Southern Denmark, Odense M, Denmark, <sup>2</sup>Cell Biology/Electron Microscopy, University of Bayreuth, Bayreuth, Germany, <sup>3</sup>Alba Nova University Center, Royal Institute of Technology (KTH), Stockholm, Sweden, <sup>4</sup>Department of Biology, University of Copenhagen, Copenhagen, Denmark

The centriole is a microtubule based barrel-shaped multifunctional organelle serving as a common scaffold for the centrosome, mitotic spindle and the basal body of cilia. Each structure is tightly coupled with distinct cell cycle stages and associates with a large number of proteins that change dynamically during these stages. The identity of most centrosomal proteins has been revealed, but the macromolecular composition of substructures such as the distal and

subdistal appendages and how they interact with the centrioles and the pericentriolar material remain unknown. Detailed localization studies may provide clues to the function of individual proteins, but the overall cellular pool of centriole-associated proteins could represent alternative functions. To further investigate the localization/function relationship we use quantitative mass spectrometry-based proteomics on centrosomes isolated from human cells to characterize the spatial organization and the biochemical properties of centriolar proteins. We have developed two methods profiling: 1) the depletion of proteins from the centrosomal scaffold before and after incubation in different salt concentrations, and 2) the distribution and exchange of proteins between two cellular compartments when incubating isolated human centrosomes with cytoplasm from cycling or growth-arrested human cells. We have correlated data from these two approaches and performed hierarchical cluster analysis to reveal proteins with similar functional properties. The protein Cep128 was identified as a core component of the centrosomal scaffold, supporting our previous finding that Cep128 localizes specifically to the mother centriole (L. Jakobsen et al., 2011). By performing immunogold electron microscopy on cultured human cells and purified centrosomes, Cep128 was localized specifically to the subdistal appendages. We depleted Cep128 in cultured human cells using esiRNA and analyzed the effect in growth arrested cells by immunofluorescence- and transmission electron microscopy. Cep128-depleted cells were not affected in their ability to form primary cilia, but displayed a higher number of pericentriolar dense bodies or satellites as well as of non-exocytotic vesicles in line with the cilium. This implies that Cep128 may play a role in the trafficking of satellites and vesicles to and/or from the centrosome. Our data also provide a system-level framework for further analysis of the molecular mechanisms controlling the assembly and function of the centrosome.

291

**Sub-diffraction-resolution fluorescence microscopy reveals a novel domain of the centrosome critical for pericentriolar material organization.**

V. Mennella<sup>1</sup>, K. Bettina<sup>1</sup>, K. McDonald<sup>2</sup>, B. Chhun<sup>3</sup>, F. Kan<sup>1</sup>, G. Rogers<sup>4</sup>, B. Huang<sup>3</sup>, D. Agard<sup>1</sup>; <sup>1</sup>Biochemistry and Biophysics, HHMI and University of California San Francisco, San Francisco, CA, <sup>2</sup>Electron Microscopy Lab, University of California Berkeley, Berkeley, CA, <sup>3</sup>Pharmaceutical Chemistry and Biochemistry and Biophysics, University of California San Francisco, San Francisco, CA, <sup>4</sup>Cellular and Molecular Medicine, University of Arizona, Tucson, AZ

As the main microtubule-organizing center in animal cells, the centrosome has a fundamental role in cell function. Surrounding the centrioles, the Pericentriolar material (PCM) provides a dynamic platform for nucleating microtubules. While the PCM's importance is established, its amorphous electron-dense nature has made it refractory to structural investigation. By using SIM and STORM sub-diffraction resolution microscopies to visualize proteins critical for centrosome maturation, we demonstrate that the PCM is organized into two major structural domains: a layer juxtaposed to the centriole wall (Asl and Plp), and proteins extending further away from the centriole organized in a matrix (Spd-2, Cnn and  $\gamma$ Tub). Analysis of Pericentriolar-like protein (Plp) reveals that its C-terminus is positioned at the centriole wall, it radiates outward into the matrix and is organized in clusters having quasi-nine-fold symmetry. By RNAi we show that Plp fibrils are required for interphase recruitment and proper mitotic assembly of the PCM matrix.

292

**STED super-resolution microscopy of multiciliated respiratory epithelial cells reveals structural organization of centriole and cilia components.**

Y. Lee<sup>1</sup>, L. Lau<sup>2</sup>, S. J. Sah<sup>2</sup>, W. E. Moerner<sup>2</sup>, T. Stearns<sup>1,3</sup>; <sup>1</sup>Biology, Stanford University, Stanford, CA, <sup>2</sup>Chemistry, Stanford University, Stanford, CA, <sup>3</sup>Genetics, Stanford University, Stanford, CA

Centrioles are microtubule-based organelles that template the formation of cilia. Motile cilia are involved in cellular motility and movement of extracellular fluid in specialized tissues. Non-motile primary cilia mediate signaling events in vertebrates. While the ultrastructure of centrioles and cilia has been well characterized by electron microscopy (EM), the structural organization of the molecular components of centrioles and cilia has not. A limitation has been that the relevant size scale of this organization is at, or below, the diffraction limit of light microscopy. We have used stimulated emission depletion (STED) super-resolution immunofluorescence microscopy to image the structural organization of centriole and cilia components in multiciliated respiratory epithelial cells derived from murine trachea. Imaged by STED at a resolution of 50-70 nm, the distal appendage protein Cep164 localizes with 9-fold symmetry at centrioles (Biophys. J. 102(12):2926-2935). The inner dynein arm component, Dnah2, localizes as puncta along ciliary axonemes with a ~100 nm periodicity. These findings are consistent with EM-based studies of centriole and cilia morphology, and suggest that this unique combination of technologies should facilitate the determination of the molecular anatomy of centrioles and cilia. Finally, super-resolution imaging of the ciliary axoneme with appropriate markers could facilitate diagnosis and classification of primary ciliary dyskinesias.

293

**Cryo-Electron Tomography of Centriole Assembly and Ciliogenesis in *Naegleria gruberi*.**

B. D. Engel<sup>1</sup>, E. Villa<sup>1</sup>, W. Baumeister<sup>1</sup>; <sup>1</sup>Molecular Structural Biology, Max Planck Institute of Biochemistry, Martinsried, Germany

Centrioles and cilia/flagella direct many cellular functions, from organizing the mitotic spindle to mediating cell signaling and motility. Despite the importance of these organelles, the mechanisms of their construction are not thoroughly understood. The single-celled eukaryote *Naegleria gruberi* undergoes a remarkable synchronized differentiation from amoeba to flagellate, assembling centrioles, flagella, and a complete microtubule cytoskeleton *de novo*. We aim to gain structural insights into the mechanisms of centriole assembly and ciliogenesis via cryo-electron tomography and sub-tomogram averaging of intermediate structures isolated at successive time points throughout the amoeboflagellate transition.

294

**Elucidating the pathway of centrosome formation in *Drosophila*.**

C. C. Vicente<sup>1</sup>, J. W. Raff<sup>1</sup>; <sup>1</sup>Sir William Dunn School of Pathology, University of Oxford, Oxford, UK

Centrosomes are cellular organelles that comprise two centrioles surrounded by a more amorphous pericentriolar material (PCM) that is the site of microtubule nucleation. A conserved "core" of proteins that are required for centriole duplication and PCM recruitment have been identified in *Drosophila* (comprising Sak, DSas-6, Ana2, DSas-4, Asl, DSpd-2 and Cnn). Little is known, however, about how these proteins cooperate to drive centriole and centrosome assembly. This is partly because mutations in any one of the 5 core duplication proteins (Sak, DSas-6, Ana2, DSas-4 and Asl) result in the complete absence of centrioles, making it difficult

to analyse the pathway of centriole and centrosome assembly. Here we begin to elucidate this pathway using DSas-6/Ana2 particles (SAPs), which form rapidly and at high frequency in laid *Drosophila* eggs that moderately overexpress the centriolar proteins GFP-DSas-6 and GFP-Ana2. We show that SAPs are good models of centrosomes, as all tested centriolar and PCM markers exhibit very similar localisation and dynamics at centrosomes and at SAPs. Importantly, however, unlike centrosomes, SAPs can form even in the absence of certain essential centriole duplication proteins. This has allowed us to monitor the recruitment of various centrosome proteins to the SAPs in different mutant backgrounds. This analysis has allowed us, for the first time, to propose a detailed molecular pathway for centriole and PCM assembly in *Drosophila*.

295

**Mdm1, a gene linked to age associated retinal degeneration in mice, encodes a novel centriolar protein.**

*D. P. Van de Mark*<sup>1</sup>, *R. Hoh*<sup>1</sup>, *T. Stearns*<sup>1</sup>; <sup>1</sup>*Biology, Stanford University, Stanford, CA*

Mutations in genes encoding centrosome and cilia proteins are implicated in human diseases including cancer and a class of disorders known as ciliopathies. Thus, identifying and understanding the function of centrosome and cilia proteins can shed light on the mechanisms underlying the development of these diseases. We identified Mdm1 as one of the most highly upregulated genes in a microarray study that examined gene expression during differentiation in a mouse tracheal epithelial culture (MTEC) system. Mdm1 was originally identified as a gene that is amplified on mouse double minutes in transformed NIH 3T3 cells, and it was previously linked to retinal degeneration in a mouse model of age-related retinal degeneration. We show that Mdm1 localizes to the basal body layer in MTECs, consistent with it being a centrosomal protein. We used deconvolution microscopy to show that it is present at the proximal end of centrioles, a region known to be important for centriole duplication and centrosome cohesion. Ongoing work is focused on determining the centrosomal function of Mdm1.

296

**Characterization of eta-tubulin: the final member of the vertebrate tubulin family.**

*E. Turk*<sup>1</sup>, *A. Wills*<sup>2</sup>, *S. Howes*<sup>3</sup>, *E. Nogales*<sup>4,5</sup>, *J. Wallingford*<sup>6</sup>, *T. Stearns*<sup>1,7</sup>; <sup>1</sup>*Department of Biology, Stanford University, Stanford, CA*, <sup>2</sup>*Section of Molecular Cell and Developmental Biology, University of Texas at Austin, Austin, TX*, <sup>3</sup>*Biophysics Graduate Program, UC Berkeley, Berkeley, CA*, <sup>4</sup>*Life Science Division, Lawrence Berkeley National Laboratory, Berkeley, CA*, <sup>5</sup>*Howard Hughes Medical Institute, Department of Molecular and Cell Biology, UC Berkeley, Berkeley, CA*, <sup>6</sup>*Howard Hughes Medical Institute, Section of Molecular Cell and Developmental Biology, University of Texas at Austin, Austin, TX*, <sup>7</sup>*Department of Genetics, Stanford School of Medicine, Stanford, CA*

Tubulins are a well-conserved superfamily of proteins that play vital roles in cytoskeletal, centrosomal, and ciliary biology. Superfamily members alpha, beta, and gamma are found in all eukaryotes, and are the structural elements of the microtubule polymer, and the nucleator of that polymer, respectively. Two other members of the tubulin family, delta and epsilon, are present in many, but not all, eukaryotes and are associated with centrioles. We have characterized another member of the vertebrate tubulin family, which most closely resembles eta-tubulin, previously described in *Paramecium*. Based on this similarity we will refer to this as the eta-tubulin subfamily. Eta-tubulin is present in a variety of organisms from single-celled eukaryotes, chordates, and marsupial mammals, but is absent in flies, worms, zebrafish, and placental mammals. Analysis of genome sequences indicates that eta-tubulin is the last remaining tubulin family member to be characterized in vertebrates. Eta-tubulins are the most divergent family within the tubulin superfamily, with frog and lizard eta-tubulins sharing 59%

identity compared to 70% identity between frog and lizard delta-tubulins, the next most divergent tubulin family. Comparison of the sequence of eta-tubulins with other tubulin family members suggests that it might have unique properties with respect to interaction with other tubulins. We present an *in vivo* and *in vitro* characterization of the *Xenopus laevis* eta-tubulin, including localization relative to the centrosome and cilium in cells and tissues, a preliminary functional assessment of its role *in vivo*, and biochemical determination of its interactions with other members of the tubulin superfamily.

297

**Sas-4-mediated PCM assembly is regulated by Tubulin Dimers.**

T. Avidor-Reiss<sup>1</sup>, J. Gopalakrishnan<sup>2</sup>, M. L. Basiri<sup>1</sup>; <sup>1</sup>University of Toledo, Toledo, OH, <sup>2</sup>Harvard, Boston, MA

A centrosome consists of a pair of centrioles surrounded by a protein network of pericentriolar material that is essential for centrosome function. Sas-4 was reported to be essential for both centriole and PCM recruitment in *Caenorhabditis elegans* and it was suggested that PCM recruitment defects are a consequence of structurally compromised centrioles. This idea was reinforced by the observation that in *Caenorhabditis elegans*, Sas-4 is a stable component of the centriole that is incorporated only during its initial formation. We find that, in *Drosophila*, Sas-4 has distinct characteristics, suggesting that Sas-4 may have in addition to its role in centriole formation, a specific role in PCM function. *Drosophila* Sas-4 is not only found in the centriole but can also be found in the PCM, and Sas-4 levels change along the cell cycle. Sas-4 forms complexes with multiple PCM proteins such as  $\gamma$ -tubulin, Asl, Cnn, Dplp, and CP190. Eliminating the conserved PN2-3 segment of Sas-4 leads to a reduction in PCM recruitment without blocking centriole duplication. In contrast, mutating Sas-4 tubulin binding site results in an increase in PCM recruitment without effecting centriole number. Additional evidence for the role of Sas-4 in PCM formation has come from biochemical studies of the interaction between Sas-4, tubulin dimers, PCM proteins, and whole centrosomes. Sas-4 scaffolds complexes of PCM proteins and can tether them to purified centrosomes that have been stripped of PCM. This function is regulated by a guanine nucleotide that binds to the tubulin dimer attached to Sas-4. Tubulin-GDP favors binding to Sas-4 and promotes PCM complex formation, while the binding of tubulin to a GTP analog blocks this process. Similarly, the binding of tubulin-GDP to Sas-4 promotes Sas-4-PCM complex tethering to the centrosome while the tubulin-GTP analog blocks this tethering activity. These studies suggest a model in which tubulin dimers regulate Sas-4-mediated PCM recruitment to the centrosome.

298

**PCM involvement in the formation of a centrosome-like particle that functions in basal body formation.**

A. Windhausen<sup>1</sup>, S. Wolniak<sup>1</sup>; <sup>1</sup>CBMG, University of Maryland, College Park, College Park, MD

The typical metazoan centrosome is a membrane-less cytoplasmic zone containing 2 centrioles surrounded by a lattice-like pericentriolar material (PCM). A main function of the centrosome is to serve as the MTOC, the primary organizer of the microtubule cytoskeleton in the cell. The centrosome is also the site of centriolar replication. The PCM consists of regulatory and structural proteins and changes in size and composition through the cell cycle. Plant cells lack centrioles, and accordingly, they do not possess organized centrosomes. Nevertheless, they organize microtubules in ordered arrays, usually from diffuse zones of cytoplasm. We are interested in knowing if plant cells regulate the assembly of their microtubule cytoskeletons with PCM-like arrays. Only a few select cells in a restricted group of plants possess basal bodies, and they form these 9+2 structures *de novo*, in a particle known as a blepharoplast. Though it

does not contain or consist of centrioles, the blepharoplast can serve as an MTOC, and as such, it behaves like an organized centrosome. The male gametophyte of *Marsilea vestita* provides a unique opportunity to study the recruitment of PCM components and their roles in the formation and maturation of the blepharoplast. The blepharoplast arises ~3.5 hours into gametophyte development and then reappears at 4 hours and serves as centrosome-like MTOC for the final division. It then functions as the site for *de novo* assembly of 140 basal bodies in each spermatid. RNAseq and transcriptome assembly enabled us to identify a series of likely PCM proteins present in the gametophyte. Centrin is essential for blepharoplast formation and serves as a key component in the particle. Its distribution serves as an assay for both blepharoplast and basal body formation. In functional assays, RNAi knockdowns of transcripts encoding several PCM proteins revealed that a striking number of structural proteins found in the PCM are required for proper formation and function of the blepharoplast, including Sfi1p, several CEPs, and gamma tubulin ring complex proteins. Silencing of certain PCM components blocked blepharoplast formation altogether. If the blepharoplast formed after a PCM component knockdown, it usually failed to complete its maturation for the assembly of functional basal bodies. This silencing approach should allow us to identify a variety of proteins that are essential for the *de novo* formation of the blepharoplast and basal bodies. This research was supported by NSF grant 0842525 to SMW.

#### Control of centriole replication by centrosomin proteins.

L-R. Kao<sup>1</sup>, P. T. Conduit<sup>2</sup>, J. W. Raff<sup>2</sup>, T. L. Megraw<sup>1</sup>; <sup>1</sup>Biomedical Sciences, Florida State University, Tallahassee, FL, <sup>2</sup>Sir William Dunn School of Pathology, University of Oxford, Oxford, United Kingdom

Centrosomins are conserved centrosome proteins. In *Drosophila*, centrosomin (Cnn) is required for PCM assembly and for the MTOC activity of mitotic centrosomes. In humans the centrosomin homologue *Cdk5rap2* is mutated in MCPH, a neural stem cell disease that effects brain growth. We recently reported that in *Cdk5rap2* mutant mouse cells the mitotic centrosomes have apparently normal MTOC activity but have amplified centrioles. The mechanism appears to involve loss of centriole engagement. Consistent with the role for *Cdk5rap2* in centriole replication control, we found mutations in *Drosophila cnn* that also cause unrestricted centriole duplication. One cluster of mutations causes centriole amplification in testis. These mutations knock out the expression of one of two centrosomal isoforms of Cnn in testes. By expressing a set of rescue constructs, we show that the developmental timing of Cnn expression, rather than a specific role(s) for Cnn isoforms, is responsible for restricting centriole replication. Moreover, we show that a conserved domain, the CM2 domain, is necessary for centriole replication control, while another domain required for microtubule assembly, CM1, is not required. The CM2 domain is also necessary and sufficient for targeting Cnn to the centriole, where it appears to be enriched at the proximal base of the daughter centriole. Therefore, Cnn restricts centriole replication to once per cell cycle via a conserved domain. The functional participation for a partner of the CM2 domain is under investigation.

#### Centriole duplication licensing in *C. elegans*: the role of separase.

G. Cabral<sup>1</sup>, A. Dammermann<sup>1</sup>; <sup>1</sup>MFPL/University of Vienna, Vienna, Austria

Centrioles are cytoplasmic structures that recruit pericentriolar material to form centrosomes, the major microtubule organising centers in animal cells. Given the central role of centrosomes in mitotic spindle assembly, centriole duplication has to be tightly controlled to ensure the

formation of a bipolar spindle in mitosis. New centriole assembly initiates during S phase and depends on an initial licensing step involving the separation of the previous mother-daughter centriole pair in anaphase/telophase, also referred to as disengagement. The cysteine protease separase, best known for its role in chromosome segregation in anaphase, has been suggested to play an additional role in several other events occurring in late mitosis, including the disengagement of centrioles. We therefore sought to characterize the role of separase in centrosome dynamics in the one-cell embryo of *C. elegans*. Consistent with reports in vertebrate cells, we found that depletion of the *C. elegans* separase ortholog SEP-1 resulted in a failure of centrosome separation and consequently formation of monopolar spindles in the first embryonic mitosis. However, immunofluorescence microscopy with PCM and centriole markers showed that depletion of SEP-1 did not prevent centriole disengagement. Nevertheless, centriole duplication was impaired in the majority of embryos, resulting in improper numbers of centrosomes in the subsequent division. Measurement of inter-centrosome distance across different cell cycle stages revealed a correlation between centrosome proximity and failure in centriole duplication, more consistent with a diffusible inhibitor model for regulating centriole duplication than a model based on a physical tether between mother and daughter centrioles as currently hypothesized. By analogy with chromosome segregation, separase-mediated cleavage of cohesin has been posited to underlie centriole disengagement in vertebrates. We are currently examining whether cohesin plays a direct role in centriole separation in *C. elegans*. Additionally, we are testing whether microtubule-dependent forces are involved in disengagement of centrioles in the *C. elegans* embryo. This question is particularly relevant as most previous experiments suggesting a role for separase in centriole disengagement were conducted in cell-free contexts where the role of the cytoskeleton could not be assessed.

### **RNA-binding Proteins ATX-2 and PAB-1 Interact with SZY-20 To Regulate Centrosome Assembly in *C. elegans* Embryos.**

*M. Song<sup>1</sup>, D. Zhang<sup>1</sup>, M. Bobian<sup>1</sup>, S. Mets<sup>1</sup>, K. Haynes<sup>1</sup>; <sup>1</sup>Biological Sciences, Michigan Technological University, Houghton, MI*

Centrosomes are critical sites for controlling microtubule dynamics, and exhibit dynamic changes in size, promptly responding to changing cellular demands during the cell cycle. As cells progress to mitosis, centrosomes recruit more microtubules to form bipolar spindles. The *szy-20* gene encodes a novel centrosome-associated RNA-binding protein that negatively regulates ZYG-1. *szy-20* mutants possess enlarged centrosomes, leading to abnormal microtubule processes and embryonic lethality. Thus, SZY-20 limits centrosome size by negatively regulating the recruitment of centrosome components. SZY-20 contains putative RNA-binding domains; mutating these domains perturbs RNA-binding by SZY-20 in vitro and its capacity to regulate centrosome size in vivo. Recent studies showed a number of RNAs and RNA-binding proteins associate with centrosomes and microtubules, and that they function to assemble mitotic spindles.

We used proteomics, and identified known RNA-binding proteins such as ATX-2 and PAB-1 that are reproducibly immunoprecipitated with SZY-20. In this study, we aim to understand the roles of SZY-20 and RNA-binding in regulating centrosome assembly and size, in particular, to understand how ATX-2/PAB-1 RNA-binding protein complex interacts with SZY-20 to achieve proper centrosome assembly and size. Depleting ATX-2 or PAB-1 leads to abnormal cell divisions, including cytokinesis failure, abnormal spindle positioning. Knockdown of these proteins enhances cell division defects and the embryonic lethality of *szy-20(bs52ts)* embryos, while restoring centrosome duplication in *zyg-1(it25ts)* embryos. Quantitative western analyses show that ATX-2 knockdown leads to significantly reduced levels of SZY-20, and vice versa.

Our findings suggest that ATX-2 and PAB-1 positively regulate SZY-20 by enhancing protein levels, and negatively regulate centrosome assembly which is mediated by SZY-20 via their physical and genetic interaction.

## Cilia and Flagella I

### A Quantitative Assay for Soluble Protein Entry into Primary Cilia.

*D. K. Breslow<sup>1</sup>, E. F. Koslover<sup>2</sup>, F. Seydel<sup>1</sup>, A. J. Spakowitz<sup>2</sup>, M. V. Nachury<sup>1</sup>; <sup>1</sup>Molecular & Cellular Physiology, Stanford University, Stanford, CA, <sup>2</sup>Chemical Engineering, Stanford University, Stanford, CA*

The primary cilium is a signaling organelle with a distinct complement of membrane and soluble proteins that is required for its assembly, maintenance, and function. However, the mechanisms that allow specific proteins to be concentrated within cilia or excluded from cilia remain poorly characterized. We have developed and validated a method for selective permeabilization of the plasma membrane that leaves the ciliary membrane intact, thus enabling quantitative analysis of protein entry into primary cilia. Specifically, our assay monitors the capture of soluble GFP-binding proteins (GBPs) by GFP molecules displayed on the cytoplasmic face of the ciliary membrane. As expected, we find that GBP probes first enter at the base of the cilium and spread distally until all binding sites are occupied. Using this system, we have characterized a size-dependent diffusion barrier at the base of mammalian primary cilia that restricts entry of inert proteins. The entry rate decreases for GBPs of increasing size, and entry is undetectable for proteins with diameter greater than 8.5nm. We further used this system to test the potential role of nucleoporins in forming this barrier; however, we find that reagents that either block or loosen the nuclear pore barrier do not affect ciliary entry. Similarly, no effect is seen for actin depolymerization, which disrupts the diffusion barrier at the axon initial segment of neurons. Thus the ciliary diffusion barrier appears to operate by a novel molecular mechanism. Lastly, we have used the permeabilized cell system to measure diffusion rates inside primary cilia for soluble and membrane proteins. Fluorescence recovery after photobleaching reveals that membrane protein diffusion is rapid for the ciliary GPCR somatostatin receptor 3 (Sstr3), but is blocked completely when Sstr3 is crosslinked by the lectin wheat germ agglutinin (WGA). Quantitative modeling of protein entry into cilia of WGA-treated cells enabled us to determine diffusion coefficients for soluble proteins within the ciliary lumen. Here we find diffusion coefficients similar to those reported for diffusion in the cytoplasm. Thus, diffusion may permit rapid protein movement within cilia in the absence of active transport processes such as intraflagellar transport. In summary, a permeabilized cell system enables quantitative analysis of protein entry into cilia and reveals a diffusion barrier that underlies physical compartmentalization of the primary cilium.

303

### Kinetics of ciliary protein transport.

*C. M. Louie<sup>1</sup>, D. Trivedi<sup>1</sup>, D. S. Williams<sup>1</sup>; <sup>1</sup>Departments of Ophthalmology and Neurobiology, Jules Stein Eye Institute, UCLA School of Medicine, Los Angeles, CA*

Primary cilia are specialized sensory signaling organelles with diverse functions, many of which have been implicated in human disease. Critical to these functions is the correct distribution of proteins to the ciliary membrane. Rhodopsin (RHO) is a GPCR that is targeted and restricted to the specialized cilium of retinal photoreceptors. The purpose of the current study is to compare

the kinetics of RHO movement along cilium with that of entry into the cilium. To do so, we have used live-cell imaging and fluorescence recovery after photobleaching (FRAP) on the cilium of human retinal pigmented epithelial cells (hTERT-RPE1) that have been transfected with RHO-EGFP. We have found that the recovery of RHO-EGFP, following photobleaching of the distal region of the cilium is dependent upon heterotrimeric kinesin- 2, supporting previous studies suggesting a role for this motor in the movement of RHO along the cilium. When different regions of the cilium were photobleached, we found that the recovery of RHO fluorescence in the cilium is faster (as measured by the  $t_{1/2}$  of the recovery) when the distal half of the cilium is photobleached versus when the entire cilium is photobleached. This observation is consistent with the hypothesis that the entry of RHO into the cilium is distinct from its movement along the cilium, and presents a rate-limiting step in the ciliary transport of RHO.

#### **The Architecture of the Ciliary Partitioning System.**

P. Ounjai<sup>1</sup>, K. Kim<sup>1</sup>, H. Liu<sup>2</sup>, M. Dong<sup>3</sup>, A. N. Tauscher<sup>1</sup>, A. Lo<sup>1</sup>, H. E. Witkowska<sup>2</sup>, K. H. Downing<sup>1</sup>; <sup>1</sup>Life Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA, <sup>2</sup>UCSF Sandler-Moore Mass Spectrometry Core Facility, UCSF, San Francisco, CA, <sup>3</sup>Genomics Division, Lawrence Berkeley National Laboratory, Berkeley, CA

A flurry of recent advances in cilia biology has revealed much evidence for a structure at the base of cilia and flagella that serves as a barrier to isolate both the membrane and the interior of the cilia from the rest of the cell and regulate traffic between these regions. However, structural information about the cilia pore complex and the membrane diffusion barrier in cilia has so far been limited. Recently, remarkable mechanistic homology between nuclear and ciliary transport has been recognized, including common targeting sequences and Ran-GTP-dependent, importin-mediated transport. Just as visualization of the nuclear pore complex (NPC) has set the stage for understanding architecture and function in nuclear transport, characterizing this ciliary structure would provide substantive insights on ciliary trafficking. In this study, we have identified and isolated a putative cilia pore complex from *Tetrahymena pyriformis*. As seen by electron microscopy using negative stain and cryo tomography, the complex, which we call the ciliary partitioning system, is tightly associated with the basal body and comprises three components: a disc-shaped ciliary pore complex (CPC), a ring complex and a detergent-resistant periciliary membrane. EM of plastic sections of intact and deciliated *Tetrahymena* cells reveals that the complex forms a barricade layer at the cilia opening, confirming its role in cilia development and homeostasis. MS analysis indicates strong involvement of the ring structure and detergent-resistant periciliary membrane domain in membrane trafficking, suggesting their roles as a diffusion barrier. The CPC contains 9 pores; each pore comprises a distinct region through which a microtubule doublet passes and a larger area associated with the doublet B-tubule which appears to be well suited for passage of the IFT complexes, suggesting role of the CPC as a cytosolic filter. The association of the CPC and the ring seals the ciliary opening. Our structure offers novel insights into the mechanism of ciliary trafficking.

#### **Proteins of the ciliary axoneme are found on cytoplasmic membrane vesicles during growth of *Chlamydomonas* flagella.**

C. R. Wood<sup>1</sup>, J. L. Rosenbaum<sup>1</sup>; <sup>1</sup>Molecular, Cellular and Developmental Biology, Yale University, New Haven, CT

The cilium is a specialized extension of the cell where many specific proteins are admitted and retained, while many others are excluded or expelled. In order to maintain the organelle, the cell

must possess mechanisms for the targeted delivery of proteins there, as well as for the selective gating of protein entry and exit. We hypothesize that the cell employs vesicular trafficking as a means not only to transport integral proteins destined for the ciliary membrane, but also as a vehicle for the transport of axonemal proteins to the cilium by virtue of peripheral associations with these vesicles. Thus, we think axonemal proteins, synthesized on free polysomes in the cytoplasm, "piggy-back" on vesicles already directed toward the pericentriolar region at the base of the cilium, where they are then moved up through the transition zone by intraflagellar transport (IFT). To test this hypothesis we are using the flagellated algal model system, *Chlamydomonas*, to isolate and analyze vesicles from the cytoplasm at the time of flagellar assembly. Using step-gradient procedures to fractionate cytoplasmic extracts, we have enriched for a specific class of membrane vesicles that carry integral flagellar membrane protein polycystin-2 (PKD2), as well as protein components of intraflagellar transport (IFT) and radial spokes (RSP); all showing increased levels when the vesicles are isolated during formation of flagella. Using immunogold labeling and electron microscopy, we have documented the localization of an axonemal protein, RSP1, on the outer surface of cytoplasmic vesicles in situ during regeneration of flagella. Flagellar membrane protein, PKD2, and IFT proteins were also observed to localize to cytoplasmic vesicles during flagellar regeneration. Complete biochemical and proteomic analyses of these membrane vesicle preparations will reveal key components of the mechanisms by which cells form and maintain cilia. Supported by NIH grant GM14642

**Ectosome-like vesicles released from the cilium/flagellum carry specific biologically-active proteins.**

K. Huang<sup>1,2</sup>, C. R. Wood<sup>1</sup>, D. R. Diener<sup>1</sup>, J. L. Rosenbaum<sup>1</sup>; <sup>1</sup>*Molec. Cell. Dev. Biol., Yale University, New Haven, CT*, <sup>2</sup>*Institute of Hydrobiology, Chinese Academy of Science, Wuhan, China*

It is now well established that primary and motile cilia/flagella can act as antennae, *receiving signals* from the environment, and that the activated signaling pathways are involved in normal cell functions and in ciliopathies. Here we report that ectosome-like vesicles pinch off from the flagella and have a unique protein composition, enriched in certain flagellar membrane proteins and small GTPases. To determine a function of flagella-derived vesicles, we corroborated and extended the original findings by Matsuda and colleagues (*Plant Cell Physiol.* 50:572, 2009), showing that *Chlamydomonas* cells require a serine protease (sporangin), *released from the flagella*, to digest the mother cell wall, allowing the daughter cells to be released. Sporangin is synthesized just prior to daughter cell release, transferred to the flagellum and, following daughter cell release, is down-regulated. We used negative staining with silver-enhanced immunogold labeling to show that this serine protease is carried by the vesicles released from the flagella, and we have isolated the active vesicles. Mutants that lack flagella are usually not released from the mother cell wall, but addition of isolated sporangin-carrying vesicles will permit their release. These results demonstrate that membrane vesicles originating from the flagellum have a specific and necessary bio-reactive function. Other membrane vesicles released from *Chlamydomonas gamete* flagella have been shown in the past to have an in vitro function in promoting flagella:flagella agglutination, which initiates the signaling pathways required for mating of plus and minus cells. *We hypothesize that all ciliated cells release ectosome-like vesicles from the ciliary membrane and that these vesicles are bio-active at other places.* Supported by NIH grant GM 14642-042 to JLR.

**The Exocyst subunit Exo70 and the Biogenesis of Lysosome-Related Organelles Complex-1 (BLOC-1) subunit Pallidin Interact with IFT20.**

W. J. Monis<sup>1</sup>, G. J. Pazour<sup>1</sup>; <sup>1</sup>Program in Molecular Medicine, University of Massachusetts Medical School, Worcester, MA

Cilia are conserved organelles present on most eukaryotic cells, excluding yeast and higher plants. Almost all human cells possess a single non-motile primary cilium, which is a sensory organelle that perceives the extracellular environment due to the concentration of signaling receptors in the ciliary membrane. The intraflagellar transport (IFT) system is required for assembling primary cilia and it is dependent on two protein complexes: IFT complex A and B. The IFT particles are composed of about twenty proteins and these proteins are highly conserved across ciliated species. The complex B subunit IFT20 is the only IFT protein known to localize at both the primary cilium and Golgi apparatus. Previously we showed that IFT20 interacts with the golgin GMAP210 and we suggested that these proteins are important for sorting and/or transport of ciliary membrane proteins, but the step(s) at which they function remains to be defined. It is likely that IFT20 interacts with other proteins but other binding partners have not been identified. Published large-scale yeast-two hybrid screens have identified new candidate IFT20-interacting proteins. Three proteins of interest include the exocyst subunit Exo70, the biogenesis of lysosome-related organelles complex-1 (BLOC-1) subunit Pallidin and a KxDL motif containing protein, KXD1. We find that both Exo70 and Pallidin co-immunoprecipitate with IFT20. Additionally, overexpression of Exo70 and Pallidin in IMCD cells displaces IFT20 from the Golgi apparatus. This evidence suggests that Exo70 and Pallidin interact with IFT20. Ongoing research is focused on determining the role of IFT20 and binding partners such as Exo70 and Pallidin in ciliary membrane protein trafficking.

308

**Exchange of IFT proteins between flagella and cytoplasm in *Chlamydomonas reinhardtii*.**

A. Ritter<sup>1</sup>, R. Hernandez Lopez<sup>1</sup>, J. Gunzenhaeuser<sup>1</sup>, H. Ishikawa<sup>1,2</sup>, W. F. Marshall<sup>1,2</sup>; <sup>1</sup>Physiology Course, Marine Biological Laboratory, Woods Hole, MA, <sup>2</sup>Biochemistry, UCSF, San Francisco, CA

Intraflagellar transport plays a key role in determining the length of flagella in *Chlamydomonas*. Extensive studies have shown that the quantity of IFT protein in the flagellum is roughly independent of the length of the flagellum, which leads to a simple model that can explain the regulation of flagellar length. However this model depends on the quantity of IFT protein per flagellum being constant, and the mechanisms that regulate IFT quantity in the flagellum are still unclear. One possible mechanism is the "initial bolus" model, in which a fixed quantity of IFT protein is injected into a flagellum when it is first assembled, and then that fixed set of proteins circulates back and forth inside the flagellum without ever leaving or any new protein being injected. This simple scheme would guarantee that the quantity of IFT protein is length independent. We tested the initial bolus model using FRAP (fluorescence recovery after photobleaching) on *Chlamydomonas* cells expressing GFP-tagged IFT proteins grown in microfluidic chambers. We find that IFT proteins exchange rapidly with a pool of reserve IFT protein at the basal body, but exchange with the rest of the cytoplasm was not observed on the time scale of our measurements. These data rule out the initial bolus model but suggest that IFT dynamics involve multiple pools that exchange at vastly different rates.

309

***Chlamydomonas* nephrocystin-4 functions at the transition zone to regulate ciliary trafficking of membrane proteins and large soluble proteins.**

J. Awata<sup>1</sup>, S. Takada<sup>1</sup>, K. F. Lechtreck<sup>2</sup>, E. Johnson<sup>1</sup>, B. L. Walker<sup>1</sup>, G. J. Pazour<sup>1</sup>, G. B. Witman<sup>1</sup>; <sup>1</sup>University of Massachusetts Medical School, Worcester, MA, <sup>2</sup>University of Georgia, Athens, GA

Mutations in human *NPHP4*, encoding the protein nephrocystin-4, cause nephronophthisis and retinitis pigmentosa. To learn more about the function of nephrocystin-4 and why defects in it cause ciliopathies, we are studying its homologue in *Chlamydomonas*. Immunofluorescence microscopy using antibodies against *Chlamydomonas* nephrocystin-4 indicated that it is located at the base of the flagellum. Immuno-gold electron microscopy in which *Chlamydomonas* cells expressing HA-tagged nephrocystin-4 were probed with anti-HA antibodies revealed that nephrocystin-4-HA is specifically localized to the distal transition zone, closely associated with the Y-shaped microtubule-membrane links seen in transition zone cross sections but more distal than the transition zone protein CEP290. It has been reported that the *Caenorhabditis elegans* homologue of nephrocystin-4 likewise is located in the transition zone; therefore, the location of nephrocystin-4 is conserved among species, suggesting that the function of nephrocystin-4 also is conserved. We have identified a *Chlamydomonas* insertional mutant (*nphp4*) in which the nephrocystin-4 gene is completely deleted. The mutant has normal length flagella, normal IFT, normal phototaxis, and normal basal body and axonemal ultrastructure. Some cells have ectopic transition zones and other transition zone abnormalities, but the Y-shaped links are still present. The mutant phenotype is rescued by transformation with constructs expressing wild-type or HA-tagged nephrocystin-4. CEP290 is present in the *nphp4* transition zone and nephrocystin-4 is present in the transition zone of a mutant lacking CEP290, consistent with a report that these two transition zone proteins are in different complexes. SDS-PAGE of flagellar fractions indicated that the protein compositions of wild-type and mutant axonemes are nearly identical, but that there are numerous differences between the wild-type and mutant membrane-plus-matrix fractions, especially among proteins >60 kDa. Mass spectrometry revealed that several membrane proteins are reduced in amount while the amounts of a few other membrane proteins and many housekeeping proteins are increased in the mutant flagella. This result suggests that *Chlamydomonas* nephrocystin-4 functions at the transition zone to control traffic of membrane and large soluble proteins between the flagella and cell body.

310

**TTC26/DYF13 undergoes intraflagellar transport and is required for cilia/flagella formation and transport of inner dynein components into flagella.**

H. Ishikawa<sup>1</sup>, T. Ide<sup>2</sup>, T. Yag<sup>2</sup>, X. Jiang<sup>3</sup>, H. Yanagisawa<sup>2</sup>, H. Sasaki<sup>4</sup>, D. Stainier<sup>1</sup>, H. Qin<sup>3</sup>, R. Kamiya<sup>2</sup>, W. Marshall<sup>1</sup>; <sup>1</sup>University of California, San Francisco, San Francisco, CA, <sup>2</sup>University of Tokyo, Tokyo, Japan, <sup>3</sup>Texas A&M University, College Station, TX, <sup>4</sup>Jikei University School of Medicine, Tokyo, Japan

Cilia and flagella are hair-like organelles that protrude from the surface of cells and are important for making driving forces and sensing extracellular signals. Ciliary defects have been implicated in a wide spectrum of diseases including retinal degeneration, polycystic kidney disease, left-right asymmetry defects and hydrocephalus. Cilia/flagella are assembled and maintained by the process of intraflagellar transport (IFT), a highly conserved mechanism in almost all eukaryotes. IFT is composed of at least 20 proteins and motor proteins. However, the functions of individual IFT proteins are mostly unclear. To help address this issue, we

focused on a putative IFT protein TTC26/DYF13, which is conserved in various ciliated organisms and is a homologue of *Caenorhabditis elegans* DYF-13 and *Trypanosoma brucei* PIFTC3. TTC26/DYF13 localizes to cilia/flagella in mammalian cultured cells and *Chlamydomonas reinhardtii*. GFP-labeled mouse TTC26 moved bi-directionally along the length of cilia in mammalian cells. TTC26/DYF13 was also biochemically confirmed as an IFT complex B protein in mammalian cells and *C. reinhardtii*. Knockdown of TTC26 in zebrafish embryos produces short cilia within the Kupffer's vesicle and pronephric ducts and produces typical cilia-related defects including pronephric cysts, hydrocephalus, and the randomization of left-right asymmetry. Moreover, we identified a *dyf13* mutant in *C. reinhardtii*, which has shorter flagella and motility defects. Surprisingly, IFT behavior seems normal in *dyf13* mutant flagella. However, we identified that specific inner dynein arm components were reduced in flagella of *dyf13* mutants. Thus, TTC26/DYF13 is an IFT complex protein, which is required for transporting specific cilia/flagella proteins into flagella.

311

### Functional Analysis of FAP12, a Gliding-Associated Flagellar Protein in *Chlamydomonas reinhardtii*.

E. Bettleja<sup>1</sup>, R. A. Bloodgood<sup>2</sup>, T. Birch<sup>1</sup>, C. Pollard<sup>1</sup>, K. F. Lechtreck<sup>3</sup>, D. G. Cole<sup>1</sup>; <sup>1</sup>Biological Sciences, University of Idaho, Moscow, ID, <sup>2</sup>Cell Biology, University of Virginia, Charlottesville, VA, <sup>3</sup>University of Georgia, Athens, GA

In the biflagellate green alga, *Chlamydomonas reinhardtii*, gliding motility is a flagella-dependent whole-cell motility that occurs upon flagellar surface adhesion to a substrate. This adhesive function is mediated by the major flagellar membrane glycoprotein, FMG-1B. Essential for the assembly and function of cilia is the bidirectional transport of protein particles known as intraflagellar transport (IFT). In a search for IFT-associated cargo, pull-down assays of *Chlamydomonas* flagellar extract with the retrograde IFT motor, cytoplasmic dynein 1b/2 heavy chain (DHC1b), yielded a set of proteins, among which the most prominent were the major flagellar surface glycoprotein, FMG-1B and a flagellar-associated putative lipase of unknown function, FAP12. Reverse pull downs with anti-FMG-1B specifically co-purified FAP12 and a small fraction of the DHC1b. To address the potential functional role of FAP12 in gliding motility, artificial micro RNA interference was used to reduce expression of the *FAP12* gene. Western blot analysis of RNAi transformants showed the FAP12 protein level was significantly reduced in multiple strains that were then assayed for gliding phenotype. Cells with the greatest depletion of FAP12 protein were strongly compromised in their ability to adopt the characteristic gliding configuration upon contact with a surface where the two flagella are straight and oriented 180° from one another. Once attached in this fashion, however, the gliding velocity was unaffected. Upon electroporation of purified recombinant His<sub>6</sub>-FAP12 protein into the FAP12-deficient cells, the frequency of cells adopting the 180° gliding configuration was doubled. These results indicate that FAP12 is involved with an early stage of gliding motility in the transition from the initial surface adherence by the flagella to the adoption of the characteristic 180° gliding configuration. In contrast, the loss of FAP12 did not affect the velocity of the gliding motor nor the average distance traveled by gliding cells. Such an early role suggests that FAP12 may participate in events leading to activation of the gliding signaling pathway.

312

**The role of septin in ciliogenesis.**

L. Dai<sup>1,2</sup>, M. Kim<sup>1,3</sup>, W. S. Trimble<sup>1,2,3</sup>; <sup>1</sup>Cell Biology, Hospital for Sick Children, Toronto, ON, Canada, <sup>2</sup>Physiology, University of Toronto, Toronto, ON, Canada, <sup>3</sup>Biochemistry, University of Toronto, Toronto, ON, Canada

Primary cilia are non-motile solitary protrusions found on the surface of nearly every cell in the human body. They are composed of a cylindrically organized microtubule axoneme that stems from a centriole-derived structure called the basal body. Primary cilia function as a multisensory antenna of the cell, capable of detecting environmental inputs and regulating key signaling pathways. Recently studies have suggested a connection between primary cilia formation and a family of protein called septins. There are a total of 13 human genes encoding septins, namely SEPT1-12,14. Septins form oligomeric complexes that can join end-on-end to form filaments. Work in our lab has shown that SEPT9 binds and activates a guanine nucleotide exchange factor for Rho, SARhoGEF, to promote Rho activation. Interestingly, SARhoGEF is localized to the basal body, raising the possibility that Rho activation may be important in ciliogenesis.

We therefore examined septin distribution in RPE cells by immunofluorescence microscopy and determined the localization of SEPT2, SEPT7, SEPT9 at the primary cilium. All three septins were found at the base, as well as in the axoneme of the cilium; in contrast, SARhoGEF was concentrated at the base, but excluded from the axoneme. To investigate whether SEPT9 is required for cilium formation, we used a lentivirus to stably deplete ~70% of SEPT9 expression in RPE cells. Consequently, the average length of cilia decreased from 2.49µm to 1.74µm. We confirmed the result using transient transfection with small interfering RNA. SEPT9 expressed was reduced by ~85% upon transfection, and the average length of cilia decreased to 1.48µm. Similar inhibition was obtained by depletion of the SARhoGEF or inhibition of Rho.

Since SARhoGEF was restricted to the basal body, while septins were also found along the axoneme, we investigated whether Rho activation at the base of the cilium could rescue the ciliary length defect caused by SEPT9 knockdown. To do so we transfected SEPT9-depleted cells with a fusion construct between centrin, a basal body localized protein, and constitutively active SARhoGEF. This construct exclusively localized to the base of the cilia where it can activate Rho locally. The fusion protein was able to rescue the phenotype resulting from SEPT9 depletion and significantly increased ciliary length to 2.77µm. This indicates that the major function of SEPT9 in ciliogenesis is to activate SARhoGEF and Rho at the basal body.

**Superresolution STED Microscopy Reveals Differential Localization in Primary Cilia.**

T. T. Yang<sup>1</sup>, P. J. Hampilos<sup>1</sup>, B. Nathwani<sup>1</sup>, C. H. Miller<sup>1</sup>, N. D. Sutaria<sup>1</sup>, J-C. Liao<sup>1</sup>; <sup>1</sup>Columbia University, New York, NY

The primary cilium is an organelle that serves as a signaling center of the cell and is involved in the cAMP, Wnt and hedgehog signaling pathways. Adenylyl cyclase type III (ACIII) is a primary cilia marker that is involved in cAMP signaling, while also playing an important role in regulating ciliogenesis and sensory functions. Ciliary function relies on the transportation of molecules between the primary cilium and the cell, which is facilitated by intraflagellar transport (IFT). The detailed localization and interactions of these important proteins remain unclear due to the limited resolution of conventional microscopy. We conducted superresolution imaging of immunostained ACIII and IFT88 in human fibroblasts using stimulated emission depletion (STED) microscopy. Instead of a homogeneous distribution along a primary cilium, our STED

images revealed that ACIII formed a periodic punctate pattern with a roughly equal spacing between groups of puncta. These puncta occupied less than 50% of the area, with an average width of  $153 \pm 27$  nm. Superresolution imaging of IFT88, one important protein of the IFT complexes, demonstrated two novel distinct distribution patterns at the basal end not resolvable by confocal microscopy: a triangle of three puncta with similar fluorescence intensities, and a Y-shaped configuration of a bright punctum connected to two branches. Our results demonstrate the ability of superresolution STED microscopy to reveal novel structural characteristics in primary cilia. This project was supported by NSF CHE-0641523 and CMMI-1125760.

**The kinases MRK and MOK regulate cilia length and intraflagellar transport in renal epithelial cells.**

*J. Broekhuis<sup>1</sup>, G. Jansen<sup>1</sup>; <sup>1</sup>Cell Biology, Erasmus MC, Rotterdam, Netherlands*

Primary cilia are small cellular extensions used to sense cues from the environment. A wide variety exists in cilia length and morphology, probably reflecting their specific functions in different tissues. Cilia length and morphology are regulated by several signalling pathways. Cilia are build and maintained by a specialized transport mechanism, known as intraflagellar transport (IFT). During IFT, motor proteins transport multimeric protein complexes along the microtubule axoneme, delivering proteins to the distal tip or returning them to the cell body. We identified *C. elegans*' DYF-5, a conserved kinase that regulates cilia length and IFT.

Here we analyze the functions of MRK and MOK, mammalian homologues of DYF-5 and members of the ros cross-hybridizing kinase family (RCK). MRK and MOK GFP fusions localized to the cilia of IMCD3 cells. Knockdown of MRK or MOK resulted in longer cilia, while overexpression of MRK resulted in short cilia. These results indicate that also MRK and MOK regulate cilia length.

To visualize IFT we have generated IMCD3 clones that stably express fluorescently tagged components of the IFT machinery: Kinesin-II (KIF3B), Kif17, complex A (IFT43) and B (IFT20), and the BBSome (BBS8). We found that these proteins all moved at  $\sim 0.45$   $\mu\text{m/s}$  in anterograde and retrograde direction. Knockdown of MRK increased anterograde IFT velocity of all constructs to  $\sim 0.6$   $\mu\text{m/s}$  but did not affect retrograde IFT, correlating with delivery of more axonemal precursors at the distal tip, and cilium lengthening.

Previous studies have shown that the mTOR pathway modulates cilia length, and that MRK phosphorylates Raptor, a subunit of mTORC1. We found that the mTOR inhibitor rapamycin can block all effects of MRK and MOK depletion on cilia length and IFT, indicating that MRK and MOK interact with the mTOR pathway.

In summary, we show that MRK and MOK play important roles in regulating cilia length, IFT, and possibly cilia function.

**Analysis of photoreceptor outer segment development in a mutant KIF17 zebrafish model.**

*J. R. Bader<sup>1</sup>, B. W. Kusik<sup>1</sup>, J. C. Besharse<sup>1</sup>; <sup>1</sup>Cell Biology, Neurobiology, and Anatomy, Medical College of Wisconsin, Milwaukee, WI*

The outer segment (OS) of the vertebrate photoreceptor is a sensory cilium, which serves as a phototransduction organelle. Similar to other sensory cilia, photoreceptor OS's lack a protein synthesis machinery, and their assembly and maintenance depends on intraflagellar transport (IFT). Recent studies have suggested a role for two kinesin-2 family motors, heterotrimeric kinesin-II and the homodimeric KIF17, in vertebrate OS development. However, data on the role of KIF17 in vertebrate photoreceptor OS assembly is currently limited to antisense

knockdown or dominant negative overexpression strategies. To further elucidate KIF17's role in OS formation, we have utilized a line of zebrafish carrying an ENU generated mutation (*kif17<sup>sa0119</sup>*) causing a UGA stop codon in exon 10 that is predicted to ablate KIF17 function. We show that animals homozygous for the mutation are viable and do not show any morphological defects; even in photoreceptors. However, analysis of protein levels revealed that KIF17 expression is reduced by only about 50% in the mutant animals indicating that the mutation is not a null allele. This hypomorphic mutation has provided an ideal background for analysis using a morpholino knockdown strategy. Mutant animals treated with very low concentrations of several KIF17 specific morpholinos exhibit complete knockdown of KIF17 protein levels and severe ablation of OS formation at 3 dpf, which is consistent with previous findings from our laboratory using wild type animals. This appears specific for photoreceptors as cilia defects were not observed in other tissues. These findings show that the first available zebrafish mutation for KIF17 is a hypomorph that, nonetheless, is a valuable model when combined with additional tools that further reduce protein level. Our results strengthen the idea that KIF17 plays an important role in vertebrate OS assembly, and also emphasizes the need to carefully evaluate hypothetical loss of function ENU mutations at the level of protein expression.

316

**The role of the D1bLIC in retrograde IFT, flagellar assembly, and motility.**

J. Reck<sup>1</sup>, A. Schauer<sup>1</sup>, K. VanderWaal<sup>2</sup>, D. Tritschler<sup>2</sup>, C. Perrone<sup>1</sup>, M. E. Porter<sup>1</sup>; <sup>1</sup>Genetics, Cell Biology, Development, University of Minnesota, Minneapolis, MN, <sup>2</sup>Genetics, Cell Biology & Development, University of Minnesota, Minneapolis, MN

Eucaryotic cilia and flagella play critical roles in sensory signaling and cell motility in a variety of organisms. Assembly of these organelles depends on a bidirectional, intraflagellar transport (IFT) system. Anterograde IFT is driven by Kinesin-2, and retrograde IFT is driven by a cytoplasmic dynein known as DYNC2H1 in humans and DHC1b in *Chlamydomonas*. Mutations in either motor lead to defects in ciliary assembly and signaling and are associated with human genetic diseases known as ciliopathies (reviewed in Ishikawa and Marshall, 2011). Each motor is associated with intermediate and/or light chain subunits that contribute to cargo binding and motor regulation. We previously identified a light intermediate chain subunit (D1bLIC) as a component of the retrograde IFT motor (Perrone et al., 2003). *d1blic* mutations are associated with flagellar assembly defects and the accumulation of IFT particles (Hou et al., 2004), but the phenotype is not as severe as that observed with *dhc1b* or *dll1(LC8)* mutations (Pazour et al., 1998, 1999; Porter et al., 1999). To better understand D1bLIC function, we analyzed IFT in a *d1blic* null mutant, a GFP-tagged rescued strain, and several strains in which D1bLIC expression was reduced by RNA interference. Knockdown to ~20% of wild-type levels reduced both the frequency and velocity of retrograde IFT with minimal effects on anterograde IFT or flagellar length. Knockdown below 10% (RNAi-A) resulted in more severe defects in retrograde IFT and flagellar length, similar to the *d1blic* null. iTRAQ analysis indicated that several membrane plus matrix polypeptides were elevated. Transformation of the *d1blic* mutant with *D1bLIC-GFP* rescued the assembly defects and increased the velocity and frequency of retrograde IFT. Thus D1bLIC stabilizes the retrograde motor and increases the velocity and frequency of IFT, but it is not absolutely essential for cDHC1b function. Transformation of other strains further demonstrated that D1bLIC-GFP is expressed at levels comparable to the endogenous subunit and co-purifies with it and other subunits of the retrograde motor during dynein extraction, sucrose density gradient centrifugation and immunoprecipitation. The D1bLIC-GFP construct will be a useful reagent for the characterization of mutations in several genes that affect retrograde IFT, flagellar assembly, and ciliary signaling. (supported by the NIH).

**Regulation of intraflagellar transport in *Caenorhabditis elegans* cilia by ubiquitination.**A. van der Vaart<sup>1</sup>, S. Rademakers<sup>1</sup>, G. Jansen<sup>1</sup>; <sup>1</sup>Department of Cell Biology, Erasmus MC, Rotterdam, Netherlands

Cilia are cellular extensions that can discern several environmental cues. Many of these cues are detected by G-protein-coupled receptors and relayed by heterotrimeric G-proteins to produce a cellular response. We recently found that a dominant active mutation in the G $\alpha$ -subunit *gpa-3* (*gpa-3QL*) affects cilia development and function. This is likely caused by changes in intraflagellar transport (IFT), the protein transport machinery in cilia. In wild type *C. elegans* anterograde transport is mediated by two kinesin motor complexes; kinesin-II and OSM-3 (mammalian KIF17). Together they transport particles in the middle segment of cilia, while only OSM-3 enters the distal segment where it moves at a higher speed. In *gpa-3QL* mutants the two motors move at different speeds and thus seem uncoordinated. We are setting up dual-colour live imaging of fluorescently-tagged IFT proteins to determine the IFT particle composition in *gpa-3QL* mutants. Using transgenic animals that express fluorescently-tagged IFT proteins specifically in ASI neurons, we found that the dynamics of the IFT proteins are affected by their expression levels. This indicates that the stoichiometry of the IFT proteins is important for their coordination. We are currently determining the optimal conditions for dual-colour live imaging.

In addition, we have performed a genetic screen for mutants that suppress the *gpa-3QL* induced ciliary defects. We have identified the E2 ubiquitin-conjugating enzyme variant UEV-3 as a suppressor of *gpa-3QL*. UEV-3 belongs to the highly conserved UBC family of proteins, however it lacks the cysteine necessary to conjugate ubiquitin. Although the UEV proteins lack catalytic activity, it has been suggested that these proteins play a role in the ubiquitination pathway. *gpa-3QL* animals that lack *uev-3* show wild type cilium length, while *gpa-3QL* animals have short cilia. Mutation of *uev-3* on its own does not affect cilium length. Furthermore, IFT measurements in the suppressor strain shows that OSM-3 and kinesin-II move at different speeds compared to both wild type animals and *gpa-3QL* mutants. Future experiments are directed to determine the precise role of UEV-3 in cilia formation and the regulation of IFT.

**The *Chlamydomonas* NIMA-related kinase CNK2 regulates flagellar resorption.**L. K. Hilton<sup>1</sup>, K. Gunawardane<sup>1</sup>, J. Kim<sup>1</sup>, L. M. Quarmby<sup>1</sup>; <sup>1</sup>Department of Molecular Biology and Biochemistry, Simon Fraser University, Burnaby, BC, Canada

Cilia and flagella are resorbed prior to cell division and in response to certain environmental stimuli. *Chlamydomonas* flagella also resorb when cells are transferred from liquid culture to agar media. We have uncovered a relationship between resorption in response to environmental stimuli and the regulation of flagellar length. Both RNAi knockdown of CNK2 (Bradley and Quarmby, 2005) and a null mutation in the *CNK2* gene cause an increase in flagellar length. This *cnk2-1* mutant also fails to resorb its flagella in response to growth on solid media, or exposure to sodium pyrophosphate (NaPPi) or IBMX. In contrast, other *Chlamydomonas* mutants with long flagella (*If3* and *If4*) resorb their flagella more quickly than wild-type in response to these same stimuli, suggesting that *If* mutant length defects arise from dysregulated flagellar assembly. Double mutants between *cnk2-1* and *If3* or *If4* have flagella that are considerably longer than any of the single mutants, which indicates that the disassembly pathway limits flagellar length in *If* mutants. We are currently studying the CNK2 pathway in order to understand the signals that stimulate resorption and their role in flagellar length control.

**Protein Methylation During Flagellar Resorption in *Chlamydomonas*.**R. Werner-Peterson<sup>1</sup>, R. D. Sloboda<sup>1</sup>; <sup>1</sup>Biological Sciences, Dartmouth College, Hanover, NH

We are studying protein methylation during flagellar resorption in *Chlamydomonas*. Previously (Mol. Biol. Cell 19:4319) we showed that resorbing flagella contain increased levels of the enzyme Met E, plus several polypeptides containing asymmetrically methylated arginine residues. Met E produces methionine, and methionine is then converted to S-adenosyl methionine (SAM), which serves as the methyl donor in protein methylation reactions. Met E in resorbing flagella is phosphorylated, and in full-length flagella it is dephosphorylated. When cells are induced to resorb their flagella by treatment with 3-isobutyl-1-methylxanthine (IBMX) and the axonemal proteins are resolved on 2-D gels and immunoblotted, seven polypeptides can be identified containing asymmetrically methylated arginine residues. Polypeptides with this modification are not detected in samples from full-length flagella. Tandem mass spectrometry has been used to identify these seven polypeptides and the position(s) of their methylated residues in the primary sequences: four of these polypeptides are radial spoke proteins 1, 2, 5, & 6, a fifth is tektin, a structural component of the outer doublets, and the remaining two are as yet uncharacterized flagellar associated proteins. The enzyme PRMT 1 (protein arginine methyl transferase 1) is a type I PRMT; this class of enzymes produces asymmetric dimethyl arginine by transferring two methyl groups to one of the two terminal nitrogens of the guanidino moiety of the R-group. A peptide antibody specific for *Chlamydomonas* PRMT 1 labels full-length flagella in a punctate pattern along the length of the axoneme. When cells are induced to resorb their flagella by treatment with IBMX, PRMT 1 localization changes. In the presence of IBMX, PRMT 1 localizes to the flagellar tip complex (FTC), the site of net disassembly of the flagellar axoneme during resorption. These results, when considered in combination with relevant data from the literature, are consistent with a model in which resorbing conditions induce the activity of CALK, an Aurora-like kinase. CALK phosphorylates Met E stimulating production of methionine and subsequent conversion to SAM. PRMT 1 then uses SAM as the donor to methylate asymmetrically these seven axonemal polypeptides in the region of the FTC. These specific methylations induce axonemal disassembly directly and/or enhance the interaction of the disassembled polypeptides with intraflagellar transport particles to move these axonemal components in the retrograde direction to the cell body for degradation and/or recycling. We are currently using cloned enzymes to recapitulate the methylation pathway *in vitro* to study further the effect of protein methylation on the stability of the axoneme. Supported by NSF MCB 0950402 to rds.

**A CDK-like protein kinase is involved in flagellar shortening in *Chlamydomonas*.**Z. Hu<sup>1</sup>, J. Pan<sup>1</sup>; <sup>1</sup>School of Life Sciences, Tsinghua University, Beijing, China

Primary cilia assemble in interphase, and disassemble prior to mitosis. The disassembly of primary cilia is implicated in controlling cell cycle progression from in G1 to S transition. Protein phosphorylation plays a critical role in ciliary disassembly. By using *Chlamydomonas* as a model system, we are studying the mechanism of ciliary disassembly. Here, we report that a CDK-like protein kinase is involved in flagellar disassembly. By using insertional mutagenesis, we have generated a mutant fs1 (3-1) that was defective in flagellar shortening. Upon induction of flagellar shortening by NaPPI or IBMX, fs1 exhibited slower kinetics compared to wild type cells. Prior to mitosis, wild type cells shortened their flagella rapidly within 1 hr, whereas flagellar shortening in fs1 (3-1) took 1 to 2 hrs. Biochemical study showed that CALK phosphorylation, which occurs immediately upon induction of flagellar shortening, was delayed. Molecular cloning identified the mutated gene encoding a CDK-like protein kinase, named CrCDKL1C.

Transformation of HA-tagged CrCDKL1C gene complemented the mutant phenotype, confirming the identity of the mutated gene. CrCDKL1C is localized in the flagella as well as in the cell body. Upon induction of flagellar shortening, CrCDKL1C became phosphorylated. Defective CALK phosphorylation in *fs1* (3-1) mutant upon induction of flagellar shortening indicates that CrCDKL1C acts upstream of CALK activation. Taken together, CrCDKL1C is a new player of the protein phosphorylation pathway in regulation of flagellar disassembly. This work is partly supported by the National Natural Science Foundation of China (Grants 30988004, 30830057) and Tsinghua university (2010THZ0).

**Rootletin is required for intraflagellar transport and ciliary maintenance.**

S. Mohan<sup>1</sup>, T. A. Timbers<sup>1</sup>, M. R. Leroux<sup>1</sup>; <sup>1</sup>Molecular Biology and Biochemistry, Simon Fraser University, Burnaby, BC, Canada

Primary cilia are microtubule based sensory organelles anchored by a basal body that is closely associated with rootletin, a protein often found as striated rootlets. Rootletin is known to function in centriole cohesion, and its disruption causes ciliary photoreceptor degeneration. However, it remains unresolved whether rootletin is universally required for ciliary maintenance, and if so, by what mechanism. Here we identify *C. elegans* chemosensory gene, *che-10*, as a rootletin homolog. CHE-10/rootletin localizes proximally and distally to basal bodies of cilia and maintains the structural and/or functional integrity of the cilium. In *C.elegans*, cilia extend from the dendritic tip of 60 sensory neurons, 3 of which possess conspicuous striated rootlets. In cilia that lack conspicuous rootlets, we demonstrate that CHE-10 is required for the assembly and sustained function of intraflagellar transport (IFT) particles, a process known to be critical for ciliary maintenance. In the absence of CHE-10, ciliogenesis occurs but cilia degenerate over time. In these cilia, CHE-10 is also required for the stability of the ciliary transition zone, basal body and the periciliary membrane compartment. In cilia that possess striated rootlets, we show that CHE-10 is required for its functional maintenance. Although the cilia remain structurally intact, in the absence of CHE-10/rootletin, their ability to function is altered (observed as a prolonged response to stimuli). Our findings provide mechanistic insights into how rootletin, either as rootlets or non-filamentous forms, supports the continued function of cilia by modulating IFT.

**Actin polymerization and turnover are required for normal flagellar assembly in *Chlamydomonas*.**

P. Avasthi<sup>1</sup>, W. Sparagon<sup>2</sup>, W. Marshall<sup>1</sup>; <sup>1</sup>University of California San Francisco, San Francisco, CA, <sup>2</sup>Whitman College, Walla Walla, WA

*Chlamydomonas* actin has 90% identity with mammalian skeletal muscle actin. It is known to be required for inner dynein arm assembly in flagella and the formation of fertilization tubules in mt+ gametes. In vegetative cells during G1, total actin labeling is seen in perinuclear regions. Localization shifts to the anterior of the cell below flagella early in mitosis and is at the cleavage furrow during cytokinesis. It was previously thought that vegetative *Chlamydomonas* cells contain very little F-actin due to inability of fluorescent phalloidin to label this population but successfully label gametic fertilization tubules. However, here we show functional consequences of filament disruption. Acute disruption of actin polymerization using a variety of small molecule inhibitors at non-toxic concentrations results in flagellar shortening. In a null mutant of actin and when disrupting actin filament formation, flagellar elongation and regeneration are impaired. Stabilization of actin filaments also resulted in impaired flagellar

assembly. These data suggest that normal actin polymerization dynamics are required for flagellar length maintenance through regulation of flagellar assembly.

323

### Primary Cilia Respond to Uniaxial Strain by Reorienting and Elongating Along the Axis of Stretch.

L. Seldin<sup>1</sup>, E. Wu<sup>1</sup>, H. Ishikawa<sup>1,2</sup>, W. F. Marshall<sup>1,2</sup>; <sup>1</sup>Physiology Course, Marine Biological Laboratory, Woods Hole, MA, <sup>2</sup>Biochemistry, UCSF, San Francisco, CA

Primary cilia, the cellular 'antennae' found in nearly every cell type, are critical chemosensory organelles that transduce external signals into the cell interior. These signaling centers are essential for maintaining normal cellular activity and tissue integrity, as genetic mutations affecting ciliary function can cause debilitating diseases such as polycystic kidney disease and Bardet-Biedl syndrome. Primary cilia are key sensors of extracellular chemical cues, exemplified by their established role in sonic hedgehog signaling, however their role in mechanosensation remains elusive. In this study, we seek to determine whether primary cilia are involved in mechanosensation by testing their response to mechanical strain across an epithelial cell sheet. Epithelial cells are thought to coordinate and dissipate responses to mechanical stresses through robust intercellular junctions that are critical for maintaining sheet integrity. Using a PDMS stretching device, we test the effect of uniaxial strain on cilia behavior in a confluent sheet of retinal pigment epithelial cells. We find that primary cilia rotate and elongate along the axis of stretch. In addition, we find that this behavior is dependent on actin network integrity and myosin activity. This interesting result suggests a potential mechanism of primary cilia in regulating and coordinating epithelial cell behavior, namely through sensing and transducing mechanical signals. Our novel observations propose a potential link between primary cilia behavior, cellular mechanosensation and actomyosin contractility.

324

### Smad2/3 activity is induced by fluid shear stress in proximal tubular epithelial cells, which is more prominent in *Pkd1*<sup>-/-</sup> cells.

S. J. Kunnen<sup>1</sup>, W. N. Leonhard<sup>1</sup>, A. de Bray<sup>1</sup>, M. H. Breuning<sup>1</sup>, P. ten Dijke<sup>2</sup>, B. P. Hierck<sup>3</sup>, D. J. Peters<sup>1</sup>; <sup>1</sup>Human Genetics, Leiden University Medical Center, Leiden, Netherlands, <sup>2</sup>Molecular Cell Biology, Leiden University Medical Center, Leiden, Netherlands, <sup>3</sup>Anatomy and Embryology, Leiden University Medical Center, Leiden, Netherlands

Autosomal dominant polycystic kidney disease (ADPKD) is characterized by formation of many fluid-filled cysts, leading to loss of renal function in adulthood. ADPKD is caused by mutations in the *PKD1* or *PKD2* genes, encoding polycystin-1 (PC-1) and polycystin-2 (PC-2), respectively. PC-1 and PC-2 co-localize at cell-cell interactions and the primary cilium of renal epithelial cells, where PC-2 functions as Ca<sup>2+</sup> channel in a complex with PC-1. Lack of this complex in cilia is one of the mechanisms of cyst formation. Moreover, mutations or deletions of other ciliary proteins can also cause polycystic kidneys in mouse models and patients, indicating the role of cilia during cystogenesis. Primary cilia are essential in organizing various signaling systems that sense environmental cues, triggered by fluid flow and growth factor stimulation, and transmit signals to the cell interior.

To study flow dependent signaling in ADPKD, we make use of an *in vitro* conal flow system in which mouse *Pkd1* wild-type and knockout proximal tubular epithelial cells (PTEC) are exposed to laminar shear stress. Smad2/3 activation of the TGF- $\beta$  signaling pathway was analyzed using the CAGA luciferase-reporter assay, using qRT-PCR and RT-MLPA to measure expression of down-stream targets, and immunofluorescence microscopy to study nuclear localization of pSmad2.

PTEC exposed to shear stress showed increased Smad2/3 activation and nuclear localization of pSmad2. In addition, expression of the Smad2/3 targets *Pai1* and *Fibronectin* was dramatically increased. An inhibitor of the upstream receptors Alk4/5 completely blocked Smad2/3 activity, indicating that increased autocrine TGF- $\beta$  or activin signaling is involved. Strikingly, this response is more pronounced in *Pkd1* knockout PTEC compared to wild-type cells.

Our data suggest that *Pkd1* knockout cells are more responsive to fluid shear stress than wild-type cells with respect to TGF- $\beta$  signaling activation. We hypothesize that *Pkd1* disruption sensitizes cells to increased Smad2/3 dependent signaling, leading to processes that are involved in cyst formation, like dedifferentiation, proliferation, and fibrosis.

## Cytokinesis I

325

### Role of Cytokinetic Ring in Coordinating Septum Formation.

Z. Zhou<sup>1,2</sup>, F. Chang<sup>1</sup>; <sup>1</sup>Department of Microbiology and Immunology, Columbia University Medical Center, New York, NY, <sup>2</sup>Integrated Program of Cellular Molecular and Biomedical Studies, Columbia University Medical Center, New York, NY

Cytokinesis in fungal cells requires both a contractile actin-based ring and the assembly of a cell wall septum. In *S. pombe*, ingression of the plasma membrane at the cleavage furrow is accompanied by polymerization of the cell wall fibers on the extracellular side of the membrane, and pulling from contractile ring on the cytoplasmic side. Previous work in the lab suggests that a large force is needed from the division apparatus to counter large internal turgor pressure, and that most of this force is from pushing by the growth of the cell wall, not from pulling forces of the contractile ring (Proctor et al, Curr Biol 2012). Ingression of the septum continues even after removal of the ring by Latrunculin A treatment. However, the rate of septum ingression is decreased when the ring is absent or defective. Here, we examine the function of the contractile ring in coordinating septum assembly. We find that the ring keeps the ingressing membrane in a circular shape. In the absence of F-actin or in various ring mutants, the septum ingresses, but in a disorganized and asymmetric manner, so that the furrow is non-circular. If we physically manipulate the cell to distort the division site to an oval, the septum grows asymmetrically to reform a circular shape. We propose that the glucan synthases responsible for septum assembly at the plasma membrane may be mechanically sensitive to forces exerted by the ring. In this manner, the ring globally coordinates cell wall assembly to keep the closing furrow in circular shape.

326

### Phosphorylation of Iqg1 by Cyclin Dependent Kinase (CDK), Cdc28, Temporally Regulates Actin Ring Formation.

D. P. Miller<sup>1</sup>, K. B. Shannon<sup>1</sup>; <sup>1</sup>Biological Sciences, Missouri S&T, Rolla, MO

Cytokinesis is the final step in cell division when the cell separates the cytoplasm by contracting a ring composed of filamentous actin (F-actin) and type II myosin. Iqg1, an IQGAP family member, is an essential scaffolding protein in budding yeast (*S. cerevisiae*) required for actin recruitment to, and contraction of, the actomyosin ring. Actin is recruited by the calponin homology domain (CHD) late in anaphase after Iqg1 is localized to the bud neck. Four perfect consensus sites for the cyclin-dependent kinase (CDK) Cdc28 were identified flanking the CHD, which lead to the model that Cdc28 phosphorylation of Iqg1 negatively regulates F-actin binding to prevent actin ring formation before anaphase. To test this model the four consensus sites

were mutated into a non-phosphorylatable form (4A) and a phosphomimetic form (4E). Morphological analysis of mutant cells showed that preventing phosphorylation resulted in 40% chained cells, while mimicking phosphorylation caused 60% chained cell phenotype, indicating that phosphorylation of Iqg1 by CDK is important for cytokinesis. Immunofluorescence data on synchronized cells indicates that actin ring formation occurs 20 minutes early in cells that express Iqg1-4A. We are currently analyzing the timing of ring formation in Iqg1-4E mutant cells, and we plan to determine if the mutants have altered binding to F-actin. Our data so far supports the hypothesis that phosphorylation of Iqg1 by CDK inhibits actin ring formation.

327

**Genetically separable roles of IQGAP Rng2p in the formation and constriction of the cytokinetic contractile ring in *S. pombe*.**

I. R. Tebbs<sup>1,2</sup>, T. D. Pollard<sup>1,2,3</sup>; <sup>1</sup>Department of Molecular Biophysics and Biochemistry, Yale University, New Haven, CT, <sup>2</sup>Department of Molecular, Cellular and Developmental Biology, Yale University, New Haven, CT, <sup>3</sup>Department of Cell Biology, Yale University, New Haven, CT

Cytokinesis by the fission yeast *Schizosaccharomyces pombe* requires formation and constriction of a contractile ring of actin and myosin. Contractile rings normally form by condensation of precursor protein assemblies, called nodes, but contractile rings form from strands of actin filaments and myosin-II if the node based mechanism is compromised. We report a systematic analysis to determine why fission yeast IQGAP Rng2p is required for cytokinesis. Rng2p is required for ring formation by both the primary, node-based mechanism or the alternative strand-based mechanism. Rng2p is also required for efficient ring constriction. Complementation experiments with deletion constructs lacking each of the four predicted domains of Rng2p revealed how each domain contributes to cytokinesis. The N-terminal actin binding calponin homology domain is not required for viability, ring formation or ring constriction. The IQ motifs are required for normal ring constriction, and the GAP related domain is required for node based ring formation. The C-terminal domain of Rng2p is the only domain essential for viability.

328

**Assembly and Architecture of Interphase Contractile Ring Precursor Nodes in *S. pombe*.**

M. Akamatsu<sup>1</sup>, T. Pollard<sup>1,2,3</sup>; <sup>1</sup>Molecular Biophysics and Biochemistry, Yale University, New Haven, CT, <sup>2</sup>Cell Biology, Yale University, New Haven, CT, <sup>3</sup>Molecular, Cellular, and Developmental Biology, Yale University, New Haven, CT

During cytokinesis, cells form a contractile ring of actin and myosin to split the cell in two. In the fission yeast *S. pombe*, the contractile ring forms from an equatorial band of ~75 discrete protein structures called nodes. Understanding how these nodes assemble is necessary to understand the mechanism of contractile ring assembly and constriction. We used quantitative confocal microscopy to measure the times of appearance and numbers of seven node proteins long before mitosis, during interphase. We identified two distinct classes of nodes. One class of nodes tracks with the nucleus as it divides, appearing as new bands of nodes around daughter nuclei least 5 min before the daughter cells separate. The second class of nodes appears during the disassembly of the contractile ring at the old cell's equator, corresponding to the new tip of each daughter cell. These nodes then disperse through the cell cortex until they join the first class of nodes at the equators of the daughter cells, within 50 min after the cells separate. Quantitative fluorescence measurements indicate that proteins from each class of nodes exist in stoichiometric ratios. Based on time-lapse microscopy, particle tracking, and simulations of a mathematical model, we propose a mechanism by which the two classes of

nodes rejoin after cell birth. These measurements account for the location and movement of contractile ring precursor nodes throughout the course of the cell cycle.

329

**Cytokinesis in fission yeast: the pulling force behind ring assembly.**

C. Laplante<sup>1</sup>, T. D. Pollard<sup>1,2,3</sup>; <sup>1</sup>Molecular, Cellular and Developmental Biology, Yale University, New Haven, CT, <sup>2</sup>Molecular Biophysics and Biochemistry, Yale University, New Haven, CT, <sup>3</sup>Cell Biology, Yale University, New Haven, CT

The physical separation of a cell during cytokinesis requires spatial and temporal regulation of specialized cytoskeletal machinery to form and constrict a contractile ring. The cytokinetic ring of the fission yeast *Schizosaccharomyces pombe* assembles by coalescence of ~65 protein assemblies named precursor nodes distributed in a broad, cortical band around the equator of the cells. Different actin regulating proteins localize to nodes including myosin II and formin Cdc12p. The search-capture-pull-release hypothesis proposed that myosin II in one node captures and pulls on actin filaments polymerized by Cdc12p from a neighboring node, thus bringing the nodes closer together. This model assumed that myosin II is the sole source of force necessary to coalesce the nodes into a ring. Numerical simulations of this model reproduce the temporal and spatial features of contractile ring formation.

To test directly the force generating potential of myosin II during node coalescence, we analyzed ring formation in cells with different alleles of the myosin II heavy chain *myo2* (*myo2-E1*, *myo2-S1*, *myo2-S2* and *myo2-ΔIQ1*) and expressing a fluorescently-tagged node marker. As predicted by the search-capture-pull-release mechanism, cells with defective Myo2p took longer for nodes to coalesce than wild-type cells. However, a detailed analysis of node movements showed that their velocities were similar in *myo2* mutants and wild-type cells, indicating that the total force exerted on motile nodes was the same. Unconventional myosin II Myp2p is dispensable for cytokinesis under most conditions, but deletion of *myp2+* exacerbated the slow formation of contractile rings in *myo2* mutant cells, suggesting that Myp2p compensates for Myo2p during node coalescence when Myo2p function is compromised. Consistent with this hypothesis, Myp2p localized to nodes in cells with *myo2* mutations rather than concentrating only in fully formed rings and not in nodes.

330

**F-BAR protein Cdc15p is required for equatorial retention of the cytokinetic contractile ring in fission yeast.**

R. Arasada<sup>1</sup>, T. D. Pollard<sup>1,2</sup>; <sup>1</sup>Department of Molecular Cellular and Developmental Biology, Yale University, New Haven, CT, <sup>2</sup>Department of Molecular Biophysics and Biochemistry, Yale University, New Haven, CT

Cytokinesis is the final stage of cell division that involves partitioning of the mother cell into two equal daughter cells. The machinery required for cytokinesis is conserved in from fungi to humans. The fission *Schizosaccharomyces pombe* is an excellent model system to investigate the mechanism of cytokinesis. Cytokinesis in *S. pombe* begins by recruiting proteins that determine the position of the contractile ring followed by those that are required for the ring assembly. The contractile ring undergoes maturation for a short period of time before it begins to constrict. *S. pombe* recruits three different F-BAR proteins during different stages of cytokinesis: Cdc15p, Imp2p and Rga7p. Cdc15p is a phosphoprotein that is recruited before the assembly of the contractile ring and its localization depends in part on dephosphorylation by a Cdc14 phosphatase, Clp1p. We investigated the role of Cdc15p during cytokinesis by depleting the protein from *41xnm1cdc15* mutant cells by repressing expression of the gene. Cells

depleted of Cdc15p exhibit multiple cytokinesis defects at 25°C including misplaced and multiple septa. Contractile rings assemble normally in cells depleted of Cdc15p, but most of these rings slide along the cortex away from the cell center where they constrict or disassemble similar to cells depending on a truncated construct lacking the SH3 domain *cdc15ΔSH3* (Roberts-Galbraith et al., 2009). The temperature sensitive allele *cdc15-140* interacted negatively with mutations in many cytokinesis genes and was synthetically lethal with deletion of unconventional myosin-II, *Δmyp2*. Myp2p concentrates in contractile rings at approximately the time when contractile rings begin to slide in cells depleted of Cdc15p and in *cdc15ΔSH3* cells. In cells also lacking Myp2p contractile rings slide slowly and none constricted. Contractile rings assembled normally in cells lacking Myp2p but became irregular during constriction and septum deposition. In some *Δmyp2* cells the primary septum advanced ahead of the irregular contractile ring, suggesting a lack of coordination between ring constriction and septation. Contractile rings in *41xnm1cdc15* and *cdc15ΔSH3* cells stopped sliding when Bgs1p, a transmembrane enzyme that synthesizes the primary septum, appeared in the membrane next to these rings. Timely appearance of Bgs1p next to the contractile ring depended on the Clp1p phosphatase.

**Anillin phosphorylation by Polo-like kinase 1 promotes a stable cleavage furrow in cytokinesis.**

*H. Kim<sup>1</sup>, M. E. Burkard<sup>2</sup>; <sup>1</sup>Cell and Molecular Biology Program and the Department of Medicine, University of Wisconsin Madison, Madison, WI, <sup>2</sup>University of Wisconsin Carbone Cancer Center and the Department of Medicine, Hematology and Medical Oncology Division, University of Wisconsin Madison, Madison, WI*

Cytokinesis is the final step of cell division, partitioning the genetic information evenly into daughter cells. Failure in cytokinesis causes polyploidy and genetic instability, which can lead to cancer. Polo-like kinase 1 (Plk1) plays essential roles at multiple stages of cell cycle, yet little is known about its role in cytokinesis. Two screens identified Anillin as a possible Plk1 substrate. Anillin is a crucial organizer for furrow initiation that is highly concentrated at cleavage furrow and anillin depleted cells fail to complete cytokinesis. Here, we show that the levels of anillin phosphorylations peak in mitosis and then drop as cells exit from mitosis. We also found that Plk1 directly phosphorylates anillin in vitro and identified eight Plk1 phosphorylation sites on Anillin using tandem mass spectrometry. To investigate physiological significance of those phosphorylations, we generated stable HeLa cells expressing phosphorylation-deficient Anillin (Anillin 8A). Interestingly, Anillin 8A causes asymmetric furrow localization, anillin aggregation and membrane blebs. In concordance with these defects, Anillin 8A results in higher fraction of binucleate cells, indicative of complete cytokinesis failure, compared to its wild type counterpart (Anillin WT). These results demonstrate that Plk1 phosphorylates Anillin and stabilizes the cleavage furrow to enable successful cytokinesis.

332

**Anillin patterns the cortex by localizing to astral microtubules during cytokinesis.**

*C. Van Oostende Triplet<sup>1</sup>, H. Haji Bik<sup>1</sup>, M. Jaramillo Garcia<sup>1</sup>, A. Piekny<sup>1</sup>; <sup>1</sup>Biology, Concordia University, Montreal, QC, Canada*

Animal cell cytokinesis occurs by the ingression of an actin-myosin contractile ring that bisects the parental cell. The anaphase spindle, comprised of polar astral microtubules and central spindle microtubules, spatially and temporally regulates the contractile ring to ensure that the cell cleaves after sister chromatids have segregated to their respective poles.

Cues from the central spindle activate RhoA, the upstream regulator of contractile ring assembly and ingression. However, additional cues from the astral microtubules also reinforce the

localization of active RhoA in a tight zone. Using cultured human cells, we show that astral and central spindle microtubules independently regulate the localization of contractile proteins during cytokinesis. Astral microtubules prevent the accumulation of contractile proteins during metaphase and early anaphase, and restrict their localization during ingression. The central spindle helps these proteins form a discrete ring, likely by directing the activation of RhoA in the equatorial plane. Anillin is a scaffold that crosslinks actin and myosin to the overlying membrane, and is required for cytokinesis. Previously, we found that co-depletion of anillin and MKLP1 (a central spindle component) blocked furrowing, supporting that anillin functions redundantly with the central spindle for determining the division plane. Similar to *C. elegans* anillin, we found that human anillin localizes to astral microtubules, and this localization competes with its recruitment to the cortex. Over-extension of astral microtubules restricts the localization of contractile proteins, and this is overcome by depleting anillin. The sequestration of anillin by microtubules may alter the organization of contractile ring proteins at the cortex to help establish the division plane.

333

### **Anillin mediates feedback between the cortex and microtubules to define the division plane.**

*M. Jaramillo Garcia*<sup>1</sup>, *M. Ricci*<sup>1</sup>, *H. Haji Bik*<sup>1</sup>, *A. Piekny*<sup>1</sup>; <sup>1</sup>*Concordia University, Montreal, QC, Canada*

Cytokinesis separates a cell into two daughter cells by the ingression of an acto-myosin contractile ring. The mitotic spindle, which is comprised of central spindle and astral microtubules, dictates the site of contractile ring assembly. Central spindle microtubules provide positive cues to the overlying equatorial cortex, while astral microtubules negatively regulate the recruitment of contractile proteins at the cell poles. Anillin is a scaffold protein that interacts with several components of the division machinery and is a key regulator of cytokinesis. In human cells, these components include acto-myosin filaments, their upstream regulators, RhoA and Ect2 (GEF for RhoA), and membrane-associated septins. Recently, the *C. elegans* anillin homologue, ANI-1, was shown to interact with astral microtubules. This interaction removes anillin from the cortex, causing a change in the organization of contractile proteins. In this manner, anillin functions as a component of the astral pathway. Therefore, anillin crosslinks the contractile ring to the plasma membrane and relays signals from the mitotic spindle to maintain the division plane.

The mitotic spindle can provide signals to the cortex, but it is not known if there are also signals that feedback from the cortex to the mitotic spindle. An attractive hypothesis is that anillin, which scaffolds the acto-myosin cytoskeleton to the membrane and associates with microtubules in *C. elegans* embryos, could be part of this feedback pathway. To address this, we are investigating possible anillin-microtubule interactions in cultured human cells. Preliminary results show that anillin co-localizes with microtubules at different stages of mitosis. Upon disruption of signals that normally recruit anillin to the cortex, such as decreasing RhoA activation, anillin's association with microtubules is enhanced. Anillin's localization to microtubules is also enhanced after increasing microtubule stability. Depletion of anillin causes a decrease in the proportion of central spindle microtubules and in monopolar cells, causes a complete loss of central spindle microtubules. These phenotypes are similar to those that arise after depletion of central spindle regulators, such as the centralspindlin components MKLP1 or MgcRacGAP/Cyk-4. This data suggests that anillin stabilizes or bundles central spindle microtubules, which could reinforce the division plane by ensuring that the cues that promote formation of the contractile ring are maintained throughout cytokinesis.

334

**Anillin couples polarity- and spindle-directed cleavage furrows during *Drosophila* neuroblast asymmetric cell division.**

M. Connell<sup>1</sup>, K. Prehoda<sup>1</sup>; <sup>1</sup>Institute of Molecular Biology, University of Oregon, Eugene, OR

Neuroblasts divide to generate a large daughter cell that maintains the neuroblast fate and a smaller one that differentiates. Asymmetric cell division results from two contractile actomyosin populations-the mitotic spindle directs contraction at the equatorial cortex (as in symmetrically dividing cells), whereas polarity proteins regulate myosin at the basal pole (unique to asymmetrically dividing cells). The link between polarity proteins and basal actomyosin contraction is poorly understood. It is also unclear how the two myosin populations collaborate to generate a single asymmetric furrow. We surveyed polarity factors for their ability to regulate basal myosin and identified the heterotrimeric G-protein subunit G $\beta$  as a critical downstream component. We also examined which proteins from the canonical furrow pathway might be important. Although centralspindlin localizes with myosin at the neuroblast basal cortex, it is not required for basal furrowing. However, the Rho nucleotide exchange factor Pebble is required, suggesting that the polarity pathway may regulate basal furrowing by impinging with the canonical pathway at this node. The scaffold protein Anillin does not control basal myosin, but instead regulates the connection between the spindle and polarity furrows. Reduction of Anillin function leads to formation of a basal furrow, followed by a spatially separate equatorial furrow. Our results indicate that asymmetric cell division in this system results from the coupling of two distinct actomyosin populations that are regulated by related pathways.

335

**The transition from contractile ring to midbody ring is controlled by distinct mechanisms of retention and removal of Anillin.**

N. El-amine<sup>1,2</sup>, A. Kechad<sup>1,2</sup>, S. Jananji<sup>1</sup>, G. R. Hickson<sup>1,2</sup>; <sup>1</sup>Cell Biology, Université de Montréal, Montreal, QC, Canada, <sup>2</sup>CHU-Ste Justine, Montreal, QC, Canada

**Background:** During cytokinesis, closure of a dynamic actomyosin contractile ring (CR) is followed by formation of a stable midbody ring (MR). Towards understanding the architecture of these two structures and their relationship to one another, we have analyzed the behavior and regulation of the scaffold protein, Anillin, known to stabilize the furrow during CR closure and to allow formation of the MR.

**Results:** Time-lapse microscopy of *Drosophila* S2 cells revealed that the MR forms and thins via a maturation process lasting approximately 1 hr from CR closure. During this time, membrane-associated Anillin-GFP was progressively removed from the nascent MR by mechanisms that included extrusion, shedding and internalization, until only a mature MR remained. Depletion of the Citron kinase, Sticky, led to complete removal of Anillin-GFP and MR disintegration, resulting in either premature abscission or furrow regression. Sticky depletion also blocked the ability of an Anillin N-terminal fragment to prevent furrow oscillations during CR closure and to form persistent MR-like structures. Conversely, depletion of the septin, Peanut, or deletion of the C-terminal domains of Anillin, blocked Anillin extrusion and perturbed the normal maturation and thinning of the MR. Co-depletion of Sticky and Peanut led to cleavage furrow oscillations and disrupted both the normal retention and removal mechanisms of Anillin-GFP during MR formation.

**Conclusions:** These data show that the transition from dynamic CR to mature MR occurs via a gradual maturation process involving Sticky-dependent retention of a select pool of Anillin N-termini at the midbody that protects against septin-dependent removal mechanisms acting on the Anillin C-terminus. Proper coordination of these antagonistic mechanisms of retention and removal is important for furrow stability, MR maturation and the fidelity of cytokinesis.

**PAR-5/14-3-3 Inhibits Cortical Association of Centralspindlin to Limit the Site and Extent of the Cytokinetic Furrow.**

A. Basant<sup>1</sup>, Y. Tse<sup>1</sup>, M. Glotzer<sup>1</sup>; <sup>1</sup>Department of Molecular Genetics and Cell Biology, University of Chicago, Chicago, IL

During cytokinesis, a cell furrows at a unique position between segregating chromosomes to successfully divide into two daughter cells. The mechanism by which a single, well-focused cleavage furrow is generated is inadequately understood.

The small GTPase RhoA promotes the cortical recruitment and organization of actomyosin for furrow ingression. RhoA is activated by signals from the mitotic spindle. In particular, the centralspindlin complex, a heterotetramer of a kinesin-like protein ZEN-4 and a RhoGAP protein CYK-4, associates with the RhoGEF ECT-2 at the central spindle, an interaction that is required to activate RhoA. However, because the spindle is not adjacent to the cortex, it is unclear how RhoA activation is achieved and fine-tuned at the cell cortex.

To gain insight into this process, we examined early *C. elegans* embryos deficient in PAR-5/14-3-3 which were previously shown to have dramatically increased contractility during polarization, through an unknown mechanism (Morton et al., 2002). Recent studies demonstrate that contractility during cytokinesis depends on the combined action of a recently characterized protein, NOP-1, and CYK-4 (Tse et al., unpublished results). During polarization of wild-type embryos, all contractility requires NOP-1 and centralspindlin has no role. We find that PAR-5 depletion results in a hypercontractile phenotype during both polarization and cytokinesis. The hypercontractile phenotype is CYK-4 dependent and is associated with increased accumulation of CYK-4 and ZEN-4 on the cortex. This demonstrates that PAR-5 is an inhibitor of centralspindlin-dependent contractility. CYK-4 and ZEN-4 are interdependent for their cortical localization, though surprisingly they are not microtubule dependent. It has previously been shown in HeLa cells, that 14-3-3 binding to ZEN-4 prevents centralspindlin clustering, thereby inhibiting its stable localization to the central spindle (Douglas et.al., 2010). This inhibition is released upon phosphorylation of ZEN-4 by Aurora B kinase. Intriguingly, we have found that while Aurora B is required for centralspindlin-mediated furrowing in wild-type embryos, it is not required in PAR-5-depleted embryos. These results are congruent with the pathway shown to regulate centralspindlin oligomerization in HeLa cells. Thus, both central spindle and cortical localization of the centralspindlin complex may be modulated through its clustering activity. Centralspindlin oligomerization may promote cortical activation of RhoA, and spatial regulation of this activity could help focus the position of cleavage furrow formation to a single site.

337

**FIP3-Endosome Dependent Activation and Delivery of p50RhoGAP to the Cleavage Furrow Regulates Actin Depolymerization and ESCRT-III Recruitment to the Abcission Site During Cytokinesis.**

*J. Schiel<sup>1</sup>, R. Prekeris<sup>1</sup>; <sup>1</sup>Cell and Developmental Biology, University of Colorado Anschutz Medical Campus, Aurora, CO*

The last step of cell division is a physical separation of two daughter cells via process known as cytokinesis. After replication of the genetic material, mother cell divides by the formation of the cleavage furrow that constricts cytoplasm leaving two daughter cells connected by a thin intracellular bridge (ICB). The resolution of this bridge (abscission) results in separation of two daughter cells. Although mechanisms that govern abscission are not fully understood, recent evidence suggest that Rab11/FIP3-containing recycling endosomes (FIP3-endosomes) and the ESCRT protein complex play critical role in this process. The focus of this study was to dissect the roles of endosomes and ESCRT complex during cytokinesis and investigate the cross-talk between the ESCRT, cytoskeleton and endocytic membrane transport. First, we used correlative high-resolution 3D tomography and time-lapse microscopy to study the dynamics and localization of FIP3-endosomes and various ESCRT complex components. As the result of these studies, we demonstrate that FIP3-endosome fusion with the furrow plasma membrane mediate the initial thinning of the ICB to ~100 nm, known as the secondary ingression. In contrast, ESCRT-III complex components are only recruited after the formation of the secondary ingression and appear to only mediate the final scission event. Consistent with that, inhibition of FIP3-endosome targeting to the ICB and fusion block the recruitment of the ESCRT-III to the abscission site.

To further understand the role of endosomes during cytokinesis, we analyzed the proteome of immuno-isolated FIP3-endosomes. As the result of this analysis, we identified p50RhoGAP as a protein that is delivered to the furrow by FIP3-endosomes. We also demonstrate that p50RhoGAP is activated by association with FIP3-endosomes and is required to inactivate RhoA at the furrow during late telophase. Finally, we demonstrate that p50RhoGAP accumulatation at the ICB is required for localized actin depolymerization, secondary ingression formation and ESCRT-III targeting to the abscission site. Thus we propose that FIP3-endosomes regulate the disassembly of the ICB cortical actin network during the formation of the secondary ingression and are required for ESCRT-III recruitment to the secondary ingression site and subsequent abscission. These results provide a novel framework for the coordinated efforts of actin, FIP3-endosomes and ESCRT complexes to mediate abscission.

**Dissection of the temporal requirement for cytokinetic proteins.**

*S. N. Jordan<sup>1</sup>, T. Davies<sup>1</sup>, J. C. Canman<sup>1</sup>; <sup>1</sup>Pathology & Cell Biology, Columbia University, New York, NY*

The physical division of one cell into two, or cytokinesis, is highly regulated both spatially and temporally. Separation of the chromosomes during anaphase must be coordinated with the assembly and constriction of a contractile ring at the division plane. Many of the proteins necessary during division also play crucial roles during oogenesis and development, making them difficult to study by traditional forward and reverse genetic approaches. The use of fast-acting (<30s), temperature-sensitive (*ts*) cytokinesis-defective mutants allows one to bypass any developmental requirements in order to study the role of these proteins specifically during cytokinesis. The proteins encoded by these alleles are functional at low, permissive temperatures and are inactivated at high, restrictive temperatures. A number of fast-acting *ts*

mutants in the nematode worm *Caenorhabditis elegans* have been identified that affect crucial functions in the division process, including myosin-II motor activation, actin filament nucleation, Rho GTPase-mediated signal transduction, and chromosomal segregation. Using novel, rapid temperature-shifting technology in conjunction with time-lapse confocal microscopy, we have achieved precise temporal control over these *ts* mutants. We have found that they are rapidly reversible by shifting single-cell embryos from permissive to restrictive temperature for a short period following anaphase onset, before returning the embryos to permissive temperature and scoring for cytokinesis completion. We are currently dissecting the precise temporal requirement for the proteins affected by each *ts* mutation relative to furrow initiation, contractile ring constriction, and contractile ring closure, by shifting embryos from permissive to restrictive temperature at various time points following anaphase onset. As has been published (Liu et al., *Dev. Biol.*, 2010, 339:366–373), we have found myosin motor activity is required for furrow initiation, constriction, and for a brief time following furrow closure. However, we have also found other cytokinetic proteins that are necessary during furrow initiation but dispensable during furrow closure. The determination of these proteins' temporal requirements will aid in better understanding the precise roles they play throughout division.

339

### Vertebrate Cytokinesis: Nonmuscle Myosin II Exerts Tension but does not Translocate Actin.

X. Ma<sup>1</sup>, M. Kovács<sup>2</sup>, R. S. Adelstein<sup>1</sup>; <sup>1</sup>LMC, NHLBI/NIH, Bethesda, MD, <sup>2</sup>Department of Biochemistry, Eötvös University, Budapest, Hungary

In vertebrate cells, nonmuscle myosin II (NM II) and cytoplasmic actin compose two major contractile proteins at the contractile ring mediating cytokinesis. It is generally thought that contractile ring constriction is driven by NM II translocation of antiparallel actin-filaments, similar to the sliding filament model in muscle contraction. Using a combination of in situ (COS-7 cells treated with siRNA and blebbistatin), kinetic (stopped flow experiments with baculovirus-expressed protein), as well as in vivo (genetically altered cardiomyocytes in mouse hearts) approaches we provide evidence that NM II translocation of actin is not essential for vertebrate cytokinesis. The three NM II paralogs (II-A, II-B and II-C), similar to skeletal muscle myosin, are composed of catalytically active heads, which bind to and translocate actin in an ATP-dependent manner, and bipolar filament-forming rods. NM II-B is the major paralog expressed in cardiac myocytes and COS-7 cells. Ablation of NM II-B in mouse cardiac myocytes in vivo or siRNA depletion of NM II-B in cultured COS-7 cells results in cytokinesis defects indicating the requirement of NM II-B for cytokinesis. Graded knockdown of NM II in cultured COS-7 cells reveals that the amount of NM II limits the rate of ring constriction. Restoration of the constriction rate with motor-impaired NM II mutants shows that the ability of NM II to translocate actin is not the rate-limiting factor for cytokinesis. Blebbistatin inhibition of cytokinesis further reveals the importance of myosin strongly binding to actin thereby exerting tension during cytokinesis. This role is substantiated by transient kinetic experiments showing that the mechanochemical properties of mutant NM II support efficient tension maintenance despite loss of the ability to translocate actin. Under loaded conditions, mutant NM II exhibits a prolonged actin attachment in which a single mechanoenzymatic cycle spans most of the time of cytokinesis. This prolonged attachment promotes simultaneous binding of essentially all NM II heads to actin, thereby increasing tension and resisting expansion of the ring and cell cortex. Importantly, in the three dimensional context of the mouse heart in vivo, mutant NM II-B R709C that cannot translocate actin filaments also rescues multinucleation in NM II-ablated cardiac myocytes. We propose that the major roles of NM II in vertebrate cell cytokinesis are to bind and crosslink actin-filaments and to exert tension on actin during contractile ring constriction.

340

**Characterizing cortical myosin mini-filament length and its macroscopic implications in cytokinetic dynamics.**

*C. P-Descovich<sup>1</sup>, J. Dorn<sup>1</sup>, J. Boisvert<sup>2</sup>, L. Zhang<sup>1</sup>, P. S. Maddox<sup>1</sup>, A. S. Maddox<sup>1</sup>; <sup>1</sup>Pathology and Cell biology, Inst Research Immunol/Cancer, Montreal, QC, Canada, <sup>2</sup>Bioinformatics, Inst Research Immunol/Cancer, Montreal, QC, Canada*

Non-muscle myosin II (here called myosin) is the sole motor implicated in closing the contractile ring during cytokinesis. While myosin has long been assumed to slide actin filaments in a motor capacity, several recent papers propose that myosin's crosslinking activity plays more prominently in cytokinesis. Myosin holoenzyme dimers can assemble into oligomeric bipolar mini-filaments. The size and abundance of myosin mini-filaments likely dictates the relative contributions of myosin's activities to ring closure. However, mini-filaments have never been directly observed or characterized in animal cell cytokinesis.

To determine the composition of individual myosin-containing cortical features, we use a novel TIRF microscopy-based imaging assay, specifically illuminating cortical GFP-tagged myosin heavy chain (NMY-2) in transgenic *C. elegans* embryos. Cortical NMY-2-GFP is immobilized by fixation and completely photobleached. A custom image analysis algorithm calculates bleaching events from the decrease in intensity throughout photobleaching, therefore counting GFP molecules per diffraction-limited feature. Based on the ratio of endogenous to functional GFP-tagged myosin, the total number of NMY-2 dimers per feature is calculated.

Control cells possess two populations: mini-filaments with an average of 17 dimers and those with 25 dimers. Statistical analysis of the distributions around these averages indicates that mini-filaments incorporate variable amounts of labeled myosin, but are built to consistent specifications. Depletion of the myosin activator Rho-Kinase increases the relative abundance of larger myosin mini-filaments.

To test the macroscopic implications of perturbations that alter cortical myosin assembly, we depleted myosin kinases and measured myosin recruitment and organization, and contractile ring kinetics and geometry (concentricity within the division plane). Rho-K depletion decreases myosin cortical recruitment and organization, slows ring closure and makes it less concentric. Our unpublished work suggests that ring concentricity is dictated by the relative efficiency of cytoskeletal filament sliding and alignment. Thus, we predict that larger mini-filaments participate more in actomyosin sliding, perhaps via load-dependent enhancement of motor activity. Depletion of MRCK-1, a less well-understood conserved myosin kinase, increased myosin cortical recruitment but had little effect on furrowing kinetics. Following simultaneous depletion of both kinases, cortical myosin organization and recruitment were drastically reduced and, as expected for a much weaker cortex, a unique concentric phenotype emerged. Thus, while Rho-k is the more important kinase for myosin activation, MRCK-1 contributes to myosin organization and contractile ring dynamics.

We conclude that myosin is recruited to the cortex as multi-headed mini-filaments whose assembly is tightly regulated and which impacts several aspects of contractile ring function.

341

**A novel protein Rng8 binds type V myosin Myo51 and is involved in cytokinesis.**

*N. Wang<sup>1</sup>, Y. Zhu<sup>1</sup>, J-Q. Wu<sup>1</sup>; <sup>1</sup>Department of Molecular Genetics, The Ohio State University, Columbus, OH*

Cytokinesis, the final stage of cell-division cycle, partitions a mother cell into two daughter cells. More than 100 proteins have been identified to be involved in cytokinesis in the fission yeast *Schizosaccharomyces pombe*. However, more proteins were implicated in cytokinesis. Rng8 is a novel coiled-coil protein that has been localized to the division site in a global analysis of protein localization in fission yeast. We found that Rng8 colocalizes with type V myosin Myo51 in the contractile ring during cytokinesis as well as in the cable and particle structures during interphase. rng8 deletion phenocopies myo51 deletion in cytokinesis defects, especially in the contractile-ring assembly. Surprisingly, localization of Myo51 is dependent on Rng8, whereas myo51 deletion partially compromises Rng8 localization. Moreover, Rng8 interacts with Myo51 in a co-immunoprecipitation assay. Thus we hypothesize that Rng8 is an adaptor protein for Myo51 and regulates Myo51's localization and function. To test the hypothesis, we identified the domains involved in the Rng8 and Myo51 interaction. Rng8 is predicted to contain three coiled-coil domains and an EF-hand motif. Our data suggest that the third coiled-coil domain (CC3) is required for binding to Myo51, while the second coiled-coil domain (CC2) is critical for Rng8 localization. Through domain analyses of Myo51, we found that the rod region in the tail is necessary for Rng8 association, and the globular tail domain may stabilize the interaction.

Interestingly, we discovered that rng8 deletion but not myo51 deletion suppressed the contractile-ring assembly defects in rlc1 deletion, suggesting Rng8 may have roles other than recruiting and regulating Myo51. Genetic evidence further suggested that Rng8 may negatively regulate the motor activity of type II myosin Myo2, although the mechanism is currently unknown. Taken together, our data suggest that the novel protein Rng8 is involved in cytokinesis through regulating Myo51 and probably also Myo2.

342

**Chromatin mediates MLC contraction during cytokinesis by regulating Aurora B kinase.**

*A. O. Polanco<sup>1</sup>, W. Saunders<sup>1</sup>; <sup>1</sup>Biological Sciences, University of Pittsburgh, Pittsburgh, PA*

Typical cell division requires coordinated chromosomal separation, cleavage furrow ingression, and abscission. The Saunders' lab is interested in how defects in mitosis, including lagging chromosomes and anaphase bridges, contribute to aberrant cytokinesis. This cortical contraction is dependent upon the dynamics of the acto-myosin cytoskeleton. Myosin light chain (MLC) is phosphorylated by a dedicated kinase (MLCK) and initiates contraction following movement of the chromosomes away from the metaphase plate. This process is regulated by the Aurora B kinase, which moves away from segregating chromosomes to the site of cell division as part of the chromosomal passenger complex (CPC). Our current model is that Aurora B acts to inhibit MLCK to regulate the timing of cortical contraction. We are focused on the role of chromatin in activating Aurora B to prevent ingression of the cleavage furrow until the chromosomes have moved away from the divisional plane. After instigating lagging chromatin with gamma irradiation cells overexpress Aurora B, show decreased levels of MLCK activity and pMLC, and have a significantly larger propensity for cytokinesis failure. Cytokinesis failure from lagging chromatin can be mostly prevented by inhibiting Aurora B, phosphomimetic MLC or constitutively active MLCK. We propose a pathway by which Aurora B, which is activated by chromatin, inhibits MLCK and thereby prevents phosphorylation of MLC to prevent premature contraction until all chromosomes have cleared from the site of cell division. Furthermore, we show that cancer cells become tetraploid, a precursor of genomic instability, by initial DNA

damage causing lingering chromatin and Aurora B activation, leading to inhibition of MLCK and furrow regression.

343

**Identifying the role of Cin85 and CD2AP in Septin mediated cytokinesis.**

*K. Y. Fung<sup>1,2</sup>, M. P. Estey<sup>1</sup>, W. S. Trimble<sup>1,2</sup>; <sup>1</sup>Biochemistry, University of Toronto, Toronto, ON, Canada, <sup>2</sup>Cell Biology, Hospital for Sick Children, Toronto, ON, Canada*

Cytokinesis is the last step of cellular division where the mother cell is split into two daughter cells. During telophase an actomyosin ring constricts until the two daughter cells remain attached by a thin, microtubule-stabilized intercellular bridge. The center of this is referred to as the midbody and the last step of cytokinesis, abscission, is the physical breakage of the bridge at the midbody. We have previously shown that Septin 9 (SEPT9) is required for abscission in HeLa cells, and depletion of SEPT9 results in the accumulation of cells connected by midbody bridges. Structure-function studies have revealed that overexpression of the N-terminus of SEPT9 also causes cell division defects at the abscission stage, raising the possibility that we may be titrating out a critical binding partner of SEPT9 important in cell division. Perusal of the sequence of the SEPT9 N-terminus revealed the presence of two proline-rich motifs that would be predicted to serve as binding sites for Src Homology Domain 3 (SH3). In particular, these sequences match the consensus binding sequence of the SH3-containing Cbl- Interacting Protein of 85kDa (Cin85) and CD2-Associated Protein (CD2AP) adaptor proteins. These proteins belong to a family of adaptor proteins and are the human homologs of Cindr which has been implicated in Drosophila cytokinesis. We therefore hypothesize that the proline-rich motifs at the N-terminus of SEPT9 serve as binding for Cin85 and CD2AP. Preliminary immunofluorescence results from HeLa cells revealed that both Cin85 and CD2AP are localized to the intercellular bridge and midbody, respectively. In vitro pull down assays show an interaction between both adaptors with the Sept9 N- terminus and this interaction is dependent on the two proline rich motifs of Sept9. In addition, these studies have revealed specificity of the among the SH3 domains in each protein. Current studies are now investigating the individual roles of Cin85 and CD2AP in cytokinesis and the importance of SEPT9 binding in this process.

344

**Single molecule analysis of septin assembly.**

*A. Bridges<sup>1</sup>, S. Mehta<sup>2</sup>, T. Tan<sup>2</sup>, A. S. Gladfelter<sup>1</sup>; <sup>1</sup>Biological Sciences, Dartmouth College, Hanover, NH, <sup>2</sup>Marine Biological Laboratory, Woods Hole, MA*

Septins are conserved GTP-binding proteins that can self-assemble into filaments with an affinity for phospholipid-containing membranes. Septin filaments are knit together into cortical assemblies where they act as protein scaffolds for diverse events such as cytokinesis, membrane remodeling, and cell polarization. We have combined TIRF and polarization microscopy to analyze the kinetics and mechanisms driving septin assembly in vitro on supported membrane bilayers and in vivo in fungal cells. In vitro, septin filaments are initiated from paired protofilaments that extend by diffusion and annealing. The presence of PIP2 enhances the rate of assembly. Similarly, in vivo, septin-puncta are diffusing in two-dimensions on the plasma membrane. Puncta that have not assembled into a higher order structures in vivo contain minimally a paired protofilament but in some cases puncta contain higher numbers of labeled septin molecules. This suggests that septins are in extended complexes before the initiation of a higher-order structure at a specified location. Orientation analysis using polarized light has revealed that transient septin complexes always align relative to the growth axis even while diffusing and not committing to an assembled state. This indicates that there is either a

membrane or some other cytoskeletal-based template that may spatially restrict annealing-driven septin polymerization in vivo.

345

**Mechanism of F-actin assembly during cytokinesis in fission yeast.**

J. Huang<sup>1</sup>, Y. Huang<sup>2</sup>, J. Yu<sup>3</sup>, D. Subramaniam<sup>4</sup>, A. Padmanabhan<sup>2</sup>, R. Thadani<sup>4</sup>, E. Yao<sup>1</sup>, X. Tang<sup>4</sup>, R. Wedlich-Soldner<sup>3</sup>, M. Balasubramanian<sup>4</sup>; <sup>1</sup>DBS, The National University of Singapore, Singapore, Singapore, <sup>2</sup>Mechanobiology Institute, Singapore, Singapore, <sup>3</sup>Max Planck Institute, Martinsried, Germany, <sup>4</sup>Temasek Life Sciences Laboratory, Singapore, Singapore

In many eukaryotes, cytokinesis requires the assembly and constriction of an actomyosin-based contractile ring. Despite the central role of this ring in cytokinesis, the mechanism of F-actin assembly and accumulation in the ring is not fully understood. Here we investigate the mechanism of F-actin assembly during cytokinesis in *Schizosaccharomyces pombe* using lifeact as a probe to monitor actin dynamics. Previous work has shown that F-actin in the actomyosin ring is assembled de novo at the division site. Surprisingly, we find that a significant fraction of F-actin in the ring is recruited from formin-Cdc12p nucleated long actin cables that are generated at multiple non-medial locations and incorporated into the ring by a combination of myosin-II and myosin-V activities. Our results together with findings in animal cells suggest that de novo F-actin assembly at the division site and directed transport of F-actin cables assembled elsewhere can contribute to ring assembly.

**Cooperation between the formins Cdc12 and For3 for cytokinesis in fission yeast.**

V. C. Coffman<sup>1</sup>, D. R. Kovar<sup>2</sup>, J-Q. Wu<sup>1</sup>; <sup>1</sup>Molecular Genetics, The Ohio State University, Columbus, OH, <sup>2</sup>Molecular Genetics and Cell Biology, The University of Chicago, Chicago, IL

Cytokinesis is the final step of the cell-division cycle, resulting in formation of two daughter cells. The fission yeast *Schizosaccharomyces pombe* is an ideal model organism to study eukaryotic cytokinesis, because the components, mechanisms, and regulatory pathways are well conserved. Cells from yeast to humans assemble the contractile ring of actin, myosin-II, formin, and other proteins, which constricts to divide the cells. Formins nucleate long, unbranched actin filaments. The fission yeast has three formins, but only Cdc12 is essential for contractile-ring assembly. Cells lacking Cdc12 fail to divide and become long multi-nucleated cells before dying. Cdc12 localizes to cytokinesis nodes, precursors of the contractile ring, where it nucleates actin filaments that interact with myosin-II in neighboring nodes to pull them together into a ring. Two temperature-sensitive alleles of *cdc12*, *cdc12-112* and *cdc12-299*, lack the ability to nucleate actin filaments in vitro but localize normally to nodes. However, the nodes condense into clumps rather than rings at the restrictive temperature. Clump formation in the absence of Cdc12 nucleation activity suggests the presence of other actin nucleators. Another formin, For3, nucleates ~10% of the actin filaments at the division site, although its primary role is nucleating actin cables in interphase for polarized growth. For3 depends on F-BAR protein Cdc15 for its localization to the division site during anaphase A in puncta that resemble cytokinesis nodes but do not overlap with myosin-II. Observation of node movements in *cdc12-112 for3* deletion double mutant at the restrictive temperature suggests that actin filaments nucleated by For3 might be responsible for pulling nodes together into clumps in *cdc12-112* single mutant. Consistently, overexpressing For3 could rescue *cdc12-112* at the restrictive temperature, suggesting that For3 might assist Cdc12 in contractile ring assembly. Amino-terminal truncations of Cdc12 can replace the endogenous copy, but they compromised cell viability in combination with other cytokinesis mutants. Moreover, such truncations depended on actin to localize to the division site and were synthetic lethal with *for3* deletion or the actin-binding

mutant *for3-1930A*. Both *for3* mutants were also synthetic lethal with ring assembly mutants *rng2-D5* and *cdc4-8*. Together, these results reveal a novel role for For3 at the division site and cooperation between two formins for successful completion of cytokinesis.

**Interaction of Iqg1 with formins in budding yeast cytokinesis.**

*C-H. Huang<sup>1,2</sup>, M. Ponzer<sup>1</sup>, Y-C. Yu<sup>1,2</sup>, M. Choudhry<sup>1</sup>, K. B. Shannon<sup>1</sup>; <sup>1</sup>Biological Sciences, Missouri S&T, Rolla, MO, <sup>2</sup>Department of Life Science, National Taiwan Normal University, Taipei, Taiwan*

In budding yeast, both the IQGAP Iqg1 and the formins Bni1 and Bnr1 are required for actin ring formation, either cooperatively or through parallel pathways. Evidence that IQGAPs can interact with formins in mammalian cells and *C. albicans* suggests that these proteins act together to organize F-actin. Our goal is to determine how these proteins function to assemble the actin ring. The possible mechanisms, which are not mutually exclusive, are 1) Iqg1 is required for formin localization to the bud neck, 2) binding keeps one or both proteins in an active conformation, 3) Iqg1 bundles F-actin nucleated by formins. To determine if Iqg1 is required to localize the formins, we examined Bni1-GFP localization after cell synchronization and *GAL1-IQG1* shut-off. Quantitative analysis of fluorescence intensity indicates that there is no loss of Bni1 at the bud neck when Iqg1 is depleted. We are currently performing similar experiments with Bnr1-GFP. In human cells, the C-terminus of Iqg1 was shown to be necessary and sufficient for binding to the FH3 region of formin Dia1, and the authors termed this region Dia1 binding region (DBR). We created GST fusions with the N terminus of Bni1 and Bnr1, which contain the FH3 regions. These GST-formin-N-terminus proteins pull down full length Iqg1 from yeast extracts. Surprisingly, we found that the DBR region of Iqg1 is not required for this interaction. We are currently using Iqg1 deletion mutants to determine the region of Iqg1 that mediates binding to the formins. Once this interaction domain has been mapped, we can use Iqg1 deletion mutants in yeast cells to determine the effects on actin ring formation.

**Biomechanics of actomyosin ring contraction in budding yeast.**

*B. Rubinstein<sup>1</sup>, I. Mendes Pinto<sup>1</sup>, A. Kucharavy<sup>2</sup>, J. R. Unruh<sup>1</sup>, R. Li<sup>1</sup>; <sup>1</sup>Stowers Institute for Medical Research, Kansas City, MO, <sup>2</sup>Ecole Polytechnique, Palaiseau, France*

In this work we constructed a quantitative biomechanical model of actomyosin ring constriction mediated by filament sliding driven by actin depolymerization coupled with crosslinkers and myosin motor activity. Model simulations using the parameters constrained by experimental measurements confirmed that actin depolymerization is the predominant force for ring constriction. The model predicts the proportionality of the contraction speed to cell size, which is validated by measurements for rings with different initial sizes in yeast cells with different ploidies.

### 17 $\beta$ -estradiol-induced apoptosis is mediated by impaired bipolar microtubule array causing prometaphase arrest, Cdk1-dependent phosphorylation of Bcl-2 family proteins, and activation of Bak and the mitochondrial caspase cascade in human Jurkat T cells

C. Han<sup>1</sup>, D. Jun<sup>1</sup>, Y. Kim<sup>2</sup>, Y. Kim<sup>1</sup>; <sup>1</sup>School of Life Science and Biotechnology, Kyungpook National University, Daegu, Korea, <sup>2</sup>Daugu Science High School, Daegu, Korea

In Jurkat T cell clones (JT/Neo), G2/M arrest, apoptotic sub-G1 peak, mitochondrial membrane potential ( $\Delta\psi_m$ ) loss, and TUNEL-positive DNA fragmentation were all induced following exposure to 17 $\beta$ -estradiol (17 $\beta$ -E2), whereas all these events except for G2/M arrest were not induced in JT/Bcl-2 cells overexpressing Bcl-2. Under these conditions, phosphorylation of Cdc25C at Thr-48, dephosphorylation at Tyr15 and phosphorylation at Thr161 of Cdk1, upregulation of the cyclin B1 level, histone H1 phosphorylation, Bcl-2 phosphorylation at Thr-56 and Ser-70, Mcl-1 phosphorylation, and Bim phosphorylation were detected, regardless of Bcl-2 overexpression. However, 17 $\beta$ -E2-induced the upregulation of the Bak level, Bak activation, activation of caspases-9, -8, and -3, and PARP degradation were abrogated by Bcl-2 overexpression. In the presence of G1/S blocking agent hydroxyurea, 17 $\beta$ -E2 failed to induce G2/M arrest and all apoptotic events including activation of Cdk1 and phosphorylation of Bcl-2, Mcl-1, and Bim. The 17 $\beta$ -E2-induced phosphorylation of Bcl-2 and Bim, and the mitochondria-dependent apoptotic events were suppressed by Cdk1 inhibitor, but not by Aurora A and Aurora B kinase inhibitors. Analysis by immunofluorescent microscopy showed that an aberrant bipolar microtubule array, incomplete chromosome congression at the metaphase plate and prometaphase arrest, which appeared to be reversible, were the underlying factors for 17 $\beta$ -E2-induced mitotic arrest. The in vitro microtubule polymerization assay demonstrated that 17 $\beta$ -E2 could directly inhibit microtubule formation. These results demonstrate that the apoptogenic activity of 17 $\beta$ -E2 was attributable to the impaired mitotic spindle assembly causing prometaphase arrest and prolonged activation of Cdk1 and resultant phosphorylation of Bcl-2, Mcl-1 and Bim, and the activation of Bak and the mitochondria-dependent caspase cascade in Jurkat T cells.

### Cell death after mitotic arrest: the role of Bub1 and Survivin.

M. A. Andonegui<sup>1</sup>, R. E. Cáceres<sup>1</sup>, A. López<sup>1</sup>, D. Prada<sup>1</sup>, L. A. Herrera<sup>1</sup>; <sup>1</sup>Universidad Nacional Autónoma de México - Instituto Nacional de Cancerología, Distrito Federal, Mexico

The Spindle Assembly Checkpoint (SAC) is a surveillance mechanism that halts mitosis until all kinetochores are attached to microtubules, by inhibiting the Anaphase Promoting Complex (APC). Drugs that target microtubules can activate the SAC and induce a protracted mitotic arrest. After a prolonged arrest cells can die in mitosis, in the subsequent G1 phase or survive. However, mechanisms dictating the cell fate after a prolonged mitosis are unknown. Bub1 and survivin are proteins involved in the SAC and in chromosome alignment. Moreover, both proteins have been proposed as regulators of cell death in some models. As previously reported, we observed cells dying in mitosis or interphase in time lapse experiments with paclitaxel treated HTC116 cells. Bub1 is localized to the kinetochore from the beginning of mitosis until metaphase, and it is diffusely localized during interphase. Immunofluorescence experiments revealed that Bub1 nuclear foci can be found in cells released from a prolonged mitosis. We did not observe changes in Bub1 protein levels during the mitotic arrest as were evaluated by immunoblotting. Survivin localization is unmodified during a prolonged mitosis, but

levels of this protein are diminished. We hypothesize that Bub1 foci in treated cells could be complexes of Bub1 coupled with other proteins and may be playing a role in functions not linked to mitosis. On the other hand, low levels of survivin after a mitotic arrest could be related to cell death in cells treated with antimetabolic drugs. Grants: PAPIIT (IN213311-3), CONACYT (83959)

### Investigating the biochemical properties of the Chromosomal Passenger Complex *in vitro*.

A. Cormier<sup>1</sup>, D. Drubin<sup>1</sup>, G. Barnes<sup>1</sup>; <sup>1</sup>University of California, Berkeley, Berkeley, CA

The chromosomal passenger complex (CPC) is a major regulator of mitosis in eukaryotes. It is comprised of four essential and conserved proteins known in mammals/yeast as Aurora B/Ipl1, INCENP/Sli15, Survivin/Bir1 and Borealin/Nbl1. These subunits act together in a highly regulated fashion. Two activities important for CPC function are the regulation of its kinase activity and its localization. Although kinase activity regulation at centromeres and regulation of localization have been investigated extensively, studies on the CPC's basic biochemical properties are still in their infancy. Here we describe the biochemical characterization of purified *S. cerevisiae* CPC. Our *in vitro* findings show that the Sli15/INCENP microtubule-binding domain (MTB) is not necessary for CPC binding to microtubules (MTs), but only provides regulatory fine-tuning of the CPC/MT interaction. Furthermore, the Sli15/INCENP linker domain, comprised of residues E91 to I631, is not necessary for physical association of Ipl1/Aurora B with Bir1/survivin and Nbl1/borealin, suggesting that a direct interaction between Ipl1 and Bir1 exists and is strong enough to ensure CPC's integrity and stability. The CPC interaction with microtubules appears to be electrostatic in nature and depends on the C-terminal tail of tubulin. The Ipl1 kinase activity requires activation by auto-phosphorylation. Microtubules activate CPC kinase activity, suggesting a cooperative model for activation.

### Regulation of the chromosomal passenger complex and cell cycle checkpoints during early embryogenesis.

M. Zhang<sup>1</sup>, S. Nair<sup>2</sup>, F. Pelegr<sup>2</sup>, M. Lampson<sup>3</sup>; <sup>1</sup>Department of Cell and Molecular Biology, University of Pennsylvania, Philadelphia, PA, <sup>2</sup>Department of Genetics, University of Wisconsin-Madison, Madison, WI, <sup>3</sup>Department of Biology, University of Pennsylvania, Philadelphia, PA

Following fertilization most metazoans undergo a characteristic stage typified by rapid, transcriptionally silent cell cycles that oscillate between replication and mitoses without G1 and G2 phases. Cell volume halves at each cleavage without cell growth until the mid-blastula transition (MBT) occurs at a threshold nuclear to cytoplasmic ratio (N:C). The MBT is characterized by activation of zygotic transcription, cell cycle lengthening, acquisition of gap phases and checkpoint function. Mechanisms underlying this cell cycle remodeling at the MBT and the regulatory burdens of the enormous pre-MBT cells are poorly understood. We first addressed the absence of cell cycle checkpoints before the MBT in zebrafish embryos. We find that changes in checkpoint function are not explained by activation of zygotic transcription or cell cycle lengthening at the MBT. Additionally, we find that pre-MBT cells can recognize DNA damage and initiate the DNA damage response, based on histone H2AX phosphorylation, yet remain unable to arrest the cell cycle. We propose that while nuclear checkpoint function is intact and checkpoint components are maternally provided, the N:C ratio achieved at the MBT is required for proper checkpoint function. Second, we addressed regulation of the chromosomal passenger complex (CPC) in large pre-MBT cells. The CPC, composed of Aurora B kinase and regulatory components INCENP, Borealin and Survivin, modulates many events during mitosis.

The CPC is concentrated at structures such as chromatin and spindle microtubules, where Aurora B is activated by autophosphorylation, and can reach distant substrates by diffusion. Because soluble CPC will be diluted in the cytoplasm, changes in cell size may have significant consequences for Aurora B function. Zebrafish have two forms of survivin, birc5a and birc5b. Birc5b is a maternal effect gene, highlighting its early embryonic importance. We demonstrate using *birc5b* maternal effect mutant embryos that birc5b is required for the efficient phosphorylation of soluble but not chromatin-bound Aurora B substrates. We propose that birc5b contributes to the generation of diffusible Aurora B activity that can handle the spatial demands of large pre-MBT cells.

**The transition from prometaphase to metaphase in mitosis is determined by a switch-like cellular state change.**

*L. Kabeche<sup>1</sup>, D. Compton<sup>1</sup>; <sup>1</sup>Biochemistry Department, Geisel School of Medicine, Hanover, NH*

The cell cycle is an orderly sequence of events governed by switch-like changes in cellular biochemistry to ensure unidirectionality. For example, the transition from G1 to S phase and from metaphase to anaphase in mitosis is driven by switch-like cellular changes regulated by threshold levels of cyclin/Cdk activities. In contrast, the transition from prometaphase to metaphase in mitosis is not viewed as a switch-like transition because it has historically been defined only by chromosome congression which occurs progressively as chromosomes interact with spindle microtubules. However, we show that the stability of kinetochore-microtubule (k-MT) attachments undergoes a switch-like change in RPE-1 cells increasing from an average  $t_{1/2}$  of  $1.8 \pm 0.5$  min in prometaphase to  $3.8 \pm 0.5$  min in metaphase. Similar switch-like changes in k-MT stability also occur in PTK-1 and U2OS cells. To rule out that the variability in our measurements arise from a progressive stabilization of k-MTs during prometaphase, we performed repeated measurements on the same cells using photoactivation of GFP-tubulin. Equivalent k-MT stabilities were obtained for each measurement when the same cell was photoactivated twice during prometaphase ( $1.7 \pm 0.5$  min and  $1.7 \pm 0.4$  min). In contrast, photoactivating the same cell twice, once in prometaphase and once in metaphase, yielded different k-MT stability ( $2.0 \pm 0.5$  min in prometaphase and  $3.9 \pm 0.5$  min in metaphase). Strikingly, the difference in k-MT stability between prometaphase and metaphase on these single cell analyses was consistently  $1.9 \pm 0.2$  min, in line with the differences obtained from averaging populations of prometaphase and metaphase cells. Thus, the variability in our data using populations of cells reflects cell-to-cell variation and not the progressive stabilization of k-MT during prometaphase. Furthermore, the stabilization of k-MT attachments in metaphase was abolished by inhibition of proteasome activity with either epoximicin or high concentrations of MG-132, but only if the inhibitor was added before prometaphase onset. Thus, by examining the stability of k-MT attachments during mitosis, our data reveal that the transition from prometaphase to metaphase cannot be defined solely by morphological criteria (i.e. chromosome positioning) and that it is governed by a switch-like change in the cellular state akin to other defined cell cycle transitions.

354

**SPISO is a novel Pik1 substrate involved in spindle orientation.**

*I. Hoffmann<sup>1</sup>, M. Zhu<sup>1</sup>, F. Settele<sup>1</sup>, S. Kotak<sup>2</sup>, P. Gönczy<sup>2</sup>, L. Ehret<sup>1</sup>; <sup>1</sup>German Cancer Research Center, DKFZ, Heidelberg, Germany, <sup>2</sup>EPFL, Lausanne, Switzerland*

For accurate placement of the cleavage plane, the mitotic spindle needs to be precisely oriented. Spindle positioning is mediated through a cortical machinery by capturing astral microtubules thereby generating pushing/pulling forces at the cell cortex. These cortical cues

are spatially defined by retraction fibers modulating the positioning of actin regulators and therefore force generation. Moreover, astral MTs are engaged with these cortical structures through so-called +TIPs including adenomatous polyposis coli (APC), CLASPs and the dynein/dynactin complex, which have been shown to regulate spindle orientation and positioning. The cortically localized dynein/dynactin complex is believed to provide pulling forces on astral MTs and is recruited by heterotrimeric G proteins/LGN/NuMA during spindle positioning in *C. elegans* embryos, *Drosophila* and human cells. However, the detailed mechanisms underlying the correct positioning and orientation of the mitotic spindle are still not fully understood and further investigation is needed to identify potential missing components involved in this process.

Here we identified a previously uncharacterized protein - SPISO (C19orf21) as a substrate of Plk1 and Cdk1 that is required for correct positioning of the mitotic spindle. SPISO is broadly conserved among metazoans down to *Drosophila* with homology to human AKAP2. We demonstrate that SPISO is an actin-associated protein throughout the cell cycle. Depletion of SPISO leads to a Plk1-dependent block in mitosis at the metaphase to anaphase transition with fragmented centrosomes, scattered chromosomes and misoriented, rocking spindles. Loss of SPISO induces mitotic defects including spindle misorientation that is accompanied by shortened astral microtubules. Furthermore, we find that SPISO forms a complex with and regulates the cortical distribution of the +TIP binding protein p150glued, a subunit of the dynein/dynactin complex. Our findings implicate that Plk1 targets an actin binding protein to regulate spindle orientation. We propose that SPISO establishes a link between astral microtubules and the cell cortex required for proper mitotic spindle positioning.

355

#### **Cell elongation- an adaptive response clearing long chromatid arms from the cleavage plane.**

*E. Montembault<sup>1</sup>, S. Kotadia<sup>2</sup>, W. Sullivan<sup>2</sup>, A. Royou<sup>1</sup>; <sup>1</sup>IECB, Pessac, France, <sup>2</sup>Department of Molecular, Cell and Developmental Biology, University of California, Santa Cruz, CA*

Chromosome segregation must be coordinated with cell division to ensure proper transmission of the genome to daughter cells. Studies in budding yeast and mammalian cells revealed an Aurora B-dependent pathway that prevents complete closure or regression of the cleavage furrow when chromatin is present at the cleavage plane. In addition, Aurora-B increases the compaction of trailing chromatid arms during sister chromatid segregation. Here we identify a novel mechanism by which *Drosophila* larval neuroblasts coordinate chromosome segregation with cell division. Cells adapt to a dramatic increase in chromatid arm length by transiently elongating during anaphase/telophase. This cell elongation is concomitant with a slight increase in spindle length and the spreading of cortical myosin rings without compromising cytokinesis. Rho Guanine-Nucleotide Exchange Factor (Pebble)-depleted cells failed to elongate during segregation of long chromatids. As a result, Pebble-depleted adult flies exhibit morphological defects likely due to cell death during development. These studies reveal a novel pathway between trailing chromatid arms and cortical myosin that ensures the clearance of chromatids from the cleavage plane prior to completion of cytokinesis.

356

### REEP proteins are new microtubule membrane linkers required for positioning the endoplasmic reticulum during mitosis.

A-L. Schlaitz<sup>1</sup>, R. Heald<sup>2</sup>; <sup>1</sup>Dept. of Molecular and Cell Biology, UC Berkeley, Berkeley, CA, <sup>2</sup>Molecular and Cell Biology, UC Berkeley, Berkeley, CA

The spatial internal organization of cells is determined in part by interactions of organelle membranes with the microtubule cytoskeleton. For cell division, organelles undergo essential morphological changes and need to be cleared from the spindle area. These behaviors might be based on altered contacts of organelles with microtubules during mitosis. However, a complete inventory of the molecular linkers between cell organelles and microtubules and an understanding of their regulation during the cell cycle are lacking. With a purification approach to isolate new candidates for organelle-microtubule linker proteins we identified REEP4, a previously uncharacterized member of the DP1-family of endoplasmic reticulum (ER) morphogenic proteins. We found that REEP4 and the closely related REEP3 act redundantly to ensure nuclear envelope homeostasis. REEP3/4 depletion from HeLa cells results in irregularly shaped nuclei, displaying deep invaginations of the nuclear envelope. Remarkably, during mitosis the endoplasmic reticulum associates aberrantly with the mitotic chromatin in REEP3/4-RNAi cells and these contacts between ER and chromatin lead to morphologically altered interphase nuclei. Moreover, late stages of cell division are impaired upon REEP3/4 depletion with daughter nuclei separating insufficiently. These observations suggest that REEP3/4-mediated mitotic positioning of the ER away from the chromatin promotes correct progression of mitosis and proper nuclear envelope formation and that previously unappreciated microtubule-membrane interactions contribute to the generation of proper intracellular architecture during the cell cycle.

357

### Human Mio is required for progression through metaphase and completion of cytokinesis.

M. Platani<sup>1</sup>, W. C. Earnshaw<sup>1</sup>; <sup>1</sup>Wellcome Trust Centre of Cell Biology, Institute of Cell Biology, University of Edinburgh, Edinburgh, United Kingdom

The Nup107 complex is an evolutionary conserved nucleoporin subcomplex that plays a crucial role in nuclear pore complex assembly. A fraction of the Nup107 complex localises to kinetochores from early prophase to late anaphase (*Belgareh et al., 2001*). Efficient depletion of the Nup107 complex causes chromosome congression defects and a spindle checkpoint-dependent delay in mitosis via control of the localisation state of the chromosome passenger complex (*Platani et al., 2009*). We used Seh1, a member of the Nup107 complex to identify interacting partners by co-immunoprecipitation in mammalian cells. We identified an interaction between Seh1 and human homologue of *missing oocyte (mio)*, a drosophila protein required for proper meiosis (*Iida and Lilly, 2004*). We depleted Mio in human cells and observed pro-metaphase arrest, chromosome bridges in anaphase, and severe defects in mitotic progression. We are currently characterising the pathway that leads to these chromatin and cell cycle defects.

358

**Kinase crosstalk: interactions between the Chromosomal Passenger Complex and Polo kinase at the centromere.**

*M. Carmena<sup>1</sup>, X. Pinson<sup>2</sup>, M. Platani<sup>1</sup>, Z. Salloum<sup>2</sup>, Z. Xu<sup>1</sup>, A. Clark<sup>1</sup>, F. MacIsaac<sup>1</sup>, U. Eggert<sup>3</sup>, D. M. Glover<sup>4</sup>, V. Archambault<sup>2</sup>, W. C. Earnshaw<sup>1</sup>; <sup>1</sup>Wellcome Trust Centre for Cell Biology., University of Edinburgh, Edinburgh, United Kingdom, <sup>2</sup>Institut de Recherche en Immunologie et en Cancérologie, Montreal, Canada, <sup>3</sup>School of Biomedical Sciences, King's College London, London, United Kingdom, <sup>4</sup>Department of Genetics, University of Cambridge, Cambridge, United Kingdom*

Crosstalk between Aurora and Polo kinases is essential for cell cycle progression. On mitotic entry, Aurora A is the kinase responsible for the activation of Plk1 at centrosomes, but the identity of the kinase(s) that perform this function later in mitosis and at other locations had remained elusive.

The coordinated activities at centromeres of Polo and Aurora B kinases are critical for ensuring that the two sister kinetochores of each chromosome are attached to microtubules from opposite spindle poles. In early stages of the attachment process errors occur frequently as this process is largely based on chance interactions between kinetochores and dynamic microtubules. The balance between microtubule binding and error correction (e.g. release of bound microtubules) requires the activities of Polo and Aurora B kinases. Current evidence indicates that Polo promotes stable attachments and Aurora B promotes detachment. Here we present our recent studies concerning the coordination of the activities of these two kinases in vivo.

We have shown that Aurora B (but not Aurora A) is responsible for Polo kinase activation at the centromere in *Drosophila* cultured cells. These results were validated in vivo in larval neuroblast mitoses. The CPC component INCENP plays an essential role in Polo kinase regulation: it interacts with Polo and it is required for its activation by T-loop phosphorylation. This activation happens at the inner centromere where both proteins colocalise early in mitosis. This mechanism of activation of Polo kinase by the CPC at the centromere is conserved in human cells.

Here we further demonstrate that Polo activity is required for the stable localisation and activity of the CPC at the centromere in cultured *Drosophila* cells. Analysis of *polo* alleles revealed that this mechanism is important in mitosis in vivo and also in the meiotic divisions.

We propose that INCENP acts as a platform for the coordination of the activities of Polo and Aurora B kinases at the centromere.

359

**Activation of the membrane/actin linkers ERM guides the orientation of cell division axis.**

*M. Machicoane<sup>1</sup>, C. Alvarez<sup>2</sup>, J. Fink<sup>3</sup>, S. Garef<sup>2</sup>, M. Pie<sup>3</sup>, A. F. Echard<sup>1</sup>; <sup>1</sup>Institut Pasteur, Paris, France, <sup>2</sup>IBENS, Paris, France, <sup>3</sup>Institut Curie, Paris, France*

Accurate control of spindle orientation during mitosis is crucial for the determination of animal cell division axis, thus for embryogenesis, morphogenesis and adult tissue homeostasis. Spindle orientation depends on the localization of cortical landmarks which ultimately enable proper interactions between microtubules of the mitotic spindle and the polarized cellular cortex in metaphase. Several reports showed that cortical F-actin depolymerization impinged on spindle orientation. ERM (Ezrin, Radixin, Moesin) proteins are attractive candidates for

organizing the cell cortex in metaphase as, upon activation, they directly link F-actin to integral plasma membrane proteins. We have proposed that ERM activation could provide inputs in spindle orientation (1,2) but direct evidence is still lacking.

We observed that the three ERM proteins expressed in mammalian cells are strongly activated upon mitotic entry, and we identified the major and direct kinase responsible for mitotic ERM activation. Taking advantage of fibronectin micropattern technology to reproducibly control spindle orientation in culture cells, we found that ERM proteins are essential for the proper orientation of cell division axis. Of note, both the levels and the asymmetric (polarized) localization of activated ERM impinge on spindle orientation and dynamics. Consistent with this observation, we similarly found an asymmetric localization of activated ERM *in vivo*, in mouse apical progenitors that are known to divide in a remarkably stereotyped manner within the embryonic neuroepithelium. Importantly, specifically impairing ERM activation in apical progenitors strongly disturbed spindle orientation. In addition, ERM activation was essential for the correct cortical localization of well-established molecules at the interface between the plasma membrane and the spindle microtubules.

We propose that activated ERM behave as polarized cortical marks that are important for guiding mitotic spindle orientation.

### **Disruption of Arf1 GTPase Activity Can play A Role In Mitotic Chromosome Segregation in *Drosophila* Embryos.**

R. Khodary<sup>1</sup>, B. Riggs<sup>1</sup>; <sup>1</sup>Biology, San Francisco State University, San Francisco, CA

Proper assembly of the microtubule based bipolar spindle is a prerequisite step for a faithful segregation of sister chromatids during mitosis. Although dynamics of mitotic chromosomes have been well studied, a defined model of spindle assembly and chromosome segregation is not fully understood. Previous studies have suggested a role for membrane-associated proteins in major mitotic events including spindle assembly and cytokinesis. Recently, it has been proposed that the small GTPase Arf1, a key regulator for Golgi structure and retrograde transport, may play a potential role in chromosome segregation. Here, we report a role for Arf1 in regulating spindle dynamics and morphogenesis during the early syncytial divisions of the *Drosophila melanogaster* embryo. RNA inhibition of Arf1 in transgenic embryos containing GFP-tubulin / RFP-histone showed a mass defect in chromosome segregation and spindle organization, with a prolonged mitotic delay. A similar phenotype was also observed with microinjections of Brefeldin A (BFA), a small molecular inhibitor of Arf1, upon mitotic entry in GFP-tubulin / RFP-histone embryos. In addition, we show that the Arf1-dependent metaphase delay is independent of the spindle assembly checkpoint (SAC). RNA inhibition of Arf1 and BFA microinjections were performed in transgenic embryos containing a GFP tagged Mad2, a reporter of SAC activity. Mad2 localization was unaffected by inhibition of Arf1 or treatment with BFA. Specifically, Mad2 was not present at the kinetochores during the Arf1 / BFA induced metaphase delay indicating that the SAC is not active. Therefore, we conclude that Arf1 GTPase activity may play a distinct role in normal patterns of spindles and chromosomes, and metaphase-anaphase transition. Thus, our findings may explain a novel pathway that further determines the mechanism behind the coordination between organelles inheritance and functional regulation of spindles.

**A SxIP motif in the yeast kinesin Kar3/Cik1 is necessary for anaphase spindle elongation.**E. Davidson<sup>1</sup>, T. Davis<sup>1</sup>; <sup>1</sup>Biochemistry, University of Washington, Seattle, WA

Cells carrying out mitosis must maintain and regulate the distance between the spindle poles in order to successfully deliver a full set of chromosomes to each daughter cell. This pole separation is established by interpolar microtubules (ipMTs) that emanate from either pole and are bundled together in the spindle midzone. Several microtubule-binding proteins, including the budding yeast kinesin-14 Kar3/Cik1, have important roles in ipMT bundling, but their exact functions remain unclear. Cik1's N-terminus contains a widely conserved motif (SKIP), that resembles the established animal EB1-binding motif SxIP, suggesting that Cik1 may function in a complex with the yeast EB1 homolog Bim1. However, that interaction has not been shown to occur.

To investigate what role Cik1's SKIP motif plays on the mitotic spindle, we have mutated the motif to alanines in a *CIK1-GFP* background. Cik1 spindle fluorescence is reduced but not eliminated in strains carrying this allele (*cik1-4A-GFP*), and Cik1's movement across the spindle appears unaffected. The strain does, however, suffer from a clear defect in anaphase spindle elongation: wild-type yeast spindles often reach 7  $\mu\text{m}$  in length, but elongating anaphase *cik1-4A-GFP* spindles slow sharply at 3  $\mu\text{m}$  and rarely surpass 4.5  $\mu\text{m}$ . The spindle elongation phenotype is specific to mutation of the SKIP motif and does not appear in all Cik1 mutants. Interestingly, the phenotype also does not appear in Bim1 mutants.

To determine whether the SKIP motif recruits Cik1 to microtubule plus ends, we have introduced a SKIP motif into the Cik1 paralog Vik1, which normally accumulates at the spindle poles. However, introduction of the SKIP motif had no discernible effect on Vik1 localization, even in Cik1 mutant backgrounds.

Together, these data suggest that Cik1's SKIP motif is a significant part of the protein and plays a role in spindle length regulation. However, the exact mechanism of that regulation, as well as whether the motif functions as a Bim1 binding site, are still under investigation.

**Kinetochores association of the Ska complex enhances degradation of mitotic targets to promote anaphase and mitotic exit.**S. Sivakumar<sup>1,2</sup>, G. J. Gorbsky<sup>1,2</sup>; <sup>1</sup>Cell Biology, University of Oklahoma Health Sciences Center, Oklahoma City, OK, <sup>2</sup>Cell Cycle and Cancer Biology, Oklahoma Medical Research Foundation, Oklahoma City, OK

The Spindle- and kinetochores-associated (Ska) protein complex is a heterotrimeric complex that accumulates on microtubules and at kinetochores after nuclear envelope breakdown. The Ska complex becomes most enriched at kinetochores at metaphase. Previously we showed that the major phenotype seen after siRNA-mediated depletion of the Ska3 protein in HeLa cells and other cell lines was metaphase arrest or delay with many cells exhibiting chromosomes that eventually undergo asynchronous chromatid separation, a phenomenon we term cohesion fatigue. The strong pulling forces required to induce cohesion fatigue indicate that Ska3-depleted cells in mitosis have robust kinetochores-microtubule attachments. In support of this conclusion we find that Ska3 depleted cells have cold stable kinetochores fibers and metaphase levels of checkpoint proteins at kinetochores suggesting that the spindle checkpoint may be satisfied in cells depleted of Ska complex. Further we found that anaphase onset induced by depletion of checkpoint proteins is slowed in cells co-depleted of Ska3 indicating that the Ska complex may have a direct role in promoting anaphase onset. Treatment of cells with a

chemical inhibitor of Cdk1 at any point after nuclear envelope breakdown induces rapid degradation of cyclin B and biochemical progression to G1 even in cells arrested in mitosis with microtubule drugs. Thus treatment of cells with Cdk1 inhibitor allowed us to assay rates of cyclin B degradation in the presence or absence of microtubules and in the presence or absence of Ska complex. The persistence of kinetochore-associated tubulin in cells treated with taxol or with low levels of nocodazole correlated with accelerated Cyclin B breakdown induced by Cdk1 inhibitor. The concentration of Ska complex at kinetochores is partially dependent on kinetochore-associated tubulin. High concentrations of nocodazole deplete tubulin from kinetochores and significantly reduces kinetochore-associated Ska complex. Forced localization of Ska complex to kinetochores in cells treated with high nocodazole resulted in accelerated cyclin B degradation after addition of Cdk1 inhibitor. We propose that Ska complex-tubulin-kinetochore association enhances degradation of mitotic targets to sharpen the metaphase-anaphase transition and promote mitotic exit. Supported by the National Institute of General Medical Science of the National Institutes of Health under award number R01GM50412.

**The DNA damage checkpoint triggers autophagy to regulate the initiation of anaphase.**

*F. Dotiwala<sup>1</sup>, V. Eapen<sup>1</sup>, J. C. Harrison<sup>1</sup>, A. Arbel-Eden<sup>1</sup>, V. Ranade<sup>1</sup>, S. Yoshida<sup>1</sup>, J. E. Haber<sup>1</sup>;  
<sup>1</sup>Brandeis University, Waltham, MA*

Budding yeast cells suffering a single unrepaired double-strand break (DSB) trigger the Mec1 (ATR)-dependent DNA damage response that causes them to arrest prior to anaphase for 12-15 h. Hyperactivation of the cytoplasm-to-vacuole autophagy pathway causes the permanent G2/M arrest of cells with a single DSB that is reflected in the nuclear exclusion of Esp1 and partial degradation of Pds1. Arrest persists even when the DNA damage-dependent phosphorylation of Rad53 diminishes. Permanent arrest can be overcome by blocking autophagy, by deleting the vacuolar protease Prb1 or by driving Esp1 into the nucleus with a SV40 nuclear localization signal. Autophagy in response to DNA damage can be induced in three different ways: by deleting the Golgi-Associated Retrograde Protein complex (GARP), by adding rapamycin or by overexpression of a dominant-negative ATG13-SA8 mutation.

**Anaphase B induction by Patronin-mediated repression of Kinesin-13-dependent Poleward Flux.**

*H. Wang<sup>1</sup>, I. Brust-Mascher<sup>1</sup>, J. M. Scholey<sup>1</sup>; <sup>1</sup>Molecular & Cellular Biology, University of California, Davis, Davis, CA*

Chromosome segregation during mitosis involves chromosome-to-pole motility (anaphase A) and spindle elongation (anaphase B). While most attention is currently focused on anaphase A, the equally important process of anaphase B spindle elongation, in which the spindle poles themselves separate pulling the chromosomes along with them, has received less attention. We propose that anaphase B is driven by a kinesin-5-generated interpolar (ip) microtubule (MT) sliding filament mechanism that engages when poleward flux is turned off. In pre-anaphase B spindles the outward sliding of ipMTs is balanced by depolymerization of their minus ends at the poles producing flux. Following cyclin B degradation, depolymerization ceases, allowing ipMT minus ends to push apart spindle poles as their plus ends grow, building a robust midzone where the sliding motors act. In the current study, we have used live cell imaging combined with biochemical and genetic manipulations to illuminate the molecular mechanism of anaphase B induction, using the *Drosophila* embryo as a model system. We have developed an

experimental system for arresting spindles at their characteristic pre-anaphase B spindle length in the presence of cyclin B, whereupon poleward flux persists and the spindle does not elongate. We show that when the kinesin-13 depolymerase (KLP10A) is experimentally dissociated from spindle poles, poleward flux ceases and the spindle elongates pulling apart the chromosomes, in a manner similar to normal anaphase B spindles. Conversely, inhibiting a recently-discovered minus end capping protein, Patronin, causes flux to persist and inhibits wild type anaphase B while chromosome-to-pole motility proceeds. This suggests that Patronin induces anaphase B spindle elongation by protecting MT minus-ends against kinesin-13-induced depolymerization and that this cessation of depolymerization is sufficient to induce anaphase B. Significantly, the anaphase B-like spindle elongation induced by kinesin-13 inhibition was not accompanied by the redistribution of ipMT plus ends to the spindle equator whereas Patronin inhibition had no effect on MT plus end redistribution during anaphase B. Thus the anaphase B switch in *Drosophila* embryos involves two, probably independent mechanisms, namely: i) Patronin mediated suppression of kinesin-13-dependent MT minus end depolymerization, which is sufficient to convert MT poleward flux to anaphase B spindle elongation; and ii) spindle midzone re-organization including the redistribution of ipMT plus ends, which is neither sufficient nor required for anaphase B.

### **Dynamics of kinesin motors throughout the anaphase B switch in *Drosophila* syncytial embryos.**

*I. Brust-Mascher*<sup>1</sup>, *G. Civelekoglu-Scholey*<sup>1</sup>, *D. Cheerambathur*<sup>2</sup>, *P. Sommi*<sup>3</sup>, *J. M. Scholey*<sup>1</sup>;

<sup>1</sup>*Molecular and Cellular Biology, University of California, Davis, CA,* <sup>2</sup>*Cellular and Molecular Medicine, University of California, San Diego, CA,* <sup>3</sup>*Physiology, University of Pavia, Pavia, Italy*

The mitotic spindle is a dynamic protein machine. In *Drosophila* syncytial embryos, Fluorescence Recovery after Photobleaching (FRAP) experiments have shown that tubulin exhibits turnover on the order of a few seconds during all stages of mitosis. However, the extent of recovery changes at anaphase B onset: before anaphase B, recovery is complete all along the spindle, whereas during anaphase B, recovery near the poles is lower. Microtubule based motor proteins are important for spindle assembly, maintenance and elongation. Here, we present our studies of motor dynamics using FRAP, Fluorescence Speckle Microscopy (FSM) and quantitative mathematical modeling using a computational model that describes the dynamics of the MTs and the mitotic kinesins' binding and detachment from the MTs. The bipolar kinesin-5 KLP61F, required during mitosis, and kinesin-14 Ncd, which acts antagonistic to kinesin-5, have turnover rates of 3-4 seconds and recover 80 to 90% of fluorescence intensity. KLP61F-GFP exhibits a decrease in recovery near the poles during anaphase B similar to that seen in tubulin FRAP. Fluorescence Speckle Microscopy (FSM) of these proteins shows that a fraction of KLP61F-GFP motors is stationary on the spindle, while interpolar microtubules (MTs) are slid apart. The kinesin-8 KLP67A also has a turnover rate of approximately 4 seconds and recovers 70 to 90% with the lower recoveries near the poles. KLP10A, a kinesin-13, exhibits a full recovery with rates of 1 to 2 seconds, the slowest recovery occurs near the poles during anaphase B. Finally, the kinesin-4 KLP3A exhibits a complete recovery with a halftime of approximately one second all along the spindle. The motors' data conform to a reaction-diffusion model in which a fraction of the motor is bound to spindle MTs and the remainder diffuses freely.

**PP2A<sup>Cdc55</sup> opposes Cdk1 activation of anaphase onset by inhibiting the APC<sup>Cdc20</sup> and Separase.**

N. Lianga<sup>1</sup>, C. Dore<sup>1</sup>, S. Pilon<sup>1</sup>, E. Williams<sup>1</sup>, A. Rudner<sup>1</sup>; <sup>1</sup>Department of BMI, Ottawa Institute of Systems Biology, Ottawa, ON, Canada

Deletion of *CDC55*, which encodes a B-subunit of Protein Phosphatase 2A (PP2A) causes defects in both the morphogenesis and spindle checkpoints. Checkpoint bypass in *cdc55Δ* cells differs from most checkpoint mutants in that the anaphase promoting complex (APC) is only partially active, and APC substrates are slowly degraded as cells bypass the mitotic arrest caused by checkpoint activation. We have explored the possible mechanisms for how PP2A<sup>Cdc55</sup> inhibits activation of the APC and anaphase onset. First, we have tested if PP2A<sup>Cdc55</sup> opposes Cdk1 activity and inhibits the activation of the APC<sup>Cdc20</sup>. We have shown that *cdc55Δ* cells have increased APC phosphorylation on previously mapped Cdk1 sites on the APC subunits Cdc16, Cdc23 and Cdc27. Blocking Cdk1 phosphorylation by mutating these sites (the *APC-12A* mutant) partially suppresses the checkpoint defects of *cdc55Δ*. However, this suppression is not complete, as *cdc55Δ APC-12A* mutant cells still initiate anaphase after activation of the morphogenesis checkpoint. Additionally, deleting multiple APC substrates (including *PDS1*, the budding yeast Securin) does not bypass the morphogenesis checkpoint-dependent block to anaphase. These data suggest that PP2A<sup>Cdc55</sup> dephosphorylates and inhibits a second substrate that regulates anaphase downstream or independently of the APC. Our preliminary data suggests that Esp1 (the budding yeast Separase), like the APC, is dephosphorylated and inhibited by PP2A<sup>Cdc55</sup>, and Cdk1 phosphorylation opposes PP2A<sup>Cdc55</sup> dephosphorylation. Phosphorylation of Esp1 in vivo depends on Cdk1 activity, and purified Cdk1/Cyclin can phosphorylate Separase on six potential Cdk1 sites. We are currently testing if preventing phosphorylation of Esp1 will suppress *cdc55Δ* checkpoint defects, and if mimicking constitutive phosphorylation increases Esp1 activity in vitro, and causes premature anaphase onset.

**Aurora B-dependent phosphorylation of condensin is required for telomere disjunction in mitosis.**

C. Reyes<sup>1</sup>, C. Serrurier<sup>1</sup>, T. Gauthier<sup>1</sup>, S. Tournier<sup>1</sup>, Y. Gachet<sup>1</sup>; <sup>1</sup>CNRSumr5088, Toulouse, France

It is now well established that the spatial organization of telomeres is non random within the nuclear space. However, how is this organization controlled throughout the cell cycle including mitosis is still elusive. The segregation of centromeres and telomeres is coordinated in space and time in order to prevent the formation of aneuploid cells, a phenotype frequently observed in cancer. One potential source of mitotic instability is chromosomes with dysfunctional telomeres, which give rise to chromatin bridges at anaphase, leading to chromosome loss. The mechanisms leading to these bridges are just beginning to be elucidated.

Aurora B kinase is one of the key regulators of mitotic events such as chromosome condensation, chromosome bi-orientation and cytokinesis in a wide range of organisms, including fission yeast. Here, we have investigated the spatio-temporal control of telomere positioning throughout the cell cycle in live fission yeast cells. We have uncovered a new mechanism leading to telomere disjunction in early mitosis, which requires the activity of the Aurora kinase Ark1. Our study identifies the condensin subunit Cnd2 as a specific substrate of Aurora B, which controls telomere disjunction in early mitosis to prevent the formation of anaphase chromatin bridges in cells.

**Cell Cycle Regulated Chs2p Endocytosis during Mitotic Exit.**

*C. Chin<sup>1</sup>, B. Augustine<sup>1</sup>, F. Yeong<sup>1</sup>; <sup>1</sup>Department of Biochemistry, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore*

Cytokinesis is the final step in cell cycle in which a dividing cell undergoes physical separation to form two progeny cells. In budding yeast, cytokinesis is accomplished by the spatio-temporal coordination of acto-myosin ring (AMR) constriction and primary septum (PS) formation. The PS is synthesized by a transmembrane protein, chitin synthase II (Chs2p) and it plays a crucial role in stabilizing the AMR throughout cytokinesis. During metaphase-anaphase transition, Chs2p is retained in the endoplasmic reticulum due to the phosphorylation on clusters of Cdk1 sites at its N-terminus by mitotic cyclin dependent kinase, Cdk1p. At the end of mitosis, loss of mitotic kinase Cdk1p activity and reversal of Chs2p phosphorylation by cytoplasmic Cdc14p triggers Chs2p ER export. Chs2p then translocates to the neck where PS is laid. After completion of cytokinesis, Chs2p will be removed and internalized through endocytosis. Clathrin Mediated Endocytosis (CME) is a major route of endocytosis in budding yeast. The dynamic of key CME machineries at the plasma membrane is well characterized in interphase cells. However, the cell cycle specific regulation of CME at the cytokinesis site during mitotic exit remains unexplored. Here, we employ Chs2p as an internal endocytic cargo to study the relationship between Cdk1 activity reduction, cytokinesis and endocytosis at the end of mitosis. By utilizing time-lapsed fluorescence microscopy, we characterized the dynamic localization of CME proteins during cell division cycle. We also investigated the timing of neck localization of endocytic proteins relative to Chs2p neck localization and AMR constriction.

369

**A maternal effect screen in *Drosophila* to map PP2A-dependent pathways in mitotic exit.**

*V. Boudreau<sup>1</sup>, X. Pinson<sup>1</sup>, P. Wang<sup>1</sup>, P. S. Maddox<sup>2</sup>, V. Archambault<sup>1</sup>; <sup>1</sup>Biochemistry, IRIC, Montreal, QC, Canada, <sup>2</sup>IRIC, Montreal, Canada*

Mitotic progression is largely governed by kinases, phosphatases and ubiquitin ligases. Whereas high levels of CycB-Cdk1 kinase activity trigger mitotic entry, mitotic exit requires the inactivation of this kinase and the activation of a phosphatase at the onset of anaphase. It has recently been demonstrated that PP2A plays a major role in CycB-Cdk1 substrate dephosphorylation in mitotic exit in higher eukaryotes. PP2A in complex with adaptor subunits of the B55 subtype (Tws in *Drosophila*) is required for this process. The substrates that must be dephosphorylated by PP2A-B55/Tws to allow mitotic exit events and other regulators that could promote this process are unknown.

Here, we used a genetic approach to identify genes that collaborate with PP2A-B55/Tws in mitotic exit. We exploited the fact that meiosis and early embryonic mitoses are particularly sensitive to cell cycle perturbations. We conducted a second-site non-complementation, maternal effect lethal screen. Large genetic deletions altogether covering over 60% of the fly genome were screened against both the catalytic Mts and regulatory Tws PP2A subunit genes. Further mapping identified several genes that collaborate with PP2A-B55/Tws for cell cycle progression. Phenotypic examination reveals a variety of specific cell cycle defects in meiosis and mitosis.

We suggest that PP2A-B55/Tws regulates multiple events during mitotic exit, including chromosome segregation and centrosome-nuclear envelope cohesion. Our results also identify

specific kinases and nuclear transport factors as potential co-regulators of these processes. Future work will be aimed at the elucidation of these mechanisms.

370

**Clathrin Mediated Endocytosis of Chs2p at the End of Mitosis.**

*B. Augustine<sup>1</sup>, C. Chin<sup>1</sup>, F. Yeong<sup>1</sup>; <sup>1</sup>Department of Biochemistry, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore*

Chs2p (Chitin Synthase II) is a transmembrane protein that lays down the primary septum (PS) during cytokinesis in budding yeast. At the onset of mitotic exit, activation of Mitotic Exit Network (MEN) and release of Cdc14p into the cytoplasm trigger Chs2p ER export through COPII secretory pathway. Upon its arrival at the neck, Chs2p synthesizes chitin, which forms the PS and stabilizes the acto-myosin ring constriction during cytokinesis. Subsequently, Chs2p is removed from the cytokinesis site. Previous study from our lab demonstrated that Chs2p endocytosis during cytokinesis is regulated in a Sla2p-dependent manner. Nonetheless, the underlying mechanism for Chs2p endocytosis remains poorly understood. In this study, we establish that Chs2p is indeed a cargo of clathrin mediated endocytosis (CME) and we determine which key endocytic components are needed for Chs2p internalization during cytokinesis. We examined if post-translational modifications on Chs2p are required for its endocytosis. We also investigated the relationship between endocytosis and cytokinesis. Interestingly, Chs2p endocytosis at the neck is not affected in MYO1 null cells that failed to perform cytokinesis. Taken together, we propose that Chs2p is a cargo of CME and the endocytic pathway that functions at the plasma membrane also functions at the mother-bud neck during cytokinesis.

371

**Feedback control of anaphase spindle elongation by Aurora B spatially regulates nuclear envelope reassembly.**

*O. Afonso<sup>1</sup>, I. Matos<sup>2</sup>, M. Lampson<sup>3</sup>, H. Maiato<sup>1,4</sup>; <sup>1</sup>IBMC, Porto, Portugal, <sup>2</sup>Rockefeller University, New York, NY, <sup>3</sup>University of Pennsylvania, Philadelphia, PA, <sup>4</sup>FMUP, Porto, Portugal*

Faithful chromosome segregation during anaphase requires the physical and synchronous separation of two sets of sister-chromatids that will give rise to genetically identical daughter cell nuclei. Critically, nuclear envelope reassembly must therefore enclose each and entire set of sister-chromatids, implying spatiotemporal coordination with the mechanisms that govern anaphase. Using *Drosophila melanogaster* S2 cells as model system, we identified a novel feedback control mechanism that delays chromosome decondensation and nuclear envelope reformation in response to slow spindle elongation during anaphase. We show that this mechanism is dependent on Aurora B activity since its inhibition at anaphase onset causes premature chromosome decondensation and nuclear envelope reformation before complete separation of two sister-chromatid sets. We show that an anaphase Aurora B phosphorylation gradient is also present in S2 cells, accounting for the observed spatial regulation of chromosome decondensation and nuclear envelope reformation. We further obtained evidence that PP1 phosphatase counteracts the effect of this gradient, whose inhibition originates super-elongated spindles, highly condensed DNA and impaired nuclear envelope reformation. Finally, we show that Barren, the *Drosophila* homolog of human Cap-H subunit of Condensin I whose loading into chromosomes is Aurora B-dependent, is required for the observed feedback mechanism. We propose that an Aurora B phosphorylation gradient at the spindle midzone is part of a post-anaphase checkpoint, which provides the necessary spatial cues that prevent

premature chromosome decondensation and nuclear envelope reassembly before effective separation of sister chromatids is reached.

372

**Regular spacing is not required for nuclear autonomy in multinucleate cells.**

*S. E. Roberts<sup>1</sup>, C. Lee<sup>1</sup>, A. S. Gladfelter<sup>1</sup>; <sup>1</sup>Dartmouth College, Hanover, NH*

In mononucleate cells, it is known that cell cycle progression is regulated by the presence of cytoplasmic factors. In some syncytia, however, individual nuclei are able to progress through mitosis independently of their neighbors despite bathing in the same cytoplasm. In order for these two models to be consistent, limitations must exist on exchange of gene products between nuclei. In the multinucleate filamentous fungus *Ashbya gossypii*, inter-nuclear spacing and the overall number of nuclei per unit area is tightly regulated, resulting in minimal variation in the distances between adjacent nuclei. In order to test the role of spacing in nuclear division autonomy, we utilized a strain lacking the dynein-interacting protein dynactin. This mutation results in the formation of large clusters where 10-30 nuclei are <0.5  $\mu\text{m}$  apart. Individual clusters are far from each other in the cell, resulting in large regions lacking nuclei. Remarkably, despite the close proximity of nuclei to each other in these clusters, asynchronous division still occurs. We investigated cell cycle activity at the level of single nuclei by analyzing the fluorescence of single molecule FISH probes against cyclin transcripts using an automated MATLAB based quantification program. Using this technique for transcript visualization yields fluorescent peaks of homogenous size and intensity in the cytoplasm. Within nuclei, however, signals of brighter intensity and larger size are detectable which correspond to sites of gene expression. In wild type cells, only a subset of nuclei produces any specific cell cycle transcript. Remarkably, this also holds true for clustered nuclei in dynactin mutants, despite their being greater than five times closer to each other than wild type nuclei and presumably being bathed with the exact same cytoplasmic signals. A small proportion of nuclei can be found on their own and not part of a cluster in these cells. These lone nuclei are more likely to produce some of the transcripts investigated than nuclei in clusters or wild type, regularly spaced, nuclei. These data provide tantalizing clues into how nuclei sense their local environment and respond depending on the proximity of neighboring nuclei. These multinucleate cells are able to maintain nuclear autonomy in gene expression and cell cycle progression despite the extremely abnormal nuclear localization.

373

**Separase biosensor reveals that cohesin cleavage timing depends on phosphatase PP2A<sup>Cdc55</sup> regulation.**

*G. Yaakov<sup>1</sup>, K. Thorn<sup>2</sup>, D. O. Morgan<sup>1</sup>; <sup>1</sup>Physiology, UCSF, San Francisco, CA, <sup>2</sup>Biochemistry & Biophysics, UCSF, San Francisco, CA*

In anaphase, sister chromatids separate abruptly and are then segregated by the mitotic spindle. The protease separase triggers sister separation by cleaving the Scc1/Mcd1 subunit of the cohesin ring that holds sisters together. Polo-kinase phosphorylation of Scc1 promotes its cleavage, but the underlying regulatory circuits are unclear. We developed a separase biosensor in *Saccharomyces cerevisiae* that provides a quantitative indicator of the rate and timing of cohesin cleavage in single cells. Separase is abruptly activated and cleaves most cohesin within one minute, after which anaphase begins. Cohesin near centromeres and telomeres is cleaved at the same rate and time. Protein phosphatase PP2A<sup>Cdc55</sup> inhibits cohesin cleavage by counteracting polo-kinase phosphorylation of Scc1. In early anaphase, the previously described separase inhibition of PP2A<sup>Cdc55</sup> promotes cohesin cleavage. Thus, separase acts directly on Scc1 to cleave it, and also indirectly, through inhibition of PP2A<sup>Cdc55</sup>, to

stimulate its phosphorylation and cleavage. This may provide a feedforward loop that could contribute to a robust and timely anaphase.

374

**Cohesion fatigue: chromatid separation in the absence of Cohesin cleavage.**

*J. Daum<sup>1</sup>, S. Sivakumar<sup>1,2</sup>, G. Gorbsky<sup>1,2</sup>; <sup>1</sup>CCCB, Oklahoma Medical Research Foundation, Oklahoma City, OK, <sup>2</sup>Cell Biology, OUHSC, Oklahoma City, OK*

During chromosome duplication in S phase, the cohesin complex is loaded upon and provides cohesion between homologous sister chromatids until the onset of anaphase in mitosis. Cohesion resists the pulling forces generated by the mitotic spindle and allows the cell to orient paired sister chromatids such that each individual chromatid will form interactions with microtubules emanating from opposing centrosomes of the mitotic spindle. At the transition from metaphase to anaphase, cohesion is lost and individual chromatids proceed to opposite poles of the cell ensuring that both daughter cells receive the appropriate complement of chromosomes. During this transition, the loss of cohesion is accompanied by the cleavage of SCC1/RAD21, a component of the cohesin complex. Accordingly, the strict regulation of cohesion by the cohesin complex is critical for the maintenance of ploidy. Recently, we described a phenomenon termed cohesion fatigue that occurs when cells are delayed at metaphase wherein paired sister chromatids separate from each other prior to the regulated cleavage of SCC/RAD21 and the onset of anaphase. We isolated chromosomes from mitotic cells that had undergone cohesion fatigue and from cells with intact sister chromatid cohesion. Surprisingly we found little difference between levels of SCC1/RAD21 and other cohesin complex members associated with paired sister chromatids and the amounts associated with separated individual chromatids. Therefore it is possible to lose sister chromatid cohesion without cleaving SCC1/RAD21 and without observable loss of chromosome-associated cohesin complex. Cohesion fatigue proceeds asynchronously within cells and evidence of fatigue, noted by abnormal increases in distances between paired sister centromeres, is apparent in a subset of chromosomes when the duration of metaphase is increased only two to threefold. This condition can arise spontaneously in a subset of untreated cells as they attempt to form appropriate centromere-microtubule interactions. We show that additional recruitment of the centromeric protein, BUB1, is an early indicator of cohesion fatigue. We postulate that the earliest elements of cohesion fatigue may induce inappropriate centromere-microtubule attachments by spatially altering the intracentromeric components responsible for forming and maintaining correct interactions. Cohesion fatigue may cause additional delays in mitotic progression, lagging chromosomes during anaphase, centromere fission, or the generation of micronuclei. These errors are implicated in the failure to maintain ploidy during mitosis and meiosis and in carcinogenesis.

375

**Induction of Premature Chromosome Condensation without Histone H1 Phosphorylation.**

*J. R. Paulson<sup>1</sup>, E. Vander Mause<sup>1</sup>, T. J. Schultz<sup>1</sup>, W. C. Earnshaw<sup>2</sup>; <sup>1</sup>Chemistry, University of Wisconsin Oshkosh, Oshkosh, WI, <sup>2</sup>Institute of Cell and Molecular Biology, University of Edinburgh, Edinburgh, Scotland*

We have found that calyculin A, a specific inhibitor of Protein Phosphatases 1 and 2A, induces prematurely condensed chromosomes (PCC) in interphase HeLa cells at any point in the cell cycle. However, under conditions where Cdk1 is inhibited or at points in the cell cycle where Cdk1/Cyclin B cannot be activated, histone H1 does not become phosphorylated in the calyculin A-induced PCC. These results indicate that H1 phosphorylation and Cdk1/cyclin B activity are

not essential for PCC. They also suggest that when Cdk1/cyclin B triggers mitosis, it may exert its effects at least in part by inactivation of protein phosphatases, and this role can be mimicked by calyculin A. We propose that in the onset of mitosis, inactivation or sequestration of protein phosphatases may be just as important as activation of protein kinases.

376

**Aurora B function depends on dissociation kinetics at the inner centromere.**

*E. R. Ballister<sup>1</sup>, M. Li<sup>2</sup>, M. A. Lampson<sup>2</sup>; <sup>1</sup>BMB Graduate Group, University of Pennsylvania, Philadelphia, PA, <sup>2</sup>Department of Biology, University of Pennsylvania, Philadelphia, PA*

The Chromosomal Passenger Complex (CPC), localizes predominantly to inner centromeres during mitosis. Aurora B kinase, the enzymatic component of the CPC, phosphorylates spatially distant substrates, particularly microtubule-binding proteins at the outer kinetochore, to destabilize erroneous kinetochore-microtubule attachments. How the CPC physically accesses its outlying substrates, and how this access is regulated to achieve proper Aurora B function are unknown. We propose a model in which the CPC is fully activated by autophosphorylation at high concentration in the inner centromere, and this activated form of the complex accesses distant substrates by dissociation and diffusion from the inner centromere. This model implies that Aurora B function depends on the dissociation rate of the CPC from the inner centromere. To test this hypothesis, we sought to experimentally decrease the rate of dissociation of the CPC by increasing its affinity for the inner centromere. We constructed a mutant version of INCENP, the CPC scaffolding protein, with an extra copy of the domain that binds Borealin and Survivin, the CPC members which direct localization to the inner centromere. This “two-footed” or “bipedal” INCENP localizes normally to the inner centromere but dissociates more slowly than wild-type INCENP, as measured by FRAP. In addition, bipedal INCENP is retained at centromeres following anaphase, consistent with increased affinity for centromeres. We compared wild-type to bipedal INCENP in functional assays for correction of chromosome attachment defects. Cells expressing bipedal INCENP exhibit increased frequency of chromosome attachment errors following recovery from either a monopolar spindle (monastrol washout) or from microtubule depolymerization (nocodazole washout). These errors are characteristic of defective Aurora B function. We conclude that Aurora B-mediated error correction depends on its localization to the inner centromere and its dissociation rate.

377

**Phosphoregulation of Ndc80 and Dam1 subcomplexes promotes release of kinetochores from microtubules via multiple mechanisms.**

*K. K. Sarangapani<sup>1</sup>, B. Akiyoshi<sup>2</sup>, N. M. Duggan<sup>3</sup>, S. Biggins<sup>3</sup>, C. L. Asbury<sup>1</sup>; <sup>1</sup>Physiology & Biophysics, University of Washington, Seattle, WA, <sup>2</sup>Molecular Microbiology, University of Oxford, Oxford, England, <sup>3</sup>Division of Basic Sciences, Fred Hutchinson Cancer Research Center, Seattle, WA*

During mitosis, multiprotein complexes called kinetochores orchestrate chromosome segregation by forming load-bearing attachments to dynamic microtubule tips, and by participating in phosphoregulatory error correction. Aurora B kinase phosphorylates the major microtubule-binding subcomplexes, Ndc80 and (in yeast) Dam1, to promote release of erroneous attachments, thereby giving another chance for proper attachments to form. It is unknown whether Aurora phosphorylation promotes release directly, by increasing the rate of kinetochore detachment, or indirectly, by destabilizing the microtubule tip or disrupting the kinetochore structure itself. Moreover, the relative importance of phosphorylation of Ndc80 versus Dam1 in the context of whole kinetochores is unclear. To address these uncertainties we isolated native yeast kinetochore particles carrying phosphomimetic mutations on Ndc80

and Dam1, and applied advanced laser trapping techniques to measure the strength and stability of their attachments to individual dynamic microtubule tips. Composition of the purified particles was unaffected by the phosphomimetic mutations, suggesting that phosphorylation at these sites does not disrupt kinetochore structure. Rupture forces were reduced by phosphomimetics on both subcomplexes, in an additive manner, indicating that both subcomplexes make independent contributions to attachment strength. Likewise, phosphomimetics on either subcomplex reduced attachment lifetimes under constant force, primarily by accelerating detachment during microtubule growth and shortening. Phosphomimetics on Dam1 also increased the likelihood of switches from microtubule growth into shortening, further promoting release in an indirect manner. Together our results suggest that, *in vivo*, Aurora B releases kinetochores via at least two mechanisms – by directly weakening the kinetochore-microtubule interface, and also by destabilizing kinetochore-attached microtubule tips.

378

**Mad2 is essential in the absence of centrosomes for cell cycle progression.**

A. Wainman<sup>1</sup>, J. Raff<sup>1</sup>; <sup>1</sup>Pathology, University of Oxford, Oxford, United Kingdom

Centrosomes act in eukaryotic cells as the major microtubule organizing centers (MTOCs). In addition, many important regulatory and signalling proteins localise to the centrosome. In light of this it is somewhat surprising that flies get to adult stages of life in the absence of centrosomes (Basto et al.). Here, we have taken a genetic approach to elucidate whether compensatory mechanisms exist to enable cell division in the absence of centrosomes. We observe that cells lacking centrosomes and the protein Mad2, essential for proper spindle assembly checkpoint function, arrest in the cell cycle. This phenotype appears to be non mitotic and microtubule independent suggesting an interphase role for Mad2 which facilitates non-centrosomal cells to divide.

**Characterizing Laulimalide using *C. elegans* embryo.**

M. S. Baja<sup>1</sup>, M. Srayko<sup>1</sup>; <sup>1</sup>Biological Sciences, University of Alberta, Edmonton, AB, Canada

Marine organisms have served as an important source for chemicals that target eukaryotic microtubules and hence they have been used to isolate new anti-cancer molecules. In one such screen done using the marine sponge, *Cacospongia mycofijiensis*, a crude lipophilic extract yielded the compound laulimalide (Mooberry S.L., et al 1999, Pryor D.E., et al 2002). Laulimalide is known to disrupt the normal microtubule assembly and cause bundling of microtubules. It is known to inhibit cell proliferation and initiate mitotic arrest. Studies done using mammalian cell lines suggests that laulimalide leads to failure in proper chromosome segregation and cytokinesis. In some cases it has been observed that, similar to paclitaxel, it induces microtubule stabilization. Studies done so far using mammalian cell lines show that laulimalide causes cytotoxicity however, its precise effect on cytoskeletal structures and mode of action is unclear. Mammalian cells can take up to 20 hours to divide; therefore acute effects of the drug are often not readily apparent.

In the present study we have used the first mitotic division in the *Caenorhabditis elegans* embryo to characterize laulimalide. The early cell division events in *C. elegans* have been studied in detail. The *C. elegans* embryo serves as an excellent system for the preliminary characterization of microtubule-targeted drugs because morphological changes to the cytoskeleton occur rapidly and are highly stereotypical. In *C. elegans* embryo the use of small molecule inhibitors is limited by eggshell impermeability. We have used an RNAi-based

approach to create a permeable eggshell (Carvalho A., et al 2011). We have observed dose-dependent phenotypes for laulimalide, whereby different concentrations lead to stabilization or destabilization of microtubules. We have also carried out experiments to look for synergistic effects of laulimalide and paclitaxel on microtubules. In the present study, results will be presented to characterize the similarities and differences between paclitaxel and laulimalide with respect to their effects on the microtubule cytoskeleton in the one-cell *C. elegans* embryo.

**SKAP forms a link between kinetochore core complex KMN and dynamic spindle microtubules.**

X. Wang<sup>1</sup>, Y. Chu<sup>1</sup>, P. Yao<sup>2</sup>, D. Cao<sup>3</sup>, Y. Huang<sup>2</sup>, T. Ward<sup>1</sup>, X. Yao<sup>3</sup>, Z. Dou<sup>4</sup>; <sup>1</sup>Physiology, Morehouse School of Medicine, Atlanta, GA, <sup>2</sup>Georgia Cancer Coalition, Atlanta, GA, <sup>3</sup>Cellular Dynamics, University of Science & Technology of China, Hefei, China, <sup>4</sup>Anhui Laboratory for Chemical Biology, Hefei, China

Chromosome segregation in mitosis is orchestrated by the dynamic interactions between the kinetochore and spindle microtubules. Our recent study shows that mitotic motor CENP-E cooperates with SKAP to orchestrate an accurate chromosome movement in mitosis (J. Biol. Chem. 287, 1500-9). However, it remains elusive as how kinetochore core microtubule-binding activity KMN (KNL-MIS12-NDC80) regulates microtubule plus-end dynamics. Here, we identify a novel interaction between MIS13 and SKAP which orchestrates accurate interaction between kinetochore and dynamic spindle microtubules. SKAP physically interacts with MIS13 and specifies kinetochore localization of SKAP. Suppression of MIS13 by small interfering RNA abrogates the kinetochore localization of SKAP. Total internal reflection fluorescence microscopic assays demonstrate that SKAP exhibits an EB1-dependent, microtubule plus-end loading and tracking in vitro. Importantly, SKAP is essential for kinetochore oscillations and dynamics of microtubule plus ends during live cell mitosis. Based on those findings, we reason that SKAP constitutes a dynamic link between spindle microtubule plus ends and mitotic chromosomes to achieve faithful cell division.

381

**Molecular mechanism of EB1 family proteins in regulating microtubule dynamics.**

M. Iimori<sup>1</sup>, S. Kiyonari<sup>2</sup>, I. Hayashi<sup>3</sup>, T. Matsumoto<sup>4</sup>, H. Kitao<sup>1</sup>, Y. Maehara<sup>5</sup>; <sup>1</sup>Department of Molecular Oncology, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan, <sup>2</sup>Innovation Center for Medical Redox Navigation, Kyushu University, Fukuoka, Japan, <sup>3</sup>Graduate School of Nanobioscience, Yokohama City University, Yokohama, Japan, <sup>4</sup>Radiation Biology Center, Kyoto University, Kyoto, Japan, <sup>5</sup>Department of Surgery and Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan

Microtubule dynamics at the plus end, called dynamic instability, is important for proper cellular functions, such as migration, differentiation and cell division. Plus-end tracking proteins (+TIPs), which accumulate selectively at growing microtubule plus ends are considered to play an important role in regulating of stability of microtubules. Among them, EB1 is highly conserved across eukaryotes. The recent studies demonstrated that most of the other +TIPs, which can directly interact with microtubules, are able to bind to EB1, suggesting that EB1 may function as a central hub in the network of +TIPs.

Mutational analysis of *mal3*, a fission yeast homolog of EB1, showed that Mal3 was phosphorylated at a cluster of serine/threonine residues in the linker connecting the CH domain and EB1-like C-terminal motif. The phosphorylation reduced the binding affinity of Mal3 to microtubules, thereby regulating microtubule dynamics. In human cells, we noticed that

treatment of cells with mitotic arrest-inducible drugs results in the phosphorylation of EB2, but not of EB1 and the phosphorylation occurred in mitosis, but not in interphase. Furthermore, phosphorylation of EB2 was diminished by inhibition of aurora B kinase. The aurora B kinase has an important role in the mitotic progression, especially in correcting spindle-kinetochore attachments during chromosome segregation. To evaluate the significance of EB2 phosphorylation, we established cell lines expressing a RNAi-resistant EB2-EGFP. Expression of EB2 nonphosphorylatable form led to chromosome alignment defect in metaphase. Currently, we are attempting to elucidate the biological significance of EB2 phosphorylation.

**Psr1p interacts with SUN/sad1p and EB1/mal3p to establish the bipolar spindle.**

*C. Fu<sup>1,2,3</sup>, K. Scheffler<sup>4</sup>, V. Syrovaktina<sup>3</sup>, T. Li<sup>1,2</sup>, P. Tran<sup>3,4</sup>; <sup>1</sup>HKU-Shenzhen Institute of Research and Innovation, Shenzhen, China, <sup>2</sup>Department of Biochemistry, The University of Hong Kong, Hong Kong, China, <sup>3</sup>Cell and Developmental Biology, The University of Pennsylvania, Philadelphia, PA, <sup>4</sup>Institut Curie - CNRS, Paris, France*

During mitosis, interpolar microtubules from two spindle pole bodies (SPBs) interdigitate to create an antiparallel microtubule array for accommodating numerous regulatory proteins. Among these proteins, the kinesin-5 cut7p/Eg5 is the key player responsible for sliding apart antiparallel microtubules and thus helps in establishing the bipolar spindle. At the onset of mitosis, two SPBs are adjacent to one another with most microtubules running nearly parallel toward the nuclear envelope, creating an unfavorable microtubule configuration for the kinesin-5 kinesins. Therefore, how the cell organizes the antiparallel microtubule array in the first place at mitotic onset remains enigmatic. Here, we show that a novel protein psr1p localizes to the SPB and plays a key role in organizing the antiparallel microtubule array. The absence of psr1+ leads to a transient monopolar spindle and massive chromosome loss. Further functional characterization demonstrates that psr1p is recruited to the SPB through interaction with the conserved SUN protein sad1p and that psr1p physically interacts with the conserved microtubule plus tip protein mal3p/EB1. These results suggest a model that psr1p serves as a linking protein between sad1p/SUN and mal3p/EB1 to allow microtubule plus ends to be coupled to the SPBs for organization of an antiparallel microtubule array. Thus, we conclude that psr1p is involved in organizing the antiparallel microtubule array in the first place at mitosis onset by interaction with SUN/sad1p and EB1/mal3p, thereby establishing the bipolar spindle.

**Branching microtubule nucleation in *Xenopus* egg extracts mediated by augmin and TPX2.**

*S. Petry<sup>1</sup>, A. C. Groen<sup>2</sup>, K. Ishihara<sup>2</sup>, T. J. Mitchison<sup>2</sup>, R. D. Vale<sup>1</sup>; <sup>1</sup>UCSF, San Francisco, CA, <sup>2</sup>Harvard Medical School, Boston, MA*

Mitotic and meiotic spindles are formed by local nucleation of microtubules. Nucleation occurs at centrosomes in animal mitotic spindles. It is also thought to occur within metazoan spindles, stimulated by signals from chromatin, but this has not been observed directly. Here, we demonstrate microtubule nucleation from existing microtubules in meiotic *Xenopus* egg extracts. Daughter microtubules grew with the same polarity as mother filaments, preserving local polarity. Branching microtubule nucleation reaction required g-tubulin and augmin and was stimulated by RanGTP and its effector Tpx2, factors previously implicated in chromatin-stimulated nucleation. A low branch angle leading to local preservation of polarity make microtubule-dependent microtubule nucleation well suited for spindle assembly and maintenance.

384

### Differences in Ran regulation and the microtubule-associated protein TPX2 contribute to interspecies spindle scaling in *Xenopus* egg extracts.

K. Helmke<sup>1</sup>, R. Heald<sup>1</sup>; <sup>1</sup>Department of Molecular and Cell Biology, University of California Berkeley, Berkeley, CA

A bipolar, microtubule (MT)-based spindle performs the crucial and universal function of segregating chromosomes during eukaryotic cell division, but spindle size, assembly mechanism and architecture vary depending on the organism and cell type. We previously established an egg extract system that recapitulates size differences between meiotic spindles of the frog *Xenopus laevis* and its smaller relative *Xenopus tropicalis*, and identified differential phosphorylation of the MT severing factor katanin as a spindle length scaling mechanism. However, katanin activity does not fully account for meiotic spindle differences between the two species. Interestingly, we have found that the small *X. tropicalis* spindles are resistant to inhibition of RCC1, the chromatin-bound nucleotide exchange factor that generates a gradient of RanGTP, whereas the large *X. laevis* spindles are disrupted with concomitant mislocalization of downstream factors including the spindle MT-associated protein TPX2. Interestingly, TPX2 is present at three-fold higher levels in *X. tropicalis* extract and is missing a 7 amino acid insertion found in *X. laevis* TPX2 that introduces two consensus Polo kinase phosphorylation sites. When added to *X. laevis* extract in equal amounts, both *X. tropicalis* TPX2 and an *X. laevis* TPX2 mutant lacking the 7 amino acid insertion induce dramatic MT nucleation compared to wild-type *X. laevis* TPX2. We are testing the hypothesis that phosphorylation inhibits TPX2 activity in *X. laevis* extract, causing a decrease in MT nucleation that affects spindle size. Consistent with this model, addition of excess TPX2 to *X. laevis* extract reduced spindle length. Higher levels and activity of TPX2 may decrease average MT length in the *X. tropicalis* spindle, and could also act to decrease kinesin-5 dependent MT sliding. Both of these mechanisms would limit the distance that a spindle MT slides poleward in its lifetime, thereby decreasing steady state spindle length. Thus, differences in meiotic spindle size in the two *Xenopus* species are accompanied by changes in MT nucleation and stability that reflect differences in spindle architecture and assembly pathway.

385

### Incremental phosphorylation of competing NDC80 complexes tunes kinetochores for diverse mitotic functions.

A. V. Zaytsev<sup>1,2</sup>, L. J. Sundin<sup>3</sup>, B. Nikashin<sup>1</sup>, K. F. DeLuca<sup>3</sup>, J. Mick<sup>3</sup>, G. J. Guimaraes<sup>3</sup>, F. I. Ataullakhanov<sup>2,4</sup>, E. L. Grishchuk<sup>1</sup>, J. G. DeLuca<sup>3</sup>; <sup>1</sup>Physiology Department, University of Pennsylvania, Philadelphia, PA, <sup>2</sup>Ctr Theoretical Problems Physicoche, Moscow, Russia, <sup>3</sup>Department of Biochemistry, Colorado State University, Fort Collins, CO, <sup>4</sup>Physics Department, Moscow State University, Moscow, Russia

The stability of kinetochore-microtubule (KMT) attachments is finely tuned to drive different mitotic processes. This dynamic regulation is essential for accurate chromosome segregation, and involves phosphorylation of NDC80, a major component of the MT-binding interface at kinetochores. The fundamental question of how the number and stability of KMT attachments is regulated by phosphorylation remains unanswered. To address this question and create an integrated view of the KMT interface, we used a combination of quantitative approaches in vivo, in vitro and in silico. To determine the molecular characteristics and dynamic range of Hec1 phosphorylation in human cells we replaced Hec1 with a series of mutants that prohibit its phosphoregulation. Although chromosome segregation was perturbed, some mitotic processes, including release of erroneous kinetochore-microtubule attachments and chromosome oscillations, proceeded normally. However, they required different numbers of phospho-mimetic

substitutions in Hec1. With single molecule methods in vitro we then determined the molecular characteristics of MT binding of the Hec1-containing NDC80 complexes, and how these interactions depend on Hec1 tail phosphorylation. We found that Hec1 tail phosphorylation leads to a graded increase in NDC80 diffusion and shortening of residency time, but cooperativity of NDC80-MT binding is only weakly affected by Hec1 tail phosphorylation. Using four independent approaches we conclude that phosphorylation of the Hec1 tail results in the incremental decrease in NDC80-MT binding energy. To seek a quantitative understanding of regulation of KMT attachments by NDC80 phosphorylation the data from single molecular and cellular scales were then linked with advanced computational approaches. We show that modeling the KMT interface with “repetitive sites” of NDC80 complexes greatly amplified the phosphorylation-dependent tuning of single NDC80 complexes, but a “dynamic lawn” interface of un-clustered NDC80 complexes produced an excellent fit to the phosphorylation-driven KMT affinity both in prometaphase and metaphase. We conclude that incremental phosphorylation of Hec1 drives large-scale tuning of kinetochore-microtubule affinity.

386

### **Integration of kinase/phosphatase activities at kinetochores by the mitotic pseudokinase BUBR1.**

*S. Suijkerbuijk<sup>1</sup>, G. J. Kops<sup>1</sup>; <sup>1</sup>UMC Utrecht, Utrecht, Netherlands*

Maintenance of chromosomal stability depends on error-free segregation of chromosomes. The pseudokinase BUBR1 is essential for this, as it is a core component of the mitotic checkpoint and it is required for the formation of stable kinetochore-microtubule attachments. The mechanism by which BUBR1 regulates stability of attachments is unknown, but it is controlled by PLK1 activity and involves Aurora B-mediated error-correction. We have identified a conserved and highly phosphorylated domain (KARD) in BUBR1 that is crucial for formation of kinetochore-microtubule attachments. Deletion of this domain or prevention of its phosphorylation abolishes formation of kinetochore microtubules, which can be reverted by inhibiting Aurora B activity. Tension-sensitive phosphorylation of the KARD by PLK1 promotes direct interaction of BUBR1 with the PP2A-B56 $\alpha$  phosphatase that counters excessive Aurora B activity at kinetochores. As a result, removal of BUBR1 from mitotic cells or inhibition of PLK1 reduces PP2A-B56 kinetochore binding and elevates phosphorylation of Aurora B substrates on the outer-kinetochore. We propose that PLK1 and BUBR1 cooperate to stabilise kinetochore-microtubule interactions by regulating PP2A-B56-mediated de-phosphorylation of Aurora B substrates at the kinetochore-microtubule interface.

387

### **Loss of the cohesin subunit STAG2 induces chromosomal instability by disrupting kinetochore-microtubule attachments during mitosis.**

*M. Kleyman<sup>1</sup>, L. Kabeche<sup>1</sup>, D. Compton<sup>1</sup>; <sup>1</sup>Geisel School of Medicine at Dartmouth College, Hanover, NH*

The cohesin complex is vital for proper chromosome segregation in mitosis. Mutations in cohesin genes have been found in colon cancers as well as cell lines originating from different cancers. Recently, loss of function mutations in the STAG2 gene, which encodes a cohesin subunit, have been described in a variety of tumor types. Interestingly, STAG2-deficient cells do not display a complete loss of sister chromatid cohesion or gross alterations in gene expression. Instead, they display a slight loss of centromeric cohesion and a significant increase in the frequency of lagging chromosomes during anaphase. Lagging chromosomes are a hallmark of chromosomal instability (CIN) – the persistently high rate of chromosome loss

and/or gain – and arise from persistent errors in the attachment of microtubules to kinetochores. To investigate the cause of increased lagging chromosomes in anaphase upon loss of STAG2 we are using RNA interference in human diploid RPE-1 cells. STAG2-depleted RPE-1 cells maintain a spindle assembly checkpoint response. Furthermore, they display no change in the frequency of formation of multipolar spindles indicating no increased propensity for forming erroneous kinetochore-microtubule attachments. However, we demonstrate that STAG2 depletion increases kinetochore-microtubule attachment stability from  $1.8 \pm 0.6$  min to  $4.6 \pm 2.5$  min in prometaphase and  $3.8 \pm 1.1$  min to  $8.5 \pm 3.0$  min in metaphase. This decreases the efficiency of correction of kinetochore-microtubule attachment errors and accounts for the increased frequency of lagging chromosomes in anaphase. Additionally, STAG2 depletion induces a 20% increase in centromere length as well as a mislocalization of the CPC components Aurora B and INCENP on chromosomes. Thus, loss of the cohesin subunit STAG2 induces CIN in cancer cells by disrupting the appropriate regulation of kinetochore-microtubule attachments through the inner centromere signaling pathway.

## Spindle Checkpoints

388

### Mechanical constraints induce mitotic arrest in multicellular tumor spheroid.

A. Desmaison<sup>1</sup>, K. Grenier<sup>2</sup>, B. Ducommun<sup>1</sup>, V. Lobjois<sup>1</sup>; <sup>1</sup>ITAV-CNRS, Toulouse, France, <sup>2</sup>Laas-CNRS, Toulouse, France

Modification of the extra cellular matrix stiffness has been reported to affect tumor growth. As several studies performed on monolayer cell-based model suggest that mechanical cues impair cell division, we wondered whether environmental constraints might also affect cell cycle control within a tissue.

To address that issue, we used MultiCellular Tumor Spheroid (MCTS), a 3D model recapitulating the microenvironment, the proliferative gradient and cell-cell interactions found in a tumor. We first designed, produced and used dedicated polymer microdevices in which MCTS engineered to express fluorescent biomarkers were confined to apply mechanical constraints. We observe that under constraints, MCTS display a higher proportion of proliferative cells in low compression regions. Strikingly, this modification of the proliferation gradient is associated with accumulation of mitotic cells (pHistone H3 +) in compressed regions. We show that these cells remain arrested at mitosis for at least 24 hours (EdU incorporation neg.) and that mitotic arrest is not caused by impairment of rounding.

We next used live SPIM (Selective Plane Illumination Microscopy) 3D imaging to monitor mitosis progression in isotropically constrained MCTS. We show that constraints impair bipolar spindle assembly and delay progression toward metaphase-anaphase transition.

Our data indicate that in a multicellular structure mechanical constraints are responsible for a defect in cell cycle progression associated with a mitotic arrest.

389

### The spindle checkpoint senses spindle asymmetry.

C. Tan<sup>1</sup>, S. Reggi<sup>1</sup>, I. Gašić<sup>1</sup>, M. Barišić<sup>2</sup>, H. Maiato<sup>2</sup>, P. Meraldi<sup>1</sup>; <sup>1</sup>Institute of Biochemistry, ETH Zurich, Zürich, Switzerland, <sup>2</sup>Institute for Molecular and Cell Biology, University of Porto, Porto, Portugal

The alignment of chromosomes in the middle of the mitotic spindle is a very distinctive feature of all dividing metazoan cells. Even asymmetrically dividing cells such as *Drosophila* neuroblasts

first build symmetric spindles before elongating asymmetrically during anaphase. Such a centering mechanism is likely necessary for error-free chromosome segregation and precise positioning of chromosomes after division. According to our current understanding, the spindle checkpoint only monitors kinetochore-microtubule attachments and bipolar tension of kinetochores. Is the alignment of chromosomes in the middle just a consequence of this microtubule attachment, or is its reproducibility also ensured by a checkpoint mechanism? To investigate this, we generated asymmetric mitotic spindles in HeLa cells by depleting HsSAS-6, a protein required for centriole duplication. In severe asymmetry, where only 1 centrosome is present in the cell, a highly asymmetric, monopolar spindle is formed and the spindle checkpoint is strongly activated. However, in a milder asymmetry where both centrosomes are present but one centrosome lacks a daughter centriole, a bipolar spindle can be formed but the spindle is asymmetric: the metaphase plate is displaced from the middle, further away from the centrosome with 2 centrioles. These asymmetric spindles are still able to form normal metaphase plates with oscillating, bipolarly attached kinetochores that have normal attachment and tension (based on Mad2 status and inter-kinetochore distances). Strikingly, these asymmetric cells experience a delay in the metaphase-anaphase transition, spending twice the amount of time in metaphase compared to cells with symmetric spindles. Furthermore, prior to anaphase onset, the position of the metaphase plate is corrected to the middle of the spindle, suggesting that the additional time required by the cell is used to correct spindle asymmetry. Abrogation of the spindle checkpoint not only removes the anaphase delay, it also allows the cell to progress to anaphase without correcting spindle asymmetry. This suggests that the alignment of chromosomes in the middle is not just a consequence of symmetric spindle poles, but rather the result of active correction mechanisms and a control checkpoint. We are now trying to elucidate how the spindle checkpoint is able to sense spindle asymmetry. Our preliminary results show that asymmetric spindles have different microtubule stability at the poles and different microtubule flux in each half-spindle. Additionally, cells with asymmetric spindles have more kinetochores with reduced SKAP levels, indicating higher Aurora B activity at the kinetochores. We thus hypothesize that the spindle checkpoint monitors spindle symmetry by measuring microtubule occupancy or stability at the kinetochore.

390

### **The Mad2-binding motif in Cdc20 contributes to activation of the Anaphase-Promoting Complex/Cyclosome.**

Y-F. Wu<sup>1</sup>, S. C. Schuyler<sup>1</sup>; <sup>1</sup>Department of Biomedical Sciences, Chang Gung University, Kwei-Shan, Taiwan

The spindle checkpoint prevents cell cycle progression in response to unattached kinetochores by regulating the activity of the Anaphase Promoting Complex/Cyclosome (APC/C), an E3-ubiquitin ligase. Cell Division Cycle 20 (Cdc20), a co-activator of the APC/C in mitosis, is targeted for inhibition, in part, by the spindle checkpoint component mitotic arrest deficient 2 (Mad2). Cdc20 has four known functional motifs and domains: the Mad2-binding motif, a WD40 domain, the C-box motif, and the IR motif. The IR and C-box motifs have been proposed to contribute to Cdc20's ability to interact with and/or activate the APC/C, and the WD40 domain is thought to interact with both target substrates and APC/C subunits to promote substrate ubiquitinylation. Currently, the only proposed role for the Mad2-binding motif is to serve as the binding site for Mad2. How Mad2 interacting with the Mad2-binding motif leads to APC/C<sup>Cdc20</sup> inhibition remains unknown. Previously isolated mutant alleles of Cdc20 that allow cells to bypass Mad2-dependent spindle checkpoint inhibition of cell cycle progression were found to contain mutations in the Mad2-binding motif, where these separation of function mutant alleles are still able to support APC/C activation *in vivo*. In order to investigate how Mad2 interacting with the Mad2-binding motif leads to APC/C<sup>Cdc20</sup> inhibition, we have employed quantitative *in*

*in vitro* APC/C<sup>Cdc20</sup> and APC/C<sup>Cdc20-127</sup> enzyme assays to characterize one of these mutant by-pass alleles, namely Cdc20-127. As expected, the addition of Mad2 inhibited APC/C<sup>Cdc20</sup> activity, but had no effect on APC/C<sup>Cdc20-127</sup> activity. However, we have observed a significant difference in the ability of Cdc20-127 to function as an APC/C co-activator. *In vitro* transcription/translation in the presence of <sup>35</sup>S-Methionine revealed no difference in protein amounts or stability between Cdc20 and Cdc20-127 proteins. This suggested that the observed difference in co-activator activity was due to a change in the ability of Cdc20-127 to interact with or activate the APC/C. These observations have led us to hypothesize that the Mad2-binding motif in Cdc20 may have dual functions: one as the binding site for Mad2 with Cdc20, and a second function as an activator that promotes APC/C enzyme activity. To explore this hypothesis, we are currently engaged in investigating the co-activator activities of several other spindle checkpoint by-pass alleles of Cdc20, all of which contain mutations in the Mad2-binding motif.

391

**Mad2B is involved in the DNA damage response and not in the mitotic checkpoint.**

J-H. Kim<sup>1</sup>, P. Lara-Gonzalez<sup>2</sup>, R. Patel<sup>1</sup>; <sup>1</sup>Biochemistry, University of Leicester, Leicester, United Kingdom, <sup>2</sup>Faculty of Life Sciences, University of Manchester, Manchester, United Kingdom

Mad2B (also called Rev7 or Mad2L2) is a regulatory subunit of DNA polymerase  $\zeta$  that is involved in translesion DNA synthesis. Previous studies have implicated Mad2B in several cell functions including cell cycle regulation, where it was shown to inhibit the Anaphase Promoting Complex (APC)/cyclosome by binding to Cdc20/Cdh1. As Mad2B shares 26% identity and 48% similarity at the amino acid level with the human mitotic checkpoint protein Mad2, it has been suggested that Mad2B may also function as a mitotic checkpoint protein. However, the results of our studies indicate that Mad2B is not a mitotic checkpoint protein. Instead, our data show that Mad2B does bind to Cdc20, but only following DNA damage, and suggests that Mad2B has a role in the mammalian DNA damage response.

392B442

**Measuring aneuploidy by counting yeast artificial chromosomes in *mad2* spindle checkpoint mutant cells.**

S. C. Schuyler<sup>1</sup>, Y-S. Ding<sup>1</sup>, Y-C. Lee<sup>1</sup>, L-I. Wang<sup>1</sup>, P. Lai<sup>1</sup>; <sup>1</sup>Department of Biomedical Sciences, Chang Gung University, Kwei-Shan, Taiwan

Our goal was to investigate the degree of aneuploidy arising in response to loss of *MAD2* spindle checkpoint function in budding yeast. In the past, yeast artificial chromosomes have been employed to measure chromosome loss rates in both wild and *mad2* mutant cells. However, a corresponding direct measurement of the degree of aneuploidy in *mad2* mutants, as determined by counting the average number of artificial chromosomes per cell, has not been reported. Towards this end, the phenotypes and average copy number per cell for both low-copy and high-copy short-linear and circular artificial chromosomes was explored in haploid and diploid cells where Mad2 expression was either normal, reduced, or removed. As expected, in a previously developed genetically sensitized plate assay, where cell growth depends upon loss of *MAD2* function in response to loss of chromosome tension, cells carrying low-copy and high-copy circular artificial chromosomes do not display a phenotype. By contrast, and consistent with previous observations with low-copy short-linear chromosomes, both haploids and diploids carrying low-copy or high-copy short-linear chromosomes displayed a similar loss of *MAD2*-dependent growth phenotype. In this same sensitized genetic background, and consistent with previous observations on wild type cells, short-linear chromosomes also displayed an increase in average copy number per cell relative to circular chromosomes. Combined, the plate

phenotypes and the observed increases in aneuploidy both correlate with a unique feature short-linear chromosomes: namely that they undergo premature sister chromatid separation, leading to a loss in chromosome tension, whereas circular chromosomes do not. Wild type diploid cells accumulated high-copy short-linear chromosomes, with an average limit of 8-9 chromosomes per cell. Consistent with previous observations in wild type diploid cells, forcing *MAD2/MAD2* diploid cells in our genetic background to carry a high-copy number of short-linear chromosomes led to a decrease in the chromosome retention rate. By contrast, *MAD2* heterozygotes and *MAD2* homozygous delete diploid cells displayed a decrease in the average chromosome copy number per cell, but maintained normal chromosome retention rates. Our observations indicate that Mad2 function is required to maintain high levels of aneuploidy, but that Mad2 also contributes to a decrease in chromosome retention rate when chromosome numbers become aberrantly high.

393

**Catalytic Amplification of the BubR1-Cdc20 Mitotic Checkpoint Inhibitor by Mad2-induced Conformational Switch in Cdc20.**

*J. Han<sup>1,2</sup>, A. J. Holland<sup>1</sup>, D. Fachinetti<sup>1</sup>, A. Kulukian<sup>1</sup>, B. Cetin<sup>1</sup>, D. W. Cleveland<sup>1,2</sup>; <sup>1</sup>Ludwig Institute for Cancer Research, La Jolla, CA, <sup>2</sup>Cellular and Molecular Medicine, University of California at San Diego, La Jolla, CA*

The mitotic checkpoint acts to maintain chromosome content by generation of a diffusible “wait anaphase” inhibitor. Unattached kinetochores catalyze a conformational shift in Mad2, converting an inactive open form into a closed one that can capture Cdc20, the mitotic activator of the APC/C ubiquitin ligase. Mad2 binding is now shown to promote a conformational switch in Cdc20, exposing a previously inaccessible site for binding to BubR1’s conserved Mad3 homology domain. BubR1, but not Mad2, binding to APC/CCdc20 is demonstrated to inhibit ubiquitination of cyclin B. Closed Mad2 is further shown to catalytically amplify production of BubR1-Cdc20 without necessarily being part of the complex. Thus, the mitotic checkpoint is produced by a cascade of two catalytic steps, an initial one acting at unattached kinetochores to produce a diffusible Mad2-Cdc20 intermediate and a diffusible one in which that intermediate amplifies production of BubR1-Cdc20, the inhibitor of cyclin B ubiquitination by APC/CCdc20.

394

**Differential regulation of the mitotic spindle assembly checkpoint in stem and progenitor cells.**

*S. Kollu<sup>1,2</sup>, A. Brack<sup>1,2</sup>; <sup>1</sup>Center for Regenerative Medicine, Massachusetts General Hospital, Boston, MA, <sup>2</sup>Harvard Stem Cell Institute (HSCI), Harvard University, Boston, MA*

Cell cycle checkpoints are crucial gatekeepers monitoring the fitness of the cell to generate new progeny. For this reason, they are considered indispensable to all eukaryotic cells. However, this isn’t universally true as there are reports of differential dependencies of stem and committed progenitors on cell cycle checkpoints. For example, embryonic stem (ES) cells and immature neural progenitor cells have dormant G1/S and G2 decatenation checkpoints, which become activated only upon differentiation.

The spindle assembly checkpoint (SAC) oversees chromosome-microtubule attachments and tension during mitosis to ensure fidelity of chromosome segregation. Although extensively studied in cultured somatic cells and cancer cell lines, very little is known about it in stem and progenitor cells.

Muscle satellite cells (MuSCs) are the sole source of tissue specific stem cells for adult muscle repair. Here, we investigate the effects of disrupting the SAC in MuSCs compared to progenitor

cells (myoblasts). To this end, we have used a conditional truncated form of the critical SAC kinase Mps1 (Mps1<sup>Δ ff</sup>) that is unable to localize to the kinetochore to carry out its checkpoint function even though it has an intact kinase domain. To confer MuSC-specificity, we crossed Mps1<sup>Δ ff</sup> with Tamoxifen (Tmx) inducible Pax7Cre<sup>ER</sup> mice, which allow inducible expression of truncated form of Mps1 in MuSCs and their progeny. Induction of this truncated mutant in committed myoblasts leads to proliferative defects, which are not observed when the mutation is induced in MuSCs. Moreover, committed myoblasts with this mutation fail to differentiate, while mutant stem cells are able to differentiate normally. These results indicate that mutant stem cells are able to compensate and withstand proliferative arrest. Furthermore, when subjected to mitotic insult through nocodazole, we observe that myoblasts with the truncated Mps1 fail to arrest, suggesting an impaired SAC, but not mutant stem cells.

These results indicate that stem and progenitor cells have distinct ways of regulating their mitotic spindle assembly checkpoint.

**Localization dynamics of the Survivin splice variants in mitosis.**

R. E. Cáceres<sup>1</sup>, M. A. Andonegui<sup>1</sup>, A. López-Saavedra<sup>1</sup>, D. G. Prada<sup>1</sup>, L. A. Herrera<sup>1</sup>;

<sup>1</sup>Medicina Genómica y Toxicología Ambiental, IIB-UNAM-INCan, Mexico City, Mexico

Survivin is a multifaceted member of the IAP family of proteins with functions in the Chromosome Passenger Complex that has been shown to be over-expressed in nearly every human tumor type. Survivin splice variants 2B and Deltaex3 have been strongly correlated to cancer cell death and survival, respectively. However, the study of their roles in mitotic progression has derived in contradictory results and the mechanisms by which they exert their death regulatory functions remain largely unexplored. Furthermore, much of the Survivin isoforms study has been achieved by exogenously expressing these proteins.

Our goal was to define the endogenous Survivin variants localization throughout the cell cycle in HCT116 dividing cells in order to gain insights in their potential roles in the cell cycle regulation.

We assessed Survivin variants expression with the use of RT-PCR and found that all three isoforms studied are consistently expressed in the cell line HCT116. According to previous reports, we observed that Survivin Deltaex3 is the least expressed transcript, while Survivin and Survivin 2B show comparable levels of expression.

We then proceeded to determine Survivin variants subcellular localization in different phases of the cell cycle by the use of confocal and ELYRA high resolution microscopy (Zeiss). In interphase cells, Survivin 2B was almost exclusively localized to non-heterochromatin pinpoint regions in the nucleus. Contrarily to previous reports, no fraction of the protein was found in mitochondria. In mitosis, Survivin 2B was confined to centrosomes in prophase, metaphase and anaphase cells and later re-localized to the contractile ring during cytokinesis. However, we did not find it at any other structure of the mitotic spindle. Staining with MitoTracker revealed that Survivin 2B does not co-localize with mitochondria at any phase of mitosis either.

On the other hand, Survivin Deltaex3 was mainly accumulated at non-heterochromatin regions in the nucleus. However, there was also a pool in the cytoplasm and mitochondria. During mitosis, Survivin Deltaex3 is found outside the chromosomes. Interestingly, Survivin Deltaex3 shows a sharp decrease in anaphase, revealing a potential Anaphase Promoting Complex-dependent degradation mechanism. The mitochondrial pool of Survivin Deltaex3 seems to decrease in mitotic cells.

Survivin isoforms have not been shown to contribute to chromosome segregation. However, the localization and degradation dynamics observed in this study might have some biological significance. The question is then raised whether Survivin 2B dynamic localization or Deltaex3 degradation play a role in mitosis, other than directly participating in chromosome segregation.

### **Structure Function Analysis of the Mitotic Checkpoint Kinetochores protein, hSpindly.**

*D. Kaur<sup>1</sup>, G. Chan<sup>1</sup>; <sup>1</sup>University of Alberta, Edmonton, AB, Canada*

Spindly was shown to recruit dynein to the kinetochores in *Drosophila* S2 cells and the dynein/dynactin complex in human cells. The dynein/dynactin complex is required for alignment of chromosome during prometaphase and silencing the mitotic checkpoint following the proper attachment of chromosomes by mediating the transport of the checkpoint proteins off the kinetochores. Recruitment of Spindly to the kinetochores is dependent on the RZZ (Roughdeal, Zeste-White10 and Zwilch) complex in *Drosophila*, *C. elegans* and human cells. Spindly is localized to kinetochores at prometaphase and once the chromosomes are aligned properly on the metaphase plate, it is translocated to the poles. Little is known about the interactions of Spindly or its mechanism of function. It has been shown that Spindly mediates the mitotic checkpoint signaling by acting as an adaptor between RZZ and the dynein complex but its interacting partners are not yet known. The aim of the study is to characterize the structural and functional domains of hSpindly. hSpindly consists of two coiled coil domains, which are separated by a conserved spindly box. We have made 18 insertion, 16 truncation, 15 site-directed, and 15 phospho hSpindly mutants (non-phosphorylatable and phospho-mimics). These mutants were transfected into HeLa cells followed by fluorescence microscopy analysis. My kinetochores mapping studies indicated that both coiled-coil domain II and far C-terminus of hSpindly are required for kinetochores localization, which correspond to the data, published by Barisic et al. The non-phosphorylatable mutants of hSpindly localized to the kinetochores but showed enhanced localization at the spindle poles in both prometaphase and metaphase. The phospho-mimics localized to the kinetochores and did not show enhanced spindle pole localization. Furthermore, we are interested if the phospho-mimics can be transported to the poles at metaphase. Also, we are looking into the potential interacting partners of Spindly using yeast 2-hybrid and pull down assays. We are interested in how hSpindly is recruited to kinetochores by RZZ complex and downstream dynein/dynactin complex recruitment by hSpindly.

### **Activity-dependent modulation of the interaction between CaMKII $\alpha$ and Abi1 regulates structural plasticity of dendritic spines.**

*M. Shin<sup>1</sup>, E. Park<sup>1</sup>, D. Park<sup>1</sup>; <sup>1</sup>School of Biological Sciences, Seoul National University, Seoul 151-742, Korea*

Remodeling of dendritic spines through regulation of actin dynamics is a key event in activity-dependent structural plasticity. However, the molecular mechanism underlying this process is poorly understood. Here, we show that activity-dependent modulation of Abi1-CaMKII $\alpha$  interaction, and thereby their activity, is important for regulation of spine morphology in cultured rat hippocampal neurons. Abi1 interacts with CaMKII $\alpha$  at resting conditions through its tSNARE

which harbors striking homology with CaMKII $\alpha$  regulatory domain. The interaction of the two proteins results in their simultaneous inhibition, inhibition of CaMKII $\alpha$  activity and also Abi1-dependent Rac activation. Their functional impediment is released when they dissociate from each other by Calmodulin binding through glutamate receptor activation. Prior to dissociation, Abi1 is phosphorylated by CaMKII $\alpha$  at serine 88 which is crucial for Rac activation and spine maturation. Our results suggest that modulation of the interaction between Abi1 and CaMKII $\alpha$ , through the glutamate receptor pathway, may be a molecular mechanism underlying activity-regulated structural plasticity.

### **Asef2, a Rac and Cdc42 Guanine Nucleotide Exchange Factor, Regulates Dendritic Spine Formation in Hippocampal Neurons.**

*C. Evans<sup>1</sup>, M. Shi<sup>1</sup>, D. J. Webb<sup>1,2</sup>; <sup>1</sup>Department of Biological Sciences and the Kennedy Center for Research on Human Development, Vanderbilt University, Nashville, TN, <sup>2</sup>Cancer Biology, Vanderbilt University, Nashville, TN*

The Rho family of small GTPases consists of molecular switches that are integral for the formation of dendritic spines – small, actin-enriched structures that establish excitatory synapses with presynaptic axons. Upon activation by guanine nucleotide exchange factors (GEFs), these GTPases are thought to regulate actin cytoskeletal dynamics in dendritic spines. While the functions of several key members of the Rho GTPase family have been described, the roles of many GEFs in spine development are not currently known. Here, we show that Asef2, a GEF that has been shown to activate Rac1 and Cdc42, is important for the formation of dendritic spines in hippocampal neurons. A short-hairpin interfering RNA (siRNA) targeting Asef2 causes a significant decrease in the number of spines and synapses. Conversely, expression of GFP-tagged Asef2 causes an increase in the density of spines and synapses. These experiments suggest that Asef2 is important for dendritic spine formation. We hypothesized that Asef2's GEF activity, which is facilitated by its DH domain, is responsible for the observed effects on spine formation. Thus, we generated DH domain mutations that greatly reduce GTPase activation. Disruption of Asef2's GEF activity results in a decrease in the number of spines compared to wild-type Asef2. To better understand the mechanism of Asef2-mediated spine formation, we altered the levels of activated Rac1 downstream of Asef2. Treatment with the Rac inhibitor NSC23766 causes a reduction in spine density in Asef2-expressing neurons. In addition, our data indicate that an siRNA targeting Rac1 abrogates Asef2-mediated spine formation. Collectively, our data show that Asef2 mediates dendritic spine formation via its GEF activity, potentially through a Rac-dependent mechanism.

399

### **Myosin-X and its Motorless Isoform Play Distinctive Roles in Regulating the Development and Morphology of Dendritic Spines.**

*J. T. Hurley<sup>1</sup>, W-H. Lin<sup>1</sup>, A. N. Raines<sup>2</sup>, R. Cheney<sup>2</sup>, D. J. Webb<sup>1,3</sup>; <sup>1</sup>Biological Sciences and the Kennedy Center for Research on Human Development, Vanderbilt University, Nashville, TN, <sup>2</sup>Cell and Molecular Physiology, University of North Carolina, Chapel Hill, NC, <sup>3</sup>Cancer Biology, Vanderbilt University, Nashville, TN*

Dendritic spines are small, actin-rich structures that serve as the postsynaptic component of most excitatory synapses. The formation of spines and synapses most likely begins with the extension of dendritic filopodia, which are dynamic, finger-like protrusions from the dendrite that make initial contact with axons. Alterations in the morphology and plasticity of dendritic spines and filopodia are mediated by actin remodeling and underlie cognitive processes, such as

learning and memory. Myosin-X (Myo10), an unconventional actin motor, and a headless isoform (HL), which lacks the motor head domain, are expressed in the brain. However, their role in regulating neuronal processes is not well understood. Here, we show that full-length (FL) Myo10 and its HL isoform differentially modulate the morphology and development of spines in hippocampal neurons. FL Myo10 localizes to the tips of dendritic filopodia, whereas HL Myo10 is enriched at the heads of dendritic spines. While most HL Myo10 puncta co-localize with presynaptic terminals, the majority of FL Myo10 puncta do not make stable contacts. Elevated expression of FL Myo10 results in a 2.3-fold and a 1.7-fold increase in the number and length of dendritic filopodia. A 1.5-fold increase in the speed of extension and a 1.6-fold increase in the speed of retraction of dendritic filopodia are also observed in neurons expressing FL Myo10. Conversely, knockdown of FL Myo10, using an siRNA approach, leads to an approximately 2-fold decrease in the density of dendritic filopodia. In contrast with FL Myo10, HL Myo10 expression increases spine number by 2.3-fold and promotes a 1.5-fold increase in spine head size. Collectively, these results indicate that expression of FL Myo10 increases the number, length, and dynamics of dendritic filopodia, while HL Myo10 induces the formation and expansion of spine heads. Thus, FL and HL Myo10 cooperatively modulate the formation and maturation of dendritic spines.

**Myosin 18A-alpha is highly concentrated in the dendritic spines of mouse cerebellar Purkinje neurons: possible implications for spine morphogenesis and function.**

M. Barzik<sup>1</sup>, I. Fujiwara<sup>1</sup>, R. S. Petralia<sup>2</sup>, Y. Yang<sup>1</sup>, J. R. Sellers<sup>1</sup>, J. A. Hammer<sup>1</sup>; <sup>1</sup>NHLBI, National Institutes of Health, Bethesda, MD, <sup>2</sup>NIDCD, National Institutes of Health, Bethesda, MD

Dendritic spines are small, actin-rich protrusions on the surface of neuronal dendrites that serve as sites of excitatory synaptic input and memory formation. Previous studies have implicated myosin II, the conventional non-muscle myosin, in spine organization and function. Here we have explored the localization within cerebellar Purkinje neurons (PNs) of myosin 18A (M18A)-alpha and M18A-beta, two spliced isoforms of M18A, a recently discovered member of the myosin super family that is similar to, and yet distinct from, class II myosins. These distinctions include a C-terminal PDZ-ligand motif in both spliced isoforms, and in the case of M18A-alpha, a 333-residue N-terminal extension that harbors an apparent ATP-independent actin-binding site, a Lys- and Glu-rich region (KE region), and a PDZ domain. The fact that M18A-beta lacks this N-terminal extension suggests distinct functions for these two isoforms. Using GFP-tagged versions of M18A-alpha and beta and a novel system for gene transduction, we find that M18A-alpha, but not M18A-beta, localizes dramatically to the dendritic spines of PNs in dissociated culture. Moreover, M18A-alpha's spine distribution overlaps extensively with that of F-actin, as revealed using a novel reporter for F-actin (F-Tractin). The postsynaptic, spine localization of M18A-alpha was confirmed by immuno-EM of cerebellar tissue sections using a highly specific anti-M18A antibody. Importantly, M18A-alpha's N-terminal extension by itself targets extensively to spines, arguing that it is largely if not entirely responsible for the myosin's spine localization. Function-blocking point mutations show that the KE region and the PDZ domain within M18A-alpha's N-terminal extension do not determine spine targeting. Rather, the interaction of the ATP-independent actin-binding site with actin filaments appears to drive the spine localization of M18A-alpha. Consistently, *in vitro* binding assays using M18A-alpha's N-terminal extension show that it binds F-actin with moderately high affinity ( $305 \pm 105$  nM). We suggest that M18A-alpha may play important roles in the development, organization, and/or function of PN spines. Future experiments using a conditional M18A knockout mouse and the PN-specific expression of Cre recombinase will be used to address the physiological significance of the myosin's spine localization in PNs.

### **Regulation of Filopodia Dynamics in Outgrowing Neurites by Rho GTPase Signaling Programs.**

*M. Bagonis<sup>1</sup>, L. Fusco<sup>2</sup>, O. Pertz<sup>2</sup>, G. Danuser<sup>1</sup>; <sup>1</sup>Department of Cell Biology, Harvard University, Boston, MA, <sup>2</sup>Institute of Biochemistry, University of Basel, Basel, Switzerland*

Early stages of neuronal differentiation involve extensive cell polarization, characterized by the outgrowth of long tubular structures called neurites from the neuron cell body. Since neurites possess a dynamic, actin-rich tip called the growth cone, it is not surprising that the RhoGTPase proteins, ubiquitous regulators of the actin cytoskeleton, are heavily involved in coordinating neurite extension, retraction, and turning events. However, the precise spatial and temporal pattern of RhoGTPase activity corresponding to these events, as well as how these patterns are maintained and manipulated by extracellular cues is not established. Important actin structures likely contributing to neurite outgrowth and turning are the growth cone filopodia, long filamentous actin bundles at the tip of an outgrowing neuron. Filopodia are generally thought to be “sensors” of the extracellular environment serving to effectively “steer” the outgrowing neurite in response to external cues. Therefore, understanding the signaling and dynamics that control filopodia is fundamental to effectively manipulating the processes associated with neuronal development.

Here, using a combination of live-cell imaging and computer vision, we are developing methods to comprehensively and quantitatively characterize how Rho GTPase signaling programs initiated specifically in the growth cone filopodia may be functionally linked to local filopodia dynamics and larger-scale growth cone outgrowth and turning. We present a novel method for fully automated detection and tracking of filopodia in the fluorescently labeled growth cone. This software provides a framework to systematically quantify and cluster filopodia dynamic behavior (ie filopodia protrusion, retraction, lateral movement etc) – a critical local morphological “output” of actin related signaling in the navigating neurite. To explore how different RhoGTPase signaling pathways may serve to maintain specific filopodia dynamic populations, we have used our approach to methodically compare filopodia dynamics upon knockdown of select RhoGTPase activity modulators and effectors recently pre-screened for robust and diverse neurite outgrowth/growth cone structural phenotypes. While here we focus on the responses elicited in N1E-115 neuroblastoma cells in the presence of the extracellular matrix protein laminin, our method for filopodia dynamics measurement is generic and provides a means to quickly quantify functionally relevant signaling outputs - a vital first step in future neurite outgrowth signal-pathway reconstruction studies.

### **+TIP-Kinesin complexes steer microtubule growth in vitro.**

*Y. Chen<sup>1,2</sup>, M. Rolls<sup>1,3</sup>, W. Hancock<sup>1,2</sup>; <sup>1</sup>Cell and Developmental Biology, The Pennsylvania State University, University Park, PA, <sup>2</sup>Department of Bioengineering, The Pennsylvania State University, University Park, PA, <sup>3</sup>Department of Biochemistry and Molecular Biology, The Pennsylvania State University, University Park, PA*

In neurons, proper microtubule orientation in axons and dendrites is essential for targeting intracellular cargo to their correct destinations. However, the mechanisms by which uniform microtubule organization is established and maintained are poorly understood. In vivo imaging in *Drosophila* dendrites showed that microtubules growing into branch points were consistently directed towards the cell body, thus maintaining their minus-end out orientation. RNAi knockdown experiments established that proper microtubule steering required EB1, APC and kinesin-2. Further two-hybrid assays indicated that APC interacts with both EB1 and the kinesin-2 subunit KAP3, forming a +TIP-kinesin complex. These findings led to the hypothesis that

kinesin, concentrated at the plus-tips of growing microtubules by EB1, bends the growing microtubule by walking along static microtubules present at junctions. However, this mechanical role of EB1 is not consistent with the rapid kinetics reported for EB1 dissociating from microtubule plus-ends. To elucidate the minimum requirements for microtubule steering and investigate the mechanical activities of EB1 and kinesin during steering, we immobilized microtubule seeds on glass surfaces in vitro, extended them with free tubulin and observed encounters between dynamic growing microtubule plus-ends and the lattice of stable microtubules. To reconstitute +TIP-kinesin complexes in vitro, purified EB1 and kinesin were linked together through the Rapamycin-induced heterodimerization of FKBP-FRB. From gel filtration, the binding ratio of EB1 to kinesin ranged from 1.5:1 to 2:1. Under TIRF microscopy, EB1-kinesin complexes moved along microtubules and preferentially accumulated at growing microtubule plus-ends, indicating that association with EB1 promotes the localization of kinesin to growing plus-ends. More importantly, when +TIP-kinesin complex was present, the growing microtubules were bent and directed toward the plus-ends of immobilized microtubules, demonstrating that the +TIP-kinesin complex is sufficient to steer microtubule growth. We conclude that EB1 can localize kinesin to growing microtubule plus-ends and EB1 binding to microtubule plus-ends is sufficiently strong to steer microtubule growth. The work is supported by NIH.

**Microtubule dynamics in neocortical neurons during distinct modes of migration and polarization in the developing mouse cerebrum.**

A. Sakakibara<sup>1</sup>, R. Ando<sup>1</sup>, T. Sato<sup>1</sup>, N. Noguchi<sup>1</sup>, M. Masaoka<sup>1</sup>, T. Miyata<sup>1</sup>; <sup>1</sup>Nagoya University Graduate School of Medicine, Nagoya, Japan

Neuronal migration and process formation require cytoskeletal organization and remodeling. Recent studies suggest that centrosome translocation is involved in initial axon outgrowth, while the role of centrosomal positioning is not clear. Here we study the relations between centrosome translocation, axonogenesis, and microtubule (MT) polarization in multipolar and bipolar neocortical neurons undergoing migration and axonogenesis. To monitor the dynamic movements of centrosomes and MT plus ends in migratory neurons in embryonic mouse cerebral slice, we expressed PACT-mKO1 and EB3-EGFP by using in utero electroporation. In the developing mouse cerebrum, young pyramidal neurons born in the ventricular zone migrate toward the brain surface through the intermediate zone and cortical plate. In multipolar migrating neurons in the intermediate zone, new processes emerged irrespective of centrosome localization, followed by centrosome movement toward the dominant growing process. In bipolar-shaped locomoting neurons in the cortical plate, the centrosome targeted the pia-directed leading process. We observed distal tip-directed movements of MT plus ends predominantly in multipolar neuron processes. MT plus ends were enriched in the leading process at the transition from multipolar to bipolar morphology. In bipolar neurons, distal-directed MT plus end movements were prominent in leading processes, while trailing processes showed bidirectional movements. We further observed that in multipolar neurons axons form by tangential extension of a dominant process and the centrosome orients toward the growing axon, while in locomoting neurons an axon forms opposite to the direction of migration and the centrosome localizes to the base of the leading process. Our observations suggest that MT organization between processes may alter centrosomal localization and that centrosomal positioning does not direct process formation.

404

**CSPR-1 stabilizes the microtubule cytoskeleton and presynaptic specializations of neurons in *C. elegans*.**

J. Marcette<sup>1,2</sup>, R. Bost<sup>2</sup>, J. J. Chen<sup>1</sup>, M. Nonet<sup>1</sup>; <sup>1</sup>Anatomy and Neurobiology, Washington University School of Medicine, St. Louis, MO, <sup>2</sup>Arts and Sciences, Harris-Stowe State University, St. Louis, MO

Lesions in cytoskeletal-associated proteins are associated with a variety of degenerative and excitatory neurobiological disorders in humans. Remodeling of synapses and changes in neuronal morphology are thought to underlie diseases as diverse as Alzheimer's and epilepsy. Here we report that the cytoskeletal-associated gene *cspr-1* is required for proper morphology and cytoskeletal stability of several distinct classes of *C. elegans* neurons. Remodeling of neuronal morphology including both the formation and retraction of branches and synapses occurs throughout development in *cspr-1* mutants. By contrast, in wild type animals, the same neurons exhibited virtually no morphological changes in the same time period. Our subcellular localization data indicates that CSPR-1 acts near the periphery of the soma and in neuronal processes. Because the phenotypes we see in *cspr-1* mutants mimic alterations caused by microtubule destabilizing mutations, and *cspr-1* mutant phenotypes are exacerbated by growing worms in conditions where microtubule polymerization is slowed, we suggest a paradigm whereby microtubule stabilization mediated by a functional CSPR-1 is necessary for both formation and maintenance of correct neuronal morphology. We speculate that the human homolog is likely involved in the prevention of disorders associated with changes in cellular morphology

405

**JNK phosphorylation of hnRNP K is required for axon outgrowth during nervous system development in *Xenopus laevis*.**

E. J. Hutchins<sup>1</sup>, B. G. Szaro<sup>1</sup>; <sup>1</sup>Biological Sciences, University at Albany, State University of New York, Albany, NY

The RNA-binding protein hnRNP K is required for axon outgrowth during development. Its suppression in *Xenopus* embryos causes defects in the translation of mRNAs of multiple cytoskeletal genes. Studies in cell lines have established that hnRNP K shuttles between the nucleus and the cytoplasm to bind and regulate the fates of its target RNAs, from splicing to export and translation. At each step, hnRNP K is regulated through post-translational modifications that alter its nucleic acid and protein interactions, and subcellular localization. Precisely how this happens in developing neurons to coordinate cytoskeletal gene expression with the extracellular signals directing axon outgrowth is unknown. We have identified a JNK phosphorylation site within hnRNP K that is essential for its function during neuronal development. Treatment with SP600125, a pharmacological inhibitor of JNK, prevented formation of axons in primary neuronal cultures; a phospho-mimetic mutation of the JNK site on hnRNP K successfully rescued axon outgrowth in the presence of SP600125, implicating hnRNP K as a major substrate on which JNK acts to effect axonogenesis. Western analysis and qRT-PCR on extracts from SP600125-treated cultures revealed the involvement of JNK in the post-transcriptional control of the medium neurofilament (NF-M) and microtubule-associated protein tau, both mRNA targets of hnRNP K. Polysome profiling experiments further demonstrated involvement of JNK in translational regulation; a phospho-deficient mutation of the JNK site on hnRNP K caused a shift of hnRNP K into the non-translating, premonosomal fractions. We propose a mechanism whereby JNK controls translation of hnRNP K's target mRNAs, and by extension axon outgrowth, at the point of translation initiation through prevention of 80S ribosome assembly. JNK has long been implicated in the intracellular

signaling pathways that mediate effects of several receptors on axon outgrowth, although a mechanism of its action had not previously been described. These data suggest a role for hnRNP K as a central regulatory component linking extracellular signals that regulate axon outgrowth directly with the expressions of key axonal structural components. *Supported by NSF IOS-951043 (BGS), a Sigma Xi Grant-in-Aid (EJH), and an AAUW dissertation fellowship (EJH).*

**Kinesin-mediated microtubule sliding drives axon outgrowth in *Drosophila* neurons.**

W. Lu<sup>1</sup>, P. Fox<sup>1</sup>, M. Lakonishok<sup>1</sup>, M. Davidson<sup>2</sup>, V. Gelfand<sup>1</sup>; <sup>1</sup>Department of Cell and Molecular Biology, Northwestern University Feinberg School of Medicine, Chicago, IL, <sup>2</sup>National High Magnetic Field Laboratory and Department of Biological Science, The Florida State University, Tallahassee, FL

How neurons extend axons is a key long-standing question in neuronal cell biology. Recently, our lab revealed a novel role of the microtubule motor kinesin-1 in driving microtubule-microtubule sliding and formation of long processes in tissue culture cells. Here, we use *Drosophila* embryonic neurons as a model system to study whether a similar mechanism operates in axon outgrowth. By using transgenic flies that carry a photoconvertible tubulin, EOS- $\alpha$ tub, we are able to track microtubule dynamics at different stages of embryonic neuron development in culture. We observe that microtubules are very actively sliding in young developing neurons. Within a few minutes, microtubules photoconverted within a small area are found to be distributed throughout the full neuron by sliding. Furthermore, these sliding microtubules push directly against the cytoplasmic membrane of the growing neurite tip and very often become looped, suggesting that sliding microtubules generate mechanical force for axon extension during neuronal development. In mature, fully-developed neurons, microtubules become very stationary, and very little sliding can be detected. The strong correlation between microtubule sliding and axon growth rate strongly suggests that microtubule sliding can contribute to axon growth. Consistent with these findings, we demonstrate that neither actin depolymerization nor inhibition of microtubule polymerization blocks axon extension at initial stages of neuronal development. Finally, we have data to show that kinesin-1 powers microtubule sliding, which is important for axon growth in young neurons. These results reveal a novel mechanism driving initial axonal outgrowth in *Drosophila* neurons. Due to the high evolutionary conservation of kinesin-1, a similar mechanism may function in other neurons.

407

**Cytoskeletal architecture and assembly of the axon initial segment in hippocampal neurons.**

S. L. Jones<sup>1</sup>, F. Korobova<sup>1,2</sup>, T. Svitkina<sup>1</sup>; <sup>1</sup>Biology, University of Pennsylvania, Philadelphia, PA, <sup>2</sup>Biochemistry, Geisel School of Medicine at Dartmouth, Hanover, NH

The axon initial segment (AIS) is a special compartment of differentiated neurons that is essential for regulating action potential initiation and axono-dendritic polarity. For maintaining polarity, the AIS is thought to act as a diffusion barrier that prevents mixing of axonal and dendritic components, or as a sorting station that uses oriented cytoskeletal tracks to direct molecules to proper destinations. However, the cytoskeletal organization at the AIS is unknown, making it difficult to distinguish between these two models. Although the integrity of the actin cytoskeleton is known to be essential for the barrier functions of the AIS, it remains unclear whether actin filaments act by forming a molecular sieve or oriented tracks. Using platinum replica electron microscopy, we have determined the architecture of the AIS cytoskeleton in cultured hippocampal neurons and its development during neuronal maturation. We show that

as early as 3 days in vitro (DIV) the proximal axon has structural features distinguishing it from the distal axon or dendrites. The formation of the AIS begins with appearance of microtubule bundles (DIV 3-4), which then become covered with ankyrin G-positive fibrillar/granular networks, whose density progressively increases, while composition shifts from predominantly fibrillar (DIV 7-10) to mostly granular (DIV 21). Actin filaments of appreciable lengths are very rare in mature AISs (DIV 7-21). Accordingly, phalloidin staining reveals some F-actin enrichment in the AIS only up to DIV 4, but not at later time points. Decoration with myosin S1 showed that the existing actin filaments display no predominant orientation. Remarkably, the AIS architecture remains apparently intact even after depletion of microtubules (by calcium and cold treatment), or actin filaments (by gelsolin treatment), or both, from the cytoskeletal preparations of mature neurons. Collectively, we show that the mature AIS cytoskeleton is a self-maintained fibrillar/granular structure, which lacks oriented actin filament tracks for directional myosin-driven transport. Our results suggest that the AIS submembranous cytoskeleton predominantly functions as a molecular sieve, which likely represents a large supramolecular assembly of spectrin, ankyrin G, and very short gelsolin-resistant actin filaments, similar to the membrane skeleton of red blood cells.

408

#### **Cortactin functions as a clutch molecule to promote axon outgrowth.**

Y. Kubo<sup>1</sup>, M. Toriyama<sup>1</sup>, S. Kozawa<sup>2</sup>, K. Ikeda<sup>2</sup>, T. Sugiura<sup>2</sup>, N. Inagaki<sup>1</sup>; <sup>1</sup>Graduate School of Biological Sciences, Nara Institute of Science and Technology (NAIST), Ikoma, Japan, <sup>2</sup>Graduate School of Information Science, Nara Institute of Science and Technology (NAIST), Ikoma, Japan

Axon outgrowth is essential for the formation of neuronal networks. The nerve growth cone is the migrating tip of growing axons and plays a central role in axon outgrowth and guidance. Linkage between the treadmilling actin filaments (F-actins) and cell adhesion molecules (CAMs) in the growth cone is thought to transmit the force of F-actin retrograde flow to extracellular substrates via CAMs, thereby providing traction force for neurite outgrowth ("clutch" mechanism) (Mitchison and Kirschner, *Neuron*, 1988; Suter and Forscher, *J. Neurobiol.*, 2000). Recently, we reported that shootin1 mediates the linkage between F-actin retrograde flow and L1-CAM to promote axon outgrowth as a "clutch molecule" (Shimada et al., *J. Cell Biol.*, 2008). However, components of the clutch modules in axonal growth cones are largely unknown and the molecular linkage between F-actin retrograde flow and shootin1 remains elusive.

Cortactin is an actin-binding protein and is known to be involved in growth cone formation in neurons. In this study, by co-immunoprecipitation (IP) assays, we found that cortactin interacts with shootin1. Cortactin was co-localized with shootin1 and F-actin in the peripheral domain of the axonal growth cone. *In vitro* binding assay and co-IP study showed that endogenous cortactin binds directly to endogenous shootin1. Fluorescent speckle imaging of EGFP-cortactin revealed that cortactin also interacts with F-actin retrograde flow in the axonal growth cones. Furthermore, we found that cortactin mediates the interaction between F-actin and shootin1 *in vitro* and *in vivo* and that the driving force of F-actin retrograde flow is transmitted to L1-CAM via cortactin. By impairing this linkage using cortactin RNAi, clutch engagement was attenuated and L1-dependent axon outgrowth was inhibited. These findings suggest that cortactin functions as a clutch molecule to promote axon outgrowth by mediating the linkage between F-actin retrograde flow and shootin1 in the axonal growth cones.

409

**JNK reduces SCG10 protein level to regulate axon formation.**

S-I. Hirai<sup>1</sup>, S. Ohno<sup>2</sup>; <sup>1</sup>Biology, Wakayama Medical University School of Medicine, Wakayama, Japan, <sup>2</sup>Molecular Biology, Yokohama City University School of Medicine, Yokohama, Japan

Axon formation in neurons depends on the microtubule dynamics, which is regulated by a variety of microtubule associated/regulatory proteins. We have shown that axon formation of neocortical neurons depends on the component of the MAP kinase cascade, dual leucine zipper kinase (DLK) and c-Jun N-terminal kinase (JNK), using mutant mice and *in vitro* mRNA knockdown systems. JNK phosphorylates some microtubule associated/regulatory proteins including MAP1b, MAP2, DCX, and SCG10. Among them, SCG10 forms a complex with tubulin tetramer and destabilizes microtubules, while others associate with polymerized tubulin, microtubules. It has been reported that MAP kinases including JNK phosphorylate Ser62 and Ser73 of SCG10 and reduce its activity as a microtubule destabilizer. These observations are consistent with our observation that treatment with taxol, a microtubule stabilizer, partially rescues the reduction of axon formation caused by the suppression of DLK-JNK pathway. However, how JNK inactivates SCG10 remains to be elucidated. In this paper, we show that JNK activation reduces SCG10 protein level: Endogenous SCG10 protein in primary cortical neurons increased upon DLK knockdown or JNK inhibitor treatment. The expression of exogenous DLK or active JNK in DLK knockdown cells reduced SCG10 protein level. The protein level of ectopically expressed SCG10 in COS-1 cells was also sensitive to JNK activation, which became insensitive when Ser62 and Ser73 were converted to alanine. These observations suggest that DLK-JNK pathway regulates SCG10 protein level via phosphorylation of Ser62 and Ser73. While SCG10 is one of critical factors for axon formation, spatiotemporal regulation of its quantity will be essential, which may, at least in part, depend on DLK-JNK pathway.

**Characterization of dendrite morphology defects caused by overexpression of DCX patient mutations in cortical neuronal cultures.**

C. Yap<sup>1</sup>, M. Babraj<sup>1</sup>, K. Kruczek<sup>1</sup>, B. Winckler<sup>1</sup>; <sup>1</sup>Neuroscience, University of Virginia, Charlottesville, VA

Proper functioning of neuronal circuits depends critically on the correct wiring of large numbers of neurons. Dendrites play a crucial role in synaptic connections and any change in their morphology can affect neuronal connectivity and impact brain function. The growth of dendrites is a precisely regulated process. During development, dendrites extend and reach their final destinations, a process regulated by both extracellular and intracellular proteins. Doublecortin (DCX) has been implicated in multiple steps in brain development. Mutations in DCX underlie lissencephaly and subcortical band heterotopia in humans, caused by disrupted neuronal migration during development. These defects are phenocopied in rats by DCX downregulation whereas the defects in DCX null mice are more subtle. Patients with mutations in DCX also have other defects, which are not related to the disruption in neuronal migration. For instance, hypoplasia of the corpus callosum is likely caused by defects in axon growth. DCX is most studied as a microtubule associated protein. Thus, the various developmental roles of DCX are thought to be due to its essential role in microtubule organization, dynamics and function. In addition, DCX has been proposed to be involved in regulating protein transport, possibly by interacting and regulating the function of microtubule motors. Interestingly, rat DCX knock down neurons have aberrantly short dendrites as do neurons from the hippocampus of DCX *-/-* mice. It is not yet established if human patients carrying DCX mutations have defects in dendrite morphology as well. Most work on understanding DCX has centered on analyzing the loss-of-

function phenotypes using knock-out or knock-down approaches. To date, around 52 mutations have been mapped to the DCX gene. The disease severity is related to the location of the mutation in the DCX protein. We are studying a set of patient mutations in DCX, which are located in different regions of the protein and have different biochemical behaviors with respect to microtubule binding. We find that expression of wild type DCX in rat cortical neurons increases dendrite complexity. Similarly, the patient mutation DCX-G253D still increases dendrite complexity. In contrast, other patient mutations (patient mutation DCX-272X) are deficient in increasing dendrite morphology. Furthermore, a microtubule binding-deficient DCX (patient mutation DCXR89G) causes shortening of dendrites after 5 days. Therefore, different DCX patient alleles have separable phenotypes and not all patient mutations are loss of function mutations.

**Regulation of neuronal morphogenesis and intracellular transport by NudE.**

A. Arthur<sup>1</sup>, Y. Jan<sup>2</sup>, J. Wildonger<sup>3</sup>; <sup>1</sup>University of Wisconsin-Madison, Madison, WI, <sup>2</sup>Howard Hughes Medical Institute, UCSF, San Francisco, CA, <sup>3</sup>Biochemistry, University of Wisconsin-Madison, Madison, WI

Dynein plays a role in a variety of cellular processes, yet it remains unclear how this motor complex performs such different tasks. Our previous studies revealed that within the developing fly nervous system, dynein is necessary for two fundamental aspects of neuronal polarity: the polarized localization of dendritic proteins and organelles, and the uniform plus-end distal organization of axonal microtubules. Dynein interacts with several different co-factors, including NudE. Similar to the loss of functional dynein, the loss of NudE disrupts axon and dendrite morphogenesis. Fly dendritic arborization (da) neurons typically extend unbranched axons into the ventral nerve cord, with axonal microtubules uniformly oriented with their plus-ends positioned distally. Unlike wild type, but similar to dynein loss-of-function, the axons of neurons lacking nudE split into multiple branches and contain microtubules of mixed polarity, suggesting these axons have acquired dendritic characteristics. To further probe the function of NudE in the transport of different cargo within neurons, we developed and are employing a fluorescently-tagged NudE protein to follow NudE dynamics live within da neurons. Through this combination of techniques, our results further elucidate the role of NudE in neuronal morphogenesis as well as its roles in intracellular transport.

412

**Branching Kinase (Branck) regulates arborization of neurites.**

M. Kishi<sup>1</sup>, T. Nagaoka<sup>1</sup>, S. Uemura<sup>1</sup>, A. Inutsuka<sup>1</sup>, M. Abe<sup>2</sup>, A. Watanabe<sup>1</sup>, Y. Huang<sup>3</sup>, M. Yokoyama<sup>2</sup>, K. Sakimura<sup>2</sup>, M. Igarashi<sup>4</sup>; <sup>1</sup>Lab of Molecular Neuroimaging, Niigata University, Niigata, Japan, <sup>2</sup>Brain Research Institute, Niigata University, Niigata, Japan, <sup>3</sup>Department of Pathology & Immunology, Washington University Graduate School of Medicine, St. Louis, MO, <sup>4</sup>Division of Molecular and Cellular Biology, Niigata University, Niigata, Japan

Ramification of neuronal processes is essential for formation of elaborate neural network in the brain. During the screen to identify novel regulators of neuronal morphogenesis, we found a serine/threonine kinase whose over-expression strongly induces neurite branching of cultured hippocampal neurons. We tentatively named this molecule Branching Kinase (Branck). To examine if Branck plays a crucial role for neural development, Branck gene was disrupted in mouse ES cells by homologous recombination. In the hippocampi of the Branck-null mice, arborization of the pyramidal neurons is slightly impaired. Divergency of the axonal processes of the developing peripheral nervous systems is reduced as well. We are currently analyzing the molecular mechanism of Branck-mediated bifurcation by identifying physical binding partners

and functional interactors. The preliminary results of our yeast two-hybrid screen as well as in vitro examination of candidates for the downstream molecules will be presented.

**Microtubules promote filament formation from unmodified full-length Tau *in vitro*.**

*A. Duan<sup>1</sup>, E. Ottenweller<sup>1</sup>; <sup>1</sup>University of Notre Dame, Notre Dame, IN*

Tau is a neuronal protein that stabilizes the microtubule network, but it also forms filaments associated with Alzheimer's disease. Understanding Tau-microtubule and Tau-Tau interactions would help to establish Tau function in health and disease. For many years, literature reports on Tau-microtubule binding behavior and affinity have remained surprisingly contradictory. Tau-Tau interactions have also been investigated, but whether microtubules might affect Tau filament formation is unknown. We have addressed these issues through binding assays and microscopy. We assessed Tau-microtubule interactions via cosedimentation and found that the measured affinity varies greatly depending on the experimental design and the protein concentrations used. To investigate this dependence, we used fluorescence microscopy to examine Tau-microtubule binding. Strikingly, we found microtubules promote Tau filament formation without characterized Tau filament inducers. We propose that these novel Tau filaments account for the incongruence in Tau-microtubule affinity measurements. Moreover, these filaments appear similar to the heparin-induced Alzheimer's model by electron microscopy. These observations suggest that the microtubule-induced Tau filaments provide a new model for Alzheimer's studies and support the possibility that microtubules play a role in the formation of Alzheimer's associated neurofibrillary tangles.

**Stably transfected PC12-TAU as a model to study Neuronal Toxicity associated with Extracellular Hyperphosphorylated TAU in Alzheimer Disease.**

*N. J. Nunez Rodriguez<sup>1</sup>, C. Beharry<sup>2</sup>, R. Romero<sup>1</sup>, C. Corbo<sup>2</sup>, S. Debnath<sup>2</sup>, J. Fata<sup>2</sup>, A. Alonso<sup>2</sup>; <sup>1</sup>Hostos Community College, Bronx, NY, <sup>2</sup>College of Staten Island, Staten Island, NY*

Neuronal cell death in Alzheimer Disease damaged brain regions is associated with the presence of TAU tangles. At present, there is no disease described where TAU accumulates and is not hyperphosphorylated. Indeed, phosphorylation of some specific TAU sites is sufficient to induce cell death. Moreover, neurodegeneration associated with TAU has also been related to the spreading of its pathological form. Those neurons that are successful in keeping low levels of hyperphosphorylated TAU are able to survive longer. Our previous results indicated that cells stably transfected with TAU survived better against pathological agents such as TNF $\alpha$  and Staurosporine. This work aimed to understand if PC12 cells and PC12 cells stably transfected with human TAU (PC12-TAU) could be used as a model system to study the role of intracellular TAU phosphorylation balance on cell survival. In doing so, we built up a foundation to test if the presence of TAU stably transfected to the neurons could protect against substances such as the minimal TAU sequence inducing aggregation. PC12 and PC12-TAU cells were cultured in different cell culture media and plated with different coating protocols. This work demonstrated that PC12 and PC12-TAU exhibited different patterns of proliferation and survival in a different coating and medium conditions. Specifically, both types of cells are attaching and growing healthy in RPMI-1640 supplemented with 15% FBS and Penn 1/500 in wells previously coated either with Roche-collagen or Sigma-Poly-D-lysine. Other media such as RPMI-1640 supplemented with 10% Horse Serum, Fetal Bovine Serum and Penicillin/Streptomycin showed a healthy growth pattern for PC12-TAU cells but not for PC12 cells. Collagen-based coating also produced different growth patterns, with PC12-TAU cells

growing healthy in all conditions. While these results point to an impact of TAU in cellular growth, their interpretation is complicated by the observation that PC12 cells appear to be particularly sensitive to differences in the quality of serum among different suppliers and batches. This could lead to a selection of subclones different from the original cells influencing poor cell attachment to plastic. In order to circumvent these difficulties, we plan to use neuronal cell line B35/B50 as an alternative to PC12 cells to test the toxic effect of pseudophosphorylated TAU. All together, these results will help to establish a best model to study the cellular balance regarding TAU phosphorylation and its relation with neuronal commitment to death in pathological conditions. Indeed, the avenues for successful treatment for tauopathies may involve down regulation of the phosphorylation and up regulation of the clearance of the abnormal form of TAU.

415

### **Expression of HDAC Enhances Mistargeting of Phosphorylated Tau to Soma of Hippocampal Neurons.**

*K. A. Medeiros<sup>1</sup>, J. J. Chambers<sup>1</sup>; <sup>1</sup>Chemistry, University of Massachusetts Amherst, Amherst, MA*

Alzheimer disease (AD) is a devastating neurodegenerative disease that currently affects millions of people worldwide and has no cure. Extracellular amyloid plaques and intracellular neurofibrillary tangles, the two hallmark lesions in a typical AD brain, are comprised of aggregated beta-amyloid (A $\beta$ ) and hyperphosphorylated tau (p-tau), respectively. The accumulation of oligomers of A $\beta$  and p-tau correlate with disease progression and deficits in learning and memory. Accumulation of these proteins, are associated with disrupted synaptic function and neuronal death. Here we focus on understanding the underlying molecular mechanisms leading to the accumulation of aggregated A $\beta$  and p-tau. We investigate the role of a histone deacetylase (HDAC), which has been shown to have increased protein levels in the neural tissue of patients who have succumbed to the disease. Our experiments have focused on characterizing the biochemical interaction between this HDAC and Protein Phosphatase 1 (PP1), a protein that is known to play a key role in regulating tau pathology. By using standard biochemical techniques in a heterologous expression system, as well as confocal imaging using dissociated neurons, we have found that overexpression of this HDAC causes an increase in the amount of phosphorylated tau. Of particular interest is the enhanced level of p-tau in the soma of these neurons. This data suggest that this HDAC is an underlying molecular factor mediating tau pathology.

416

### **Hyperphosphorylation of Tau.**

*C. Beharry<sup>1</sup>, E. M. Alaniz<sup>1</sup>, C. Corbo<sup>1</sup>, P. C. Cales<sup>1</sup>, A. Alonso<sup>1</sup>; <sup>1</sup>Biology, College of Staten Island, Staten Island, NY*

Tau is a microtubule associated protein that is expressed in neurons of the central nervous system. It regulates microtubule stability and axonal transport. Neurodegenerative diseases known as tauopathies are characterized by the abnormal hyperphosphorylation and subsequent assembly of tau protein. Normal tau contains ~ 2-3 mol of phosphate per mole of protein. Hyperphosphorylated tau contains ~7-10 mol of phosphate per mole of protein. Hyperphosphorylated tau aggregates into straight and paired helical filaments, the primary component of neurofibrillary tangles. It also binds to and sequesters normal tau, inhibiting its function to promote microtubule assembly. It is not proven whether neurodegeneration is the cause or a consequence of tau hyperphosphorylation. In vitro studies demonstrated that hyperphosphorylated tau promotes neurodegeneration and that the combination of

phosphorylation at Thr212, Thr231 and Ser262 produces toxic effect in the cells. To study these specific sites, pseudophosphorylated tau constructs were generated. The above-mentioned threonine or serine residues were switched by site directed mutagenesis of that specific codon to a glutamic acid, to mimic the negative charge carried to that site by a phosphate. This pseudophosphorylated tau is termed PH-tau. These same constructs were used to generate a transgenic *Drosophila* line expressing inducible PH-tau. Here, *Drosophila* were used to investigate the *in vivo* mechanism of tau toxicity induced by phosphorylation. They were controlled by yeast upstream activating sequence (UAS). PH-tau was expressed in a pan-neural pattern (Elav-Gal4) in the background of wild-type human tau (wt-tau), or tau carrying one of the point mutations associated with FTDP-17, R406W. Additionally, the lab has generated an inducible mouse model to study the effects of inducing degeneration in a mammalian system. Transgenic mice were generated to express PH-tau under regulation by the tetracycline-controlled transactivator protein (tTA) linked to the calcium-calmodulin dependent kinase II promoter (CAMk2a) to express PH-tau only in neurons. The expression of the target gene can be blocked by administration of the doxycycline feed (1g/kg). PH-tau expressing cells have shown tau no longer associated with the microtubule network, membrane blebbing, excessive intracellular vacuolization, protein aggregation and a breakdown of polymerized actin and increased caspase activation. To confirm that the toxic effect seen in cells was a product of phosphorylation and not the mutation, cells expressing wild type tau were treated with okadaic acid, which inhibited phosphatase activity and caused wild type tau to become hyperphosphorylated. These cells exhibited the same pathologies as those expressing PH-tau. Our results show that flies expressing hyperphosphorylation of tau had shorter lifespan and impaired motor function. This expression also interfered with their ability to learn. Flies kept at 23°C expressed lower levels of tau expression and flies kept at 29°C demonstrating the PH-tau expression is temperature dependent. Behaviorally, the expression of PH-Tau in mice caused a cognitive impairment in the Morris Water Maze. Pathologically, PH-tau expression in the mouse brain has shown an increase in silver stained cells and increased levels of fibers in the tissue, suggesting that presence of aggregated protein in the tissue. Additionally, immunohistochemical analysis has shown the presence of human tau in the brains of double transgenic mice off of the doxycycline food. In the presence of doxycycline, no human tau is detectable demonstrating that the inducible system is functional. Taken together our results suggest that hyperphosphorylated tau is an early event in the process of neurodegeneration.

## Membrane Trafficking at the Synapse

### Expression of Glutamate Transporters are increased in the Prefrontal Cortex and Hippocampus of Rats Reared in Isolation from Weaning.

K. K. Moriyama<sup>1</sup>, M. R. dos Santos<sup>1</sup>, N. B. Bosaipo<sup>2</sup>, M. M. Iyomasa<sup>1</sup>, M. L. Rosa<sup>1,3</sup>; <sup>1</sup>Laboratory of Neuroscience, School of Medicine of Catanduva - FIPA, Catanduva, Brazil, <sup>2</sup>Psychobiology, Faculty of Philosophy, Science and Letters of Ribeirao Preto - USP, Ribeirao Preto, Brazil, <sup>3</sup>Institute of Neuroscience and Behavior (INeC-USP), Ribeirao Preto, Brazil

There is growing evidence implicating the glutamate in the pathophysiology of schizophrenia. It has been reported that glutamatergic neurotransmission is decreased in the prefrontal cortex and hippocampal formation in schizophrenics. Rats reared in isolation from weaning have been used as an experimental model of schizophrenia. In this model it was reported a decrease in the expression of AMPA receptors in rat hippocampus. This study aimed at evaluating the changes in the expression of glutamate transporters, EAAC1 and GLT1, in hippocampus, amygdala,

prefrontal cortex (PFC) and entorhinal cortex (EC) of rats reared in isolation from weaning. Two groups of Wistar rats (n=11-12/each) were used. In both groups the pups remained with their mothers (6 pups per mother) until weaning (21 days - 40g) when they were allocated randomly to one of two conditions: 1) grouped, housed 3 per cage and handled 3 times a week; 2) isolated, housed individually and handled once a week for cleaning purpose. After 10 weeks all animals were anaesthetized, perfused and their brains removed. 40-um sections of the brain areas were used for immunohistochemistry. The number of immunopositive cells (IC) was quantified bilaterally in 3 sections/rat and the average for grouped and isolated compared by Student t-test ( $p < 0.05$ ). Isolation rearing induced a significant increase on the expression of EAAC1 in the PFC (38%,  $p = 0.017$ ), hilus of dentate gyrus (81%,  $p < 0.01$ ) and CA3 (144%,  $p < 0.05$ ). However, no difference was found in CA1 and EC. A non-significant increase in EAAC1 expression was induced by isolation rearing in basolateral (13%) and lateral (6%) amygdala. The number of GLT1-IC did not change in the PFC ( $p < 0.05$ ) of rats reared in isolation when compared to grouped rats. However, immunofluorescent labeling for GLT1 was seen associated to glial and neuronal cells in the PFC and EC. These results contribute with additional experimental evidence for the reduction in the glutamatergic neurotransmission reported in schizophrenia. These results may also contribute for considering this pathology a syndrome of "hypofrontality" and for considering the glutamate transporters a future therapeutic target for the treatment of schizophrenia.

#### The kinesin-3 family motor KLP-4 regulates anterograde trafficking of GLR-1 glutamate receptors in the ventral nerve cord of *C. elegans*.

M. Monteiro<sup>1</sup>, S. Ahlawat<sup>2</sup>, J. Kowalski<sup>1,3</sup>, E. Malkin<sup>1</sup>, S. Koushika<sup>2,4</sup>, P. Juo<sup>1</sup>; <sup>1</sup>Molecular Physiology and Pharmacology, Tufts University School of Medicine, Boston, MA, <sup>2</sup>Neurobiology, National Centre for Biological Sciences, Bangalore, India, <sup>3</sup>Biology, Butler University, Indianapolis, IN, <sup>4</sup>Biological Sciences, Tata Institute of Fundamental Research, Mumbai, India

The transport of glutamate neurotransmitter receptors from the cell body to synapses is essential during neuronal development and may contribute to the regulation of synaptic strength in the mature nervous system. We previously showed that cyclin-dependent kinase-5 (CDK-5) positively regulates the abundance of GLR-1 glutamate receptors at synapses in the ventral nerve cord (VNC) of *C. elegans*. Here, we identify a kinesin-3 family motor *klp-4* in a *cdk-5* genetic suppressor screen for genes that regulate GLR-1 trafficking. KLP-4 is homologous to Drosophila kinesin Khc73 and mammalian KIF13. We found that *klp-4* mutants have decreased abundance of GLR-1 at synapses in the VNC. Genetic analysis of *klp-4* and the clathrin adaptin *unc-11/AP180* indicates that *klp-4* functions prior to GLR-1 endocytosis in the ventral cord suggesting that KLP-4 regulates anterograde trafficking. To test directly whether KLP-4 regulates GLR-1 transport, we performed time-lapse imaging of GLR-1 tagged with the photoconvertible fluorescent protein Dendra2. Kymograph analysis indicates that *klp-4* mutants exhibit decreased anterograde flux, run length and velocity of GLR-1 in the VNC. Genetic analysis of *cdk-5* and *klp-4* suggests that they function in the same pathway to regulate GLR-1 trafficking. Interestingly, GLR-1 accumulates in cell bodies of *cdk-5* but not *klp-4* mutants suggesting that GLR-1 might be degraded in the absence of KLP-4 motors. Consistent with this idea, we found that GLR-1 does accumulate in *klp-4* mutant cell bodies if receptor degradation in the MVB/lysosome pathway is blocked. In summary, this study identifies the kinesin KLP-4 as a novel regulator of anterograde glutamate receptor trafficking in *C. elegans*, thus implicating the KIF13 family of motors in GluR trafficking in mammals. Furthermore, we reveal an interesting cellular control mechanism where GLR-1 receptor cargo is targeted for

degradation in the absence of its motor KLP-4. Thus, the cellular fate of receptor cargo early in the secretory pathway, and consequently the abundance of GluRs at synapses, could be controlled by regulating the expression level or availability of KLP-4 motors.

### Inactivity up-regulates the levels of rabaptin-5 leading to enhancement of synaptic delivery of GluA1.

*K. Kiyosue<sup>1</sup>, K. Kameyama<sup>2</sup>; <sup>1</sup>AIST, Ikeda, Japan, <sup>2</sup>AIST, Tsukuba, Japan*

The control of glutamate receptor delivery to the synapse is a mechanism that is critical for determining synaptic strength and potential of plasticity. but, it still remains unclear whether synaptic activity history controls receptor trafficking at the synapse. We focused on rabaptin-5, which is a putative mediator molecules for receptor trafficking. We found that rabaptin-5 was down-regulated by substantial neuronal circuit activity. Conversely, over-expression of rabaptin-5 promoted GluA1, not GluA2 surface expression at spines. We explored the role of rabaptin-5 in synaptic plasticity. Synaptic scaling in response to inactivity of neuronal circuit, a type of plasticity affected by chronic circuit activity, was prevented by rabaptin-5 siRNA treatment. It indicated preventing up-regulation of rabaptin-5, which would to be increased by inactivity, prevented GluA1 mediated expression of synaptic scaling. Our results demonstrate that synaptic activity controls rabaptin-5 level and that define the GluA1 surface delivery at synapse. A part of this work was supported by KAKENHI (20500304)

### Recycling endosomes undergo kiss-and-run exocytosis in hippocampal neurons.

*D. Jullie<sup>1</sup>, D. Choquet<sup>1</sup>, D. Perrais<sup>1</sup>; <sup>1</sup>IINS, Bordeaux, France*

Membrane trafficking is essential for neuronal function: from growth of neurons and synapse formation to recycling of synaptic vesicles and receptors, questions concerning exocytosis and endocytosis are stimulating neurobiology research. In particular, trafficking of glutamate receptors present in recycling endosomes (REs) is necessary for the expression of synaptic plasticity. The localization and the characteristics of exo- and endocytic events are thus crucial determinants of synapse function and plasticity. To investigate these parameters, we have imaged cultured rat hippocampal neurons transfected with transferrin receptor (TfR), a classical marker of REs, tagged with superecliptic pHluorin (SEP), a green fluorescent protein which is not fluorescent at the low pH of acidic intracellular organelles. Single exocytosis events were of two types: in most cases, receptors diffuse quickly in the plasma membrane after exocytosis (discharge events), but in about 25 % of cases, receptors remain clustered (display events). Events observed with other markers, the AMPA receptor subunit GluA1 or the  $\beta$ 2-adrenergic receptor, had similar characteristics, as previously shown. However, their frequency was much lower than for events in cells expressing TfR-SEP. Using fast extracellular pH changes around the recorded cell, we show that display events are characterized by a short opening (median 2.6 s) followed by re-internalization, or kiss-and-run exocytosis. Moreover, using two color imaging of single exocytosis events with markers of neuronal compartments, we found that Rab11a-mCherry is enriched at the exocytosis site, confirming the endosomal origin of the vesicles. Rab11a-mCherry is released from the RE in a few seconds after discharge exocytosis, but not after display exocytosis. Overexpression of a dominant negative form of Rab11a, which largely blocks receptor recycling, decreases the frequency of discharge events and give rise to the formation of large (up to 11  $\mu$ m) tubular REs. In conclusion, the last steps of RE exocytosis and receptor release are controlled in neurons in a manner which could depend on Rab11a.

421

**Detecting the formation of endocytic vesicles in the soma and dendrites of live cultured neurons.**

D. Jullié<sup>1</sup>, M. Rosendale<sup>1</sup>, W. Abdou<sup>1</sup>, D. Perrais<sup>1</sup>; <sup>1</sup>Cnrs UMR 5297 & University of Bordeaux, Interdisciplinary Institute of Neuroscience, Bordeaux, France

Endocytosis is a fundamental process regulating the number of receptors at the surface of cells. In neurons, blocking clathrin mediated endocytosis (CME) leads to an increase of the number of postsynaptic AMPA glutamate receptors within minutes and blocks long term depression of synaptic transmission. Moreover, clathrin coated pits are concentrated near synapses, consistent with a specific role of CME in synaptic plasticity. To clarify the link between CME and synaptic plasticity, it would be important to directly detect the formation of clathrin coated vesicles (CCVs) in live neurons. To do so, we have adapted a method based on extracellular pH changes which detect the moment when transferrin receptors labeled with superecliptic phluorin (TfR-SEP) are isolated from these changes, i.e. the moment of CCV formation (Merrifield, Perrais & Zenisek, Cell 2005). We have imaged cultured hippocampal neurons (9-15 days in vitro), transfected with TfR-SEP, with TIRF (total internal reflection fluorescence) microscopy. When neurons were submitted to the so-called ppH protocol, we detected the formation of CCVs throughout the somato-dendritic compartment. CCVs were formed at clathrin coated structures labeled with CLC-DsRed, which are very stable in these cells. Consequently, CCV formation cannot be detected just by imaging the clathrin structures. We determined whether the ppH protocol affected CME in neurons. The frequency of detected CCVs was constant during the recording, and transferrin labeled with Alexa568 was normally internalized and trafficked within cells. However, application of low pH solution evokes large currents in these cells which are due to the opening of acid sensing ion channels (ASICs). Blocking ASICs with amiloride (500  $\mu$ M) did not affect the formation of CCVs. Moreover, when the low pH solution was replaced by a cell impermeable quencher of SEP fluorescence, Trypan Purple, we could monitor the formation of CCVs with similar frequencies, demonstrating that the activity of endocytic pits can be recorded in live neurons in basal conditions. We will now monitor the possible changes in rate of vesicle formation during protocols inducing synaptic plasticity.

422

**Investigating Nogo-A and its potential role with maspardin in Mast Syndrome.**

M. H. Joyce<sup>1</sup>, M. Hanna<sup>1</sup>; <sup>1</sup>Texas A&M University - Commerce, Commerce, TX

Hereditary spastic paraplegias (HSPs) are a family of inherited, heterogeneous neurological disorders that are defined by progressive spasticity and weakness of the lower limbs. One particular autosomal recessive form of HSP, known as Mast syndrome (SPG21; MIM 248900), is the result of a mutation in SPG21 gene (aliases MASPARDIN, ACP33, MAST, BM-019 AND GLO10). Though the normal functions of maspardin are still unknown, it is ubiquitously expressed and hypothesized to be involved in protein sorting and trafficking in the *trans*-Golgi network/endosomal pathway. Our investigation of maspardin function includes studying its potential interaction with a member of the reticulon family, RTN4. An isoform of RTN4 known as RTN4A (Nogo-A) is expressed in oligodendrocytes and localizes to the endoplasmic reticulum. Numerous studies have shown that Nogo-A acts to repress neuronal regeneration in the central nervous system, implying that Nogo-A may be a contributing factor in the pathology of certain HSPs. Maspardin-Nogo-A interaction has been suggested by others using yeast two-hybrid. Here we demonstrate *in silico* analyses suggest a direct interaction between maspardin and Nogo-A. We sought to confirm this interaction *in vivo* and *in vitro*. The correct orientation of a commercially available Nogo-A clone has been confirmed using the restriction digest technique. Successful transfection of the Nogo-A clone into Cos7 cells, confirmed through Western Blot

analysis, has been achieved and used to study any interactions in cells over-expressing the Nogo-A protein. Preliminary results suggest an interaction exists. Immunoprecipitation experiments have also been employed in brain homogenates extracted from SPG21 mouse models. Samples have been co-immunoprecipitated with either anti-Nogo-A or anti-masparidin antibodies and subjected to Western Blot analysis as a means for confirming interactions between masparidin and Nogo-A. Preliminary results indicate an *in-vivo* interaction. These results suggest disruption of masparidin and Nogo-A may contribute to pathogenesis.

423

**Granulocyte colony stimulating factor (G-CSF) positive effects on muscle fiber degeneration and gait recovery after nerve lesion in MDX mice.**

G. F. Simões<sup>1</sup>, S. U. Benitez<sup>1</sup>, A. L. Oliveira<sup>1</sup>; <sup>1</sup>Structural and Functional Biology, University of Campinas, Campinas, Brazil

Duchenne muscular dystrophy causes degeneration of muscle fibers what results in retrograde changes that affect the CNS. In this sense, spinal motoneurons show the typical signs of chromatolysis and loss of synapses during the course of the disease. G-CSF is a neuroprotective drug that has also positive effects on muscle fibers after lesion, mostly by its anti-inflammatory capabilities. Such properties may positively act on both CNS and skeletal muscle fibers following peripheral nerve lesion, influencing the process of nerve regeneration and motor function recovery. Therefore, the present work investigated muscle fiber preservation, peripheral nerve regeneration, and motor function recovery after axotomy and treatment with G-CSF (200 µg/kg/day, subcutaneously). For this, six weeks old male MDX mice were treated for seven days before and twenty one days after unilateral sciatic nerve crush. C57BL/10 mice were used as the control strain. The recovery of motor function was monitored for three weeks using the walking track test (Catwalk system). The animals were sacrificed and the sciatic nerves processed for immunohistochemistry (neurofilament and pan-neurotrophin receptor antisera – p75NTR) and transmission electron microscopy. The soleus muscles were processed for H&E staining for histopathological analysis. The results showed that MDX mice present a significant forty percent ( $p < 0.05$ ) motor deficit as compared to control animals even before injury. The motor recovery following crush injury was similar for both strains, although MDX mice showed a significantly decreased motor function after three weeks post lesion (MDX+G-CSF  $-18.71 \pm 2.66$ , C57BL/10+G-CSF  $-9.50 \pm 3.70$ ; sciatic nerve index,  $p < 0.05$ ). Neurofilament and p75NTR immunolabeling increased in both strains after nerve crush and G-CSF treatment. Histological analysis showed an increased percentage of normal fibers (23%) in soleus muscles from MDX mice treated with G-CSF. Also, a decreased percentage of regenerated muscle fibers (24%) and a decreased percentage of degenerated fibers (46%) were obtained in MDX mice. The ultrastructural analysis showed an increased total number of axons (21%) in the dystrophic mice after treatment and a decrease of the total number of degenerated axons (8%). Overall, the results herein indicate that G-CSF treatment cannot reverse the decreased motor function in MDX mice. However, this pharmacological approach preserves postural muscle fibers and positively influences the regenerative potential of spinal motoneurons, what may in turn facilitate the reinnervation of regenerated fibers during the course of the disease.

### Investigating the contribution of Neurotrypsin and Agrin in Rett Syndrome's associated synaptic defects.

S. N. Kim<sup>1,2,3</sup>, C. Carromeu<sup>2,3,4</sup>, A. Acab<sup>2,3,4</sup>, A. R. Muotr<sup>2,3,4</sup>, L. S. Goldstein<sup>2,3,5</sup>, A. Almenar-Queral<sup>2,3</sup>; <sup>1</sup>Department of Biological Sciences, University of California San Diego, La Jolla, CA, <sup>2</sup>Department of Cellular and Molecular Medicine, University of California San Diego, La Jolla, CA, <sup>3</sup>Sanford Consortium for Regenerative Medicine, La Jolla, CA, <sup>4</sup>Department of Pediatrics, Rady Children's Hospital, San Diego, San Diego, CA, <sup>5</sup>Department of Neurosciences, University of California San Diego, La Jolla, CA

Rett syndrome is a neurodevelopmental disorder primarily caused by mutations in the X-linked methyl CpG binding protein 2 (*MECP2*) gene. It is characterized by regressions of acquired skills, particularly in language and motor abilities, development of stereotypic hand movement, and seizures. However, the underlying molecular mechanisms causing the disease's neuronal dysfunction are not fully understood. Recently, we found that MeCP2 represses expression of the *Neurotrypsin* gene, which encodes a serine protease primarily expressed in neurons of the cerebral cortex, hippocampus, and lateral amygdala. Neuronal activity induces the release of neurotrypsin to the synaptic cleft and the neurotrypsin-dependent cleavage of the heparan sulfate proteoglycan agrin. Deficiency or excess in neurotrypsin-dependent cleavage of agrin leads to mental retardation and important synaptic defects, suggesting that appropriate levels of neurotrypsin and/or agrin are key for proper synaptic function. Therefore, our findings linking MeCP2 to the regulation of the neurotrypsin/agrin system suggest that alterations in neurotrypsin/agrin expression and function might contribute to the synaptic defects associated with Rett syndrome. Recently, synaptic defects associated with Rett syndrome have been recapitulated in Rett syndrome induced pluripotent stem cell (iPSC)-derived neurons, allowing us to study the underlying molecular mechanisms. Thus, we have determined the levels of *Neurotrypsin* and *Agrin* expression in fibroblasts and neuronal precursor cells (NPCs) derived from controls and Rett syndrome patients carrying the nonsense *MECP2* mutation Q83X (Q83X) or a *MECP2* duplication. qPCR analysis revealed increased *Neurotrypsin/Agrin* expression in Q83X fibroblasts and NPCs while no significant changes were observed in *MECP2* duplication cells, suggesting that a lack of MeCP2 has a larger effect over *Neurotrypsin/Agrin* expression than an excess of MeCP2 in this system. As a complementary approach, we analyzed *Neurotrypsin/Agrin* expression changes in different brain regions of *Mecp2*-deficient mice, a mouse model for Rett syndrome. We observed *Neurotrypsin* up-regulation in cortex and in hippocampus, but not in cerebellum, suggesting that *Neurotrypsin* expression regulation by MeCP2 might be brain region specific. These results suggest that MeCP2 loss of function leading to Rett syndrome alter *Neurotrypsin* and/or *Agrin* expression. Given that the appropriate levels of neurotrypsin-dependent cleavage of agrin are key for normal synaptic function, our findings suggest that an altered neurotrypsin/agrin system might contribute to the synaptic defects observed in Rett syndrome models.

425

### Unknown protein and GAP-43 expression in the thalamus in post-mortem schizophrenic brains.

A. Steen<sup>1</sup>, W. A. Hossain<sup>1</sup>, L. A. Carver<sup>2</sup>; <sup>1</sup>Department of Psychiatry and Neuroscience, University of Missouri-Kansas City School of Medicine, Kansas City, MO, <sup>2</sup>Departments of Psychiatry/Neurology, Kansas University Medical Center, Kansas City, KS

The symptom complex we term schizophrenia has been known for at least 3500 years, (Lehmann, 1967). Yet the circumstances that are believed to be the etiology of this disorder still remain a conundrum. Numerous studies have found cortical and subcortical abnormalities,

while some studies have suggested structural damage to the thalamus may play an important role in schizophrenia. Several of these studies have suggested that thalamic volume reduction characterizes patients with schizophrenia. Other studies suggest a lower metabolic rate in the thalamus of schizophrenic patients. Previous studies from our lab have shown that there is an increase level of dopamine in the thalamus of schizophrenic patients when compared to controls (Oke, Carver, & Adams, 1993). Our research also shows that the possibility of the failure to convert dopamine into norepinephrine is not related to the increased levels of dopamine. The theory proposed in this study is that the increased concentration of dopamine in the thalamus of individuals with schizophrenia could be due to synaptic disturbance and or an abnormal distribution of growth protein in the thalamus that could possibly stimulate aberrant growth of dopaminergic neurons from the dopamine enriched areas surrounding the thalamus. To test the hypothesis that synaptic disturbances are involved in the pathogenesis of schizophrenia, we looked at the levels of Growth-Associated Protein-43 (GAP-43), a neuro-specific phosphoprotein localized in the presynaptic terminals that is associated with the initial establishment, regeneration, and functional modulation of synaptic relationships. Western blots using both polyclonal and monoclonal antibodies were done to detect the levels of GAP-43 protein in post-mortem thalamic brain tissue of schizophrenic patients and controls. This data was controlled for confounding factors such as age, post-mortem time delay, and antipsychotic medication. Negative controls were also run with each blot. Quantitative analysis showed a significantly decreased level of GAP-43 protein expression in the thalamic brain tissue of schizophrenic compare to control. Furthermore it also showed an unknown protein of a molecular weight of approximately 100kDa in the thalamic tissue of schizophrenic patients, but not in the controls. Our data may indicate impaired synaptic plasticity in the thalamus of the schizophrenic brain. Our data also demonstrate an unknown protein that could be precursor/splice variant of GAP-43 or an aberrant form playing an important role along with reduced level of GAP-43 expression in schizophrenia. Further studies are needed to identify the unknown protein and learn if there is any connection with the increased levels of dopamine in the thalamus of schizophrenic patients.

### **G protein signaling tunes R7BP activity by regulating its palmitoylation turnover.**

*L. Jia<sup>1</sup>, M. E. Linder<sup>2</sup>, K. J. Blumer<sup>1</sup>; <sup>1</sup>Department of Cell Biology and Physiology, Washington University, St. Louis, MO, <sup>2</sup>Department of Molecular Medicine, Cornell University, Ithaca, NY*

Signaling molecules in the nervous system are abundantly lipidated, including G protein coupled receptors (GPCR), channels, signal transducers and their regulators. Protein palmitoylation is the only reversible lipid modification. Cycles of palmitoylation-depalmitoylation alter protein localization and activity, which are critical for diverse cell functions. We have discovered that palmitoylation cycling occurs on an important neuronal protein called R7BP (R7-family binding protein). In neurons, R7BP forms obligatory complexes with R7 family of G protein regulators. The R7BP serves as membrane anchor and allosteric regulator of the R7 family of G protein signaling regulators. In cultured cells, palmitoylated R7BP is membrane localized, while depalmitoylated R7BP mutants accumulates in the nucleus. However, the molecular mechanism that regulates the palmitoylation and localization of the R7BP associated complexes are not known. Using a combination of biochemistry, cell imaging and cell signaling approaches, we identified distinct roles of palmitoylation and depalmitoylation processes in R7BP intracellular trafficking and GPCR signaling regulation. We identified protein acyl transferase DHHC2 to mediate de novo and turnover palmitoylation of R7BP. DHHC2 silencing redistributes R7BP from the plasma membrane to the nucleus. Furthermore, we found that R7BP depalmitoylation can be inhibited by Go signaling in cultured cells. Inhibition of depalmitoylation also significantly

alters R7BP membrane localization. These results indicate that the R7BP palmitoylation cycling machinery is adaptive to cellular signaling activity. Given the critical roles of R7 complexes in neuronal signal transduction regulation, our studies indicated the importance of palmitoylation cycling on regulated protein trafficking in signaling processes important for neuronal development and function.

427

**Major histocompatibility complex of class I (MHC I) gene silencing increases stability of synapses and reduces astrocyte pro-inflammatory response in vitro.**

*R. C. Hell<sup>1</sup>, A. L. Bombeiro<sup>1</sup>, G. F. Simões<sup>1</sup>, A. L. Oliveira<sup>1</sup>; <sup>1</sup>Structural and Functional Biology, University of Campinas, Campinas, Brazil*

The establishment of neuronal networks is a complex process that is still not well understood. Stability of synapses depends on different factors including the degree of reactive gliosis within the CNS microenvironment. The MHC I expression by neurons and glial cells and its correlation with synaptic plasticity revealed a molecular mechanism of interaction between such cells. Nevertheless, the correlation between MHC I expression and the degree of astrogliosis may be a key factor for the stability of newly formed synapses. Based on this fact, the present study aimed to analyze, in spinal neurons and astrocyte co-cultures, the influence of GFAP and MHC I gene silencing on the expression of major interleukins as well as on the synaptic marker synaptophysin. In this way, astrocyte primary cell cultures were obtained from newborn C57BL/6J mice cerebral cortices and transfected with siRNA for beta 2 microglobulin (B2M) using magnetic nanobeads. Also, MHC I upregulation was achieved by treating the cultures with interferon 1 beta (IFN1B). The levels of mRNA for GFAP, beta-2 microglobulin, BDNF, GDNF, IL-1, IL-6, TNF-alpha, IL-12 and IL-17 were analyzed by quantitative RT-PCR. For immunocytochemistry, the cultures were fixed and incubated with GFAP, OX18 (MHC I), Synaptophysin, NeuN and neurofilament primary antisera followed by Cy3-conjugated secondary antibodies. The results showed that B2M silencing lead to 50% reduction of MHC I and GFAP expression, indicating a reduction of astroglial reaction. In line with this, B2M silencing resulted in significant reduction of pro-inflammatory cytokines, namely IL-1, IL-6, TNF-alpha, IL-12 and IL-17 ( $p < 0.05$ ). Also, the levels of neurotrophins were significantly downregulated. Interleukin gene expression was partially reversed ( $p < 0.05$ ) and BDNF and GDNF mRNA levels were totally recovered after IFN1B treatment. Contrarily, IFNB treated control cultures presented decreased mRNA levels for all parameters, except for IL-12 and IL-17. The immunocytochemistry results were in line with the RT-PCR data and indicated a decreased astroglial reaction, coupled with decreased dendrite elongation and increased synaptic formation in the absence of MHC I. Overall the present data indicate that MHC I downregulation decreases astrogliosis as well as the transcript levels of pro-inflammatory cytokines. This may, in turn, contribute to the establishment of more complex neural circuits and increased number of synapses.

428

**Downregulation of the major histocompatibility complex of class I (MHC I) by COUP-TF II increases the synaptic circuits density and the size of dendrites in PC12 cells.**

*R. F. Inácio<sup>1</sup>, M. C. Bajgelman<sup>2</sup>, M. Sabha<sup>1</sup>, A. L. Bombeiro<sup>1</sup>, H. Marques-Souza<sup>1</sup>, A. L. Oliveira<sup>1</sup>; <sup>1</sup>Structural and Functional Biology, University of Campinas, Campinas, Brazil, <sup>2</sup>LNBio, University of Campinas, Campinas, Brazil*

The molecular mechanisms behind the establishment of complex neural circuits are still not well understood. It is already known, however, that the expression of MHC I by neurons and glial cells, influence the stability of newly formed synapses. In this sense, the identification of

molecules able to regulate MHC I transcription may lead to new therapeutic approaches following CNS lesion and disease. The present study aimed at studying the regulation of MHC I expression by COUP-TF II in PC-12 cells, that constitute a neuron-like cell line in the presence of nerve growth factor (NGF). For this purpose, PC-12 cells were transduced with viral vectors containing plasmids designed either to silence (sh-COUP-TF II) or overexpress COUP-TF II (rescue-COUP-TF II). The transfection effectiveness was obtained by Western-blotting and flow-cytometry and cell selection was achieved by treatment with hygromycin. All cell lines were cultured in 24 well plates with an initial density of  $5 \times 10^3$  cells. In order to induce neuron-like differentiation, the cultures were treated with NGF, in a dose of 250 micrograms/ml. After 5 and 10 days of culturing, the cells were fixed in phosphate buffered 4% paraformaldehyde. Immunocytochemistry with primary antisera against synaptophysin and MHC I (OX-18) were used to evaluate the size of dendrites, synaptic boutons density as well as the levels of MHC I protein immunoreactivity. The results revealed that COUP-TF II silencing results in approximately 50% increased levels of MHC I coupled with significant reduction of dendrite branching and elongation. In this way, the size of dendrites did not reach more than 25 micrometers, so that the occurrence of long dendrites was absent. On the contrary, COUP-TF II overexpression results in downregulation (~30%) of MHC I and increased number of long dendrites, resulting in significantly more complex neural circuits. Long sized dendrites reached more than 250 micrometers, after 10 days of culturing. Overall, the present results indicate a connection between COUP-TF II activation and the downregulation of MHC I by neuronal cells. This finding may in turn lead to the better understanding of the mechanisms behind synaptic plasticity in the CNS, allowing future strategies to treat neural tissue damage and to reduce the pace of neurodegenerative diseases.

429

#### ***Fmr1* transcripts with shifted translational reading frame in the embryonic rat telencephalon.**

J. Correa<sup>1</sup>, M. Valpeteris<sup>1</sup>, F. Velloso<sup>1</sup>, S. Chiavegatto<sup>2</sup>, L. Haddad<sup>1</sup>; <sup>1</sup>Department of Genetics and Evolutionary Biology, Universidade de São Paulo, São Paulo, Brazil, <sup>2</sup>Department of Pharmacology, Universidade de São Paulo, São Paulo, Brazil

Fragile mental retardation protein (FMRP), encoded by the Fragile Mental Retardation 1 (*FMR1*) gene, is an important mRNA translation regulator in the central nervous system (CNS), notably in the cerebral cortex, hippocampus and cerebellum. Alternative exclusion of *Fmr1* exon 14 may be combined to the choice among three splicing acceptor sites in the exon 15, shifting the reading frame and eliminating FMRP nuclear export signal and RGG-box, a domain that binds and regulates several mRNA species. Translation stop codons are prematurely found in *Fmr1* messages where exon 13 is directly ligated to exon 15, except if the third splicing site is used. It is currently unknown if those alternative splicing forms of *Fmr1* are functionally relevant. Therefore, we present here a developmental expression analysis of *Fmr1* exon 14 in the rat CNS, based on RT followed by qPCR.

We first studied the period around birth, E19 and P2, when *Fmr1* brain expression is known to increase. In the hippocampus, both *Fmr1* and specific exon 14 transcripts increased from E19 to P2. A ratio between specific exon 14 over total *Fmr1* transcripts was defined as an inclusion rate (IR) of that exon. In both ages, nearly all hippocampal *Fmr1* transcripts contained the exon 14, indicating an IR of about 100%. In the cerebellum, the exon 14 IR decreased between E19 and P2 from 84 to 66%. Conversely, we found an increased exon 14 IR from 56% (E19) to ~100% (P2) in the cerebral cortex, which was not due to an elevation on *Fmr1* total transcripts between time points. On E14, 20% to 45% of *Fmr1* transcripts lacked exon 14 in the telencephalic vesicle. Therefore, E14 telencephalic vesicle, E19 cerebral cortex and P2 cerebellum may indicate developmental time points, and CNS structures, where *Fmr1* exon 14

exclusion is relevant. Immunoprecipitation of the eukaryotic translation initiation factor 4E (eIF4E) was used to evaluate if the nonsense-mediated mRNA decay (NMD) system could remove *Fmr1* messages harboring premature stop codons in the telencephalic vesicle. Co-immunoprecipitated mRNA were reversely transcribed and analyzed by RT-PCR with a forward primer plus any of the three chimeric primers tagging *Fmr1* exons 13 and 15. Our preliminary results indicate the stability of *Fmr1* messages lacking exon 14 and using the third splicing site from exon 15 in the rat E14 telencephalic vesicle. Ongoing experiments are likely to provide a relative quantification of those results.

### **Characterization of the aggregation the poly-glutamine domains of presynaptic proteins Piccolo and Bassoon: Potential determinants of the active zone assembly.**

*L. A. Barra<sup>1</sup>, J. A. Villalobos<sup>1</sup>, Y. M. Cruz<sup>1</sup>, C. Tapia<sup>1</sup>, M. Gatica<sup>1</sup>, P. Zamorano<sup>1</sup>; <sup>1</sup>Biomedicine, University of Antofagasta, Antofagasta, Chile*

Piccolo and Bassoon are two related multidomain presynaptic proteins suggested to play a crucial role in the formation of the active zone. The specific functions of these molecules at the synapse are poorly understood as well as their mechanism of synaptic recruitment. We have identified domains of poly-glutamine (PQ) in Piccolo (PQ 1, 2 and 3) and Bassoon (PQ 1 and 2). Some of these domains are similar to PQ domain of the CPEB dendritic protein of *Aplysia californica*, which has been shown to have prion-like behavior and aggregation properties suggested to be important for its function. Here, we evaluate the ability of aggregation and distribution of Piccolo and Bassoon PQ domains in different heterologous cell lines (HEK, COS-7) and their distribution in primary cultures of hippocampal neurons. Heterologous cells showed different levels of aggregation in the cytoplasm as well as nuclear localization. In neurons, PQ domains showed a similar localization with a juxtannuclear aggregation, in addition to clusters found at growth cones. The aggregation properties of these domains suggest that these motifs could be important for their clustering to active zones.

## **Establishment and Maintenance of Polarity I**

431

### **Loss of Ciliary Polycystin-2 in Induced Pluripotent Stem Cells from Polycystic Kidney Disease Patients.**

*B. S. Freedman<sup>1</sup>, A. Q. Lam<sup>1</sup>, J. L. Sundsbak<sup>2</sup>, R. Iatrino<sup>1</sup>, S. J. Koon<sup>2</sup>, J. Zhou<sup>1</sup>, L. Daheron<sup>3</sup>, P. C. Harris<sup>2</sup>, J. V. Bonventre<sup>1</sup>; <sup>1</sup>Renal Division, Brigham and Women's Hospital, Boston, MA, <sup>2</sup>Division of Nephrology and Hypertension, Mayo Clinic, Rochester, MN, <sup>3</sup>Harvard Stem Cell Institute, Cambridge, MA*

We investigated the potential of induced pluripotent stem (iPS) cells to model polycystic kidney disease (PKD), a very common, multi-organ ciliopathy in which epithelial cysts and fibrosis replace the normal kidney architecture. Fibroblasts with characterized mutations from three autosomal dominant (ADPKD) and two autosomal recessive (ARPKD) patients were reprogrammed into iPS cells. Undifferentiated PKD iPS cells and healthy controls exhibited similar rates of proliferation, apoptosis, and ciliogenesis, and expressed the PKD disease genes polycystin (PC)-1 and -2. However, PC2 localization to the primary cilium was reduced ~75 % in ADPKD iPS cells, compared to ARPKD and control lines. A single PKD1 mutation was observed in ADPKD fibroblasts and iPS cells, suggesting that reduced ciliary PC2 occurred without

complete PC1 loss. Somatic epithelial cells and hepatoblast-biliary precursors differentiated from ADPKD iPS cells had ~50 % fewer cilia with detectable PC2, compared to controls. Reduced ciliary PC2 in PKD iPS cells may be a useful metric to better understand ADPKD pathophysiology and guide therapeutics.

432

### **Planar Cell Polarity Orients Airway Cilia.**

*E. K. Vadar<sup>1</sup>, J. D. Axelrod<sup>1</sup>; <sup>1</sup>Pathology, Stanford University School of Medicine, Stanford, CA*

Propulsion of contaminants out of the lungs by coordinated action of motile cilia is essential for airway function. Multiciliated airway epithelial cells undergoing ciliogenesis generate hundreds of basal bodies that traffic to the surface, elongate motile axonemes and align with the tissue axis for coordinated motility. The mechanisms of cilium polarization remain poorly explored. We showed that a conserved set of planar cell polarity (PCP) proteins polarize airway epithelial cilia: PCP proteins localize asymmetrically to the cell cortex at the level of the apical junctions, revealing that PCP signaling starts before ciliogenesis; molecular and morphological polarity are disrupted in PCP mutant epithelia; and PCP mutants display defective airway clearance, highlighting the requirement for ciliary alignment. Studying the cytoskeleton, a target of PCP signaling, we uncovered two temporally-distinct, cell type-specific, planar polarized microtubule (MT) networks. Prior to ciliogenesis, MTs are necessary in all cells for asymmetric PCP protein localization. Subsequently, after cilia appear, MTs extend from the polarized appendages of basal bodies toward the apical junctions present within an asymmetric PCP protein domain. These MTs are PCP-regulated, ciliated cell-specific, interact with the cortex via their plus ends, and are required for basal body distribution and alignment. Our data suggest that MTs have two separable PCP functions: MTs are first required in every cell for trafficking PCP proteins to the cortex, and later they interact with and align cilia. Our studies reveal strong conservation of PCP mechanisms initially described in *Drosophila*, and cilium alignment by PCP-oriented MTs provides the first mechanistic description of how asymmetric PCP proteins at the cortex orient cilia along the cell surface.

433

### **MCC is a PCM/centrosome component that coordinates cilia formation.**

*B. A. Liu<sup>1</sup>, G. Gish<sup>1</sup>, V. Nguyen<sup>1</sup>, M. Bashkurov<sup>1</sup>, A-C. Gingras<sup>1</sup>, L. Pelletier<sup>1</sup>, T. Pawson<sup>2</sup>; <sup>1</sup>Samuel Lunenfeld Research Institute, Toronto, ON, Canada, <sup>2</sup>Molecular Genetics, Samuel Lunenfeld Research Institute, Toronto, ON, Canada*

Mutated in colorectal cancer, MCC, is a putative tumor suppressor gene found somatically mutated in familial polyposis coli and Gardner's syndrome. Previous studies have identified MCC as molecular scaffold involved in numerous cellular processes ranging from cell cycle, DNA damage response, cell proliferation, cell migration to cell polarity. However, the function and mechanism of MCC as a scaffold remains largely unknown. Using mass spectrometry we identified novel protein interaction partners of MCC including centrosomal proteins CEP170, AZI1 (CEP131), NDE1 (NudE) and components of the pericentriolar material (PCM). Here we uncovered a new function of MCC in cilia formation as demonstrated by depletion of MCC by siRNA knockdown which result in a defect in proper cilia formation. MCC functions as a scaffold to recruit multiple GTPase regulators such as RasaL2, whereby knockdown of MCC disrupts localization of RasaL2 to the base of the cilium. We further demonstrate that MCC and RasaL2 function to play an important role in coordinating membrane and cargo trafficking at the ciliary base. Here we propose a model for MCC as a molecular scaffold during ciliogenesis and further suggest a broader role in planar cell polarity.

434

**Analysis of mouse forebrain lateral wall polarity: multi-scale implication of PCP genes.**C. Boutin<sup>1</sup>, A. M. Goffinet<sup>1</sup>, F. Tissir<sup>1</sup>; <sup>1</sup>DENE, UCL, Brussels, Belgium

Ciliated epithelia are essential for development and correct functioning of many organs. In the mouse forebrain, lateral walls of lateral ventricles are lined by multiciliated ependymal cells that participate to correct circulation of cerebro-spinal fluid (CSF). Ependymal cells display different levels of organization and polarization. At the cell scale, each ependymal cell bears a tuft composed of multiple cilia beating in a polarized and coordinated manner. Furthermore, this tuft is always positioned in anterior side of the cell relative to the anatomical axis. At the tissue scale, neighboring ependymal cells coordinate their polarity leading to a precisely polarized tissue that propels CSF unidirectionally. In the present study, we investigated the implication of planar cell polarity (PCP) genes in regulation of lateral wall organization. We combined genetic approach and confocal microscopy to analyze in vivo the consequences of PCP genes deletion on cell and tissue polarity. In *Celsr1* mutant mice, we found that while intra-cellular organization was preserved, the coordination of tissue polarity was lost. In contrast, *Vangl2* deficient lateral walls showed defect both at the cell and tissue scales. Both phenotypes have drastic consequences on the tissue function since mutants mice displayed impaired flow at the ventricular surface and developed hydrocephalus. Our results demonstrate that in ventricular walls establishment of tissue and cell polarities are distinct process sharing common regulators.

435

**E-cadherin is recruited to the apical membrane by Enteropathogenic *E.coli*.**G. A. Pedersen<sup>1</sup>, C. Toft<sup>1</sup>, M. Amieva<sup>2</sup>, L. N. Nejsum<sup>1</sup>; <sup>1</sup>Department of Molecular Biology & Genetics, Aarhus University, Aarhus C, Denmark, <sup>2</sup>Dept of Pediatrics and Microbiology & Immunology, Stanford University, Stanford, CA

E-cadherin is the major component of adherens junctions that connect neighboring cells in polarized epithelia. Adherens junctions are dynamic structures that are subject to regulation by controlling E-cadherin stability in the membrane. E-cadherin interacts with catenins that are involved in downstream signaling pathways that affect cell mobility and proliferation. We studied regulation of adherens junctions in epithelial cells infected with Enteropathogenic *E.coli* (EPEC), a foodborne pathogen that colonizes the epithelium of the small intestine. EPEC attaches to the apical side of epithelial cells where it injects several bacterial effector proteins that manipulate host cellular signalling pathways. EPEC effectors are known to disrupt tight junctions making the epithelium permeable and presumably allowing EPEC access to nutrients through paracellular diffusion.

We investigated whether EPEC infection of polarized epithelial cells also modifies the adherens junctions. We found that E-cadherin was dispersed from the adherens junctions in the infected cells and recruited to the infection site on the apical membrane where it colocalized with EPEC. The recruitment of E-cadherin proved to be specific since other members of the cadherin superfamily (N-cadherin, desmosomal cadherins, and protocadherins) were not recruited. Preliminary data indicate that E-cadherin is recruited by redirecting endosomal trafficking from the existing adherens junctions.

We also investigated the localization of catenins during EPEC infection. We saw that  $\beta$ -catenin dissociated from E-cadherin in the infected cells but was not recruited to the EPEC attachment site. In contrast, p120-catenin was found at the EPEC attachment site and was also observed in the nucleus of the infected cells suggesting activation of the p120-catenin signaling pathway. The role of E-cadherin recruitment for bacterial survival is unknown, however, we propose that

E-cadherin signaling takes place locally at the infection site through activation of the p120-catenin signaling pathway.

436

**Robust polarity establishment via an endocytosis-based cortical corraling mechanism.**

M. Jose<sup>1</sup>, S. Tollis<sup>1</sup>, D. Nair<sup>2</sup>, J-B. Sibarita<sup>2</sup>, D. W. McCusker<sup>1</sup>; <sup>1</sup>European Institute of Chemistry and Biology, Pessac, France, <sup>2</sup>Institut Interdisciplinaire de NeuroScience, Bordeaux, France

Formation of a stable polarity axis underlies many essential biological processes. Here, using high-resolution imaging and complementary mathematical modeling we find that cell polarity can be established via the spatial coordination of opposing membrane trafficking activities: endocytosis and exocytosis. During polarity establishment in budding yeast, these antagonistic processes become apposed. Endocytic vesicles corral a central exocytic zone, tightening it to a vertex that establishes the polarity axis for the ensuing cell cycle. Concomitantly, the endocytic system reaches an equilibrium where internalization events occur at a constant frequency. Mutants in which endocytosis was depolarized failed to initiate internalization events with normal periodicity within the corral, resulting in wide, unstable polarity axes. These results, predicted by novel *in silico* modeling and verified by high resolution *in vivo* studies, identify a requirement for endocytic corraling during robust polarity establishment.

437

**Control of Epithelial Polarization and 3D Morphogenesis by the APC Tumor Suppressor.**

J. R. Prosper<sup>1</sup>, A. Schwertner<sup>2</sup>, F. F. Yang<sup>2</sup>, K. H. Goss<sup>2</sup>; <sup>1</sup>Indiana University School of Medicine, South Bend, IN, <sup>2</sup>University of Chicago, Chicago, IL

Adenomatous polyposis coli (APC) is a multifunctional tumor suppressor that is frequently mutated or lost in most epithelial-derived tumor types, including colorectal, breast and renal cancer; however, the mechanisms by which APC suppresses tumorigenesis are incompletely understood. We have previously demonstrated that germline heterozygous *Apc* mutation disrupts mammary epithelial architecture and that this effect was likely to represent a Wnt-independent activity of APC. The objectives of the present study were to extend these observations to *in vitro* models and begin to identify the molecular mechanism by which APC regulates epithelial polarization and morphogenesis. Using lentiviral-mediated RNA interference, APC was stably suppressed in MDCK kidney and HC11 mammary epithelial cells. Although the APC-knockdown cells did not show any significant morphological or growth differences compared to control vector-only or scrambled shRNA-infected cells on plastic, they displayed a dramatic multi-layering phenotype when cultured on Transwell permeable supports. The polarized localization of basolateral markers, such as Dlg and Scrib tumor suppressor proteins, and apical proteins, including MUC1 and gp135, was severely perturbed in APC-knockdown cells. When these cells were cultured under three-dimensional (3D) conditions, APC-knockdown epithelial cells formed enlarged, non-spherical cysts or acini with filled-in lumens, many of which were invasive into the surrounding matrix, as compared to controls. Remarkably, inverted polarity was observed in the MDCK APC-knockdown cells such that gp135 localized to the periphery of the cysts. All of the polarization and morphogenesis phenotypes associated with APC-knockdown were specific since they were rescued by stable introduction of full-length APC, but, similar to our previous *in vivo* studies, the epithelial architecture defects associated with APC loss did not involve hyperactivation of the Wnt signaling pathway. APC depletion or mutation in colonic epithelial cells also resulted in 3D morphogenesis defects, suggesting that the control of epithelial architecture may be a major tumor suppressive activity of APC in the colon. Collectively, these data indicate that APC is a

potent regulator of epithelial polarization and morphogenesis and predict that one mechanism by which APC loss promotes tumorigenesis is by disrupting epithelial architecture to subsequently drive tumor cell growth, survival and invasion.

438

**Molecular control of apical polarization during endothelial lumen formation in 3D collagen matrices: Role for tubulin acetylation, Rac1-, Cdc42-, and Src-dependent signaling.**

*D. Kim<sup>1</sup>, P. R. Norden<sup>1</sup>, G. E. Davis<sup>1</sup>; <sup>1</sup>Medical Pharmacology and Physiology, University of Missouri-Columbia, Columbia, MO*

Our laboratory has focused for many years on elucidating the molecular basis for endothelial cell lumen formation in 3D extracellular matrix environments. We have elucidated a key role for Cdc42 and Rac1 which act in conjunction with the p21-activated kinases (Pak)-2, and Pak-4 as well as protein kinase C epsilon and Src family kinases during these events. Here, we show that the microtubule cytoskeleton including post-translationally modified tubulins such as acetylated tubulin are distributed in a sub-apical domain which is highly polarized while F-actin is strongly distributed in a basal fashion. This distribution depends on the microtubule plus-end regulatory proteins, EB1, p150Glued and Clasp1, which control EC lumen formation as well as this asymmetric apical-basal cytoskeletal polarity which appears to be a fundamental requirement for the EC lumen formation process. We further expressed GFP-Rac1 wild-type or its V12 constitutively active form and also GFP-Cdc42 during lumen formation and observe a strong apical polarization of targeting particularly with Rac1V12, but also with wild-type Rac1 and Cdc42. This expression leads to increased tubulin acetylation in a polarized subapical location which appears to support or facilitate targeting of vesicles with apical membranes during this process. Blockade of Rac1 and Cdc42 interferes with tubulin acetylation which corresponds to inhibition of lumen formation. Finally, we also identify very strong apical targeting of phosphorylated Src which similarly localizes to the apical membrane as well as to vacuoles and vesicles which target this tubulin-rich region to fuse with the developing apical membrane surface to control EC lumen formation in 3D matrices.

439

**FIP5 Phosphorylation by GSK3 $\beta$  Regulates its Interaction with SNX18 and Kinesin-2 and is Required for Epithelial Lumen Formation In Vitro and In Vivo.**

*D. Li<sup>1</sup>, C. Willenborg<sup>1</sup>, R. Prekeris<sup>1</sup>; <sup>1</sup>University of Colorado Anschutz Medical Campus, Centennial, CO*

Proper sorting and targeting of endocytosed proteins is necessary for the maintenance of epithelial cell polarity and apical lumen formation. A leading model of epithelial lumen morphogenesis suggests that to form the apical lumen, apical proteins must be transcytosed via Rab11-containing recycling endosomes and fuse at the lumen formation site, also known as apical membrane initiation site (AMIS). While the importance of Rab11-endosomes in the formation of the apical lumen is now well established, we know little about the machinery that regulates formation, transport and targeting of these Rab11-endosomes during lumen formation. FIP5/Rip11, a Rab11 effector protein, is known to be involved in apical-directed transport in polarized cells and is thought to act as a scaffolding protein that recruits and binds effectors of endocytosis. It was recently demonstrated that FIP5/Rip11 is required for the formation and targeting of Rab11-endosomes to AMIS. Additionally, it was shown that FIP5/Rip11 functions by binding to Sorting Nexin 18 (SNX18) and kinesin-2 to mediate formation/scission and transport of endocytic carriers. In this study we demonstrate that during apical lumen formation

FIP5/Rip11 is phosphorylated by GSK3 $\beta$ , and that this phosphorylation regulates FIP5/Rip11 binding to SNX18 and kinesin-2 and is required for apical lumen formation in vitro.

The following model of lumen formation in epithelial cells is largely derived from studies conducted in 3D tissue culture systems. It remains unclear whether the same molecular machinery is used during epithelial tissue morphogenesis in vivo. To test whether FIP5-dependent endocytic transport also mediates lumen formation in vivo, we used zebrafish intestine development model. Here we show that depletion of FIP5 inhibits the proper formation of zebrafish intestinal lumen and also leads to ectopic formation of microvilli-containing apical membranes. In summary, this study finds that FIP5 mediates the formation of the epithelial lumen via sequential interaction with SNX18 and kinesin-2, and the function of FIP5 during lumen initiation and expansion is regulated by GSK3 $\beta$  phosphorylation.

**Regulation of epithelial apical polarity orientation by phosphorylation of the Podocalyxin complex.**

*D. Bryant<sup>1</sup>, A. Datta<sup>1</sup>, K. Mostov<sup>1</sup>; <sup>1</sup>Anatomy, University of California, San Francisco, San Francisco, CA*

Formation of epithelial lumens requires the spatiotemporal co-ordination of apico-basal polarization in cells contributing to the lumen. In addition, a fundamental requirement for organogenesis is that the orientation of apical polarity is correctly formed away from the axis provided by the extracellular matrix (ECM). We previously demonstrated that this requires sensing of the ECM by beta1-integrins, regulating activation of a Rac1-dependent, RhoA-antagonized orientation pathway. Moreover, we demonstrated that correct polarity orientation involves endocytosis and transcytosis of the apical glycoprotein, podocalyxin (Podxl), initially from the ECM-abutting surface to the nascent lumen. This is dependent on a Rab11-Rab8 GTPase cascade, controlling such transcytosis, and resulting in formation of the Cdc42-Par3-aPKC polarity complex upon delivery of Podxl to the lumen. We here demonstrate that rather than being a passive apical cargo, podxl itself controls the orientation of apical polarity in three-dimensional MDCK cyst cultures. Podxl associates with the NHERF1/2 scaffold proteins, as well as Ezrin, and this multimeric complex controls subsequent apical polarity establishment. Dynamic spatiotemporal phosphorylation of the Podxl-NHERF-Ezrin complex controls the assembly-disassembly of the complex to ensure apical identity is excluded from the ECM-abutting surface, and occurs only at the lumen. We thus describe a molecular mechanism for correct formation and orientation of apical polarity by dynamic phosphorylation of the Podxl complex.

441

**Phosphatidylinositol Synthase regulates the polarized deposition of basement membrane components.**

*O. Devergne<sup>1</sup>, T. Schupbach<sup>1</sup>; <sup>1</sup>Department of Molecular Biology, HHMI/Princeton University, Princeton, NJ*

Epithelial cells are characterized by their polarized architecture that enables them to exert their varied functions in embryonic and adult organisms. Epithelia exhibit a profound apical-basal polarity that is manifested in the cytoplasmic and surface organization of individual cells. Loss of their apical-basal cell polarity is often associated with carcinoma progression and tumor metastasis. The establishment and maintenance of polarity relies on the regulated transport of newly synthesized and recycled proteins to these specific domains. The basement membrane (BM), a specialized sheet of the extracellular matrix contacting the basal side of epithelial tissues, plays a major role in the establishment and maintenance of epithelial cell polarity.

However, little is known about how BM proteins themselves achieve a polarized distribution. An attractive model system for the study of epithelial structure and morphogenesis is the development of the follicular epithelium (FE), which envelops the germline during *Drosophila* oogenesis. To unravel the molecular mechanism regulating the polarized deposition of BM, we have previously performed a genetic screen in which we identified *Crag*, a DENN domain containing protein, as a regulator of polarized BM secretion (1). We recently isolated a new gene involved in this process, *pis*, encoding Phosphatidylinositol synthase, which plays a critical role in phosphatidylinositol 4,5-bisphosphate (PIP2) regeneration after its hydrolysis into inositol 1,4,5-trisphosphate (IP3) and diacylglycerol (DAG) by Phospholipase C (PLC). PIP2 regulates many cellular functions, such as intracellular trafficking and membrane and ion transport. Significantly, in follicular cells mutant for *pis*, we detect a strong accumulation of BM components apically. This defect is not generally observed in mutants affecting epithelial polarity. In *pis* mutant cells, BM components are secreted at the apical side of the epithelium leading to the formation of an "apical" BM. However, apical, junctional and basolateral polarity is not affected. Altogether, our data indicate a specific role for *pis* in the organization of epithelial architecture by regulating the polarized deposition of BM components.

**The clathrin adaptor AP-1B generates an alternative recycling pathway for Transferrin Receptor in polarized and non polarized cells.**

A. E. Perez Bay<sup>1</sup>, R. Schreiner<sup>1</sup>, F. Mazzone<sup>1</sup>, J. M. Carvajal-Gonzalez<sup>1</sup>, D. Gravotta<sup>1</sup>, E. Perret<sup>1</sup>, G. Leman Mantaras<sup>1</sup>, Y-S. Zhu<sup>2</sup>, G. Kreitzer<sup>3</sup>, E. J. Rodriguez-Boulan<sup>1</sup>; <sup>1</sup>Ophthalmology, Weill Cornell Medical College, New York, NY, <sup>2</sup>Medicine, Weill Cornell Medical College, New York, NY, <sup>3</sup>Cell and Developmental Biology, Weill Cornell Medical College, New York, NY

In non-epithelial cells, such as CHO, the small GTPase rab11a mediates recycling of fast endocytic receptors from juxtacentriolar perinuclear endosomes. In contrast, in polarized epithelial cells (MDCK) many of these receptors utilize the clathrin adaptor AP-1B to recycle basolaterally from juxtacentriolar common recycling endosomes, whereas rab11a localizes to apical recycling endosomes clustered around the subapical centrosome. Here, we show that knock-down of AP-1B promotes re-routing of transferrin receptor (TfR), an AP-1B cargo, from its regular basolateral recycling route into a transcytotic route to the apical membrane that involves apical recycling and apical sorting endosomes. Trafficking of TfR along this route requires microtubules, the plus-end microtubule motor KIF16b, glycan signals and rab11a. Additional experiments show that AP-1B also mediates rab11a-independent recycling of TfR in subconfluent MDCK and CHO cells. Our experiments demonstrate a transcytotic route likely to be key in the organization and function of AP-1B deficient epithelia and identify a microtubule motor involved in transcytosis.

**Par6b is Required For Both the Membrane E-cadherin expression and the Apicobasal Polarity of *Xenopus* Ectoderm Cells.**

S. Wang<sup>1,2</sup>, S-W. Cha<sup>1</sup>, C. Wylie<sup>1</sup>; <sup>1</sup>Cincinnati Children's Research Foundation, Cincinnati, OH, <sup>2</sup>MDB program, University of Cincinnati, Cincinnati, OH

Epithelia is a sheet of highly polarized cells connected by Adherens Junctions(AJs). Loss of apicobasal polarity and AJs is an early hallmark of tumor progression. Par6b (partitioning defective 6 beta) is expressed in *Xenopus* ectoderm. Here we show that Par6b is required for

cadherins expressed by ectoderm cells. Depletion of Par6b in the non-neural ectoderm (the presumptive epidermis) causes a loss of membrane E-cadherin and skin cells dissociation at tailbud stage. Depletion of Par6b does not change the mRNA level but the protein level of E-cadherin, which indicates that this regulation is post-transcriptional. Further experiments suggest that Par6b depletion reduces the translational efficiency of E-cadherin. The changes of the apical markers Crumbs3 and aPKC caused by Par6b depletion suggest that Par6b controls the apicobasal polarity of deep ectoderm cells and outmost ectoderm cells differently. Depletion of Par6b reduces the protein level of the basolateral marker Lgl2, which may link to the loss of basolaterally expressed E-cadherin. In addition, tight junctions that structurally define the apical-basolateral border are also reduced by depletion of Par6b.

444

**Lipid and protein interactions coordinate aPKC polarization and activation during asymmetric cell division.**

M. L. Drummond<sup>1</sup>, K. E. Prehoda<sup>1</sup>; <sup>1</sup>Institute of Molecular Biology, University of Oregon, Eugene, OR

The Par complex protein atypical Protein Kinase C (aPKC) polarizes cells through a cortical exclusion mechanism in which substrates are removed from the cortex by phosphorylation. However, aPKC is not catalytically active until it undergoes a dramatic conformational change in which an inhibitory “pseudosubstrate” is displaced from the kinase domain. While correct targeting and activation of aPKC determine Par-mediated polarity, little is known about the coordination of these processes. Using *Drosophila* neuroblasts as a model system we found that two pathways cooperate to ensure aPKC polarity and activity are properly regulated. We find that interactions with the Par complex protein Par-6, along with a newly identified lipid interaction, are both required for aPKC polarization. Although previously thought to completely specify aPKC polarity, the interaction with Par-6 fails to target aPKC to the cortex. However, interaction with membrane phospholipids leads to cortical but symmetric aPKC. Neither interaction on its own is sufficient to activate aPKC. Taken together, these data suggest that aPKC requires at least two separate interactions to become polarized: a general cortical targeting mechanism through phospholipid binding and an apical targeting mechanism mediated by PAR complex interactions. Finally, we show that proper control of these two signals is required to prevent neuroblast overproliferation. We hypothesize that a conformational change induced by these interactions activates aPKC’s catalytic activity, thereby coupling polarization and activation.

445

**Guanylate kinase domains of the MAGUK family scaffold proteins as specific phospho-protein binding modules.**

J. Zhu<sup>1</sup>, Y. Shang<sup>1</sup>, C. Xia<sup>2</sup>, W. Wang<sup>2</sup>, W. Wen<sup>2</sup>, M. Zhang<sup>1</sup>; <sup>1</sup>Division of Life Science, Hong Kong University of Science and Technology, Kowloon, Hong Kong, China, <sup>2</sup>Department of Chemistry, Fudan University, Shanghai, China

Membrane-associated guanylate kinases (MAGUKs) are a large family of scaffold proteins that play essential roles in organ developments, cell–cell communications, cell polarity establish and maintenance, and cellular signal transductions. Despite extensive studies over the past two decades, the functions of the signature guanylate kinase domain (GK) of MAGUKs are poorly understood.

Here we show that the GK domain of DLG1 binds to asymmetric cell division regulatory protein LGN in a phosphorylation-dependent manner. The structure of the DLG1 SH3-GK

tandem in complex with a phospho-LGN peptide reveals that the GMP-binding site of GK has evolved into a specific pSer/pThr-binding pocket. Phospho-LGN peptide binds to a hydrophobic cradle and phospho-site of the GK domain. Residues both N- and C-terminal to the pSer are also critical for the specific binding of the phospho-LGN peptide to GK.

We further demonstrate that the previously reported GK domain-mediated interactions of DLGs with other targets, such as GKAP/DLGAP1/SAPAP1 and SPAR, are also phosphorylation dependent. Finally, we provide evidence that other MAGUK GKs also function as phospho-peptide-binding modules which indicates that MAGUK scaffold mediated signalling complex organizations are dynamically regulated.

446

**PAR proteins regulate the localization of LET-99 during asymmetric division.**

*E. B. Espiritu<sup>1</sup>, J-C. Wu<sup>1</sup>, L. S. Rose<sup>1</sup>; <sup>1</sup>Molecular and Cellular Biology, University of California, Davis, Davis, CA*

Mitotic spindle positioning is essential for asymmetric divisions, where the spindle must be aligned with the axis of cell polarity. In many systems, PAR polarity proteins establish polarization of the cell and regulate spindle movements via a complex including Gα, GPR and LIN-5. We previously showed that LET-99 is a key regulator of GPR asymmetry in *Caenorhabditis elegans* one-cell embryos. LET-99, a DEPDC1 family protein, is asymmetrically localized at the cortex in a lateral-posterior band pattern, where it inhibits GPR localization. Analysis of LET-99 localization in mutant backgrounds showed that PAR-3 inhibits cortical LET-99 at the anterior cortex, while a gradient of PAR-1 inhibits LET-99 at the posterior-most cortex. In addition, PAR-1, a Ser/Thr kinase, was found to associate with LET-99 *in vitro*. To gain further insight in the mechanism of LET-99 localization, we tested LET-99 for association with the *C. elegans* 14-3-3 protein, PAR-5. In other systems, phosphorylation of targets by PAR-1 and the PAR-3 associated kinase PKC-3 generates binding sites for 14-3-3 proteins, which alters the targets' localization. We found that PAR-5 bound to His-LET-99 in wild-type embryo extracts, but PAR-5 binding was greatly diminished in extracts from *par-1*(RNAi) embryos. Computer predictions for 14-3-3 binding sites followed by yeast-two hybrid (Y2H) assays identified two LET-99 serine residues essential for PAR-5 binding. To determine the *in vivo* relevance of these sites, we introduced S-to-A mutations into an otherwise full-length rescuing LET-99 transgene (LET-99-AA). When transferred into a *let-99* deletion mutant background, the transgene-encoded LET-99-AA protein mislocalized to the entire posterior cortex of the one-cell embryo, similar to what was observed for LET-99 in *par-1* mutant embryos. These and other results support the model that PAR-5 binds to LET-99 to prevent association with the posterior-most cortex, and that this interaction is regulated by phosphorylation of LET-99 by PAR-1. To begin to determine how LET-99 localization is restricted from the anterior cortex, we analyzed LET-99 after depletion of anterior PAR components. We found that PAR-3 is not sufficient for normal LET-99 localization, but rather the PAR-3 associating proteins, PAR-6 and PKC-3, restrict LET-99 localization from the anterior. In the future, we will test the hypothesis that PAR-1 and PKC-3 directly phosphorylate LET-99 using *in vitro* kinase assays. Additionally, we are testing LET-99 interacting proteins for a role in anchoring LET-99 at the cortex.

447

**Dynamic polarization during asymmetric cell division by cell cycle control of the Inscuteable-Bazooka interaction.**

J. F. Mauser<sup>1,2</sup>, K. E. Prehoda<sup>1,2</sup>; <sup>1</sup>Chemistry, University of Oregon, Eugene, OR, <sup>2</sup>Institute of Molecular Biology, University of Oregon, Eugene, OR

Asymmetric cell division is a highly dynamic process in which protein localization patterns dramatically change during the cell cycle to control daughter cell fate. During interphase, fate determinants are symmetrically distributed, but become highly polarized during mitosis so that they can be segregated by the cleavage furrow. For example, in *Drosophila* neuroblasts the Par complex protein Bazooka (Baz aka Par-3) is cytoplasmic during interphase, but is targeted to the apical cortex at metaphase. Although polarization dynamics are likely to be important for regulating fate determinant activity, little is known about the temporal aspects of this process. Using high-speed time-lapse imaging of larval brain neuroblasts we identified Inscuteable (Insc) as a key polarity landmark as it is restricted to the apical cortex throughout the cell cycle. Although Baz is known to bind directly to Insc, it is not recruited to Insc until prophase. Analysis of the primary sequences of Insc and Baz reveal several putative phosphorylation sites for mitotic kinases and we find that the *in vitro* Insc-Baz interaction is phosphatase sensitive. We hypothesize that the Insc-Baz interaction is regulated by a mitotic kinase, allowing for dynamic control of Par complex polarization. Thus, the Insc-Baz interaction is a key “regulatory node” that specifies neuroblast polarization dynamics and may link polarity to the cell cycle.

448

**Par1b orchestrates cell polarity with symmetric or asymmetric cell divisions in columnar and hepatic epithelial cells.**

F. Lazaro-Diequez<sup>1</sup>, D. Cohen<sup>1</sup>, D. Fernandez<sup>1</sup>, S. van Ijzendoorn<sup>2</sup>, A. Muesch<sup>1</sup>; <sup>1</sup>Department of Developmental and Molecular Biology, Albert Einstein College of Medicine, Bronx, NY, <sup>2</sup>Department of Cell Biology, section Membrane Cell Biology, University Medical Center Groningen, University of Groningen, Groningen, The Netherlands, Groningen, Netherlands

Columnar epithelia establish their luminal domains at the cell apex parallel to the basal surface while hepatocyte lumina interrupt the lateral domain of neighboring cells perpendicular to two basal domains. The serine/threonine kinase Par1b promotes a switch from columnar to hepatic polarity in kidney-derived MDCK cells. Here we report that by concomitantly organizing the localization of a sub-luminal belt of the mitotic spindle anchoring complex Gai/NuMA/LGN/dynein Par1b regulates lumen polarity and mitotic spindle orientation in hepatic and columnar cells in a concerted manner. Thus, MDCK cell spindles attach both astral microtubule arrays at opposite regions of the lateral cortex parallel to the basal domain, which results in symmetric cell divisions. Par1b overexpressing MDCK cells and hepatic WIFB and HepG2 cells orient one spindle pole toward the lateral domain underlying their lateral lumen and attach the other set of astral microtubules randomly at the opposite cell surface resulting in spindles that are not aligned with the basal domains and that yield asymmetric divisions, which distribute the luminal domain to only one of the daughters. Par1b-inhibition, on the other hand, favors symmetric divisions and columnar polarity in WIFB and HepG2 cells. We determined that Par1b orchestrates both aspects of epithelial polarity by inhibiting cell-extracellular matrix signaling in a RhoA- and IRSp53-dependent manner.

449

**Mechanisms underlying the regulation of a Rho-family GTPase.**

R. Mitteau<sup>1</sup>, A. Massoni-Laporte<sup>1</sup>, M. Jose Deepak<sup>1</sup>, S. Tollis<sup>1</sup>, D. McCusker<sup>1</sup>; <sup>1</sup>IECB, Pessac, France

During the cell cycle, cells undergo dramatic changes in cellular organization, requiring coordination between the cell cycle and proteins regulating cell polarity. Many polarity proteins are conserved; however, the regulation of these proteins during the cell cycle is poorly understood. In the budding yeast *Saccharomyces cerevisiae*, Cyclin Dependent Kinase 1 (Cdk1) directly phosphorylates regulators of Cdc42 during establishment of a polarity axis. Cdk1-dependent phosphorylation of Cdc42 regulators may link the establishment of cell polarity to the cell cycle, but the underlying mechanisms require clarification.

I am characterising the sole Cdc42 GEF, Cdc24. Cdc24 forms a complex with the scaffolding protein Bem1. Cdc42, Cdc24 and Bem1 are thought to function in a positive feedback loop, which may be crucial for maintaining polarised Cdc42. As the cell progresses through the cell cycle, Cdc24 activates Cdc42 at a specific site on the cell cortex, which recruits Bem1 that interacts with Cdc24, which in turn activates more Cdc42 molecules at the same site. This feedback loop may amplify the polarised Cdc42 signal at a specific site on the cortex to generate a robust polarity axis. We are testing how the affinity of Cdc24 and Bem1 may be regulated by Cdk1-dependent phosphorylation using biochemical and biophysical approaches.

In addition to the GEF Cdc24, Cdc42 is also regulated by the GAPs. In yeast, four GAPs have been identified for Cdc42: Bem2, Bem3, Rga1 and Rga2. We have generated strains expressing all four GAPs tagged with GFP from their endogenous promoter to provide a global view of GAP localization during the cell cycle. High-speed simultaneous imaging of the GAPs and active Cdc42 is providing a better understanding of how Cdc42 is activated and confined to a specific site during the polarisation process.

450

**Effects of Early Disruption in Polarity on Later Development in the Sea Urchin Embryo.**

K. S. Moorhouse<sup>1</sup>, H. F. Gudejko<sup>1</sup>, L. M. Alford<sup>1</sup>, D. R. Burgess<sup>1</sup>; <sup>1</sup>Biology, Boston College, Chestnut Hill, MA

Establishment and maintenance of cell polarity has become an increasingly interesting biological question in a diversity of cell types and has been found to play a role in variety of biological functions. Previously, it was thought that the sea urchin embryo remained relatively unpolarized until the first asymmetric division at the 16cell stage of development. However, there is mounting evidence to suggest that polarity is established much earlier. We analyzed roles of the cell polarity regulators, the PAR complex proteins, and how their disruption in early development affects later developmental milestones such as blastula and gastrula formation. We found that PAR6 along with aPKC and CDC42 localize to the apical cortex (free surface) as early as the 2-cell stage of development and this localization is retained through the blastula stage. Uniquely, in early cleavage stage embryos PAR1 and PAR6 also appear to colocalize in the apical cortex. PAR6, aPKC, and CDC42 are anchored in the cortex by myosin as disruption of myosin light chain kinase activity with ML-7 and ML-9 resulted in cytoplasmic pooling. Additionally, pulse treatments with ML-7 and ML-9 prevented the embryos from reaching the gastrula stage, while the Rho-kinase inhibitor, H1152, did not have this effect. This same pulse with ML-7 disrupted PAR6 localization at the fertilized egg and maintained this disruption through the first cleavage division. Interestingly, aPKC inhibition early in development prevented

blastula formation, but did not effect micromere formation. These observations suggest that disruptions of the polarity complex in the early embryo can have a significant impact on the ability of the embryo to reach later critical stages in development.

451

### **The Role of the Discs Large Tumour Suppressor in the Regulation of Anoikis.**

*P. Massimi<sup>1</sup>, L. Banks<sup>1</sup>; <sup>1</sup>ICGEB, Trieste, Italy*

The Discs Large (Dlg) tumour suppressor is involved in the regulation cell proliferation and cell polarity and its expression is frequently lost in diverse tumour types. Dlg is a target for a number of different viral oncoproteins, further indicating a role in tumour suppression. In order to more fully understand the effects of loss of Dlg upon cellular homeostasis we have made use of a panel of epithelial cell lines where hDlg expression has been stably ablated. An intriguing characteristic of these cells is an apparent increased resistance to anoikis, but normal levels of susceptibility to other forms of apoptosis induction. Using a series of transient siRNA knock-downs of Dlg expression provides a similar phenotype, indicating that this resistance to anoikis is not an off-target effect of the selection procedure. In order to more fully understand the role of Dlg in anoikis we have analysed the pattern of Dlg expression during anoikis. We obtained a marked redistribution of Dlg within the cells upon anoikis induction, with a significant accumulation within the nuclear fraction. Interestingly, in HPV positive cells where Dlg is targeted by the viral oncoprotein E6, this nuclear translocation of Dlg is not observed. Current studies are focused on determining whether HPV E6 is specifically inhibiting nuclear translocation of Dlg upon anoikis induction. Furthermore, in order to identify the signaling pathways being regulated by Dlg during anoikis, proteomic analyses are underway in order to identify the cellular proteins with which Dlg interacts post-anoikis induction.

## **Integrins and Cell-ECM Interactions I**

452

### **LFA-1 is endogenously inactivated by SHARPIN.**

*J. Pouwels<sup>1,2</sup>, N. De Franceschi<sup>1,2</sup>, P. Rantakari<sup>3</sup>, M. Karikoski<sup>3</sup>, E. Mattila<sup>2</sup>, S. Jalkanen<sup>3</sup>, C. Gahmberg<sup>4</sup>, H. Walczak<sup>5</sup>, M. Salmi<sup>3,6</sup>, J. Ivaska<sup>1,2</sup>; <sup>1</sup>Centre for Biotechnology, University of Turku, Turku, Finland, <sup>2</sup>Medical Biotechnology, VTT, Turku, Finland, <sup>3</sup>Medicity laboratory, University of Turku, Turku, Finland, <sup>4</sup>Department of Biosciences, University of Helsinki, Helsinki, Finland, <sup>5</sup>Division of Immunology and Inflammation, Imperial College London, London, United Kingdom, <sup>6</sup>Department of Medical Biochemistry and Genetics, University of Turku, Turku, Finland*

Regulated activation of integrins is critical for cell adhesion, motility and tissue homeostasis. Talin and Kindlins activate integrins, but the counteracting inhibiting mechanisms are poorly defined. Previously we identified SHARPIN as an important inactivator of  $\beta$ 1-integrins (Rantala, Pouwels et al., Nature Cell Biology 2011). SHARPIN inhibited  $\beta$ 1-integrin activity and functions (affecting cell adhesion and migration) in several human cancer cell lines and primary cells from both human and mice, which was fully rescued by re-expression of SHARPIN. Mechanistically, SHARPIN directly bound to a conserved cytoplasmic region of integrin  $\alpha$ -subunits and inhibited recruitment of Talin and Kindlin to the  $\beta$ 1-integrin. Therefore, SHARPIN binding to the cytoplasmic tail of  $\alpha$ -integrins inhibits the critical switching of  $\beta$ 1-integrins from inactive to active conformations both in vitro and in vivo.

Unpublished data now show that SHARPIN is an endogenous inhibitor of integrin LFA-1 ( $\alpha$ L/ $\beta$ 2-integrin, CD11a/CD18) in leukocytes. Multiple immune functions, including leukocyte adhesion, are regulated by activity-dependent binding of LFA-1 to its cognate ligands such as ICAM-1/CD54. SHARPIN co-localizes with inactive LFA-1 in uropods in vitro and in vivo, regulates lymphocyte adhesion to and migration on ICAM-1 and affects constitutive homing in vivo. SHARPIN directly binds to the cytoplasmic tail of  $\alpha$ L, and directly competes with talin for LFA-1 binding. The ubiquitin-like domain of SHARPIN binds in a mutually exclusive manner to LFA-1 and HOIP, the catalytic component of the linear ubiquitination complex, in vitro and in cells, showing that distinct pools of SHARPIN regulate integrin activity and linear ubiquitination. SHARPIN thus directly binds to LFA-1 and controls the dynamic balance between LFA-1 activation and inactivation during lymphocyte migration, which would explain the many aberrations of the immune system in SHARPIN null mice.

453

**Talin Activates Integrins by Altering the Topology of the  $\beta$  Transmembrane Domain.**

*F. Ye<sup>1</sup>, C. Kim<sup>1</sup>, X. Hu<sup>1</sup>, M. H. Ginsberg<sup>1</sup>; <sup>1</sup>Medicine, University of California San Diego, La Jolla, CA*

Talin binding to integrin  $\beta$  tails increases ligand binding affinity (activation). Changes in  $\beta$  transmembrane domain (TMD) topology that disrupt  $\alpha$ - $\beta$  TMD interactions are proposed to mediate integrin activation. Here, we used membrane-embedded integrin  $\beta$ 3 TMDs bearing environmentally-sensitive fluorophores at inner or outer membrane-water interfaces to monitor talin-induced  $\beta$ 3 TMD motion in model membranes. Talin binding to the  $\beta$ 3 cytoplasmic domain increased amino acid side chain embedding at the inner and outer borders of the  $\beta$ 3 TMD, indicating altered topology of the  $\beta$ 3 TMD. Talin's capacity to effect this change depended on its ability to bind to both the integrin  $\beta$  tail and the membrane. Introduction of a flexible hinge at the midpoint of the  $\beta$ 3 TMD decoupled the talin-induced change in intracellular TMD topology from the extracellular side and blocked talin-induced activation of integrin  $\alpha$ IIb $\beta$ 3. Thus, we show that talin binding to the integrin  $\beta$  TMD alters the topology of the TMD resulting in integrin activation.

454

**Kindlin-3 mediates integrin  $\alpha$ L $\beta$ 2 outside-in signaling and it interacts with the scaffold protein receptor for activated-C kinase 1 (RACK1).**

*C. Feng<sup>1</sup>, Y-F. Li<sup>1</sup>, Y-H. Yau<sup>1</sup>, X-Y. Tang<sup>1</sup>, Z-H. Xue<sup>1</sup>, Y-C. Zhou<sup>1</sup>, W-M. Lim<sup>1</sup>, T. Cornvik<sup>1</sup>, C. Ruedl<sup>1</sup>, S. Shochat<sup>1</sup>, S-M. Tan<sup>1</sup>; <sup>1</sup>Nanyang Technological University, Singapore, Singapore*

Integrins are heterodimeric ( $\alpha\beta$ ) transmembrane receptors that are essential for many biological processes, including immunity, hemostasis, wound healing and the development of metazoans. Integrins are well known for their roles in cell adhesion and migration. Equally important, integrins allow communication between the cell's cytoplasmic compartment and its extracellular micro-environment. This is achieved by integrin cytoplasmic tails interacting with cytosolic proteins, many of which are signaling proteins. A hallmark of integrin activation, which is required for its ligand-binding, is the conversion of an integrin from a bent to an extended conformation. Studies have shown that the 4.1-ezrin-radixin-moesin (FERM)-containing cytosolic protein talin induces integrin activation by binding to the integrin  $\beta$  cytoplasmic tail. More recently, it has been reported that another family of FERM-containing proteins known as kindlins serve as co-activators with talin of integrins. Of the three kindlin paralogs, kindlin3 is expressed only in platelets, endothelial cells and hematopoietic cells. Although kindlin3 is known to be essential for  $\beta$ 2 integrins-mediated immune cell adhesion and migration as underscored

by the rare genetic disease leukocyte adhesion deficiency type III, other molecular partners of kindlin3 apart from integrins have not been reported. In this study, we show that kindlin3 can promote integrin  $\alpha$ L $\beta$ 2 micro-clustering that contributes to adhesion avidity. We also show that kindlin3 is required for integrin  $\alpha$ L $\beta$ 2-mediated cell spreading, suggesting a role of kindlin3 in propagating integrin  $\alpha$ L $\beta$ 2-derived downstream signaling. Notably, we identified receptor for activated-C kinase 1 (RACK1), a scaffold protein that folds into a seven-blade propeller, to be able to associate with kindlin3. Immunofluorescence analyses show that kindlin3 and RACK1 localize to the lamellipodia of migrating T cells on integrin  $\alpha$ L $\beta$ 2 ligand ICAM-1. Because RACK1 has been shown to be involved in modulating lamellipodium protrusions, our data suggest that the interaction of kindlin3 and RACK1 could play an important function in immune cell migration.

455

### **Integrin $\alpha$ M $\beta$ 2 Clustering Triggers Phosphorylation and Activation of Protein Kinase C $\delta$ that Regulates Transcription Factor Foxp1 Expression in Monocytes.**

Z. Xue<sup>1</sup>, S. Tan<sup>1</sup>; <sup>1</sup>School of Biological Sciences, Nanyang Technological University, Singapore, Singapore

Integrins are type I transmembrane and  $\alpha/\beta$  heterodimeric adhesion receptors that attach cells to the extracellular matrix (ECM) or adjacent cells. They are present on most eukaryotic cells and participate in diverse biological functions, such as cell growth and differentiation, tissue development, neural functions, immune defense, hemostasis and bone resorption. Intracellular signals triggered by ligand-bound integrins are important for cell growth, differentiation, and migration. Integrin  $\alpha$ M $\beta$ 2 is mainly expressed on cells of the myeloid lineage, natural killer cells and  $\gamma\delta$  T cells. It plays key roles in myeloid cell adhesion, phagocytosis and degranulation.

In this study, we show that protein kinase C (PKC) $\delta$  mediates  $\alpha$ M $\beta$ 2 signaling. In human monocytic U937 cells and peripheral blood monocytes,  $\alpha$ M $\beta$ 2 clustering induces PKC $\delta$  translocation to the plasma membrane, followed by Tyr311 phosphorylation and activation of PKC $\delta$  by the src family kinases Hck and Lyn. Analysis of the  $\beta$ 2 cytoplasmic tail showed that the sequence Asn727-Ser734 is important in  $\alpha$ M $\beta$ 2-induced PKC $\delta$  Tyr311 phosphorylation. We also show that  $\alpha$ M $\beta$ 2 clustering down-regulates Foxp1 expression in monocytes and this is dependent on PKC $\delta$ . Foxp1 expression was also reduced in monocytes that were allowed to adhere to human microvascular endothelial cells. These results demonstrate a role of PKC $\delta$  in  $\alpha$ M $\beta$ 2-mediated Foxp1 regulation in monocytes.

### **$\beta$ 1 integrin regulates Arg to promote invadopodial maturation and matrix degradation.**

B. Beaty<sup>1</sup>, V. Sharma<sup>1</sup>, J. Bravo-Cordero<sup>1</sup>, M. Simpson<sup>2</sup>, R. Eddy<sup>1</sup>, A. Koleske<sup>2</sup>, J. Condeelis<sup>1</sup>; <sup>1</sup>Albert Einstein College of Medicine, Bronx, NY, <sup>2</sup>Yale University, New Haven, CT

Invadopodia are actin-rich invasive protrusions formed exclusively by tumor cells and are thought to facilitate basement membrane degradation and intravasation.  $\beta$ 1 integrin has been shown to localize to invadopodia, but the mechanism by which it regulates invadopodium function is poorly understood. We investigated the role of  $\beta$ 1 integrin in regulating invadopodium formation, maturation and dynamics in metastatic human breast cancer cells. Here, we show that  $\beta$ 1 integrin is required for invadopodial actin polymerization and matrix degradation, which are collectively referred to as invadopodial maturation.  $\beta$ 1 integrin knockdown with siRNA results in the formation of unstable invadopodia that cannot efficiently degrade extracellular matrix.  $\beta$ 1 integrin is activated in invadopodia during the maturation phase, and stimulating  $\beta$ 1 integrin-mediated adhesion accelerates invadopodial matrix proteolysis. Furthermore, FRET analysis revealed that  $\beta$ 1 integrin interacts with the Abl family kinase Arg in invadopodia and is essential for Arg-dependent cortactin Y421 phosphorylation, a key trigger for invadopodial

maturation. Cortactin remains dephosphorylated in  $\beta 1$  integrin-depleted cells and sequesters cofilin, leading to a decrease in cofilin-mediated actin barbed end formation and Arp2/3-dependent actin polymerization. Thus, we provide evidence that  $\beta 1$  integrin is a critical regulator of invadopodial maturation by stimulating the Arg-cortactin-cofilin pathway.

**Podosome Formation Requires Inhibition of Contractility and RhoA Activation.**

C-H. Yu<sup>1</sup>, N. B. Rafiq<sup>1,2</sup>, G. E. Jones<sup>2</sup>, A. D. Bershadsky<sup>1,3</sup>, M. P. Sheetz<sup>1,4</sup>; <sup>1</sup>Mechanobiology Institute, National University of Singapore, Singapore, Singapore, <sup>2</sup>Randall Division of Cell & Molecular Biophysics, King's College London, London, UK, <sup>3</sup>Department of Molecular Cell Biology, Weizmann Institute of Science, Rehovot, Israel, <sup>4</sup>Department of Biological Sciences, Columbia University, New York, NY

Clusters of matrix-activated integrins are important for the development of cell-matrix adhesions that in turn regulate cell growth and differentiation. Integrin clusters are sites of actin polymerization, and subsequent myosin contraction of the integrin clusters develops force and mature focal adhesions. Previously, we have utilized fluidic RGD-membranes, continuous supported bilayers with lipid-anchored RGD ligands, to activate integrins and investigate force dependence of initial integrin clustering during early adhesion formation (Yu et al., PNAS 2011). Here we demonstrated that cells, such as fibroblasts natively form podosomes within 45 minutes of adhesion on fluidic RGD-membranes where cell-matrix traction force cannot be stabilized. Podosome core assembly was initiated by Arp2/3-mediated actin polymerization within integrin clustering sites that were characterized by several integrin-associated proteins, such as paxillin, talin, and vinculin. In addition, myosin-1E and CARMIL1 were found as new markers at podosome cores. Interestingly, the same cells exhibited focal adhesions and actin stress fibers when adhering to identical RGD ligands immobilized on glass. We hypothesized that force on the integrin clusters produced a signal that caused matrix adhesion formation, and the absence of activated myosin contractility of integrins bound to an RGD-membrane resulted in the alternative activation of podosome formation. To test if RhoA signaling could be part of the force-activated signal, we measured RhoA-GTP levels with a FRET-based RhoA biosensor. RhoA-GTP levels were indeed low in cells forming podosomes on RGD-membranes, whereas RhoA-GTP levels were high in the cells on RGD-glass. Constitutively active RhoA-Q63L mutant blocked podosome formation on RGD-membranes. We also found that cells formed classic focal adhesions on RGD-membranes with dense line-partitions (1 $\mu$ m), but developed podosomes when plated on the same substratum with wider line-partitions (4 $\mu$ m). Dense 1 $\mu$ m-pitch line partitions in RGD-membranes provided mechanically stable sites for RGD-integrin immobilization thus stimulating adhesion maturation, but binding of the same cells to unpartitioned RGD membranes stimulated podosome formation. Maturation of focal adhesions requires local actomyosin contractility stimulated by RhoA; however, the signaling pathways downstream of activated integrins that cause podosome formation are largely unknown. From our data, we suggest that activation of myosin contractility at integrin clusters activates focal adhesion formation and inhibits podosome formation at integrin clusters, giving rise to a mutually exclusive behavior of focal adhesions and podosomes.

**Galectin-3 and phospho-caveolin-1 promote integrin-dependent EGF activation of RhoA, circular dorsal ruffles and matrix remodeling.**

C. Boscher<sup>1</sup>, I. R. Nabi<sup>1</sup>; <sup>1</sup>Cellular and Physiological Sciences, University of British Columbia, Vancouver, BC, Canada

In mammary epithelial cancer cells, galectin-3 binding to  $\beta$ 1,6-acetylglucosaminyltransferase V modified N-glycans forms a lattice that restricts EGF receptor mobility in the plasma membrane and also acts synergistically with phospho-caveolin-1 to promote integrin-dependent matrix remodeling and cell migration (Lagana et al., Mol Cell Biol. 26(8):3181-93, 2006; Lajoie et al., J Cell Biol. 179(2):341-56, 2008; Goetz et al., J Cell Biol. 180(6):1261-75, 2008). We then asked whether galectin-3 and caveolin-1 can promote EGF receptor and integrin crosstalk in motile cancer cells. We show that EGF signaling to downstream RhoA is galectin-3- and phospho-caveolin-1-dependent and is associated with circular dorsal ruffle formation and fibronectin fibrillogenesis. Circular dorsal ruffles are transient actin structures induced by growth factors in migrating cells, however their role is poorly understood. EGF-induced RhoA activation, circular dorsal ruffle formation and fibronectin fibrillogenesis are Src dependent and require expression of integrin linked kinase (ILK) and lipid raft integrity. Moreover inhibition of integrins by an RGD peptide prevents EGF induced RhoA activation and circular dorsal ruffle formation. Soluble fibronectin binding to the cell requires galectin-3 binding and galectin-3 is localized to fibronectin fibrils. This suggests that galectin-3 promotes EGF receptor-integrin crosstalk leading to phospho-caveolin-1 dependent RhoA activation, actin reorganization in circular dorsal ruffles and fibronectin remodeling. EGF-induced circular dorsal ruffles might represent a raft dependent signaling platform that recruits integrins and promotes their signaling to allow cell migration and matrix remodeling. This describes for the first time a common galectin-3/ phospho-caveolin-1 /RhoA signaling pathway that mediates EGF receptor and integrin crosstalk providing novel insight into the role of growth factor stimulated cancer cell motility.

**A novel mutation in  $\beta$  integrin reveals an integrin-mediated interaction between the extracellular matrix and cki-1/p27<sup>KIP1</sup>.**

E. Yu<sup>1</sup>, M. Lee<sup>1</sup>; <sup>1</sup>Biology, Baylor University, Waco, TX

The cell-extracellular matrix (ECM) interaction plays an essential role in maintaining tissue shapes and regulating cell behaviors such as cell adhesion, differentiation and proliferation. Previous studies suggested that the cell-ECM interaction is particularly important for progression and arrest of cell cycle. However, the mechanism by which the ECM influences the cell cycle *in vivo* is poorly understood. Here we demonstrate that the  $\beta$  integrin PAT-3 regulates the localization and expression of CKI-1, a *C. elegans* homologue of the cyclin dependent kinase inhibitor p27<sup>KIP1</sup>. In transgenic nematodes expressing wild type *pat-3* (+), CKI-1::GFP localizes primarily to nucleoli in hypodermal cells, whereas in transgenic animals expressing mutant *pat-3* (*sp*) carrying a defective splicing in intron 7, CKI-1::GFP appears clumped and disorganized in the outside of the nucleolus. In addition to the localization, the level of CKI-1::GFP protein was elevated in the splicing mutant, *pat-3* (*sp*) animal. Series of RNAi experiments linked cell adhesion genes to the regulation of CKI-1. RNAi of *unc-52/perlecan*, *ina-1/ $\alpha$  integrin*, *pat-4/ILK*, and *unc-97/PINCH* resulted in the *pat-3* (+)lines displaying the abnormal CKI-1::GFP localization, like that of *pat-3* (*sp*). Additional RNAi experiments revealed that the SCF E3 ubiquitin-ligase complex genes, *skpt-1/SKP2*, *cul-1/CUL1* and *lin-23/F-box*, are also required for the proper localization and expression of CKI-1, suggesting that integrin signaling and SCF E3 ligase work together to regulate the cellular distribution of CKI-1. These data also suggest that integrin plays a major role in maintaining proper CKI-1/p27<sup>KIP1</sup> levels in the cell.

Perturbed integrin signaling may lead to the inhibition of SCF ligase activity, mislocalization and elevation of CKI-1/p27<sup>KIP1</sup> protein. These results suggest that cell adhesion signaling is crucial for cell cycle regulation in vivo.

460

**Identification of protein synthesis and degradation genes associated with CKI-1/p27<sup>KIP1</sup> localization patterns in the hypodermis of *Caenorhabditis elegans*.**

L. Al-Rashed<sup>1</sup>, L. McKinney<sup>1</sup>, E. Yu<sup>1</sup>, M. Lee<sup>1</sup>; <sup>1</sup>Biology, Baylor University, Waco, TX

The interaction between a cell and extracellular matrix (ECM) is essential for maintaining tissue shape and regulating cell behaviors, which include cell adhesion, differentiation and proliferation. Studies have shown that cell adhesion affects cell proliferation by promoting cell cycle progression and arrest. However, the mechanism by which the ECM influences the cell cycle in vivo is poorly understood. Our previous analysis revealed that there is a link between  $\beta$  *pat-3* integrin and concentration levels of a cell cycle regulator. In the nematode *Caenorhabditis elegans*, CKI-1 is a homologue of the cyclin dependent kinase inhibitor p27<sup>KIP1</sup>. Nematodes expressing wild-type  $\beta$  *pat-3* (+)integrin showed CKI-1 localization to the nucleolus of hypodermal cells, while nematodes expressing the splicing defective *pat-3* (*sp*) showed CKI-1 localization just outside and around the nucleolus. This mutant phenotype was further linked to cell adhesion and ubiquitin mediated protein degradation pathways.

To further analyze the genes involved in CKI-1::GFP localization, we have tested the contribution of protein synthesis and degradation genes to these prominent and significant CKI-1 localization patterns. Using the bacterial feeding method, RNA interference (RNAi) analyses of more than 60 genes were carried out on multiple worm populations. Following standard RNAi protocol, young adult *pat-3* (+)or *pat-3* (*sp*) worms were subjected to gene specific RNAi. Their F1 progeny were characterized for CKI-1::GFP localization. Genes that showed significant results for CKI-1 localization included *pbs-3*, *pbs-4*, *pbs-1*, *eif-3E*, *eif-6*, *rpn-1*, and *pas-5*. In brief summary, the knockdown of the protein synthesis genes *eif-3E* and *pas-5* in *pat-3* (*sp*) worms caused CKI-1::GFP localization to the nucleolus, while RNAi of *eif-6* in *pat-3* (+)worms displayed CKI-1::GFP being localized to the outside of the nucleolus. In addition, these genes also showed appreciable effects at different embryonic stages characterized by a significant delay in development. To better understand the cause/effect relationship of these genes on the expression and localization of the cell cycle inhibitor CKI-1, further analysis is currently underway.

**Phosphoinositide specificity determines which cytohesins regulate  $\beta$ 1 integrin recycling.**

S. Oh<sup>1</sup>, L. C. Santy<sup>1</sup>; <sup>1</sup>Biochemistry and Molecular Biology, Pennsylvania State University, University Park, PA

Recycling of internalized integrins is a critical step in adhesion remodeling and cell movement. Recently, we determined that the ARF-GEFs Cytohesin 2/ ARNO and cytohesin 3/ GRP1 have opposing effects on adhesion and stimulated  $\beta$ 1 integrin recycling even though they are very closely related proteins (80% sequence identity). We have now determined the sequence differences underlying the differential actions of cytohesin 2/ ARNO and cytohesin 3/ GRP1. We find that the ability of cytohesins to promote  $\beta$ 1 integrin recycling and adhesion depends upon the presence or absence of a key glycine residue in their PH domains. This glycine residue determines the phosphoinositide specificity and affinity of cytohesin PH domains. Cytohesin PH domains with two glycines have a strong selectivity for PI-(3,4,5)P3, while those with three glycines have an equal affinity for PI-(3,4,5)P3 and PI-(4,5)P2. Switching the number of glycines in the PH domains of cytohesin 2 and cytohesin 3 is sufficient to reverse their effects

on adhesion and spreading and to reverse their sub-cellular locations. Importantly, we also find that a mutant form of cytohesin 3/ GRP1 that has 3 rather than 2 glycines in its PH domain rescues  $\beta 1$  integrin recycling in cytohesin 2/ ARNO knockdown cells. Conversely, a mutant form of cytohesin 2/ARNO with 2 glycines in its PH domain fails to rescue  $\beta 1$  integrin recycling. These data implicate the production of PI-(4,5)P2 as a key step in the formation of carriers during stimulated recycling.

**Fibroblast cluster formation on 3D collagen matrices requires cell contraction-dependent fibronectin matrix organization.**

*B. Da Rocha-Azevedo<sup>1</sup>, F. Grinnell<sup>1</sup>; <sup>1</sup>Dept. of Cell Biology, UT Southwestern Medical Center, Dallas, TX*

Studies regarding cell behavior on 3D extracellular matrices provide a biologically relevant platform for understanding cell biology in tissue-like environments. Human skin fibroblasts moving on 3D collagen matrices exhibit two distinct behaviors-depending upon growth factor environment. In serum (or lysophosphatidic acid, LPA)-containing medium, cells undergo clustering, which depends on Rho kinase/myosin II-dependent contraction. However, in platelet-derived growth factor (PDGF) containing medium cells move as individuals. The objective of the present work was to determine the role of fibronectin (FN) in cell cluster formation. In serum or LPA but not PDGF or basal medium, cells organized FN (either serum and cellular) into a fibrillar, deoxycholate (DOC)-insoluble matrix with which the cells became associated. FN fibrils were found beneath the cell clusters and along the clusters borders in regions of matrix tension. Using siRNA silencing and function-blocking antibodies, we found that cell clustering and FN matrix organization required  $\alpha 5\beta 1$  integrins and FN. Also, blocking Rho kinase or myosin II activity prevented FN matrix assembly and cell clustering. Conversely, if fibroblasts were incubated on detergent-extracted collagen matrices on which FN matrices had been pre-formed, partial cell clustering occurred in basal and PDGF-containing medium. Cell clustering was reversible if the growth factor when the growth factor conditions were switched from procontractile to promigratory. Dispersal of fibroblasts from the clusters was accompanied by disruption of the fibronectin matrix, which depended upon metalloproteinase function since dispersion was inhibited by broad spectrum MMP inhibitors. Based on these findings, we conclude that the function of cell contraction in fibroblast clustering on collagen matrices is to cause FN fibril assembly into cell cluster-organizing centers. Our findings provide new insights into how procontractile (serum/LPA) and promigratory (PDGF) growth factor environments can differentially regulate FN matrix assembly by fibroblasts on collagen matrices and thereby influence mesenchymal cell morphogenetic behavior under physiologic circumstances such as wound repair and development.

**Fibrin enables  $\alpha V\beta 3$ -directed collagen gel contraction and upregulates the expression level of genes involved in extracellular matrix assembly.**

*V. Reyhani<sup>1</sup>, P. Seddigh<sup>1</sup>, R. Gustafsson<sup>1</sup>, L. Rask<sup>1</sup>, K. Rubin<sup>1</sup>; <sup>1</sup>Dept of Medical Biochemistry and Microbiology, University of Uppsala, Uppsala, Sweden*

Fibrinogen in the concentration range 20 – 100 microgram/mL and thrombin were added to collagen type I (1 mg/mL) during collagen polymerization. Mouse myoblast C2C12 cells that lack collagen-binding  $\beta 1$ -integrins contracted the resulting fibrin/collagen composite gels in the absence of extrinsic stimulators. Inhibition of  $\alpha V\beta 3$  integrin by cyclic-RGD peptide repressed

this effect where thrombin alone had no effect on the contraction. Fibrinogen bound to immobilized native collagen type I, but not to denatured collagen in solid-phase assays. The binding was inhibited by the streptococcal protein CNE that blocks the site in collagen known to bind MMPs, fibronectin, DDR2 and SPARC. CNE suppressed the fibrin-directed collagen gel contraction. Scanning electron microscopy revealed a direct association of thin fibrin fibers to collagen fibers. This association was absent when CNE was present in the collagen gels. Expression level of several genes involved in matrix production and assembly, namely COL3A1, COL1A1, PLOD2, ITGB3, FN, POSTN, CTGF, and DECO was increased in C2C12 cells cultured in composite gels compared to C2C12 cells with a forced expression of the integrin  $\alpha 2\beta 1$  that were cultured in pure collagen gels. Our data indicates that fibrin can link collagen fibers and cells. It also suggests that fibrin reprograms the cellular expression of genes associated with matrix network assembly. Such functions would be of relevance for the physiological properties of inflammatory lesions and in carcinomas, both characterized by the deposition of fibrin.

**The fibronectin synergy site promotes breast tumorigenesis by increasing cell tension and vinculin-dependent ERK signaling through a unique  $\alpha 5\beta 1$  integrin catch-bond.**

*L. D. Cassereau<sup>1</sup>, K. Miroshnikova<sup>1</sup>, G. Rozenberg<sup>2</sup>, M. Dembo<sup>3</sup>, V. Weaver<sup>1,2</sup>; <sup>1</sup>Surgery, Center for Tissue Engineering and Regenerative Medicine, University of California San Francisco, San Francisco, CA, <sup>2</sup>Department of Pathology and Institute for Medicine and Engineering, University of Pennsylvania, Pennsylvania, PA, <sup>3</sup>Bioengineering, Boston University, Boston, MA*

Cancer cells are highly contractile and we showed that tumor tension induces extracellular matrix (ECM) remodeling and stiffening to drive tumor progression (Paszek et al., Cancer Cell 2005; Levental et al., Cell 2009; Samuel et al., Cancer Cell 2011). Integrins are mechano-transducers whose expression and activity is consistently modified in cancer, and integrin signaling promotes tumor progression by enhancing cell growth, survival and invasion and by facilitating actomyosin-dependent extracellular matrix (ECM) remodeling. Nevertheless, it is unclear whether specialized integrin heterodimers contribute to specific tumor behaviors such as force-dependent invasion, and if so how. Here, we explored the relationship between integrin specificity, cell tension and extracellular matrix-dependent malignant transformation. We determined that  $\alpha 5\beta 1$  integrin and fibronectin were up-regulated following oncogene-induced transformation of the mammary gland in vivo, and during transition from nonmalignant to malignant mammary epithelial cells (MECs) cultured in vitro (Rizki et al., Cancer Res 2008). Importantly, we found that fibronectin-ligation of  $\alpha 5\beta 1$  integrin but not  $\alpha V$  integrin, or collagen-ligation of  $\alpha 2$  integrin was necessary and sufficient for expression of the malignant phenotype of MECs in organotypic culture and in vivo. Interestingly, MECs with fibronectin-ligated  $\alpha 5\beta 1$  integrin induced more ECM remodeling and contraction and exerted higher ROCK-dependent contractility than MECs with collagen-ligated  $\alpha 2\beta 1$  integrin. Indeed, inhibiting cell contractility normalized the malignant behavior of MECs expressing high fibronectin-ligated  $\alpha 5\beta 1$  integrin, consistent with our previous data showing that ROCK-induced cell tension per se can induce cell growth and survival, destabilize cell-cell adhesions, perturb tissue polarity and promote cell invasion (Paszek et al., Cancer Cell 2005; Miroshnikova et al., J Phys Biol 2011). Because  $\alpha 5\beta 1$  integrin uniquely binds two domains in fibronectin, we asked whether the tension-induced tumor phenotype, induced through fibronectin-ligation of  $\alpha 5\beta 1$  integrin, was mediated through its force-regulated catch-bond. Consistently, we noted that mammary epithelial cells with  $\alpha 5\beta 1$  integrin ligated to a wild type, but, not to a synergy site deleted fibronectin, formed larger focal adhesions with abundant vinculin and exerted higher cell tension that destabilized adherens junctions, perturbed acini polarity, induced cell growth and survival and facilitated directed

cancer cell invasion. The high  $\alpha 5\beta 1$  integrin-induced cell tension, mediated through ligation of the synergy site, potentiated vinculin-dependent epidermal growth factor stimulation of PI3 and ERK kinases to enhance cell growth and survival, disrupt tissue integrity and foster cell invasion in culture and in vivo. The findings demonstrate how extracellular matrix structure can engage specific integrin heterodimers to tune cell force, thereby providing a novel mechanism whereby fibronectin-ligated  $\alpha 5\beta 1$  integrin could mediate tumor progression.

**Regulation of focal adhesion growth by external mechanical perturbations.**

*W. Ng<sup>1</sup>, K. Webster<sup>2</sup>, D. Fletcher<sup>1,2</sup>; <sup>1</sup>UCB-UCSF Joint Graduate Group in Bioengineering, University of California, Berkeley, Berkeley, CA, <sup>2</sup>Biophysics Graduate Group, University of California, Berkeley, Berkeley, CA*

The formation of adhesions between adherent cells and their microenvironment is crucial for various cellular processes, including migration and differentiation. Integrin-mediated adhesions, known as focal adhesions, are one of the primary mechanosensing structures that allow cells to sense the mechanical properties of their surroundings. Adhesion growth during spreading is thought to be coupled to the buildup of acto-myosin generated tension. Additionally, external forces applied to focal adhesions can modify them through a process of reinforcement, wherein more proteins are recruited to bear a higher load on these sites. Previous studies have suggested that reinforcement occurs rapidly when force on the adhesion increases, whereas slow disassembly occurs when internal cell tension dissipates. In a three-dimensional environment, however, cells can simultaneously experience forces of varying magnitudes from different directions with respect to the cell-extracellular matrix (ECM) interface plane. The response of focal adhesions to these variable mechanical inputs remains an active area of study. Here, we combine atomic force microscopy (AFM) and total internal reflection fluorescence (TIRF) microscopy to track the dynamics of focal adhesion assembly during cell spreading while simultaneously controlling cell forces. During cell spreading between a tipless cantilever on the top and a glass substrate on the bottom, we measured the intensity change in fluorescently-labeled zyxin, part of the focal adhesion complex, in response to changes in the AFM-generated tensile force that resisted cell spreading. We found that zyxin was not responsive to a broad range of applied forces, but that tensile forces above a threshold value halted spreading and induced growth of zyxin-rich adhesions within the main cell body, with a smaller effect on adhesions in the cell periphery. Interestingly, a subsequent decrease in tensile force reinitiated cell spreading and also promoted growth of both existing and new focal adhesions. These results suggest that the spatial location of focal adhesions determines their response to forces orthogonal to the cell-ECM interface plane.

**Live-cell super-resolution microscopy reveals early stages in adhesion formation and rigidity sensing.**

*H. Wolfenson<sup>1</sup>, S. Liu<sup>2</sup>, H. Cai<sup>3</sup>, S. Wind<sup>3</sup>, J. Hone<sup>2</sup>, M. Sheetz<sup>1</sup>; <sup>1</sup>Biological Sciences, Columbia University, New York, NY, <sup>2</sup>Mechanical Engineering, Columbia University, New York, NY, <sup>3</sup>Applied Physics and Applied Mathematics, Columbia University, New York, NY*

Rigidity of the extracellular matrix is a major determinant of many cellular aspects, including survival, proliferation, and differentiation [1]. Cells are able to sense rigidity and respond by modifying their adhesion, cytoskeletal organization, cellular forces, and gene expression patterns [2]. These effects are observed in many cell types, including fibroblasts, myocytes, and

neurons, and thus irregular rigidity signals underlie many medical disorders [3]. Recent studies show that rigidity sensing is an early event as cells spread on a surface that involves local lamellipodial contractions [4] and actin polymerization from nascent integrin adhesions [5]. However, we still don't understand the molecular mechanism of rigidity sensing upon initial contact with the surface. Here we show that the local nano-scale organization and kinetics of protein recruitment into nascent adhesion sites can be tracked in living cells using Bayesian analysis of fluorophores blinking and bleaching (3B microscopy [6]). We demonstrate a correlation between assembly of integrin clusters and force production, and show that talin changes its orientation upon lamellipodial retraction and pulling on the substrate. Furthermore, using nanofabricated surfaces with adhesion-permitting and non-permitting clusters of integrin ligands we distinguish which are the critical adhesion-related proteins that are required for the assembly of early adhesion sites that allow sensing matrix rigidity.

**Single piconewton forces at individual integrins support robust cell adhesion.**

*M. Morimatsu<sup>1</sup>, A. H. Mekhdjian<sup>1</sup>, A. S. Adhikari<sup>1</sup>, A. R. Dunn<sup>1</sup>; <sup>1</sup>Department of Chemical Engineering, Stanford University, Stanford, CA*

Mechanical interactions between cells and the extracellular matrix (ECM) exert a profound influence on cell migration, proliferation, and stem cell differentiation. However, fundamental aspects of how cells detect and generate mechanical forces at the cell-ECM interface remain poorly understood. Here we describe a new technique, termed Molecular Force Microscopy (MFM), that measures the forces experienced by single cellular adhesion molecules with nanometer, piconewton, and sub-second resolutions. MFM uses a new class of FRET-based molecular tension sensors that bind to an avidin-coated glass coverslip at one end and present an integrin binding site at the other. Cellular integrins transmit force to the FRET pair, resulting in decreased FRET with increasing load. Unlike previously reported force sensors (1-3), MFM sensor molecules allow quantitative FRET imaging at the single molecule level. We found that human foreskin fibroblasts (HFFs) adhered to and spread on surfaces functionalized with the MFM probes, and developed mature focal adhesions as evidenced by paxillin localization and actin stress fiber formation. We observed a bimodal distribution of FRET efficiency values for MFM sensor molecules beneath HFFs, with one peak corresponding to zero load and the other indicating a distribution of forces between 1 and 4 pN. Despite evidence of robust adhesion, the forces we measured were ~10-fold lower than the force necessary to break individual integrin-ECM bonds (4). Our data provide the first direct measurement of the tension per integrin molecule necessary to form stable contacts with the ECM. The relatively narrow range of forces that we observed suggests that mechanical tension at individual adhesion molecules is subject to exquisite feedback and control. Ongoing work uses the unique capabilities of MFM to elucidate the mechanical signal transduction mechanisms that underlie cell migration and adhesion.

**Measure the molecular tension for integrin and Notch activation.***X. Wang<sup>1</sup>, T. Ha<sup>1</sup>; <sup>1</sup>Physics, University of Illinois at Urbana-Champaign, Urbana, IL*

Cells interact with extracellular matrix (ECM) or adjacent cells and regulate various cell functions using mechano-sensitive receptors on the cell membrane. Activation of these receptors is speculated to depend on molecular tension on the receptor-ligand bonds. To study the relation between the tension and receptor activation, we developed Molecular Tension Ladder (MTL). In MTL, ligand molecules are immobilized on a substrate through single rupturable tethers. Cells are cultured on such substrate and the target receptors bind with the tethered ligands. To activate the receptors, cells apply a tension on the receptor-ligand bonds. If the tether tension tolerance is lower than the threshold required by receptor activation, the tether would rupture and abolish the activation. Otherwise the receptor would be activated. A series of such ligand constructs with tension tolerances ranging from 12~56 pN were coated on different regions of one surface and therefore provides a ladder to test the tension threshold for the receptor activation. First, we applied MTL to study the molecular tension on integrins in the process of cell adhesion. MTL analysis of five different cell types showed that cells apply a universal, well-defined tension of about  $38 \pm 5$  pN to single integrin-ligand bonds during initial cell adhesion and spreading. We also applied this method to Notch activation study and found that either no tension or a tension less than 12 pN is required to activate Notch receptor. More than a measurement tool, MTL can also provide a defined mechanical niche at the molecular level to regulate cell functions. We observed that focal adhesion and stress fiber well formed in the CHO-K1 cells adhered on 56 pN surface but not on 43 pN surface.

**Respective contribution of cell shape and matrix stiffness on the regulation of contractile forces.***T. Vignaud<sup>1</sup>, F. Senger<sup>1</sup>, Q. Tseng<sup>1</sup>, L. Blanchoin<sup>1</sup>, M. Thery<sup>1</sup>; <sup>1</sup>iRTSV, CEA, Grenoble, France*

Matrix stiffness is known to be a key regulator of cell physiology. Matrix stiffness affects cell migration, growth, polarization and differentiation by modulating cell contractility. All reports so far led to the conclusion that matrix stiffness increases cell contractility. However, matrix stiffness has also been shown to increase cell spreading area, cell aspect ratio, focal adhesion size and alignment. Several evidences suggested that these geometrical parameters could also affect cell contraction level independently of matrix stiffness. Since cells are spatially confined in tissues, and can not freely extend their spreading area, this parameter may be highly critical in force regulation in physiological conditions. So the exact and specific contribution of matrix stiffness and cell shape to the regulation of cell contraction needs to be identified.

We distinguished the respective roles of cell shape and matrix stiffness by measuring the traction forces produced by micropatterned cells on deformable substrates. In accordance with previous reports, we found that an increase in cell spreading area, for a given matrix stiffness, promotes cell contraction. But, contrary to previous observations in which cell spreading area was not controlled, an increase in matrix stiffness did not promote cell contraction when cell spreading was limited.

A surprising absence of correlation between fiber width and the sustained forces prompted us to reconsider the structure-force relationship in stress fibers. We coupled laser nano-ablation, FRAP and traction force microscopy to quantify both actin filament dynamics and force production in micropatterned cells stress fibers. We measured the transport and renewal dynamics of fibers components in fibers of controlled size. The eventual severing and measurement of the corresponding substrate relaxation allowed us to measure the exact force production in the observed fiber.

Thereby we could draw a new framework for the production of mechanical force in stress fibers with respect to their size, sub-cellular location and internal dynamics.

#### **Effect of cytoskeletal tension on vascular smooth muscle cell adhesion.**

*H. Sreenivasappa<sup>1,2</sup>, S-M. Lim<sup>1</sup>, J. P. Trzeciakowski<sup>1</sup>, G. Rivera<sup>2</sup>, M. W. Davidson<sup>3</sup>, A. Trache<sup>1,2</sup>; <sup>1</sup>Texas A&M Health Science Center, College Station, TX, <sup>2</sup>Texas A&M University, College Station, TX, <sup>3</sup>Florida State University, Tallahassee, FL*

Cytoskeletal tension plays a central role in the development of contractile function in vascular smooth muscle cells (VSMC) and their adaptive responses to mechanical stimuli. The present study investigates the effect of cytoskeletal tension modulation by RhoA and Src on VSMC adhesion. Thus, an atomic force microscope probe functionalized with fibronectin was used to measure integrin  $\alpha_5\beta_1$ -fibronectin adhesion force and local cell stiffness on cells expressing RhoA or Src wild-type or constitutively active mutants. Our results showed that both RhoA and Src activation increased  $\alpha_5\beta_1$  integrin-fibronectin adhesion force and cell stiffness hence increased cytoskeletal tension. Fluorescence imaging experiments were performed to independently test the effect of RhoA and Src on stress fibers formation and focal adhesion activation. Actin area was quantified from confocal images of cells co-expressing RhoA-GFP mutants and actin-mRFP. The tyrosine phosphorylation at focal adhesion was quantified from total internal reflection fluorescence (TIRF) images of cells co-expressing Src-mCherry mutants and dSH2-YFP. The results showed increased actin fiber formation and focal adhesion protein activation for VSMC expressing constitutively active RhoA and Src, respectively. Moreover, constitutively-active Src translocates from cytoplasm to focal adhesions located mainly at cell edges, underscoring the role of Src pathway activation in cell adhesion and migration. To study the contribution of integrins  $\alpha_5\beta_1$  and  $\alpha_v\beta_3$ , which regulate VSMC contractile function, to focal adhesion formation we performed TIRF imaging of cells expressing  $\alpha_5$ -GFP and  $\beta_3$ -mCherry. Integrin  $\alpha_5\beta_1$  was found mainly towards the center of the cell forming dotted streaks that followed a distribution similar to that of the endogenous fibronectin deposited by VSMC. In contrast, integrin  $\alpha_v\beta_3$  was found at the cell edges forming small islands that showed similar location with the majority of tyrosine phosphorylation at focal adhesions. Due to this distribution, we hypothesize that integrins  $\alpha_v\beta_3$  and  $\alpha_5\beta_1$  may have different roles in cytoskeletal tension development. The stress fibers oriented along the long axis of the cell may anchor preferentially at focal adhesions containing  $\alpha_v\beta_3$  integrin, while the stress fibers in the center of the cell may anchor at focal adhesions containing integrin  $\alpha_5\beta_1$ . Taken together, these results show that actin cytoskeleton and focal adhesions contribute to cytoskeletal tension development, which in turn regulates cell stiffness and the strength of integrin binding to the matrix.

471

#### **The role of cell-intrinsic biophysical properties in enhancing glioma cell invasion.**

*Y. A. Miroshnikova<sup>1</sup>, I. Acerbi<sup>1</sup>, M. Paszek<sup>1</sup>, A. Persson<sup>1</sup>, G. Bergers<sup>1</sup>, V. Weaver<sup>1</sup>; <sup>1</sup>UCSF, San Francisco, CA*

Adult brain cancer continues to be a significant challenge to both clinicians and patients with more than 20,000 new cases diagnosed yearly and incredibly poor mean survival of 12 to 14 months for individuals with glioblastoma multiforme (GBM), the most common type of adult brain cancer. The mortality associated with late stage GBMs can be largely attributed to their early dissemination and intrinsic death resistance. High grade GBMs are notoriously resistant to therapy and typically disseminate throughout the brain tissue, severely compromising patient treatment. Brain cancer environment is highly vascular, abundant in hyaluronic acid (HA) and

proteoglycans/linker proteins that are deposited by the tumor cells which mechanically reinforce the extracellular matrix and locally elevate the interstitial pressure from fluid buildup. Thus, the microenvironment of the most aggressive GBMs can be viewed as mechanically-challenged and the cells themselves are likely to have altered mechano-behavior. We identified a variety of cell-intrinsic GBM cell properties that, at least partially, are responsible for driving glioma cell aggressiveness, such as alterations in cellular compliance and HA-induced changes in the glycocalyx which drives integrin clustering and alters cell adhesion. Thereby, aggressive GBMs have unique physical properties which, if prove to be robust, can be used as means for identification of the cancer-initiating and propagating cells within tumor masses from the cells lacking the aggressive and metastatic potential.

472

### **Regulation of Growth Factor Dependent Tumor Cell Proliferation by ECM Mechanics.**

V. Umesh<sup>1</sup>, T. Ulrich<sup>1</sup>, S. Kumar<sup>1</sup>; <sup>1</sup>Bioengineering, UC Berkeley, Berkeley, CA

The rapid progression of glioblastoma multiforme (GBM), the most common and lethal primary brain tumor, is driven by the diffuse infiltration of tumor cells into the brain. Recent genome sequencing efforts have revealed that many GBM tumors share lesions in the epidermal growth factor receptor (EGFR) pathway, which strongly promotes migration and proliferation. Previously, our laboratory has demonstrated that stiffening the extracellular matrix (ECM) can amplify the proliferation rate of human GBM tumor cells by more than a factor of five (Ulrich et al, Cancer Res 2009), raising the possibility that mechanical inputs can cross-talk with mitogenic signaling pathways to promote GBM tumor growth. The objective of this study was to directly explore this hypothesis by investigating the extent to which ECM biomechanics can regulate GBM cell cycle progression, chemotherapeutic sensitivity, and growth factor receptor (EGFR)-dependent signaling. We find that human glioma cells cultured on soft (80 Pa) fibronectin-coated polyacrylamide gels are more likely to be in G0/G1 and less likely to be in S phase of the cell cycle than cells cultured on stiff (119kPa) ECMs. Western Blot reveals that the expression and phosphorylation of EGFR and its downstream effectors, including Akt and PI3 kinase, depend strongly on ECM rigidity, with EGFR phosphorylation rising with increasing ECM stiffness. Furthermore, EGFR organization is highly rigidity-dependent, with EGFR co-clustering with focal adhesions on stiff substrates and receding into a diffuse distribution as matrix rigidity falls to physiological levels, suggesting that ECM stiffness may promote proliferation by spatially amplifying EGFR signaling. Together, these results support a model in which ECM stiffening acts through mechanotransductive pathways to trigger EGFR-based mitogenic signaling that promotes proliferation.

### **Analysis of integrin organization and dynamics during focal adhesion formation and turnover using fluorescence anisotropy imaging.**

S. Ghosh<sup>1</sup>, V. Swaminathan<sup>2,3</sup>, P. Nordenfel<sup>2,4</sup>, P. Gross<sup>2,5</sup>, B. Prevo<sup>2,6</sup>, T. Springer<sup>4</sup>, C. Waterman<sup>3</sup>, S. Mayor<sup>1</sup>; <sup>1</sup>National Centre for Biological Sciences, Bangalore, India, <sup>2</sup>Physiology Course, Marine Biological Laboratory, Woods Hole, MA, <sup>3</sup>National Heart Lung and Blood Institute, Bethesda, MD, <sup>4</sup>Harvard Medical School, Boston, MA, <sup>5</sup>Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, Germany, <sup>6</sup>VU University - Faculty of Sciences, Amsterdam, Holland

Integrins are transmembrane ECM receptors that link the extra-cellular matrix (ECM) and the cytoskeleton and play a crucial role in the immune response, cell migration and tissue morphogenesis. ECM-engaged integrins cluster together with proteins that mediate their signaling functions and linkage to the cytoskeleton to form focal adhesions that grow and turn

over in an actin and myosin II dependent manner. How actin and myosin mediate the clustering and organization of integrins during activation, focal adhesion growth and turnover is not known. We utilized fluorescence emission anisotropy imaging of cells expressing GFP-tagged integrins to analyze the evolution of integrin organization during focal adhesion dynamics in migrating fibroblasts and to test the role of integrin activation and actomyosin contractility in this process. Fluorescence anisotropy provides a measure of the rotational dynamics and/or degree of alignment of fluorophores. Our results show that integrins in nascent and mature adhesions have a higher value of anisotropy compared to integrins present diffusely on the cell membrane, indicating that upon clustering, integrins become more immobile and aligned in a polarized manner. Further, during the formation of a new lamellipodium, there is a relative increase in the polarization of integrins at the tip, suggesting a coupling between fast retrograde actin flow at the leading edge and integrin immobilization/polarized alignment irrespective of visible clustering. By employing specific perturbations we are attempting to understand how the association of focal adhesion components and the acto-myosin machinery affect the organization of integrins during the formation of mature adhesions.

474

**Proteomic analysis of integrin-associated complexes from multipotent and early differentiated mesenchymal stem cells.**

*J. N. Ajeian<sup>1</sup>, J. D. Humphries<sup>1</sup>, A. Byron<sup>1</sup>, J. A. Askari<sup>1</sup>, A. Millon-Fremillon<sup>1</sup>, S. E. Craig<sup>1</sup>, M. J. Humphries<sup>1</sup>; <sup>1</sup>University of Manchester, Manchester, United Kingdom*

The interaction of the extracellular matrix (ECM) with mesenchymal stem cells (MSCs) controls stem cell fate. Factors such as cell-ECM adhesion, cell-cell interactions and soluble factors contribute directly to MSC differentiation and fate determination. Adhesion of cells to the ECM is mediated principally by integrin adhesion receptors. Following adhesion, integrins cluster at the cell membrane, and protein complexes called focal adhesions (FAs) assemble inside the cells. FA assembly is likely to induce signalling events in cells and affect cell fate.

In this study, a proteomics workflow has been developed to isolate, identify and quantify integrin-associated complexes in undifferentiated MSCs and MSCs induced to an adipocyte lineage (short-term induction, 3 hours). The aim of this study was to compare the composition of FAs and the abundance of their components to identify proteins that may be involved in MSC differentiation.

MSCs were allowed to adhere to surfaces coated with defined ECM proteins. Following incubation, equal populations of MSCs were subjected to two different treatments for 3 hours: 1) the adipogenic induction medium; or 2) adipogenic maintenance medium (control). Ligand-induced integrin-associated complexes were stabilized using crosslinker. Cells were lysed, and isolated complexes were subjected to downstream proteomic analysis.

Mass spectrometry (MS) analysis showed a higher abundance of FA proteins, such as integrin  $\beta$ 1, integrin  $\alpha$ 5, vinculin, talin,  $\alpha$ -actinin-4, zyxin, tensin, filamins, kindlin-2, integrin-linked kinase (ILK) and the actin-binding proteins PDZ and LIM domain proteins 1 and 7 (Pdlim1 and Pdlim7) in ECM-bound complexes from induced MSCs compared to non-induced MSCs. Bioinformatic analysis such as hierarchical clustering and ontological analysis showed a profile of enrichment of FA proteins in induced MSCs on defined ECM proteins. These data demonstrate that FA proteins can be isolated in a reproducible manner from induced and non-induced MSCs in a way suitable for MS analysis. They also indicate that the early induction of an undifferentiated cell line (MSCs) into a specific lineage (adipogenesis) increased the abundance of key FA proteins, specifically in integrin-associated complexes induced by ECM ligands.

475

**Vinculin-vinexin  $\alpha$  interaction plays a key role in sensing extracellular matrix stiffness**

*T. Ichikawa<sup>1</sup>, H. Yamashita<sup>1</sup>, Y. Kimura<sup>1</sup>, I. Harada<sup>2</sup>, K. Ueda<sup>1,3</sup>, N. Kioka<sup>1</sup>; <sup>1</sup>Agriculture, Kyoto University, Kyoto, Japan, <sup>2</sup>Laboratory for Mechanical Medicine, Locomotive Syndrome Research Institute, Nadogaya Hospital, Chiba, Japan, <sup>3</sup>Institute for Integrated Cell-Material Sciences, Kyoto University, Kyoto, Japan*

Extracellular matrix (ECM) stiffness influences cell behaviors such as cell migration, proliferation, and differentiation. Details of how cells feel ECM stiffness is still unclear although focal adhesions (FA) seem to play a key role. Vinculin, a FA protein linking actin stress fiber (SF) to the integrin-talin complex, is recruited to and stabilizes FA depending on intracellular tension. Thus, vinculin is thought to be a key molecule for mechanosensing through FA. In this study, we investigate mechanisms for sensing substrate stiffness through vinculin by focusing on vinexin, a FA protein binding to proline-rich linker region of vinculin.

We first analyzed the effect of substrate stiffness on vinculin status by using collagen I cross-linked acrylamide gel substrates with different stiffness. FRAP (fluorescent recovery after photo-bleaching) analysis revealed that immobile fraction (IF) of vinculin at FA was increased on rigid gels compared to on soft gels. It is known that exogenous expression of vinexin  $\alpha$  accumulates vinculin at FA. Thus, we examined the effect of vinexin on vinculin behaviors depending on ECM stiffness. Interestingly, in vinexin knockout MEF cells, vinculin IF was decreased compared to WT MEF cells. Re-expression of vinexin  $\alpha$  but not vinexin  $\beta$  rescued vinculin IF. Moreover, mutation in proline-rich linker region, which disrupts the binding to vinexin, impaired the stabilization depending on ECM stiffness. These results suggest that vinculin-vinexin  $\alpha$  interaction is essential for stable localization of vinculin on rigid gels.

To test whether ECM stiffness or vinculin-vinexin  $\alpha$  affects another FA protein, we examine the paxillin behavior, using FRAP analysis. Paxillin IF at FA was decreased on rigid gels compared to on soft gels. Vinexin  $\alpha$  was necessary for the regulation of paxillin IF as well as vinculin IF. This indicates that vinculin-vinexin  $\alpha$  interaction regulates the ECM stiffness-dependent behaviors of FA proteins.

Next we examined the effect of vinexin on vinculin status in vitro. We purified vinexin  $\alpha\Delta N$ , which lacks N-terminal region but retains a function in MEFs. FRET (fluorescence resonance energy transfer) assay and actin co-sedimentation assay showed that interaction with vinexin  $\alpha$  induced the conformational change of vinculin and increased vinculin affinity to F-actin. These results suggest that interaction with vinexin  $\alpha$  promotes vinculin activation and alters properties of FA depending on ECM stiffness.

476

**Vinexin-dependent distribution of vinculin to lipid rafts stabilizes vinculin at focal adhesions.**

*H. Yamashita<sup>1</sup>, A. Nagasato<sup>1</sup>, T. Ichikawa<sup>1</sup>, M. Matsuo<sup>1</sup>, K. Ueda<sup>1,2</sup>, N. Kioka<sup>1</sup>; <sup>1</sup>Division of Applied Life Sciences, Graduate School of Agriculture, Kyoto University, Kyoto, Japan, <sup>2</sup>Institute for Integrated Cell-Material Science, Kyoto University, Kyoto, Japan*

Lipid raft, a plasma membrane domain enriched with cholesterol and sphingomyelin, is known to be required for focal adhesion (FA)-mediated signal transduction, such as Rac1 small GTPase and Src family kinases (SFKs). Signaling molecules localizing at FAs, including focal adhesion kinase, localize to and work in lipid rafts. However, it is not known whether cytoskeletal FA proteins localize to lipid rafts and whether lipid raft is involved in FA formation.

Here we investigated distribution of cytoskeletal FA proteins to lipid rafts and functions of lipid rafts in FA formation. Membrane fractions were extracted from mouse embryonic fibroblast cells

and treated with 1% Triton X-100 at 4°C, followed by density-gradient ultracentrifugation. FA proteins, including vinculin, vinexin, and paxillin, were separated into the fractions containing flotillin, a raft maker protein, but other proteins such as talin and integrin  $\beta$ 1 were not. Treatment with methyl- $\beta$ -cyclodextrin (M $\beta$ CD) disrupted the distribution of FA proteins into lipid rafts. We found that vinculin distribution to lipid rafts was regulated by cell adhesion. Detachment of cells from ECM removed vinculin from lipid rafts, and re-attachment to ECM rescued the localization to lipid rafts. Re-distribution to lipid rafts was impaired by blebbistatin, a myosin II inhibitor, suggesting that vinculin distribution to lipid rafts is regulated by cell adhesion and intracellular tension. Furthermore, we examined the effect of raft disruption on vinculin behavior. M $\beta$ CD treatment promoted vinculin turnover at FA. Similarly, lipid raft disruption induced by ABCA1 expression promoted the turnover, indicating a role of lipid rafts in regulating FA. Vinexin is a protein interacting with flotillin as well as proline-rich linker region of vinculin. Thus, we examined whether vinexin is involved in vinculin distribution to lipid rafts. We found that vinculin was not localized to lipid rafts in vinexin knockout cells. Re-expression of vinexin  $\alpha$  rescued vinculin localization. Together, these results suggest that the distribution of vinculin to lipid rafts involves the interaction with vinexin and stabilizes vinculin at FA.

477

### **Mechanotransduction through Functional Interplay between Connexin Hemichannels, Integrins, and Signaling in Osteocytes.**

*M. A. Riquelme<sup>1</sup>, N. Batra<sup>1</sup>, S. Burra<sup>1</sup>, J. X. Jiang<sup>1</sup>; <sup>1</sup>Biochemistry, University of Texas Health Science Center, San Antonio, TX*

Mechanical loading induces the release of small bone anabolic factors, such as prostaglandins, from osteocytes, the principal mechanosensory cells with long dendritic processes. This release is mediated by opening of connexin 43 (Cx43) hemichannels (HC) at the cell surface. However, the mechanism for mechanotransduction that leads to the opening of these HC is unknown. Integrins expressed on the cell surface are thought to be mechanical sensors in the osteocytes. Our recent study showed that activation of PI3K/AKT induced the conformational activation of integrin  $\alpha$ 5 upon mechanical stimulation in the form of fluid flow shear stress (FFSS), and led to the opening of Cx43 HC in osteocytic MLO-Y4 cells. Here, we show that integrin  $\alpha$ v $\beta$ 3 located in the dendritic processes is the primary mechanosensor that activates PI3K/AKT signaling. Activated AKT further phosphorylates both Cx43 and integrin  $\alpha$ 5, enhances their interaction and increases Cx43 HC activity in the cell body. Integrin  $\alpha$ v colocalized with integrin  $\beta$ 3 but not Cx43 on the dendritic side of the cells. Inhibition of integrin  $\alpha$ v activation upon FFSS attenuated the activation of PI3K/AKT and blocked HC opening on the cell body. Interestingly, integrin  $\alpha$ v $\beta$ 3 present on the dendritic processes activated PI3K, which was required for the activation of integrin  $\alpha$ 5 $\beta$ 1 and opening of Cx43 HC on the cell body. FFSS activated AKT and facilitated HC opening. Cx43 and integrin  $\alpha$ 5 were both directly phosphorylated by AKT and FFSS increased their phosphorylation due to activation of AKT. AKTi, an inhibitor specific to AKT, disrupted the interaction between Cx43 and integrin  $\alpha$ 5, preventing the HC from opening. These results show that the interaction is essential for Cx43 HC to open. Taken together, these results suggest that integrin  $\alpha$ v $\beta$ 3 is the mechanical sensor that activates PI3K/AKT leading to the increased phosphorylation of integrin  $\alpha$ 5 and Cx43 and enhanced their interaction, thereby inducing the Cx43 HC to open and release important bone anabolic factors.

## Glycoproteins and Metalloproteases

478

### Characterization of Basigin gene expression in the mouse pineal gland.

*D. R. Tokar<sup>1</sup>, J. D. Ochriotor<sup>1</sup>; <sup>1</sup>Biological Sciences, University of North Florida, Jacksonville, FL*

The Basigin gene expresses several products via splice variation. In the neural retina, two splice variants, named Basigin and Basigin-2 are expressed, with Basigin, the shorter variant, expressed by Müller glial cells and the retinal pigmented epithelium and Basigin-2, the longer variant, expressed by photoreceptor neurons. The two gene products associate with monocarboxylate transporters (MCTs) and are thought to form a metabolon that is critical for photoreceptor function. Since Basigin-2 expression has only been detected in photoreceptor neurons to date, the purpose of the present study was to determine if both Basigin and Basigin-2 are expressed in the pineal gland, which is a photoreceptive portion of the brain. Mouse pineal glands were harvested using established protocols and both RNA and protein were isolated using the TRI reagent protocol. Quantification of the relative expression of Basigin and Basigin-2 transcripts was performed through quantitative RT-PCR. Protein samples were subjected to immunoblotting analyses. The results indicate that although both transcripts were detected by quantitative RT-PCR, the longer transcript is expressed in trace amounts. Immunoblotting analyses indicate only the shorter form, Basigin, is translated into a protein in that tissue. The data suggest that while the longer transcript is generated, it is likely only a primary transcript that is used as a starting point for splicing of the shorter form. Basigin-2 protein expression remains a photoreceptor neuron-specific phenomenon. Future analyses will include quantification of MCTs in the pineal gland and comparison to their expression in the retina.

479

### Characterization of the ability of the photoreceptor-specific variant of the Basigin gene to induce expression of IL-6.

*K. B. Russell<sup>1</sup>, J. D. Ochriotor<sup>1</sup>; <sup>1</sup>Biological Sciences, University of North Florida, Jacksonville, FL*

The Basigin gene codes for two proteins in the neural retina by splice variation. Basigin and Basigin-2, members of the immunoglobulin superfamily (IgSF) are identical in amino acid sequence, with the exception of an additional Ig domain in the extracellular portion of the Basigin-2 molecule (Ochriotor et al., 2003, IOVS). The Basigin-2-specific loop is highly conserved throughout evolution, suggesting it has a specific, conserved role, most likely as a binding domain in the retina. A recent study suggests that Basigin-2 has the ability to induce expression of IL-6 from several cell lines (Redzic et al., 2011, JMB). The purpose of the present study was to determine which region of the Basigin-2-specific Ig domain is responsible for IL-6 expression. The monocytic cell line U937 was incubated with a recombinant form of the Basigin-2-specific Ig domain and IL-6 expression was assayed via enzyme-linked immunosorbant assay (ELISA). The results indicate the amino half of the Basigin-2-specific Ig domain has the ability to induce IL-6 expression in U937 cells. It is interesting to note that the amino half of the domain has also been implicated in binding to Basigin protein in the neural retina. It is not yet known if IL-6 expression is dependent on Basigin signal transduction. Future studies will be aimed at understanding the role that Basigin gene products play in IL-6 expression and its significance in the mammalian neural retina.

**Characterization of the role of Cyclophilin A in the Basigin-MCT1 complex in the neural retina.***K. M. Fletcher<sup>1</sup>, J. D. Ochriotor<sup>1</sup>; <sup>1</sup>Biology, University of North Florida, Jacksonville, FL*

It is well documented that the cell adhesion molecule Basigin and monocarboxylate transporter 1 (MCT 1) associate in the mammalian neural retina. It was suggested that Basigin acts as a molecular chaperone for the expression of MCT1 at the plasma membrane. However, a recent study from this laboratory indicated that Cyclophilin A expression overlaps that of Basigin and MCT1 in the neural retina, and may therefore chaperone the Basigin-MCT1 complex to the cell surface. The purpose of the current study was to determine whether Cyclophilin A interacts with Basigin gene products, specifically within the transmembrane domain of those molecules. Recombinant versions of the Basigin transmembrane domain were produced and used in an ELISA with endogenous mouse retina Cyclophilin A. In addition, immunohistochemical analyses for Cyclophilin A were performed on Basigin null mouse retina sections. The results indicate that Cyclophilin A binds to the central region of the Basigin transmembrane domain and is present at the plasma membrane of photoreceptors and Müller cells in Basigin null animals. These data suggest that Cyclophilin A binds to Basigin within the exocytic pathway and chaperones it to the plasma membrane. Basigin, however, is not needed for Cyclophilin A expression at the plasma membrane, as its expression was unaffected in the null animals.

481

**Characterization of the expression of Basigin and MCT1 in mouse reproductive systems.***P. J. Moran<sup>1</sup>, J. D. Ochriotor<sup>1</sup>; <sup>1</sup>Biological Sciences, University of North Florida, Jacksonville, FL*

Basigin and MCT1 are rather ubiquitously expressed transmembrane proteins that participate in cell adhesion and monocarboxylate transport respectively. Basigin null mice incur various abnormalities, including blindness and infertility, and research has suggested that a metabolic shuttling complex formed by these two proteins is necessary for proper maturation and function of photoreceptors. Without the construction of this metabolon in the neural retina, the mice are blind. This research group questions whether a similar mechanism exists in the in the uterus and testes that underlies the causes of infertility in Basigin null mice. Therefore, the expression of Basigin and MCT1 was assessed in normal mouse reproductive tissues. Immunoblotting and immunohistochemical analyses using antibodies specific for Basigin and MCT1 were performed on paraffin-embedded sections of mouse testis and uterus. Both immunofluorescence and a methyl green staining protocol were used to localize the proteins within the tissues. In the mouse testis, Basigin was found to be expressed primarily in the lumen of the seminiferous tubules and developing sperm, while MCT1 was expressed on the Leydig cells. In the uterus, preliminary analyses showed both Basigin and MCT1 to be expressed on the epithelial cells of the endometrium lining. The data suggest that it is unlikely that a faulty metabolic shuttle composed of Basigin and MCT1 is the cause of the arrest of spermatogenesis in Basigin null male mice, as the two proteins do not have overlapping expression. Conversely, both proteins were expressed in the same location within the mouse uterus. It is enticing to speculate what metabolic role Basigin and MCT1 play in the pre-placental phases of embryonic development, but additional experiments must be performed before one can truly know their role.

482

**Characterization of Basigin gene expression in mouse tissues.**

V. Sachkouskaya<sup>1</sup>, J. D. Ochrietor<sup>1</sup>; <sup>1</sup>Biological Sciences, University of North Florida, Jacksonville, FL

The Basigin gene expresses two major splice variants in the neural retina. The shorter form, named Basigin, is expressed on Müller glial cells, blood vessel endothelial cells, and the retinal pigmented epithelium in the eye and on epithelial surfaces throughout the body. The longer form, named Basigin-2 is expressed only by photoreceptor neurons. The two forms differ by one exon – exon 1A – that is found in Basigin-2 but not Basigin. Previous studies of Basigin gene expression in the neural retina suggested that the primary transcript contains exon 1A, which is spliced out in all cells but the photoreceptors, as trace amounts of exon 1A are found in the mRNA pool of Müller glial cells. Therefore, the purpose of this study was to analyze Basigin gene expression in various tissues of the mouse body to determine if the primary Basigin transcript does indeed contain exon 1A. Mice were sacrificed according to an accepted protocol and tissues were harvested for RNA isolation using the TRI reagent protocol. Quantitative RT-PCR was performed using primer sets specific for exon 1A and also for the mature Basigin transcript. The data indicate that exon 1A is present in the primary Basigin transcript, as it was detected in trace amounts in all tissues tested. This suggests that exon 1A is universally transcribed but then spliced out in all cells except for photoreceptor neurons. Future studies will be aimed at identifying the regulatory factors that regulate this splice specificity.

483

**Characterization of Basigin and Monocarboxylate transporter gene expression in the mouse olfactory system.**

H. A. Zahir<sup>1</sup>, P. Gambon<sup>1</sup>, N. Thiebaud<sup>2</sup>, D. A. Fadoo<sup>2</sup>, J. D. Ochrietor<sup>1</sup>; <sup>1</sup>Biological Sciences, University of North Florida, Jacksonville, FL, <sup>2</sup>Department of Biological Sciences, Program in Neuroscience and Molecular Biophysics, The Florida State University, Tallahassee, FL

Basigin, a member of the immunoglobulin superfamily, is known to associate with monocarboxylate transporters (MCTs) to form a complex thought to be necessary for photoreceptor function in the neural retina. Indeed, Basigin null mice do not express MCT1 or MCT4 at the photoreceptor or Müller cell plasma membrane and are blind from the time of eye opening. It has also been documented that Basigin null mice have olfactory deficits, in which they are anosmic and impervious to offensive odors such as acetic acid. Therefore, the purpose of this study was to examine the expression of Basigin and MCT-1, MCT-2, and MCT4 in the olfactory system of Basigin null mice and their control littermates in order to determine if a metabolic defect, like that in the retina, underlies the olfactory deficiencies of Basigin null animals. Immunohistochemical techniques were performed on the olfactory bulb (OB) of normal and Basigin null mice, as well as the main epithelium (MOE) of Olfactory Marker Protein (OMP)-GFP mice, using antibodies specific for Basigin, Embigin, MCT1, MCT2, and MCT4. The data indicate that MCT1, MCT2, and MCT4 expression is robust in the MOE. Conversely, MCT2 expression predominates in the OB, and is specifically associated with the glomeruli, the mitral cell layer, and the granule cell layer. The expression of MCT1 and MCT4 in the OB is limited to blood vessel endothelial cells. It is of interest to note that Basigin gene expression does not overlap that of MCT1 or MCT4 in the MOE, but does so in the OB, where it is found on blood vessel endothelial cells. A related protein, Embigin, is thought to interact with MCT2 in expressing cells, but was not detected in the OB of normal or Basigin null animals. The data suggest that a metabolic deficiency like that in the retina of Basigin null mice does not likely account for the acetic acid-specific anosmia in those animals.

**Human primary astrocytes express CD99: potential role in HIV brain infection.**

C. A. Daep<sup>1,2</sup>, E. Eugenin<sup>2,3</sup>; <sup>1</sup>Public Health Research Institute and Department of Microbiology and Molecular Genetics, University of Medicine and Dentistry of New Jersey, Newark, NJ, <sup>2</sup>Microbiology and Molecular Genetics, University of Medicine and Dentistry of New Jersey, Newark, NJ, <sup>3</sup>Public Health Research Institute, University of Medicine and Dentistry of New Jersey, Newark, NJ

CD99 (MIC2) is an intracytoplasmic glycoprotein expressed in a wide variety of cells and has been shown to play a role in a variety of function ranging from cell differentiation and apoptosis. CD99 has also been observed to be important in lymphocyte adhesion and migration across the endothelium by activating alpha4beta1 and actin polymerization. Furthermore, induction of ICAM-1 by CD99 in human gingival fibroblasts has been shown to be important in the transmigration of leukocytes across the epithelial mucosa of the oral cavity thereby participating in pathogenesis of periodontal disease. HIV infection of the central nervous system is caused by the transmigration of virus-infected macrophages across the blood brain barrier (BBB) leading to the development of NeuroAIDS leading to deterioration of the CNS. This is facilitated by specific intercellular interactions with a variety of adhesion molecules expressed within the blood brain barrier which is comprised of endothelial cells, astrocytes, and pericytes. Indeed, previous studies have shown that endothelial cells express CD99 on their extracellular surface; however, to date, the presence of these molecules has not been identified among astrocytes. Further, the role of these molecules in the cellular physiology of these cells has not yet been elucidated. We have shown that human primary astrocytes robustly express CD99 as verified by Western blot and immunofluorescence assay. Currently their role in HIV infection of the CNS is being identified. Determining the role of these molecules in the semi-permeability of the blood brain barrier as well as synaptic regulation may provide further insight into the pathogenesis of NeuroAIDS the design of better therapies against HIV.

**Matrix metalloproteinase-14 cleaves the ectodomain of syndecan-2.**

Y. Lee<sup>1</sup>, J. Park<sup>1</sup>, S. Cho<sup>2</sup>, E-S. Oh<sup>2</sup>, S-T. Lee<sup>1</sup>; <sup>1</sup>Department of Biochemistry, Yonsei University, Seoul, Korea, <sup>2</sup>Department of Life Science, Ewha Womans University, Seoul, Korea

Syndecans (SDCs) are a family of transmembrane heparan sulfate proteoglycans, consisting of four members (SDC1 to SDC4), and play critical roles in development, wound healing, inflammation, and tumor progression. Shedding of syndecan ectodomain found in many cultured cells is involved in biological events such as ligand binding and intracellular signaling. Matrix metalloproteinases (MMPs) are zinc-dependent endopeptidases which are involved in degradation of extracellular matrix components during cancer invasion and metastasis. Recently, we identified that shedding of syndecan-2 (SDC2) is mediated by matrix metalloproteinase-7 (MMP-7) in colon cancer cells. To further analyze susceptibility of SDC2 to various MMPs, an extracellular domain (ECD) of rat SDC2 tagged with a crystallizable fragment of antibody (Fc) was overexpressed in HeLa cells. The Fc-tagged rat SDC2-ECD was cleaved the most efficiently by MMP-14, even better than by MMP-7. N-terminal amino acid sequencing revealed that MMP-14 cleaves rat SDC2 between Asn138 and Leu139. Fluorescence resonance energy transfer (FRET) assay using quenched fluorescent oligopeptide substrates containing cleavage sites of SDC2 showed that rat SDC2 oligopeptide is more efficiently cleaved by MMP-14 than human SDC2 oligopeptide. Taken together, our findings demonstrate that SDC2 is a novel substrate for MMP-14. Considering that MMP-14 is upregulated during invasion and metastasis, these results suggest that ectodomain shedding of SDC2 by MMP-14

may play a role in decreased SDC2-mediated cell-cell and cell-matrix adhesion and thus increased malignancy.

**The hemopexin but not the catalytic domain of Mmp3 is required for epithelial mammary invasion and branching morphogenesis.**

*A. Correia<sup>1,2</sup>, H. Mori<sup>1</sup>, E. I. Chen<sup>3</sup>, F. C. Schmitt<sup>4,5</sup>, M. J. Bissell<sup>1</sup>; <sup>1</sup>Life Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA, <sup>2</sup>GABBA, Abel Salazar Institute for Biomedical Sciences (ICBAS), University of Porto, Porto, Portugal, <sup>3</sup>Department of Pharmacological Sciences, Stony Brook University, New York, NY, <sup>4</sup>Medical Faculty of Porto University, Porto, Portugal, <sup>5</sup>Institute of Molecular Pathology and Immunology of the University of Porto, Porto, Portugal*

Sculpting of the mammary epithelial tree requires concerted and reciprocal signaling between the epithelium and its surrounding stroma, so that branch site initiation and timely invasion into the fat pad are ensured. Breakdown of normal branched architecture causes mammary gland dysfunction and may eventually create conditions to permit malignant transformation. Previous studies from our laboratory provided evidence that inappropriate expression of the stromal matrix metalloproteinase-3 (Mmp3) in mammary epithelia in engineered mice induces its morphological reshaping, unrestrained branching and ultimately malignant transformation. Although proteolytic activity appears to be the overriding regulator of Mmp3-induced disruption of mammary architecture, inhibition of MMP3 catalytic domain have yielded disappointing results in cancer trials. Here we explored extra-catalytic sites within MMP3 that contribute to impaired epithelial morphology. By expressing distinct Mmp3 mutants in mouse mammary epithelial cells, we uncovered a previously unrecognized role for the hemopexin domain of this enzyme in promoting cytoskeleton's reorganization, elongated morphology and scattering. We found that this domain is required also for Mmp3 to choreograph epithelial invasion and branching morphogenesis in murine mammary organoids cultured in three dimensional (3D) type I collagen gels. These findings uncover a novel mechanism by which Mmp3 regulates its function. Our data suggest also that conventional strategies to inhibit Mmp3 should be revisited, and targeting extra-catalytic sites of the protein may yield more effective inhibitors of its function. Ongoing experiments are focused on the identification of proteins that may interact with Mmp3 via hemopexin domain to allow mammary epithelial function and invasion during branching.

**A Novel Mechanism to Regulate MMP-2 Activity.**

*B-H. Koo<sup>1</sup>, Y-H. Kim<sup>1</sup>, D-S. Kim<sup>1</sup>; <sup>1</sup>Biochemistry, Yonsei University, Seoul, Korea*

Matrix metalloproteinase-2 (MMP-2) functions in diverse biological processes through the degradation of extracellular and non-extracellular matrix molecules. Because of its potential for tissue damage, there are several ways to regulate MMP-2 activity, including gene expression, compartmentalization, zymogen activation, and enzyme inactivation by extracellular inhibitors. Enzyme regulation through zymogen activation is important for the regulation of MMP-2 activity. In our previous studies, we showed that thrombin directly cleaved the propeptide of MMP-2 at specific sites for enzyme activation. We also demonstrated that heparan sulfate was required for thrombin-mediated activation of pro-MMP-2 by binding to thrombin, presumably through conformational changes at the active site of the enzyme. This suggests a regulatory mechanism for thrombin-mediated activation of pro-MMP-2. In this study, we found that MMP-2 formed a

reduction-sensitive homodimer in a controlled manner and that Ca<sup>2+</sup> ion was essential for homodimerization of MMP-2. Homodimerization was not associated with protein kinase C-mediated phosphorylation of MMP-2. MMP-2 formed a homodimer through an intermolecular disulfide bond between Cys102 and the neighboring Cys102. Homodimerization of MMP-2 enhanced thrombin-mediated activation of pro-MMP-2. Moreover, the MMP-2 homodimer could cleave a small peptide substrate without removal of the propeptide. Taken together, our experimental data suggest a novel regulatory mechanism for pro-MMP-2 activation that is modulated through homodimerization of MMP-2.

### Biochemical purification and characterization of *Drosophila* MMPs.

K. LaFever<sup>1</sup>, G. Bhave<sup>2</sup>, A. Page-McCaw<sup>1</sup>; <sup>1</sup>Dept. of Cell and Developmental Biology, Vanderbilt Medical Center, Nashville, TN, <sup>2</sup>Dept. of Medicine, Vanderbilt Medical Center, Nashville, TN

The vertebrate matrix metalloproteinase (MMP) family of extracellular proteases is very large with over 20 members that have apparent functional redundancy. Vertebrate MMPs can be classified according to their localization: some are secreted while others associate with the cell membrane. In *Drosophila melanogaster*, there are only two MMPs, DmMmp1 and DmMmp2. The fly MMPs do not have clear orthologs among the vertebrate MMPs, but DmMmp1 is known to be secreted into the media and DmMmp2 has a predicted GPI anchor. Thus both classes of MMPs are represented in the fly model. Because of this simplicity, *Drosophila* is an attractive system for the genetic analysis of MMP function. However, one limitation of the fly model is that few substrates have been identified biochemically or genetically. As a first step toward substrate identification, we are purifying full-length tagged enzymes from S2 cells and characterizing their activity. As expected, two isoforms of the secreted DmMmp1 exhibit activity by zymography. A third DmMmp1 isoform, which has a predicted GPI anchor, is enigmatic at this point. DmMmp2 remains associated with the cells, and we are working to demonstrate its activity in vitro. Our goal is to incubate crude extracts of insoluble *Drosophila* ECM with affinity-purified enzymes to identify substrates of *Drosophila* MMPs. We expect cleaved fragments will be released into solution, where they can be identified by mass spectrometry.

## Cell-Cell Junctions I

### β-catenin is essential for tight junction maintenance under mechanical stress.

S. Ray<sup>1</sup>, H. Foote<sup>1</sup>, T. Lechler<sup>1</sup>; <sup>1</sup>Cell Biology, Duke University Medical Center, Durham, NC

Many tissues in our body experience and must tolerate mechanical stresses due to both internal and external forces. The skin, for example, is exposed to significant mechanical insults and is specially designed to have high mechanical resistance. Here we report a previously unrecognized role for β-catenin in providing stability to a tissue under stress. Loss of [beta]-catenin early in the development of the epidermis caused fully penetrant perinatal lethality. While broad regions of the epidermis appeared normal, sites of active morphogenesis and movement showed defects in tight junction localization and activated stress responses. These defects were not associated with detectable changes in Wnt signaling or adherens junctions in vivo. In addition, [beta]-catenin null cells formed adherens junctions and tight junctions normally in culture. Despite this, they had a specific defect in the maintenance of tight junction proteins when exposed to externally applied uniaxial stretch. In addition, [beta]-catenin null cells could not strengthen adherens junctions in response to cues from cortical microtubules, as wild-type

cells do. These data demonstrate that the full function of cell adhesion structures must take into account their role in response to mechanical stresses.

**Cell junctions, the actomyosin purse string and tension in dorsal closure.**

*U. S. Tulu<sup>1</sup>, D. Kiehart<sup>2</sup>; <sup>1</sup>Department of Biology, Duke University, Durham, NC, <sup>2</sup>Department of Biology, Department of Cell Biology, DCMB Group, Duke University, Durham, NC*

Cell sheet movements are an important aspect of embryonic development for organ and tissue formation. The functions of various junctional, cytoskeletal and motor proteins are coordinated to ensure that these movements occur at a correct time and place. Dorsal closure during *Drosophila* embryogenesis is an extensively used model to understand such movements. At the start of dorsal closure, contractile purse strings start to form as F-actin and myosin are accumulated at the leading edges of lateral epidermis. Here, we examine the roles of junctional proteins such as zyxin,  $\alpha$ -actinin, cadherin and integrin. Zyxin and  $\alpha$ -actinin localize to foci along the purse strings. Because zyxin localization coincides with the tension establishment along the purse string and it is responsive to the mechanical changes in cultured cells, we tested zyxin's response to mechanical changes in a multicellular environment using laser microsurgery. By cutting the tissue in different orientations, tension along the purse string can be abruptly increased or decreased. Contrary to the results in tissue culture cells, we found that zyxin foci disassemble when the tension along the purse string is released. In addition, the localization of zyxin and  $\alpha$ -actinin into foci on the cell membranes indicates that the cell junctions have an important role in the formation of the purse string. We compare the functions of different cell junctional proteins, mainly cadherins and integrins, in making the purse string. Our results indicate that the cadherins, rather than the integrins, have primary role in making the purse string a supracellular structure. These results suggest that tension-sensitive actomyosin purse strings are made supracellular by cadherin-mediated cell-cell junctions. Grant support: GM33830 to DPK

**Spatial Regulation of Rho-A by GEF-H1 and p190RhoGAP in Response to ECM Stiffness.**

*S. M. Ponik<sup>1,2,3</sup>, J. N. Heck<sup>2</sup>, P. J. Keely<sup>1,2,3</sup>; <sup>1</sup>Laboratory for Optical and Computational Instrumentation, University of Wisconsin-Madison, Madison, WI, <sup>2</sup>Cellular and Regenerative Medicine, University of Wisconsin-Madison, Madison, WI, <sup>3</sup>Cell and Molecular Biology, University of Wisconsin-Madison, Madison, WI*

Breast epithelial cells sense and respond to the stiffness of their ECM environment using the small GTPase Rho, however the exact signaling mechanism has not been identified. Of the known Rho regulators, p190RhoGAP-B, and the GTP exchange factor, GEF-H1, are of particular interest to our lab because changes in both of these regulatory proteins were detected by microarray analysis of mouse epithelial cells cultured in low vs. high density collagen gels. In this study, we find that p190RhoGAP-B mediates down-regulation of RhoA activity and subsequent ductal morphogenesis in a compliant matrix, while GEF-H1 mediates RhoA activation in response to extracellular matrix stiffness. Under compliant matrix conditions both RhoA and p190RhoGAP-B co-localize with p120-catenin at sites of cell-cell contact. Consistent with these findings, we utilized a RhoA specific FRET biosensor and determined RhoA activity to be significantly decreased at cell-cell contact vs. cell-ECM adhesions. This suggests that Rho is held in an inactive pool at cell-cell contacts through a complex of p190B and p120-catenin, and is recruited to cell-ECM contacts within stiff matrices. Rho is activated in stiff matrices by GEF-H1, and we demonstrate the novel finding that microtubule stability is

diminished by a stiff 3D extracellular matrix, which leads to the activation of GEF-H1. Using acetylated-tubulin as a marker for microtubule stability, we observed a striking difference in acetylated-tubulin levels in cells that were cultured in stiff compared to compliant collagen gels: in compliant 3D matrix conditions, the acetylated microtubules appeared more linear and organized, while in stiff matrices acetylated microtubules were more punctate and disorganized. Additionally, loss of GEF-H1 decreases cell contraction of and invasion through 3D matrices. These data demonstrate that RhoA along with p120-catenin, p190B-RhoGAP-B, microtubules, and GEF-H1 function together in mechanosensing, which allows breast epithelial cells to detect and respond to changes in the stiffness of their tissue microenvironment.

**The desmosomal protein, desmoplakin, is a novel binding partner of the microtubule plus-end binding protein EB1.**

*D. M. Patel<sup>1</sup>, A. Dubash<sup>1</sup>, J. Koetsier<sup>1</sup>, K. J. Green<sup>1,2,3</sup>; <sup>1</sup>Feinberg School of Medicine, Department of Pathology, Northwestern University, Chicago, IL, <sup>2</sup>Feinberg School of Medicine, Department of Dermatology, Northwestern University, Chicago, IL, <sup>3</sup>Feinberg School of Medicine, Robert H. Lurie Comprehensive Cancer Center, Northwestern University, Chicago, IL*

Desmoplakin (DP) is a desmosomal plaque protein that tethers intermediate filaments to sites of intercellular contact, and is essential for conferring mechanical integrity to tissues such as the epidermis and myocardium. DP and other desmosomal proteins are commonly mutated in arrhythmogenic right ventricular cardiomyopathy (ARVC), a cardiac disease in which arrhythmias can lead to sudden death. However, the pathogenicity of DP mutations is poorly understood. A yeast-two-hybrid screen using a construct of the DP N-terminus, which is a hot-spot for ARVC mutations, was conducted to identify binding partners of DP that contribute to disease development. Among the partners identified was the microtubule plus-end binding protein EB1 (end-binding 1). EB1 promotes border localization of the gap junction protein connexin 43 (Cx43), which is often aberrantly distributed in ARVC. Interference with EB1 binding and localization could thus be a potential mechanism by which mutation of DP leads to arrhythmogenesis. The DP-EB1 interaction was confirmed by co-immunoprecipitation of endogenous DP and EB1 from epithelial cell lysates. His-tagged EB1 constructs were used to demonstrate that the DP N-terminus binds full-length EB1 but not the EB1 head domain, suggesting that DP interacts with the EB1 C-terminus. *In situ* interaction of DP and EB1 was verified using a proximity ligation assay, in which DNA oligonucleotides produce a fluorescently detectable signal if two antigens of interest are in close proximity. To test if DP governs EB1 localization, we used structured illumination microscopy and confocal microscopy to compare the distribution of EB1 comets in control and DP-knockdown cells. Whereas control cells demonstrated a perpendicular alignment of EB1 comets with respect to cell-cell contacts, DP-deficient cells demonstrated a parallel alignment of EB1 comets and a loss of microtubule (MT) association with junctions. EB1 has been implicated in cortical capture of MTs, which confers stability to MT plus-ends. To test the importance of DP to MT stability, we treated WT and DP-knockdown cells with low concentrations of nocodazole known to preferentially target dynamic MT ends, and observed that MTs of DP-deficient cells were more susceptible to depolymerization. Importantly, cultured cardiac myocytes demonstrated a reduction in Cx43 border localization upon DP knockdown. Collectively, these results suggest potential mechanisms by which DP regulates MT organization and gap junction assembly, and by which mutations in DP contribute to ARVC development.

### **Rac1 promotes maturation of cell-cell contacts by activating the E3 ubiquitin ligase Nedd4.**

*P. L. Hordijk<sup>1</sup>, M. Nethe<sup>1</sup>, B-J. de kreuk<sup>1</sup>, D. Tauriello<sup>2</sup>; <sup>1</sup>University of Amsterdam, Amsterdam, Netherlands, <sup>2</sup>UMCU, Utrecht, Netherlands*

The Rho-GTPase Rac1 promotes actin polymerization and membrane protrusions that mediate initial contact and subsequent maturation of cell-cell junctions. Here we report that Rac1 associates to the ubiquitin-protein ligase neural precursor cell expressed developmentally down-regulated 4 (Nedd4) and co-localizes with endogenous Nedd4 at epithelial cell-cell contacts. This interaction requires the hypervariable C-terminal domain of Rac1 and the WW domains of Nedd4. Reduction of Nedd4 expression by shRNA results in reduced transepithelial electrical resistance (TER) and concomitant changes in the distribution of adherens and tight junction markers. Conversely, expression of Nedd4 promotes TER, suggesting that Nedd4 cooperates with Rac1 in the induction of junctional maturation.

We found that activated Rac1 promotes Nedd4, but not Nedd4-2, -mediated ubiquitylation and degradation of the adapter protein dishevelled-1 (Dvl1), a negative regulator of cell-cell contact. Moreover, we observed endogenous Rac1 to co-localize with endogenous Dvl1 in intracellular puncta as well as on cell-cell contacts. Finally, we show that Dvl1 impairs epithelial cell-cell contacts by increasing the acetylation of microtubules (MTs). Bypassing the Rac1-Nedd4-Dvl1 pathway and promoting MT acetylation by inhibiting HDAC6 resulted in a loss of TER. Together, these data reveal a novel Rac1-dependent signalling pathway which, through Nedd4-mediated ubiquitylation of Dvl1, reduces the level of acetylated microtubules, which in turn promotes the maturation of epithelial cell-cell contacts.

494

### **Epithelial Cell Contact Induces Zipcode-Mediated Contact Localized $\beta$ -actin Monomer Synthesis.**

*N. Gutierrez<sup>1</sup>, I. Eromobor<sup>1</sup>, A. J. Rodriguez<sup>1</sup>; <sup>1</sup>Rutgers University, Newark, NJ*

Epithelial cell-cell contact induces changes in the architecture of the actin cytoskeleton. These cytoarchitectural changes allow a cell to convert itself from a motile phenotype to an adhesive phenotype. Adherens junction complex assembly mediates the adhesive phenotype by generating a macromolecular adhesion complex that associates with the actin cytoskeleton. Previously it was demonstrated that the mRNA for  $\beta$ -actin contains a nucleotide sequence in its 3' UTR, called the zipcode, which is necessary for targeting and regulation of this transcript. The translation sequence is utilized by the zipcode binding protein, ZBP1. Consequentially deleting the zipcode sequence causes mislocalization of the mRNA transcript and its synthesized monomers inhibiting adherens junction assembly following myoblast cell contact. Here we report that the  $\beta$ -actin mRNA zipcode sequence is necessary for contact localized synthesis following epithelial cell contact.  $\beta$ -actin monomer synthesis was visualized using FIAsh & ReAsH to observe translation sites and calcium switching to induce epithelial cell contact.  $\beta$ -actin translation sites were observed at the base of filopods and later at the midline of the forming adherens junction. In fact quantifying the number of translation site at the cell contact there is a 7-fold decrease when the zipcode is deleted. Moreover under these conditions E-cadherin and F-actin failed to co-localize at cell contact sites. To quantify the extent of the adherens junction assembly defect we calculated the Pearson's correlation of E-cadherin and F-actin in the cytoplasm and cell contact sites. Dividing the Pearson's correlation calculation of the junction by the Pearson's correlation calculation of the cytoplasm yields the Asymmetry Coefficient of co-localization (AC). AC values greater than 1 represent adherens

junction events and AC values less than 1 represent adherens junction disassembly events. Zipcode-deletion causes the AC value to remain below 1 during the recovery stage of the calcium switch experiment. Taken together these data support a model where spatially and temporally regulated  $\beta$ -actin monomer synthesis drives adherens junction assembly following epithelial cell contact. Moreover this model may explain how ZBP1 functions as a potent metastasis inhibitor in cancer xenograph models.

**A novel role for Anillin in regulating cell-cell junctions in the intact epithelium.**

C. C. Reyes<sup>1</sup>, M. Jin<sup>2</sup>, R. Espino<sup>2</sup>, E. B. Breznau<sup>1</sup>, A. B. Goryachev<sup>3</sup>, A. L. Miller<sup>1,2</sup>; <sup>1</sup>Cell and Molecular Biology, University of Michigan, Ann Arbor, MI, <sup>2</sup>Molecular, Cellular, and Developmental Biology, University of Michigan, Ann Arbor, MI, <sup>3</sup>Centre for Systems Biology, University of Edinburgh, Edinburgh, United Kingdom

Anillin is a scaffolding protein that organizes and stabilizes the contractile ring by binding multiple cytokinesis regulators including F-actin, Myosin-2, Septins, the small GTPase RhoA, the RhoA activity regulator MgcRacGAP, and lipids. Anillin is required for successful cytokinesis in multiple biological organisms. Knock down of Anillin in isolated cells is associated with severe cytokinesis phenotypes such as multinucleation, oscillating cleavage furrows, improper midbody ring formation, and delocalization of RhoA, F-actin, and Myosin-2 from the contractile ring. Less is known about Anillin's role in intact epithelia where cells are polarized and make cell-cell junctions with their neighboring cells. In this situation, cells must maintain cell-cell junction integrity, which may become strained during cytokinesis, when the cell membrane experiences increased tension and shape changes as the contractile ring constricts. Here, using *Xenopus laevis* embryos as a model system, we identify a new role for Anillin in regulating junctional integrity and RhoA activation at cell-cell junctions in the intact epithelium. We find that a population of Anillin is localized at cell-cell junctions throughout the cell cycle. In Anillin knockdown embryos, both tight junctions and adherens junctions are disrupted, and F-actin at cell-cell junctions is disorganized. Additionally, we observe increased intercellular spaces, and increased permeability to small molecular weight fluorescent dextran in Anillin knockdown embryos. Because Anillin is reported to interact with RhoA, we tested the effect of knocking down Anillin on RhoA activity at cell-cell junctions. Intriguingly, Anillin knock down results in increased spontaneous flares of RhoA activity at cell-cell junctions in both dividing cells and non-dividing regions of the epithelium. These results reveal a novel role for Anillin in regulating junctional integrity through RhoA. We propose that Anillin is required to properly distribute cortical tension and RhoA activity in order to maintain cell-cell junctions.

**p115RhoGEF regulates epithelial architecture in breast epithelial cells.**

S. Kher<sup>1</sup>, R. Worthylake<sup>2</sup>; <sup>1</sup>Pharmacology, Louisiana State University Health Sciences Center, New Orleans, LA, <sup>2</sup>Oral Biology, Louisiana State University School Of Dentistry, New Orleans, LA

Maintenance of epithelial architecture is a critical feature for normal development and homeostasis. Defects in epithelial architecture can lead to pathological conditions such as cancer. The small GTPase Rho has been shown to play a critical role in the maintenance of epithelial architecture. However the regulation of Rho in this context has not been clearly understood. Rho is activated by guanine nucleotide exchange factors (GEFs). We have found that knockdown of p115 RhoGEF in MCF7 cells disrupted cell-cell junctions. When p115 RhoGEF was knocked down in MCF7 cells using siRNA, both adherens junctions and tight junctions showed a significantly disrupted morphology. In addition to disrupted junctions, the

knockdown cells also showed enhanced actin based lamella reminiscent of transformed cells. On the other hand, stable over expression of p115 RhoGEF in MCF7 cells significantly promoted both adherens junctions and tight junctions. p115 RhoGEF over-expressers also showed an enhanced cuboidal morphology as compared to GFP controls. We also tested the effect of manipulation of p115 RhoGEF expression in other cell types. The effect of p115 RhoGEF knockdown was more pronounced in MCF10A cells which are known to retain most of their epithelial characteristics. p115 RhoGEF knockdown in MCF10A cells disrupted junctions and significantly enhanced migration which was indicative of a more transformed phenotype. On the other hand over expression of p115 RhoGEF in MDA MB 231 cells which are known to be completely transformed showed a cuboidal morphology and significant inhibition of migration, thus indicating a reversal to epithelial morphology. These results indicate a novel role for p115 RhoGEF in the regulation of epithelial characteristics. To further test if the over expression phenotype was dependent on GEF activity, we made a GEF dead point mutant of p115 RhoGEF. Cells over expressing GEF dead p115 RhoGEF in MCF7 and MDA MB 231 cells did not display the over expression phenotype. This showed that the over expression phenotype was dependent on catalytic GEF activity. These results indicate a pivotal role for p115 RhoGEF in the regulation of epithelial morphology. Changes in the expression levels of p115 RhoGEF in epithelial cells could be an important contributing factor in cellular transformation.

497

**Zipcode-Mediated  $\beta$ -actin Monomer Synthesis is Required for Epithelial Cell Spreading, Adherens Junction Assembly, and Cell Adhesion.**

*S. J. Bautista<sup>1</sup>, N. Gutierrez<sup>1</sup>, A. J. Rodriguez<sup>1</sup>; <sup>1</sup>Rutgers University, Newark, NJ*

Epithelial cell contact triggers actin cytoskeleton remodeling permitting cells to switch from motile to adherent phenotypes. To elucidate molecular pathways driving epithelial cell adhesion following cell contact, we plated MDCK cells expressing GFP- $\beta$ -actin with or without its zipcode sequence at low density and allowed them to contact each other. Adherens junction complexes were identified as sites with strong colocalization between E-cadherin immunofluorescence and GFP- $\beta$ -actin. To quantify the extent of adherens junction assembly in these cultures, we calculated Pearson's correlations of colocalization for E-cadherin and GFP- $\beta$ -actin. Calculating the ratio of the Pearson's correlation from the contact site and cytoplasm yields the Asymmetry coefficient of colocalization (AC). Interestingly, deleting the  $\beta$ -mRNA zipcode from the GFP- $\beta$ -actin reporter significantly inhibits cell spreading, decreases the Asymmetry coefficient, and inhibits adherens junction assembly. Additionally, MDCK cells expressing zipcode-deleted GFP- $\beta$ -actin mRNA are unable to assemble multi-cell clusters. Incredibly, overexpressing E-cadherin in the GFP- $\beta$ -actin (zipcode-deleted) expressing MDCK cells rescues adherens junction assembly defect, increases the Asymmetry coefficient to wild-type levels, and repairs the clustering defects induced by zipcode-deletion. Together these data indicated spatially regulated  $\beta$ -actin monomer synthesis is required for epithelial cell spreading, adherens junction assembly, and cell adhesion.

498

**Identification of a phospho-domain in Alpha-Catenin that impacts epithelial sheet migration.**

*D. J. Escobar<sup>1</sup>, R. Daugherty<sup>1</sup>, A. Flozak<sup>1</sup>, R. Mo<sup>1</sup>, C. J. Gottardi<sup>1</sup>; <sup>1</sup>Feinberg School of Medicine, Northwestern University, Chicago, IL*

Alpha catenin ( $\alpha$ -cat) is the sole actin-binding component of the cadherin/catenin cell-cell adhesive complex, but how  $\alpha$ -cat binds actin at cell junctions is under intense debate given

evidence that recombinant  $\alpha$ -cat behaves as an allosteric protein that cannot bind F-actin and the cadherin complex simultaneously (Drees et al., 2005). However, it is unclear how post-translational modification of  $\alpha$ -cat may regulate these interactions. Using a mass spectrometry-based phosphoproteomic approach, our lab has discovered a highly conserved phosphorylation domain consisting of five serine/threonine residues in  $\alpha$ -cat that is situated just N-terminal to the F-actin-binding site of  $\alpha$ -cat. These phosphorylations also lie within the C-terminal end of the mechano-sensitive, auto-inhibitory region of  $\alpha$ -cat that restricts recruitment of vinculin, another actin-binding protein, to the cadherin/catenin complex (Yonemura, 2010, NCB). Using radioactive  $^{32}\text{P}$ -orthophosphate, we confirm that these sites are the major targets of phosphorylation in cells. In vitro kinase assays performed on recombinant, purified GST-tagged  $\alpha$ -cat demonstrate that these sites are targeted hierarchically by casein kinases (CK) 2 and 1, where phosphorylation at S641 by CK2 “primes”  $\alpha$ -cat for processive phosphorylation by CK1 at S652, S655 and T658. Specifically, we show that a S641A phospho-mutant of  $\alpha$ -cat is less heavily phosphorylated by CK1, whereas either a S641D phospho-mimic  $\alpha$ -cat or WT  $\alpha$ -cat that is pre-phosphorylated by CK2 is more heavily phosphorylated by CK1. Additionally, these CK1 sites are less accessible in the full-length  $\alpha$ -cat protein compared with a C-terminal fragment (aa459-906). We hypothesize that combinatorial phosphorylation by CK2 and CK1 “activates”  $\alpha$ -cat at junctions, resulting in a more open conformation that favors  $\alpha$ -cat binding to vinculin and F-actin. Using a dog epithelial cell line (MDCK) that replaces endogenous  $\alpha$ -cat with GFP-tagged forms that contain, lack or constitutively mimic phosphorylation, we find that phospho-mimic  $\alpha$ -cat enhances epithelial wound closure by promoting the speed and persistence of cell migrations. Future studies will determine whether these enhanced activities are mediated through improved association with vinculin.

#### Evaluation of Atrazine Permeation in Caco-2 Cells.

L. P. Hammonds-Odie<sup>1</sup>, S. Mwongela<sup>1</sup>, G. Bayse<sup>2</sup>, L. Mathew<sup>1</sup>, B. Thirkield<sup>2</sup>, R. Erdmann<sup>2</sup>;  
<sup>1</sup>School of Science and Technology, Georgia Gwinnett College, Lawrenceville, GA, <sup>2</sup>Chemistry Department, Spelman College, Atlanta, GA

Atrazine is one of the most commonly used herbicide in the United States, mainly in agricultural land. The use of atrazine as an herbicide is controversial. Some research studies have associated it with birth defects and menstrual problems when consumed by humans at concentrations below government standards, while other studies have reported that human exposure to atrazine does not pose a health risk. In addition, some animal model studies suggest that exposure to atrazine can cause catastrophic effects, such as feminizing male frogs. Based on these studies, it still remains unclear what the effects of atrazine are to human and animal health, and to our environment. The human intestinal cell line, Caco-2 cells, is an established model system for measuring the permeability of chemicals that can be ingested and adversely impact human health. We investigated the potential health risk of atrazine on humans by determining whether this herbicide could penetrate across the epithelial monolayer of the human gastrointestinal tract. We used Caco-2 cells to determine the transepithelial transport of atrazine from the apical or luminal side to the basolateral or serosal side. Our results from these investigations will be discussed.

**Structural and biochemical analysis of a novel, broadly specific claudin binder.**

S. Nagase<sup>1</sup>, K. Matsushita<sup>1</sup>, A. Takahashi<sup>1</sup>, H. Tsujino<sup>2</sup>, X. Li<sup>1</sup>, H. Suzuki<sup>1</sup>, H. Aoyama<sup>2</sup>, M. Kondoh<sup>1</sup>, A. Watari<sup>1</sup>, T. Uno<sup>2</sup>, T. Hamakubo<sup>3</sup>, K. Yagi<sup>1</sup>; <sup>1</sup>Laboratory of Bio-Functional Molecular Chemistry, Graduate School of Pharmaceutical Sciences, Osaka University, Suita, Osaka 565-0871, Japan, <sup>2</sup>Laboratory of Analytical Chemistry, Graduate School of Pharmaceutical Sciences, Osaka University, Suita, Osaka 565-0871, Japan, <sup>3</sup>Department of Molecular Biology and Medicine, Research Center for Advanced Science and Technology, University of Tokyo, Meguro, Tokyo 153-8904, Japan

**Objective:** Recent progress in understanding the biochemical structure of tight junctions has provided us with new insights for claudin (CL)-targeted drug development. CLs are a family of tetra-transmembrane proteins comprising over 24 members. CL binders enhance mucosal absorption of drugs, so CL targeting is a promising strategy for mucosal vaccination and cancer therapy. Previously, by using a library of mutated C-terminal fragments of *Clostridium perfringens* enterotoxin (C-CPE), we screened a CL binder, m19. Here, we performed structural and biochemical analyses of m19 and its mutants.

**Methods:** X-ray diffraction data on m19 were collected from a single crystal at 2.0 Å by using the BL44XU beamline at SPring-8, and processed with iMOSFLM and SCALA software. The structure of m19 was solved by using the BALBES system. The interactions of m19 and its mutants with CLs were investigated with ELISA and FACS analysis.

**Results:** C-CPE binds to CLs via interaction between the second extracellular loop domain of the CL and the 30 C-terminal amino acids of C-CPE. The structural backbone of m19 in the C-terminal domain is similar to that of C-CPE. An electrostatic surface map of m19 revealed that its C-terminal domain is more positively charged than that of C-CPE. Kimura et al. proposed an electrostatic interaction model for the binding of CPE and CLs (J. Biol. Chem., 285, 401, 2010) and showed that part of the second loop domain interacts with the CL-binding domain of C-CPE. The isoelectric point (pI) of CL-4 is higher than that of CL-1, -2, and -5, which interact less with CPE. Therefore, we hypothesized that if m19 binds to CL-1 via electric interaction, it would also bind to CL-2 and -5. m19 bound to CL-1, -2, -4, and -5-expressing cells; therefore, m19 is a broadly specific CL binder. Site-directed analyses showed that substitution of Ser at position 307 and Ser at position 313 with Arg and His, respectively, may be essential for the interaction with CL-1. We prepared double-substituted C-CPE mutants by changing the Ser (pI, 5.68) residue to His (pI, 7.59), Lys (pI, 9.8), or Arg (pI, 10.76). Increase in positive charge at position 307 and in negative charge at position 313, respectively, strengthened the interaction with CL-1. We also prepared double Ala (pI, 6.0)- or Asp (pI, 2.77)-substituted C-CPE mutants at positions 307 and 313 (S307A/S313A and S307D/S313D). The decrease in the charge attenuated the binding to CL-1.

**Conclusion:** Electrostatic interactions may be involved in the binding of m19 to CL-1. Therefore, modulation of the electrostatic surface may be a potent strategy for the development of CL binders.

501

**Regulation of Nectin-2 by Cadmium Chloride (CdCl<sub>2</sub>).**

X. Zhang<sup>1</sup>, W.-Y. Lui<sup>1</sup>; <sup>1</sup>School of Biological Sciences, The University of Hong Kong, Hong Kong, China

Nectin-2 is a major component of the adherens junctions (AJs) between Sertoli cells and germ cells in the testis. Recent studies have shown that male knockout mice of nectin-2 are sterile. Cadmium (Cd), an environmental toxicant, is known to be also an endocrine disruptor that affects spermatogenesis. In this study, we investigate whether cadmium chloride (CdCl<sub>2</sub>) plays a

role in nectin-2 expression. CdCl<sub>2</sub> negatively regulates mRNA and protein levels of nectin-2 in mouse Sertoli cell line, TM4 cells. Luciferase reporter assays indicated that CdCl<sub>2</sub> reduces nectin-2 promoter activity within the region of nucleotides (nt) -246 and -211 (relative to the translation start site) where putative transcription factors (TFs) binding motifs are identified. However, site-directed mutational studies have shown that no specific motif is found to involve in CdCl<sub>2</sub>-mediated nectin-2 gene repression. Hence, six consecutive cis-acting regions (each contains 6 nucleotides) between nt -246 and -211 are mutated respectively to identify the cis-acting region involved in the CdCl<sub>2</sub> effect. Results showed that the second 6-bp region (between nt -240 and -235) is involved in CdCl<sub>2</sub>-mediated reduction of nectin-2 promoter activity. In addition, putative TFs binding to this region are identified. By EMSAs, we found that DNA (nt -240 to -235)-protein complexes are formed in a dose-dependent manner and CdCl<sub>2</sub> treatment could diminish the formation of the complexes. Antibody supershift assays have shown that TFs, E2F1, Sp1 and KLF4, are present in the complexes. We also found that CdCl<sub>2</sub> down-regulates the expression level of these TFs including E2F1, Sp1 and KLF4 in the nucleus. Apart from transcriptional regulation, cycloheximide assay indicated that CdCl<sub>2</sub> negatively modulates nectin-2 protein level via post-translational modification and we are now investigating the underlying mechanism. Taken together, CdCl<sub>2</sub>-mediated down-regulation of nectin-2 is mediated through transcriptional modification by negatively affecting its basal gene transcription and post-translational modification. [This work was supported by Hong Kong Research Grants Council (HKU772009 and HKU773710) and CRCG Seed Funding for Basic Research.]

#### **MHC Class II Compartment in Human Autologous Macrophage-Lymphocyte Rosettes.**

*I. T-C. Novak<sup>1</sup>, N. S. Infante<sup>1</sup>; <sup>1</sup>Institute of Cell Biology, Faculty of Medicine, National University of Cordoba, Argentina, Cordoba, Argentina*

The contact area between a T cell and antigen-presenting cell is known as "immunological synapse" (Grakoui et al, 1999) and the multiple interactions that occur leading to a "signal" for T cell activation. Cellular association between human blood monocyte-derived macrophages and lymphocytes T CD4+ from autologous cultures total leukocytes extracted from the blood, which bind selectively forming rosettes with central macrophage and lymphocytes adhered was described as the phenomenon of multiple immunological synapses on macrophage-lymphocyte rosette (MLR) (Cabral and Novak, 1992, 99). The processing and antigen presentation are involved in MLR phenomenon (Cabral and Novak, 1999, Novak and Cabral 2008, 09) and in this phenomenon the autologous antigens of senescent neutrophils are presented by endocytic way like phagocytosis of cells undergoing apoptosis naturally in the body. Along time of culture the cells that interact in the MLR phenomenon may present special features in their areas of cell-cell interaction, and in the surrounding cytoplasm such as mitochondrial translocation (Novak y Orquera, 2011). The spatial organization of MHC class II compartment (MIIC) changes in dendritic cells maturation with morphological characteristic such as multivesicular, multilaminar and tubular structures (Van Nispen tot Pannerden et al, 2010). Objectives: ultrastructural study to observe the organization of MIIC in the cells of the MLRs along culture time. Materials and methods: Healthy human blood samples, anticoagulated with heparin (n = 10) (donated by the Blood Bank, UNC, anonymity, data serology). Autologous cultures in TC199 medium (SIGMA, St. Louis, MO). Samples: 1, 2, 3, 20, 48, 96 and 144 h. MLR technique (Cabral y Novak, 1992, 99). Samples of MLRs underwent electron microscopy. MET: Zeiss LEO-906E. Results: MLR formation starts when monocytes transformed in macrophages and increased since 20 h. We observed multivesicular, multilaminar and tubular structures in spatial organization of MIIC along time culture, according to intermediated and late structures described. However in a lymphocyte that does not participate in MLR was observed at 2 h of culture a multilaminar structure like MIIC on plasma membrane. At this time neutrophils were observed whereas at 3h

a few of them appeared. In macrophages tubular structures occurs at 48 h. At 144 h multivesicular and multilaminar bodies coexists. Conclusion: This organization of MIIC which undergo major structural changes coincides with occurrence of macrophage transformation in cultures and his role as antigen-presenting cells in MLR.

### A549 and SW-13 Cell Biomarkers for 'Spice' Cannabinoid Drugs.

O. A. Vanderpuye<sup>1</sup>, T. Smith<sup>1</sup>, B. Walker<sup>2</sup>, M. Gilbert<sup>1</sup>, O. Okediji<sup>2</sup>; <sup>1</sup>Forensic Science, Albany State University, Albany, GA, <sup>2</sup>Natural Sciences, Albany State University, Albany, GA

'Spice' refers to designer drugs consisting of plant materials spiked with different synthetic mimetics of delta tetrahydrocannabinol, a psychoactive compound in marijuana. The toxicology and bioactivity of many synthetic cannabinoids are unknown including Spice brands: Barely Legal, Brain Storm and Voodoo.

It was hypothesized that the 'Spice' brands Barely Legal, Brain Storm and Voodoo Child contain different compounds, overlap in biological activities with delta THC and affect cell physiology and morphology. This study sought possible biomarkers for the effects of 'Spice'. Fluorescence microscopy detected cannabinoid receptor type 2 proteins but not type 1 receptors on A549 and SW-13 cells. The complement system regulatory proteins CD46 and CD59 but not CD55 were detected on A549 and SW-13 cells. Glycoconjugate profiles on these cells were characterized by lectin binding. Exposure to delta THC and Barely Legal Spice caused stronger Con A lectin binding to A549 lung cells than did exposure to Brainstorm Spice or control media. This study is the first description of the complement regulatory protein profile of adrenal gland cells and provided carbohydrate structure profiles of A549 and SW-13 cells as detected by lectin binding. The results will facilitate more detailed analysis of the toxicology and bioactivities of spice.

### Overexpression of proprotein convertase 1/3 induces an epithelial-mesenchymal transition-like phenotype in airway epithelial cells.

S-N. Lee<sup>1</sup>, D-H. Lee<sup>1</sup>, J-H. Yoon<sup>1,2,3,4</sup>; <sup>1</sup>Research Center for Human Natural Defense System, Seoul, Korea, <sup>2</sup>BK 21 Project for Medical Science, Seoul, Korea, <sup>3</sup>Department of Otorhinolaryngology, Seoul, Korea, <sup>4</sup>The Airway Mucus Institute, Yonsei University College of Medicine, Seoul, Korea

The proprotein convertases are serine proteases responsible for the proteolytic maturation of many precursor proteins involved in upper airway remodeling during nasal polyposis. We have previously found that proprotein convertase PC1/3 is expressed in normal human nasal mucosa. However, whether PC1/3 is related to nasal polyp formation has not been investigated. To gain insight into the functional role of PC1/3 in the nasal polyp epithelium, we determined PC1/3 expression in nasal polyps and generated stable cell lines constitutively expressing PC1/3 using the airway epithelial cell line NCI-H292.

Nasal polyps exhibit increased PC1/3 expression compared to normal human nasal mucosa, as assessed by immunostaining, western blotting, and enzyme activity assays. PC1/3 was shown to be expressed in secretory neuroendocrine cell granules containing chromogranin A in normal nasal mucosa and it was also expressed in goblet and ciliated cells in nasal polyps. NCI-H292 stably transfected with intact PC1/3 cDNA displayed morphological changes, enhanced cell

proliferation and migration, down-regulation of E-cadherin and cytokeratin-18, and up-regulation of vimentin, matrix metalloproteinases, and  $\alpha 5$  integrin.

Proteomic analysis showed that differentially produced proteins between PC1/3-overexpressing NCI-H292 cells and mock cells are implicated in carbohydrate metabolism, cell proliferation, cytoskeletal reorganization, DNA metabolism, and signal transduction. These proteins are directly or indirectly related to the epithelial-to-mesenchymal transition process. Interestingly, UCH-L1 expression, a neuroendocrine cell-specific protein of the airway epithelium, was significantly increased in PC1/3-overexpressing NCI-H292 cells, possibly suggesting that these cells can transdifferentiate into other epithelial cells.

Taken together, our data suggest that PC1/3 overexpression induces morphological and phenotypic epithelial-mesenchymal transition changes of airway epithelial cells and these changes may contribute to the pathogenesis of nasal polyps.

#### **Isolation and Characterization of Lacrimal Gland Progenitor Cells.**

A. Gromova<sup>1,2</sup>, D. Voronov<sup>1</sup>, H. Makarenkova<sup>1,2</sup>; <sup>1</sup>The Scripps Research Institute, La Jolla, CA, <sup>2</sup>The Neurosciences Institute, La Jolla, CA

The lacrimal gland (LG) is responsible for secretion of the aqueous layer of the tear film and is comprised of two main types of tissue, epithelium and mesenchyme. Degeneration of LG leads to a lack of corneal lubrication, irritation, pain, inflammation, and in severe/untreated cases, total blindness from extensive corneal damage. These conditions are known as dry eye syndrome (DES), and can result from a wide variety of causes such as aging, auto-immune diseases, or laser eye surgery. Although millions of people suffer from DES, it remains unrecognized and untreated until later stages when the LG may be severely degenerated. Developing new therapies to restore LG function would drastically improve the quality of life of people affected by DES and one such potential approach is the transplantation of progenitor cells. It has previously been reported that the LG has an innate and rather impressive regenerative capacity, suggesting that LG progenitor cells do in fact exist. We have begun to isolate and characterize potential progenitor cells in mice using two approaches: first, gene expression studies of stem cell transcription factors found only in the epithelium and second, fluorescence-activated cell sorting (FACS) using cell surface markers that have been used to isolate stem cells from similar glandular tissues. Because the epithelium progeny forms the ductal and acinar portion of the functional LG, our search has been focused on finding progenitor cells that are epithelial. We identify several stem cell transcription factors with expression restricted to the epithelial compartment of the LG. Moreover, the runt-related family of transcription factors (Runx1, 2, and 3) were found to be important regulators of LG development and regeneration. Through flow cytometry, we have isolated a putative population of epithelial progenitor cells expressing the stem cell factor receptor c-Kit and epithelial cell adhesion molecular (EpCAM). Our studies have shown the existence of one or more putative epithelial progenitor cells in the LG. The capacity of these progenitors to restore the function of damaged LG will be determined in future studies.

#### **Coordination of mitochondrial activity across the rat salivary glands epithelium imaged by intravital two-photon microscopy.**

N. Porat-Shliom<sup>1</sup>, A. Masedunskas<sup>1</sup>, R. Weigert<sup>1</sup>; <sup>1</sup>Intracellular Membrane Trafficking Unit, Oral and Pharyngeal Cancer Branch, NIDCR, NIH, Bethesda, MD

In individual cells, levels of the reduced form of nicotinamide adenine dinucleotide (NADH) have been reported to oscillate periodically. These oscillations are linked to mitochondrial activity that is regulated through reactive oxygen species and are thought to correlate with the spatio-

temporal redox state of the cell. In order to investigate whether this phenomenon occurs in vivo, we imaged the salivary glands (SGs) of live rats using intravital microscopy, exploiting the fact that NADH emits upon two-photon excitation. Fast scan imaging allowed us to capture periodic oscillations of NADH levels under normal physiological conditions in vivo. Strikingly, we observed for the first time, that NADH oscillations are temporally and spatially synchronized across the SGs epithelium. To confirm that these oscillations were linked to mitochondrial activity, we used cationic dyes, such as TMRM and Rhodamine123, which are sensitive to mitochondrial membrane potential. Maximal mitochondrial activity was initially observed in specific areas of the epithelium and propagated throughout the tissue in a wave-like pattern. This phenomenon was not observed in confluent cell cultures, in explanted SGs, or in vivo, when the blood flow was reduced by ligation of the vessels. As expected, disruption of mitochondrial membrane potential led to the disruption of wave propagation. We hypothesized that synchronized oscillations might be related to basal secretory activity of the SGs that is mediated by several receptors. To test this hypothesis, we used a pharmacological approach. Inhibition or stimulation of muscarinic, alpha-adrenergic and purinergic receptors did not affect the propagation of the waves, whereas stimulation of beta-adrenergic receptors led to a sharp and uniform increase in NADH fluorescence across the tissue and the loss of the oscillations. Interestingly, both the oscillations and the propagation of the waves were restored 20 minutes after stimulation, consistent with the reported clearance of the agonist from the tissue. Based on our findings, we speculated that NADH oscillations and their synchronization might have implications in the coordination of tissue function under physiological conditions. Ongoing work is focusing on identifying the mode of signal propagation (e.g. through gap junctions or small diffusible molecule), on better understanding of its regulation, and the alteration of oscillations and signal propagation under pathological conditions.

507

#### **Ankyrin-B syndrome: Metabolic consequences of human genetic variations in the membrane adaptor ankyrin-B.**

*D. N. Lorenzo<sup>1,2</sup>, K. R. Nilsson<sup>3</sup>, J. Hostettler<sup>1,2</sup>, J. Q. Davis<sup>1,2</sup>, V. Bennett<sup>1,2</sup>, <sup>1</sup>HHMI, Durham, NC, <sup>2</sup>Biochemistry, Duke University, Durham, NC, <sup>3</sup>Department of Medicine, Duke University, Durham, NC*

The Ankyrin-B syndrome, caused by mutations in the membrane adaptor protein ankyrin-B, was initially identified and characterized in patients with cardiac arrhythmias and sudden cardiac death. In cardiomyocytes, ankyrin-B is required for stabilizing the Na/K ATPase, Na/Ca exchanger, and IP3 receptor proteins at specialized microdomains. In addition to the heart, ankyrin-B is selectively expressed in pancreatic beta-cells, where it is required for cholinergic modulation of insulin secretion. In isolated pancreatic islets, ankB haploinsufficiency results in reduced levels of IP3 receptor and impaired calcium signaling. These findings, along with the fact that one of the loss-of-function mutations in ankyrin-B associated with heart disease (R1788W) was also found in about 1% of Caucasians and Hispanics with type 2 diabetes, suggest that mutations in ankyrin-B affect multiple organ systems. Ankyrin-B mutations are commonly found in different ethnic patterns in 2-8% of human populations.

We have generated two knock in mouse strains to evaluate the physiological consequences of human ankyrin-B mutations and to obtain mechanistic insight into the role of ankyrin-B in disease pathogenesis. These transgenic animals bear either the L1622I variant, found in 6% of African Americans, or the R1788W mutation mentioned above, which is found in 0.2% of Caucasians. Consistent with previous findings, mutant mice show a cardiac phenotype characterized by reduced expression of ankyrin-B binding partners, arrhythmia, dilated cardiomyopathy, and lower heart rate. In addition, we found that ankyrin-B mutant mice display metabolic derangements at early ages, including abnormal oral glucose tolerance and insulin

secretion, and insulin insensitivity. Expression of mutant ankyrin-B causes reduction of ankyrin-B and IP3 receptor levels in pancreatic beta-cells, along with significant changes in the size of the pancreatic islets. Adding to the complexity of the syndrome, we also found that ankyrin-B is expressed in fat tissue, where the mutant animals show reduction in levels of ankyrin-B. Moreover, L1622I mutant mice exhibit increased accumulation of visceral and subscapular fat with bigger adipocytes, aging-associated obesity, and impaired hormone-stimulated lipolysis. Similarly, embryonic fibroblasts derived from mutant mice exhibit cell autonomous increased lipid accumulation following differentiation into adipocytes in culture.

In conclusion, Ankyrin-B syndrome is a recently recognized syndrome that affects the heart, pancreas and adipose tissue, and could potentially affect millions of people. Work underway focuses on additional metabolic and mechanistic characterizations, and additional analysis of human clinical data, all of which we expect will shed additional light into the pathophysiology of this condition.

508

**In vivo senescence in the Shwachman-Diamond syndrome pancreas.**

M. E. Tourlakis<sup>1,2</sup>, R. Gandhi<sup>1</sup>, J. Zhong<sup>1</sup>, P. R. Durie<sup>3,4</sup>, J. M. Rommens<sup>1,2</sup>; <sup>1</sup>Program in Genetics and Genome Biology, The Hospital for Sick Children, Toronto, ON, Canada, <sup>2</sup>Dept. Molecular Genetics, University of Toronto, Toronto, ON, Canada, <sup>3</sup>Program in Physiology & Experimental Medicine, The Hospital for Sick Children, Toronto, ON, Canada, <sup>4</sup>Dept. Paediatrics, University of Toronto, Toronto, ON, Canada

Loss of function mutations in the ancillary translation factor SBDS cause Shwachman-Diamond syndrome (SDS) resulting in severe exocrine pancreas pathology with acinar cell hypoplasia and fatty infiltration. SDS is one of a number of translation insufficiency disorders with shared features of poor growth, hematological anomalies and cancer predisposition but also possesses the distinguishing pancreatic phenotype. The translation burden of acinar cells is notable with their cued synthesis of over twenty digestive enzymes that are stored in zymogen granules. The targeted disruption of Sbd function in the murine pancreas results in markedly reduced organ size, perturbed ribosome profiles and loss of acinar cell markers and zymogen granules. We investigated how SDS-translation insufficiency results in this acinar cell failure.

In contrast to other organs affected in constitutive SDS mouse models, the severe hypoplasia of the pancreas was found not to be a result of apoptotic cell death. Ultrastructure analysis and an absence of immune infiltrate did not suggest prominent autophagy or necrosis, but cell morphology and acidic  $\beta$ -galactosidase activity indicated numerous senescent cells in the pancreas by 30 days of age. Transcript levels of genes commonly known to be involved in senescence pathways including osteonectin, fibronectin and genes of the innate immune response were elevated, but indicators of replicative and oxidative stress-induced senescence were not. Transcript analysis also revealed elevation of Tgfb1 and Cdkn2b (p15) consistent with cell cycle arrest. The downregulation of Myc was also noted and consistent with both cell cycle arrest and other models of acinar cell hypoplasia. A modest elevation of Trp53 (p53) transcript was also evident and was directly evaluated by breeding models to Trp53 deficient mouse strains resulting in resolution of gross pathology. However, patchy amylase immunostaining along with smaller cell size (a hallmark of translation deficiency), perturbed polysome profiles and apoptotic cells, identified by morphology and TUNEL staining, indicated that acinar cells remain dysfunctional. We conclude that the observed Tgf- $\beta$ /Myc/p15 pathway prompts *in vivo* p53-mediated senescence and may provide tumor suppression capability for the SDS pancreas.

509

**Amylin Turnover and Toxicity in Pancreatic Cells Is Not Upregulated by Copper.***S. Singh<sup>1</sup>, E. Lee<sup>1</sup>, A. M. Jeremic<sup>1</sup>; <sup>1</sup>Biological Sciences, The George Washington University, Washington, DC*

Amylin, a 37 amino acid peptide hormone, is co-secreted with insulin by the pancreatic beta cells and plays a role in regulating glucose homeostasis. Misfolding and subsequent intracellular accumulation and aggregation of human amylin is linked to mitochondrial dysfunction, oxidative stress and beta cell death, hallmarks of type 2 diabetes mellitus (T2DM). Similar to human amylin, increased serum concentrations of copper are found in diabetics. Although studies demonstrated that copper can bind to and upregulate amylin induced radical formation in cell free conditions, the extent to which this occurs in cells needs further clarification. Particularly, there is a lack of data on whether, following binding, copper can modulate amylin internalization and intracellular degradation, lack of which is associated with amylin aggregation and toxicity. Hence, the objective of this study was to determine the extent to which copper modulates amylin turnover and toxicity in pancreatic rat insulinoma beta cells (RIN m5F cells). To do so, we examined the effect of copper (1-20 $\mu$ M) on amylin internalization and intracellular trafficking using live confocal microscopy together with fluorescently labeled amylin and specific organelle markers. Colocalization analysis revealed that amylin internalized and trafficked to degradative compartments, autophagosomes and lysosomes, in beta cells. In contrast, amylin was largely absent from mitochondria and other organelles. Interestingly, addition of copper had no significant effect on intracellular amylin distribution or accumulation. Consistent with this finding, cell viability assays demonstrated a lack of stimulatory effect of copper on amylin toxicity. Taken together, these results suggest that binding of copper ions to amylin does not significantly contribute to amylin accumulation and toxicity in cells. In order to further elucidate the amylin-copper interaction, we tested the effect of amylin on copper turnover using a copper sensitive dye, Phen Green SK. Fluorescent spectroscopic analysis revealed that intracellular copper levels are increased, by ~20% relative to controls, in the presence of human amylin, indicating that copper can accumulate in cells as metalloprotein complex. Although it was previously shown that copper directly interacts with human amylin, our data does not support the model in which copper enhances its pro-oxidative and pro-apoptotic properties in cells. Further studies should clarify the biological significance of the stimulatory effect of amylin on intracellular copper accumulation and homeostasis.

510

**Nuclear receptor PPAR $\gamma$ -regulated monoacylglycerol O-acyltransferase 1 (MGAT1) expression is responsible for the lipid accumulation in diet-induced hepatic steatosis.***Y. Lee<sup>1,2</sup>, J-W. Kim<sup>1,2</sup>; <sup>1</sup>Biochemistry and Molecular Biology, Yonsei University College of Medicine, Seoul, Korea, <sup>2</sup>Brain Korea 21 Project for Medical Science, Seoul, Korea*

Recently, hepatic peroxisome proliferator-activated receptor (PPAR) $\gamma$  has been implicated in hepatic lipid accumulation. We found that the C3H mouse strain does not express PPAR $\gamma$  in the liver and, when subject to a high-fat diet, is resistant to hepatic steatosis, compared with C57BL/6 (B6) mice. Adenoviral PPAR $\gamma$ 2 injection into B6 and C3H mice caused hepatic steatosis, and microarray analysis demonstrated that hepatic PPAR $\gamma$ 2 expression is associated with genes involved in fatty acid transport and the triglyceride synthesis pathway. In particular, hepatic PPAR $\gamma$ 2 expression significantly increased the expression of monoacylglycerol O-acyltransferase 1 (MGAT1). Promoter analysis by luciferase assay and electrophoretic mobility shift assay as well as chromatin immunoprecipitation assay revealed that PPAR $\gamma$ 2 directly

regulates the MGAT1 promoter activity. The MGAT1 overexpression in cultured hepatocytes enhanced triglyceride synthesis without an increase of PPAR $\gamma$  expression. Importantly, knockdown of MGAT1 in the liver significantly reduced hepatic steatosis in 12-wk-old high-fat-fed mice as well as ob/ob mice, accompanied by weight loss and improved glucose tolerance. These results suggest that the MGAT1 pathway induced by hepatic PPAR $\gamma$  is critically important in the development of hepatic steatosis during diet-induced obesity.

511

### **Gender Differences Following Attenuation of High Cholesterol-Induced Hepatotoxicity by Rutin in Rats.**

S. Alrejaie<sup>1</sup>, H. Abuhashish<sup>1</sup>, A. Alroujaye<sup>2</sup>, O. Alkhamees<sup>2</sup>; <sup>1</sup>Pharmacology & Toxicology, King Saud University, Riyadh, Saudi Arabia, <sup>2</sup>Imam University, Riyadh, Saudi Arabia

**Background:** Hyperlipidaemia has been implicated in atherosclerosis, a leading cause of death worldwide and accounting for almost 17 million deaths annually. Experimentally, high-cholesterol-diet (HCD) supplementation to rats impairs lipid metabolism resulting increase in blood and tissue lipid profile. Earlier gender studies established that females are more protected from hypercholesterolemia-related diseases such as CVD until menopause. Furthermore, meager information expressed the different gender response following HCD and the possible potential effect of antioxidant vitamins like rutin (RT) and ascorbic acid (AA) supplementation on experimentally-induced hypercholesterolemia in rats.

**Objective:** The present study was designed to investigate the potential beneficial effects of dietary RT and AA on HCD induced hepatotoxicity in male and female Wistar rats.

**Methods:** Thirty six of each sex of Wistar albino rats was used in this study. They were subdivided into six groups; control, RT, AA, HCD, RT+HCD and AA+HCD. Animals received freshly prepared experimental diets for 6 consecutive weeks. In hepatic cells nucleic acids, total protein, thiobarbituric acid reactive substances (TBARS), Glutathione (GSH), total cholesterol (TC) and triglycerides (TG) levels were estimated. Histopathological changes following HCD with or without both antioxidants were investigated.

**Results:** In hepatic cells GSH levels significantly decreased while TC, TG and TBARS concentrations were increased in HCD fed rats regardless of sex. The supplementation of RT and AA with HCD brought back these changes to normal in both gender groups. However, the correction of changes in all parameters showed more significant in female than male rats.

**Conclusion:** Present data suggest the gene and/or metabolic regulations by dietary cholesterol could interact with that of sex hormones and explains why males are more sensitive to dietary cholesterol. And also highlights the importance of dose fixing of nutritional supplements among males and females.

512

### **BMP4 regulates podocyte injury in the diabetic nephropathy.**

T. Tominaga<sup>1</sup>, H. Abe<sup>1</sup>, K. Nagai<sup>1</sup>, A. Mima<sup>1</sup>, S. Kishi<sup>1</sup>, O. Ueda<sup>2</sup>, K-I. Jishage<sup>2</sup>, N. Fukushima<sup>2</sup>, T. Doi<sup>1</sup>; <sup>1</sup>Department of Nephrology, University of Tokushima School of Medicine, Tokushima, Japan, <sup>2</sup>Chugai Pharmaceutical Co. Ltd, Gotemba-shi, Japan

It has been proposed that podocyte injury provides the important role for diabetic nephropathy (DN), however its pathological mechanism is not clear. We have shown that bone morphogenetic protein 4 (BMP4) signaling leads glomerular changes, which are characteristic of DN.

In order to analyze the molecular mechanism of podocyte injury, the effect of BMP4 was investigated in in vivo and in vitro cultured podocyte. We studied the BMP4 expression in streptozotocin (STZ)-induced diabetic mice. In order to examine its role in vivo, the induced-

Bmp4 transgenic mice (Bmp4 tgm) were generated by the tamoxifen-regulated Cre-loxP system. Finally diabetic Bmp4 heterozygous knockout mice (Bmp4+/-) were analyzed to investigate suppressant effect of Bmp4 in vivo.

Diabetic STZ mice represented the significant expression of Bmp4, which degrees were associated with the levels of glomerular matrix hyperplasia in STZ mice ( $r = 0.927$ ,  $p < 0.01$ ). Bmp4 tgm were indicated significant mesangial matrix expansion and thickening of glomerular basement membrane, which are characteristic pathological findings of DN. Albuminuria was dramatically increased in Bmp4 tgm compared with non-inducible mice. The Bmp4 tgm decreased both the expression of nephrin and the count of WT1 positive cells, both of them are specific markers of podocyte. The glomerular matrix hyperplasia progressed in accordance with the decreased number of WT1 positive cells. The number of podocyte also decreased inversely with an increase of the albuminuria. We investigated whether the reduction of Bmp4 expression improved the diabetic glomerular changes by using Bmp4+/- mice. The diabetic Bmp4+/- mice showed to improve the nephrin expression compared with the decreased nephrin expression in diabetic wild mice. Proteinuria also decreased in diabetic Bmp4+/- mice compared with diabetic wild mice. Finally we confirmed increased expression of cleaved caspase 3 in both STZ mice and Bmp4 tgm. Cultured podocyte showed the decreased expression of Nephrin by Bmp4 treatment in a dose dependent manner in vitro. Bmp4 treatment (50ng/ml) activated p38 expression and increased cleaved caspase 3 in cultured podocyte.

These data suggest that BMP4 plays an essential role for development of podocyte injury in DN.

513

#### **AKT and AMPK activation after high-fat and high-glucose in vitro treatment on prostate epithelial cells.**

*D. L. Ribeiro<sup>1</sup>, M. E. Pinto<sup>2</sup>, R. M. Góes<sup>2</sup>, P-A. Abrahamsson<sup>3</sup>, N. Dizely<sup>3</sup>; <sup>1</sup>Federal University of Uberlândia, Uberlândia, Brazil, <sup>2</sup>Biology, São Paulo State University/Ibilce, São José do Rio Preto, Brazil, <sup>3</sup>Clinical Research Centre, Lund University, Malmo, Sweden*

Obesity is an increasing health problem worldwide. It has been proposed that prostate cancer development and prognosis is adversely affected by the comorbidities of obesity and diabetes mellitus, which are conditions associated with elevated levels of circulating fatty acids, hyperglycaemia and hyperinsulinaemia. AMPK is a cell energy-sensor kinase activated by metabolic stressors that reduces ATP-consuming functions and increases ATP-producing to restore cell energy homeostasis. Thus, AMPK is altered in obesity and cancer and currently is under investigation as a tool for treatment of these disorders. It was investigated the effects of exposure of nonmalignant human prostate epithelial cells to elevated levels of fatty acids and glucose on their proliferation, survival, AKT and AMPK activation. PNT1A cells were cultivated in RPMI medium containing palmitate (100 or 200 $\mu$ M) and/or glucose (450 mg/dl) during 24 or 48 hrs. MTS assay evaluated cell proliferation, TUNEL test measured dead cells and western blotting for phosphorylated forms of AMPK and AKT were performed after cell treatments. After 24hrs of glucose and fatty acid treatment cell proliferation did not change but there was an increase in apoptosis. Increased cell proliferation was detected after 48hrs of treatment in PNT1A cells. Initially, in 24hrs of both high-fat and high-glucose exposure, there is an increase in AMPK and AKT activation. AMPK activated blocks protein synthesis and thus, cell proliferation analyzed by MTS is not increased in this period. Following 48hrs of treatment, cells became adapted to the high-energy environment and decrease AMPK activation, but maintained activated AKT levels. In this regard, inactivation of AMPK and increased AKT after 48hrs stimulates cell proliferation which is increased in this period. In conclusion, this research shows that high concentrations of fatty acids and also glucose stimulate proliferation of PNT1A cells by decreasing the activation of AMPK and increased activation of AKT. These data open

new perspectives for the elucidation of the molecular elements responsible for the positive association between obesity and prostate cancer.

514

**Biomarkers of oxidative stress in rat male reproductive organs under experimental diabetes and interference of melatonin treatment.**

*M. G. Gobbo<sup>1</sup>, C. F. Pereira Costa<sup>1</sup>, D. G. Silva<sup>2</sup>, E. A. de Almeida<sup>3</sup>, E. Z. Pytlowanciv<sup>1</sup>, R. M. Góes<sup>2</sup>; <sup>1</sup>Cell Biology, State University of Campinas, Campinas, Brazil, <sup>2</sup>Department of Biology, Institute of Biosciences, Humanities and Exact Sciences - Univ Estadual Paulista, S. Hyperglycemia and oxidative stress are major factors which impair organ physiology in diabetes. Reproductive dysfunction is a well recognized consequence of diabetes, but the oxidative stress involvement in male reproductive damage in this disease is poorly understood. The present study investigated the antioxidant system biomarkers response in rat prostate, testis and epididymis during early and late phases of streptozotocin (STZ)-induced diabetes. It also assessed the influence of treatment with low melatonin (MLT) doses on oxidative stress biomarkers and its interference in experimental diabetes. MLT was administered to male Wistar rats, from 5<sup>th</sup> week old to the end of experiment, in the drinking water (2.5µg/Kg b.w daily) and diabetes was induced at 13<sup>th</sup> week old by STZ (4.5mg/100g b.w., i.p.). The animals were killed in the 14<sup>th</sup> (short-term diabetes) and 21<sup>st</sup> (long-term diabetes) week old. The activities of oxidative stress biomarkers - catalase (CAT), glutathione-S-transferase (GST) and glutathione peroxidase (GPx) - were quantified in blood, ventral prostate, testis and epididymal extracts using biochemical assays. The changes in antioxidant biomarkers activity were more pronounced in ventral prostate in comparison with other organs. GST activity in this gland increased in both short and long-term diabetes, but the early response involves increase in GPx and the late in CAT activities. The epididymis responded to short-term diabetes with increase in CAT activity, but no changes were detected at longer time. No alterations were observed in antioxidant enzymes activity of testis at both periods of diabetes whereas in the plasma it was observed an increase in GPx and decrease in GST activities only after two-month-diabetes. MLT treatment did not affect the activities of antioxidant enzymes in studied tissues except for an enhancement of GPx activity in the epididymis of control rats at short-term and for an inhibitory effect in CAT testis at long-term diabetes. The present study showed that testis are less susceptible to diabetes effects and it is probably related to the protection provided by the Sertoli cells in the seminiferous tubules. The GST proved to be a good marker of compensatory antioxidant defense in prostate corroborating our previous data on medium-term diabetes. Furthermore, MLT, even at low dosages, was able to normalize the enzymatic disorders in prostate and epididymis, which shows its effective antioxidant role.

**Expression of adrenoceptors on peripheral blood mononuclear cells in central obesity.**

*F. Leite<sup>1,2</sup>, A. Santos<sup>2</sup>, M. Lima<sup>2</sup>, M. Cosentino<sup>3</sup>, J. Barbosa<sup>4</sup>, L. Ribeiro<sup>1</sup>; <sup>1</sup>Biochemistry, Faculty of Medicine, University of Porto, Porto, Portugal, <sup>2</sup>Clinical Haematology, St. Antonio Hospital, Porto, Porto, Portugal, <sup>3</sup>Clinical Medicine Section of Experimental and Clinical Pharmacology, University of Insubria, Varese, Italy, Varese, Italy, <sup>4</sup>Medical Education Center, Faculty of Medicine, University of Porto, Porto, Portugal*

**Background and Aim:** Sympathetic nervous system overactivity and a state of chronic immune activation are characteristics of central-obesity-related comorbidities, such as cardiovascular

diseases. Catecholamines (CA), adrenaline (AD) and noradrenaline (NA), regulate both metabolism and innate immune response through adrenoceptors (AR). Since immune cells and adipocytes are CA-producing cells we investigated the association between central obesity (CO), AR expression in peripheral blood mononuclear cells (PBMCs), CA and innate inflammatory markers in blood donors (BD).

**Methods:** We studied 63 BD (35 men and 28 women) considering waist circumference, plasmatic CA, blood monocyte subpopulations, being the latter investigated by flow cytometry. AR expression in PBMCs was evaluated by quantitative real-time PCR. Given that  $\beta$ 2-AR are the most expressed AR in these cells, all the population was studied for these receptors. We have also looked for  $\alpha$ 1A,  $\alpha$ 1B,  $\alpha$ 1D,  $\alpha$ 2A,  $\alpha$ 2B,  $\alpha$ 2C,  $\beta$ 1, and  $\beta$ 3 –AR mRNA expression in a subgroup of subjects with and without CO, which was defined by the International Diabetes Federation criteria.

**Results:** 89% of women and 60% of men were centrally obese. Centrally obese individuals showed a more proinflammatory monocyte pattern of the CD16+ cells: lower expression of CD14 ( $p=0.025$ ) and lower cellular complexity ( $p=0.014$ ). AD correlated positively with the number of CD16+ pro-inflammatory cells ( $p=0.309$ ,  $p=0.044$ ). CO was associated with lower  $\beta$ 2-AR expression in PBMCs ( $p=0,002$ ). There were no significant differences between groups considering  $\alpha$ 1A,  $\alpha$ 1B,  $\alpha$ 1D,  $\alpha$ 2A,  $\alpha$ 2C and  $\beta$ 3 –AR mRNA levels.  $\alpha$ 2B and  $\beta$ 1-AR were not detected on PBMCs.

**Conclusion:** In our population, CO was related with a higher activation of innate immune response and with a lower  $\beta$ 2-adrenoceptor expression in PBMCs, which might be associated with a higher cardiovascular risk. We did not find differences in the expression of the other AR studied in PBMC, and  $\alpha$ 2B and  $\beta$ 1-AR subtypes were undetected in these cells. The positive correlations between CA and pro-inflammatory monocytes highlight the role of catecholaminergic system in obesity and cardiovascular risk assessment.

516

**Modulation of adipocyte differentiation by omega-3 polyunsaturated fatty acids involves proteasome-dependent degradation of fatty acid synthase and other adipogenic proteins.**

C. Wojcik<sup>1</sup>, K. Lohé<sup>2</sup>, C. Kuang<sup>3</sup>, E. Poels<sup>3</sup>; <sup>1</sup>Family Medicine, Oregon Health and Science University, Portland, OR, <sup>2</sup>IUSM - Evansville, Evansville, IN, <sup>3</sup>Mead Johnson Nutritionals, Evansville, IN

We have evaluated the effects of three different omega-3 polyunsaturated fatty acids (PUFAs) - docosahexaenoic acid (DHA), eicosapentaenoic acid (EPA) and docosapentaenoic acid (DPA) on fat accumulation and expression of adipogenic and inflammatory markers using both 3T3-L1 pre-adipocytes and differentiated 3T3-L1 adipocytes. Our results indicate that omega-3 PUFAs have beneficial metabolic effects on adipose cells. They decrease expression of adipogenic transcription factors (PPAR $\gamma$  and SREBP1) and fatty acid synthase through a proteasome mediated mechanism. Moreover, adipocytes do not undergo cell death with prolonged proteasome inhibition, which induces adipophilin, while decreasing perilipin expression. Omega-3 PUFAs induce adipophilin expression, while decreasing expression of leptin and GLUT4 at the mRNA level. Moreover, all three  $\omega$ -3 PUFAs appear to induce expression of the proinflammatory TNF $\alpha$  cytokine, while at the same time decreasing NF $\kappa$ B levels. While the effects of all three PUFAs are similar, they appear to differ in their relative potency. Therefore, further research is needed to elucidate their effects, in particular how omega-3 PUFAs trigger proteasome-dependent degradation of several adipogenic factors.

## Lipids and Membrane Microdomains I

### A Role for Sphingomyelin-Rich Lipid Domains in the Accumulation of Phosphatidylinositol-4,5-Bisphosphate to the Cleavage Furrow during Cytokinesis.

M. Abe<sup>1</sup>, A. Makino<sup>1</sup>, F. Hullin-Matsuda<sup>1</sup>, K. Kamijo<sup>2</sup>, Y. Ohno-Iwashita<sup>3</sup>, K. Hanada<sup>4</sup>, H. Mizuno<sup>5</sup>, A. Miyawaki<sup>5</sup>, T. Kobayashi<sup>1</sup>; <sup>1</sup>Advanced Science Institute, RIKEN, Wako, Japan, <sup>2</sup>Department of Stem Cell Biology and Histology, Tohoku University School of Medicine, Sendai, Japan, <sup>3</sup>Faculty of Pharmacy, Iwaki Meisei University, Iwaki, Japan, <sup>4</sup>Department of Biochemistry and Cell Biology, National Institute of Infectious Diseases, Tokyo, Japan, <sup>5</sup>Brain Science Institute, RIKEN, Wako, Japan

Cytokinesis is a crucial step in the creation of two daughter cells by the formation and ingression of the cleavage furrow. Here, we show that sphingomyelin (SM), one of the major sphingolipids in mammalian cells, is required for the localization of phosphatidylinositol-4,5-bisphosphate (PIP<sub>2</sub>) to the cleavage furrow during cytokinesis. Real-time observation with a labeled SM-specific protein, lysenin, revealed that SM is concentrated in the outer leaflet of the furrow at the time of cytokinesis. Superresolution fluorescence microscopy analysis indicates a transbilayer colocalization between the SM-rich domains in the outer leaflet and PIP<sub>2</sub>-rich domains in the inner leaflet of the plasma membrane. The depletion of SM disperses PIP<sub>2</sub> and inhibits the recruitment of the small GTPase RhoA to the cleavage furrow, leading to abnormal cytokinesis. These results suggest that the formation of SM-rich domains is required for the accumulation of PIP<sub>2</sub> to the cleavage furrow, which is a prerequisite for the proper translocation of RhoA and the progression of cytokinesis.

### Dissecting the role of PI4P in PI(4,5)P<sub>2</sub> synthesis at the plasma membrane.

G. Hammond<sup>1</sup>, M. Machner<sup>2</sup>, T. Balla<sup>1</sup>; <sup>1</sup>Section on Molecular Signal Transduction, The Eunice Kennedy Shriver National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, MD, <sup>2</sup>Unit on Microbial Pathogenesis, The Eunice Kennedy Shriver National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, MD

PI(4,5)P<sub>2</sub> is lipid with pivotal roles in plasma membrane (PM) organization and function. Through its interaction with a multitude of effector proteins, it organizes the cortical actin cytoskeleton and adhesion complexes, nucleates sites of clathrin-mediated endocytosis, maintains the activities of ion channels and transporters, facilitates regulated exocytosis and acts as a precursor for the ubiquitous PLC and PI3K signaling pathways. We recently showed that PI4P, the major intermediate lipid in PI(4,5)P<sub>2</sub> synthesis, is present in the PM where it is paradoxically mostly redundant for PI(4,5)P<sub>2</sub> synthesis. Instead, PI4P provides a metabolically distinct pool of polyanionic lipid that together with PI(4,5)P<sub>2</sub> regulates localization or activity of several effector proteins specifically at the PM (PMID 22722250). However, this raises the question as to how cells synthesize and maintain their functionally crucial PI(4,5)P<sub>2</sub> pools independently of PM PI4P. To address this question, we have used a novel PI4P biosensor derived from the Rab1 guanine nucleotide exchange factor SidM from *Legionella pneumophila*. This biosensor recognizes both the PM and Golgi PI4P pools in mammalian cells, which is a substantial improvement on previous PI4P biosensors. Chemically-inducible recruitment of PI4P phosphatase activity to either the Golgi or PM removes this sensor exclusively from the targeted organelle. Recruitment of a PI(4,5)P<sub>2</sub> 5-phosphatase to the Golgi is without effect, confirming the low abundance of this lipid in this organelle - whereas targeting the same enzyme to the PM

results in further recruitment of PI4P biosensor, owing to the conversion of PI(4,5)P<sub>2</sub> into PI4P. Treatment of cells with compounds that inhibit PI4KA activity show that the basal PI4P pool is rapidly (< 10 min) depleted, but that the pool provided by 5-phosphatase degraded PI(4,5)P<sub>2</sub> is more resistant. These data confirm the distinct metabolic profiles of the steady-state PI4P and PI(4,5)P<sub>2</sub> pools, and support a model whereby the two stages of PI(4,5)P<sub>2</sub> synthesis (namely 4- and 5-phosphorylation) are tightly coupled and do not produce substantial levels of PI4P intermediate.

519

**PI4P synthesis at the plasma membrane by PI 4-kinase III $\alpha$  and its impact on PI(4,5)P<sub>2</sub> dynamics and plasma membrane identity.**

*F. Nakatsu<sup>1</sup>, J. M. Baskin<sup>1</sup>, J. Chung<sup>1</sup>, L. B. Tanner<sup>2</sup>, G. Shu<sup>2</sup>, M. Hao<sup>3</sup>, N. T. Ingolia<sup>4</sup>, M. R. Wenk<sup>2</sup>, P. De Camilli<sup>1</sup>; <sup>1</sup>Department of Cell Biology, Howard Hughes Medical Institute and CNRR, Yale University, New Haven, CT, <sup>2</sup>Department of Biochemistry, National University of Singapore, Singapore, Singapore, <sup>3</sup>Department of Medicine, Yale University, New Haven, CT, <sup>4</sup>Department of Embryology, Carnegie Institution, Baltimore, MD*

Phosphoinositides are minor phospholipids but critical regulatory components of cellular membranes. PI4P, the most abundant mono-phosphorylated phosphoinositide, is mainly localized at the Golgi complex, in a subset of endosomes and in the plasma membrane. Regulation of this lipid, particularly at the plasma membrane, is critically important as it serves as a metabolic precursor of PI(4,5)P<sub>2</sub> and thus of several other signaling molecules derived from this phosphoinositide. Additionally, PI4P has signaling functions of its own. However, mechanisms that control this PI4P pool in cells of higher eukaryotes remain elusive because the enzyme thought to synthesize this PI4P pool, PI4KIII $\alpha$ , was reported to be localized in the ER. Here we show the presence of PI4KIII $\alpha$  at the plasma membrane and demonstrate that its targeting to this membrane is mediated by an evolutionarily conserved protein complex containing TTC7 and EFR3/rolling blackout (see accompanying poster by Baskin et al) (see also Baird et al. JCB 183:1061-74, 2008). Analysis of PI4KIII $\alpha$  KO cells derived from conditional PI4KIII $\alpha$  KO mice that we have generated revealed a profound reduction of total cellular PI4P (with a dramatic reduction of the PI4P signal at the plasma membrane) but surprisingly only a modest reduction of total cellular PI(4,5)P<sub>2</sub>, due to robust upregulation of PI4P 5-kinases. In these cells, a major fraction of both PI4P 5-kinases and PI(4,5)P<sub>2</sub>, which are typically restricted to the plasma membrane, were localized on intracellular membranes, along with several normally plasma membrane-resident proteins. Collectively, these results provide insight into the mechanisms leading to the generation of PI4P in the plasma membrane by PI4KIII $\alpha$  and reveal a major function of PI4KIII $\alpha$  in the definition of plasma membrane identity.

520

**Recruitment of PI 4-kinase III $\alpha$  to the plasma membrane is mediated by TTC7 and EFR3/Rolling blackout, a palmitoylated peripheral membrane protein.**

*J. M. Baskin<sup>1</sup>, F. Nakatsu<sup>1</sup>, J. Chung<sup>1</sup>, M. Pirruccello<sup>1</sup>, P. De Camilli<sup>1</sup>; <sup>1</sup>Yale University, New Haven, CT*

Phosphatidylinositol 4-phosphate (PI4P), the most abundant monophosphorylated phosphoinositide, is present in multiple cellular pools located on the Golgi apparatus, endosomes, and the plasma membrane. The plasma membrane pool of PI4P serves as a metabolic precursor to PI(4,5)P<sub>2</sub> and its downstream metabolites PI(3,4,5)P<sub>3</sub>, IP<sub>3</sub>, and diacylglycerol. Despite the importance of this PI4P pool in membrane biology, many questions remain about the control of its biosynthesis. Of the four mammalian PI 4-kinase isoforms, Type

III $\alpha$  (PI4KIII $\alpha$ ) is thought to produce the bulk of this pool, in spite of the proposed localization of the enzyme in the ER, a localization that has been controversial. Here we show that EFR3/Rolling blackout and TTC7, homologs of yeast Efr3 and Ypp1 respectively, can recruit PI4KIII $\alpha$  to the plasma membrane in a complex that bears some similarity to but also differences from yeast PIK patches containing the PI 4-kinase Stt4. We also show that EFR3 is a peripheral membrane protein, in contrast to studies of its *Drosophila* homolog, rolling blackout, which was proposed to function as an integral membrane lipase. Moreover, we show that membrane targeting of mammalian EFR3 is mediated by palmitoylation of an N-terminal Cys-rich motif that is conserved in higher eukaryotes but absent from yeast. Collectively, our studies, combined with an analysis of PI4KIII $\alpha$  KO cells (see accompanying poster by Nakatsu et al.), provide insight into the mechanism of PI4P generation at the plasma membrane by PI4KIII $\alpha$  and more generally propose a role for PI4KIII $\alpha$  in the determination of plasma membrane identity. Work to probe the precise functions of EFR3 and TTC7 in PI4P synthesis and to identify additional members of the mammalian PI4KIII $\alpha$ /EFR3/TTC7 complex are ongoing.

521

**Phosphorylation of ACAP4 BAR domain regulates membrane tubulation.**

X. Zhao<sup>1</sup>, D. Wang<sup>1</sup>, F. Wang<sup>2</sup>, W. Yao<sup>2</sup>, Z. Song<sup>1</sup>, L. Liu<sup>2</sup>, X. Ding<sup>1</sup>, X. Yao<sup>1</sup>; <sup>1</sup>Cellular Dynamics, University of Science & Technology of China, Hefei, China, <sup>2</sup>Physiology, Morehouse School of Medicine, Atlanta, GA

ACAP4 is an ARF6 GTPase-activating protein essential for EGF-elicited cell migration. Many ARF GAPs contain a BAR domain, a structure element to sense and elicit membrane curvature. Here, we show that ACAP4 contains a functional BAR domain and phosphorylation of BAR domain at Tyr34 is critical for EGF-elicited membrane remodeling. Domain structure analysis established that N-terminal region of ACAP4, named the BAR domain, regulates membrane curvature. EGF stimulation phosphorylates ACAP4 at Tyr-34 which subsequently promotes ACAP4 homodimer curvature. Phospho-mimicking mutant ACAP4 promotes its lipid binding activity and tubulation in vitro and facilitates the recruitment of ARF6 to the membrane ruffles of the leading edge during EGF stimulation. Persistent expression of non-phosphorylatable ACAP4 attenuates EGF-elicited cell migration. Thus, our study suggests a novel mechanism by which EGF-elicited phosphorylation of BAR domain controls ACAP4 molecular plasticity and plasma membrane dynamics during cell migration.

522

**Diverse membrane-deforming activities of F-BAR proteins.**

C. Kelley<sup>1</sup>, O. Sokolova<sup>2</sup>, A. Becalska<sup>1</sup>, A. A. Rodal<sup>1</sup>; <sup>1</sup>Biology, Brandeis University, Waltham, MA, <sup>2</sup>Biology, Moscow State University, Moscow, Russia

Subcellular membrane compartments are the hallmark feature of eukaryotic cells, but we do not understand how these compartments are sculpted into characteristic shapes that undergo dynamic remodeling and turnover. BAR domain proteins are critical for deforming subcellular membranes in the endocytic pathway, by forming a crescent-shaped dimer with varying degrees of curvature that binds to and bends the lipid bilayer. Diverse members of this protein family, including the shallow-curvature F-BAR subfamily, have adapted the BAR domain structure to specialized cellular roles, but the rules governing how these variants function to create different dynamic membrane geometries remain unknown. We have found that three neuronal *Drosophila* F-BAR proteins (Cip4, Syndapin, and Nwk) each generate different membrane tubules in cells and on purified giant unilamellar vesicles (GUVs). Remarkably, Nwk can generate both positive and negative membrane curvature, while Cip4 and Synd generate only positive curvature. We are testing the hypothesis that differential F-BAR domain assembly into

higher order structures, mediated by tip-to-tip or lateral interactions, determines the direction of membrane deformation. We have used molecular modeling together with electron microscopy and single particle analysis to determine the structural differences between diverse F-BAR domains, together with kinetic analysis of F-BAR assembly on GUVs to understand the self-assembly properties of these different proteins. Our results indicate that even related F-BAR domain proteins have unique membrane deforming properties that are specifically tailored to their cellular roles.

523

**Membrane-sculpting BAR and F-BAR domains generate stable lipid microdomains.**

H. Zhao<sup>1</sup>, A. Michelot<sup>2</sup>, E. V. Koskela<sup>1</sup>, V. Tkach<sup>3</sup>, D. Stamou<sup>3</sup>, D. Drubin<sup>2</sup>, P. Lappalainen<sup>1</sup>; <sup>1</sup>Institute of Biotechnology, University of Helsinki, Helsinki, Finland, <sup>2</sup>Department of Molecular and Cell Biology, University of California, Berkeley, CA, <sup>3</sup>Department of Neuroscience and Pharmacology & Nano-Science Center, University of Copenhagen, Copenhagen, Denmark

Bin-Amphiphysin-Rvs (BAR) domain proteins are central regulators of cellular processes involving plasma membrane dynamics. BAR domains bind phosphoinositide-rich membranes with high affinity. Depending on the geometry of the lipid-binding interface they generate either plasma membrane protrusions or invaginations to promote cell migration or endocytosis, respectively, or stabilize planar membrane sheets. Here, we report that BAR domains also generate very stable lipid microdomains by inhibiting lateral diffusion of lipids in membranes by at least two orders of magnitude. This is a general feature of BAR domains because all budding yeast endocytic BAR and F-BAR domains, and the eisosomal BAR protein Lsp1 induced phosphoinositide-clustering and inhibited lipid diffusion, despite differences in lipid-specificities and interactions with the acyl-chain region of lipid bilayer. Furthermore, the BAR domain of Pinkbar, which stabilizes planar membrane sheets, efficiently inhibited lateral diffusion of phosphoinositides. Fluorescence-recovery-after photobleaching (FRAP) analyses revealed that Lsp1 displays comparable low diffusion rates in vitro and in vivo, suggesting that BAR domain proteins form also stable scaffolds and generate lipid microdomains in cells. Collectively, these results uncover an unexpected and conserved role of BAR superfamily proteins in regulating the dynamics of lipid molecules within membranes. Stable microdomains induced by BAR domain scaffolds and specific lipids can generate phase boundaries and diffusion barriers, which may have profound importance in diverse cellular processes including endocytosis.

524

**Membrane scalloping by the F-BAR protein Nervous Wreck.**

A. N. Becalska<sup>1</sup>, T. L. Eskin<sup>1</sup>, C. Berciu<sup>1</sup>, C. F. Kelley<sup>1</sup>, K. Z. Miao<sup>1</sup>, X. Fu<sup>1</sup>, D. Nicastro<sup>1</sup>, A. A. Rodal<sup>1</sup>; <sup>1</sup>Department of Biology, Brandeis University, Waltham, MA

Proteins of the crescent-shaped BAR domain superfamily are important mediators of membrane deformation and act in a variety of cellular contexts to create membrane buds and tubules of defined geometry and lipid composition. Membrane binding by different BAR proteins has been shown to generate invaginating tubules, protrusive tubules, or flat regions of membrane. Here we have identified a new mode of membrane deformation, consisting of periodic scallops, mediated by the F-BAR family protein Nervous Wreck (Nwk). In a cell-based assay, both *Drosophila* Nwk and its mammalian homolog (FCHSD2) induce extensive actin cytoskeleton-dependent cellular protrusions, in contrast to the invaginating tubules formed by the related F-BAR proteins Cip4 and Syndapin. Using cryo-electron microscopy of purified protein on liposomes and thin-section electron microscopy of Nwk-expressing cells, we find that these protrusions are not smooth tubules like those generated by other F-BAR proteins, but instead

are composed of undulating membrane scallops, which at the micron scale can deform into structures of either net negative or net positive curvature. To further understand the activity of Nwk we performed structure-function analyses to identify key features of the protein critical to its membrane deforming function, both *in vitro* and *in vivo* at the *Drosophila* neuromuscular junction (NMJ). We show that a novel structural determinant located at the tips of the F-BAR dimer as well as the conventional convex F-BAR membrane-binding surface are required for Nwk activity *in vivo* and lipid binding *in vitro*. Furthermore we show that the activity of the F-BAR domain is intra-molecularly inhibited by C-terminal sequences *in vivo*. Our data uncover a novel membrane deforming activity for a BAR family protein, and suggest a mechanism by which highly ordered local alterations in membrane curvature can induce unexpected global changes in membrane shape.

525

**A novel mutation causing retinopathy and widespread abnormal membrane structures is linked to a small subunit of the serine palmitoyltransferase.**

L. Zhao<sup>1</sup>, S. Spassieva<sup>2</sup>, L-Y. Shi<sup>1</sup>, J. Wang<sup>1</sup>, M. Krebs<sup>1</sup>, W. Hicks<sup>1</sup>, P. Nishina<sup>1</sup>; <sup>1</sup>The Jackson Laboratory, Bar Harbor, ME, <sup>2</sup>Department of Medicine, Medical University of South Carolina, Charleston, SC

Sphingolipids are crucial components of cellular membranes. Disruptions in sphingolipid metabolism has been implicated in both retinopathy and neurodegenerative diseases, suggesting a critical role of sphingolipid homeostasis in the health of the retina and the brain. We have identified a novel mouse mutant named *Stardust* (*sd*), which exhibits shiny flecks by indirect ophthalmoscopy, and photoreceptor degeneration, as well as deposition of ubiquitylated proteins and presence of aberrant membrane structures in both the retina and the brain. A missense mutation was identified in one of the small subunits of serine palmitoyltransferase (SPT), which is the first enzyme of the *de novo* biosynthetic pathway of ceramide, a molecule that serves as the backbone of all complex sphingolipids. Our preliminary results suggest that the *sd* mutation may cause hyperactivation of SPT, resulting in elevation of particular types of ceramide species. This mouse mutant thus provides a unique model to study how the regulation of sphingolipid homeostasis affects the health of the eye and the brain.

526

**In the erythrocyte membrane, cholesterol and membrane:cytoskeleton anchorage complexes oppositely regulate micrometric segregation of fluorescent lipid analogs.**

L. D'Auria<sup>1</sup>, P. Aleksandrowicz<sup>1</sup>, M. Fenaux<sup>1</sup>, P. Van Der Smissen<sup>1</sup>, C. Chantrain<sup>2</sup>, C. Vermeylen<sup>2</sup>, M. Vikkula<sup>1</sup>, P. Courtoy<sup>1</sup>, D. Tyteca<sup>1</sup>; <sup>1</sup>de Duve Institute and Université catholique de Louvain, Brussels, Belgium, <sup>2</sup>Saint-Luc Academic Hospital and Université catholique de Louvain, Brussels, Belgium

Fluorescent (BODIPY, \*) analogs of glucosylceramide (GlcCer\*), sphingomyelin (SM\*) and phosphatidylcholine (PC\*), inserted at tracer levels into the outer plasma membrane leaflet of living cells, spontaneously gather into structurally distinct (sub)micrometric domains, visible by confocal microscopy. Specific disappearance of SM\* domains upon SM depletion suggests a link with endogenous lipids. We here address the mechanisms governing micrometric lipid\* domains at 37°C on erythrocytes attached on poly-L-lysine, as a flat featureless living cell model, with high cholesterol content and strong membrane:cytoskeleton anchorage via non-redundant 4.1R and ankyrin complexes. We found that the three lipids\* formed well-defined (sub)micrometric domains, organized into immobile assemblies of exchangeable constituents as shown by fluorescence recovery after photobleaching. Stretching by increasing poly-L-lysine

concentration and time of erythrocyte adhesion suppressed all domains, indicating repression by membrane tension. Minor cholesterol depletion preserved GlcCer\* but suppressed SM\* and PC\* domains. Uncoupling of membrane:cytoskeleton anchorage at 4.1R complexes by PKC activation increased the abundance of GlcCer\* and SM\* but not PC\* domains; uncoupling at ankyrin complexes in spherocytotic patients increased the abundance of SM\* and PC\* but not GlcCer\* domains. Thus, clustering into micrometric domains exhibited differential dependence on the two anchorage complexes. This was confirmed by confocal microscopy: distinct submicrometric protein patches, respectively enriched in 4.1R (glycophorin C) and ankyrin complexes (CD47), differentially decorated the three types of lipid\* domains. Taken together, these data suggest that the high cholesterol content of erythrocytes and the two complementary membrane:cytoskeleton anchorage complexes oppositely modulate clustering of fluorescent polar lipids into distinct types of (sub)micrometric domains. Lipid segregation into micrometric domains may be relevant for erythrocyte deformability, critical for squeezing into the narrow pores of spleen sinusoids >10.000 times in the cell lifespan.

527

### **Influence of membrane cholesterol content on the activity of the sodium taurocholate cotransporting polypeptide.**

*C. Guyot<sup>1</sup>, F. Koller<sup>1</sup>, S. Nideröst<sup>1</sup>, B. Stieger<sup>1</sup>; <sup>1</sup>Clinical Pharmacology and Toxicology, University Hospital Zurich, Zurich, Switzerland*

#### **Introduction:**

Previous studies have shown that canalicular liver plasma membranes contain microdomains defined by their resistance to solubilisation by detergents at cold temperature (Hepatology 49: 1673, 2009). These detergent resistant microdomains (DRMs) are enriched in cholesterol and ABC transporters involved in bile secretion. Cholesterol has been shown to regulate the activity of various membrane enzymes and variation of cholesterol concentration correlates with changes in membrane transport activity. In the present study we tested whether basolateral liver plasma membranes (bLPMs) also contain DRMS and we investigated the effect of membrane cholesterol content on the transport activity of the key organic anion transporter involved in bile formation: sodium taurocholate cotransporting polypeptide (Ntcp).

#### **Methods:**

bLPMs were extracted with either 1% Triton X-100 or 1% Lubrol-WX for 30 min on ice and subsequently submitted to flotation on sucrose step gradients. Gradient fractions were then used for Western blotting and lipid composition analysis. Ntcp was expressed with the baculovirus system in Sf9 insect cells. Infected cells were loaded with cholesterol by incubation with 1mM cholesterol@RAMEB complex for 30 min at 37°C. After cholesterol loading, radiolabeled taurocholate uptake assay were performed with cells or isolated Sf9 cell membrane vesicles and transport activity was compared with control condition (no cholesterol loading).

#### **Results:**

Extraction with both detergents generated DRMs containing the raft marker proteins flotillin-1 and flotillin-2. These conventional markers for microdomains remained mainly in the soluble phase indicating that they are only partially associated with microdomains in rat bLPM. Ntcp was mostly soluble in Triton X-100 whereas after extraction with Lubrol-WX Ntcp was mainly found in the DRMs. Taurocholate uptake assays performed in cells show a high transport activity in absence of cholesterol, in cholesterol loaded cells the transport activity is dramatically reduced. Taurocholate uptake assays performed in vesicles show lower transport activity in absence of cholesterol compared to cell experiments however the inhibition of transport activity in presence of cholesterol is still observed.

#### **Conclusions:**

We were able to show that bLPMS contain two different types of microdomains: Triton X-100 and Lubrol-WX microdomains. We have demonstrated that Ntcp transport activity is dramatically reduced in presence of cholesterol hence suggesting that localisation of Ntcp inside or outside of cholesterol rich microdomains might have a major impact on the regulation of transport activity.

528

**Cholesterol transbilayer distribution in mammalian cells.**

*K. Courtney<sup>1</sup>, X. Zha<sup>2,1</sup>; <sup>1</sup>University of Ottawa, Ottawa, ON, Canada, <sup>2</sup>Ottawa Hospital Research Institute, Ottawa, Canada*

Plasma membrane (PM) bilayer asymmetry is a ubiquitous feature of eukaryotic cells involved in maintaining cellular homeostasis. Both proteins and lipids are transversely asymmetric in the PM. Sterols are a major constituent in eukaryotic PM representing about 30% of total PM lipid. In model membranes, cholesterol transbilayer movement is rapid and spontaneous. This is in contrast to phospholipids, which require energy dependent flip-flop transporters. Curiously, recent studies with fluorescent cholesterol analogues suggest that sterols are enriched in the inner leaflet of the PM. It is however not known whether native cholesterol shares this transverse asymmetry. In addition, cholesterol is heterogeneously distributed laterally in the plane of the PM; it is enriched in various dynamic assemblies of lipids and proteins, known as lipid rafts. Lipid raft formation also requires sphingomyelin, a phospholipid almost exclusively resided in the outer leaflet of the PM. If cholesterol is enriched in the inner leaflet of the PM, similar to its fluorescent analogues, the lipid raft concept would need to be substantially updated.

The aim of this study is to analyze mammalian PM cholesterol transbilayer distribution in order to investigate mechanisms and functions of this asymmetry. For this, we developed a protocol that can analyze cholesterol in a leaflet-specific manner. Specifically, we show that, at 37°C, trace cholesterol in large unilamellar vesicles (LUV) can be 100% extracted by methyl- $\beta$ -cyclodextrin (MCD), consistent with rapid cholesterol flip-flop between bilayers. However, at 0°C, MCD can only extract 50% of the cholesterol from LUVs. The process of cholesterol extraction by MCD itself is not temperature-sensitive and LUV remains intact. This suggests cholesterol flip-flop between leaflets can be effectively stopped or drastically reduced at 0°C, which allows cholesterol extraction exclusively from the outer leaflet of LUVs.

We then devised a donor/acceptor exchange protocol using LUVs containing 20% cholesterol. Low concentration of  $\beta$ -cyclodextrin was used as shuttle to allow cholesterol exchange between donor LUV, labelled with <sup>3</sup>H-cholesterol, and excess acceptor LUV. We found that <sup>3</sup>H-cholesterol in the donor LUVs can be 100% transferred to acceptor LUV membranes at 37°C. However, at 0°C only 50% donor cholesterol appears in acceptor LUV. We conclude that we have established a method to analyze leaflet-specific distribution of cholesterol. We plan to apply this method to PM vesicles, red blood cells, and eventually the PM of live nucleated cells.

**Novel function of sphingolipid-enriched compartments ("sphingosomes") in vesicular transport, exosome formation, and ciliogenesis.**

*Q. He<sup>1</sup>, E. Bieberich<sup>1</sup>; <sup>1</sup>Institute of Molecular Medicine and Genetics, Georgia Health Sciences University, Augusta, GA*

Until recently, the sphingolipid ceramide has been regarded as a metabolic precursor or a cell signaling factor inducing growth arrest and apoptosis. Studies in our laboratory have shown for the first time that ceramide-enriched compartments termed "sphingosomes" constitute lipid platforms for the assembly of protein complexes and scaffolds in cell polarity, exosome

formation/secretion, and ciliogenesis. The unique biophysical properties of ceramide based on the chain length and saturation of the fatty acid linked to sphingosine leads to the formation of ceramide microdomains in the cell membrane and the endosome. Accordingly, we have found that specific ceramides, in particular C16, C18 and C24:1 ceramide are enriched in cell membrane and endosome-derived compartments. These compartments include a novel “apical ceramide-enriched compartment” (ACEC) at the base of the primary cilium and ceramide-enriched lipid vesicles generated in multivesicular endosomes (MVEs) and secreted to the medium as exosomes. Our studies suggest that these sphingolipid-enriched intra- and extra/intercellular compartments termed “sphingosomes” are critically involved in the etiology of Alzheimer’s disease and ciliopathies caused by aberrant ciliogenesis. Central to sphingosomes is the association of ceramide with atypical PKC (i.e. PKCzeta) and its interaction with proteins regulating vesicle transport (i.e. Rab11a) and cell polarity (i.e. Cdc42) in a “sphingolipid-induced protein scaffold” (SLIPS). Surprisingly, these sphingosome-associated SLIPS appear to be key regulators for microtubule nucleation and acetylation important for cell polarity and primary cilium formation. In summary, our studies reveal a previously unknown function of ceramide in the spatially organized regulation of vesicular transport and the cytoskeleton by sphingosomes. This work is supported by the NSF (1121579) and NIH (R01AG034389).

**Correlative light and electron microscopy (CLEM) with sub-micrometer alignment precision for cryo specimens: revisiting caveolae.**

*P. Schellenberger<sup>1</sup>, M. Stöber<sup>2</sup>, C. Hagen<sup>1</sup>, A. Siebert<sup>1</sup>, R. Kaufmann<sup>1</sup>, A. Helenius<sup>2</sup>, K. Grünewald<sup>1</sup>; <sup>1</sup>Division of Structural Biology, Wellcome Trust Centre for Human Genetics, University of Oxford, Oxford, United Kingdom, <sup>2</sup>Department of Biology, Institute of Biochemistry, ETH Zurich, Zurich, Switzerland*

Electron cryo tomography of vitrified cells offers the opportunity to analyze molecular structures in three-dimensions in their native cellular context. However, precisely locating a specific event of interest inside a frozen-hydrated cell has remained extremely challenging. The work presented here shows that by combining correlative light and electron microscopy (CLEM) approaches (1, 2); it is possible to achieve a high correlation precision between LM and EM of intact cells at cryogenic temperatures.

The positions of fluorescently tagged proteins are first recorded in cells grown on dedicated support grids using fluorescent live cell imaging. Following plunge-freezing of cells, we re-examine the specimen by cryo fluorescence microscopy using a dedicated cryo stage (3). The positions of electron dense Fluospheres on the support film are then used as markers to establish a common coordinate system of sub-micrometer precision between medium magnification EM grid maps and externally acquired fluorescent maps, thus giving each carbon hole a unique ‘address’. Next, electron cryo-microscopy/tomographic data sets are acquired on desired positions based on the localization information for the fluorescently tagged proteins.

We exemplify the use of this correlative pipeline for the localization of caveolar protein coats. This allows us to analyse the molecular organisation of fluorescently tagged cellular vesicles at high resolution and to define the ultrastructure of their surrounding native context.

**Cavins and Caveolae.**

*C. G. Hansen<sup>1</sup>, G. Howard<sup>1</sup>, E. Shvets<sup>1</sup>, K. Riento<sup>1</sup>, B. Nichols<sup>1</sup>; <sup>1</sup>MRC-LMB, Cambridge, United Kingdom*

Caveolae constitute up to 20% of the surface area of continuous microvascular endothelia in many mammalian tissues, and are thought to mediate transcytosis across endothelial cells. How morphologically uniform caveolae function in endothelia that have different permeability properties is not clear. The cavin proteins are important components of caveolae, and are expressed at varied amounts in different tissues. We have investigated this in detail using biochemical, electron microscopy and fluorescence microscopy methods. Our data provide direct evidence for structural and functional heterogeneity between caveolae in different capillary beds.

532

**Intra membrane surface flow in response to protein induced spontaneous curvature.**

*P. Rangamani<sup>1</sup>, K. K. Mandadapu<sup>2</sup>, G. Oster<sup>1</sup>; <sup>1</sup>Molecular and Cell Biology, Univ of California Berkeley, Berkeley, CA, <sup>2</sup>Sandia National Laboratories, Livermore, CA*

Lipid bilayers are unique in their biophysical properties. They are fluid in-plane and solid in bending. While traditional models use the Helfrich approach to model the elastic deformations of the bilayer membrane, these approaches only provide insight into the equilibrium configurations of the elastic deformations. But many membrane deformations are dynamic—viscoelastic—and can occur in response to protein binding. We have developed a model that accounts for the viscoelastic behaviour of the membrane and captures the flow of lipids on the surface of the membrane in response to deformations and/or surface pressure gradients.

An important process driving membrane deformations is the binding of proteins to the membrane surface. We use the viscoelastic model of the bilayer membrane to capture the dynamics of membrane shape change in response to protein binding. The binding of proteins to the membrane is modelled as a kinetic process, and the spontaneous curvature of the membrane is assumed to be proportional to the surface density of the proteins in that region. Numerical simulations show that binding of proteins changes the shape of the membrane and induces lipid flow at the boundaries resulting from the increase in surface area of the membrane. Additionally, the surface pressure field evolves from a uniform distribution to an inhomogeneous distribution. Regions with higher protein concentration also have a lower surface pressure. Together, these results capture the dynamics of lipid flow and surface evolution in response to protein binding.

### Low PIP<sub>2</sub> molar fractions induce nanometer size clustering in giant unilamellar vesicles containing POPC.

D. Gau<sup>1,2</sup>, I. Salvemin<sup>2</sup>, J. Reid<sup>2</sup>, L. Bagatoll<sup>3</sup>, P. Moens<sup>2</sup>; <sup>1</sup>University of Pittsburgh, Pittsburgh, PA, <sup>2</sup>University of New England, Armidale, Australia, <sup>3</sup>University of Southern Denmark, Odense, Denmark

One of the leading causes of death in the world is cancer. This has propagated expanding areas of research in pathways involved in cancer cell signaling. Phosphatidylinositol (4,5) bisphosphate (PIP<sub>2</sub>) is a key lipid signaling molecule found on the inner leaflet of the cell membrane. Polyphosphoinositides signaling play an important role in regulation of many cell processes such as cell survival, proliferation, migration, and apoptosis. Phosphoinositides regulate signal transduction by providing binding or docking sites for intracellular proteins. In order to perform these functions, it has been suggested that PIP<sub>2</sub> must be able to form localized clusters within the cell membrane.

In this study, single point fluorescence correlation spectroscopy and brightness analysis of various BODIPY-labeled PIP<sub>2</sub> was utilized to detect the presence of clusters in the membrane of giant unilamellar vesicles (GUVs) consisting of 1-palmitoyl-2-oleoyl-sn-glycero-3-phosphocholine (POPC). The number of freely diffusing fluorescent BODIPY molecules in the membrane was calculated and we found that in GUVs containing various amounts of labeled PIP<sub>2</sub> had significantly lower number of fluorescent molecules than in GUVs made with the control BODIPY labeled hexadecyl phosphatidylcholine (BODIPY-HPC). Also, an increase in brightness of the labeled PIP<sub>2</sub> particles with increasing labeled PIP<sub>2</sub> molar fraction was noted. These results show the existence of PIP<sub>2</sub> enriched clusters in the liquid disordered phase of GUVs that are smaller than the resolution limit of the fluorescent microscope. Using LAURDAN generalized polarization function, we demonstrated that the formation of these clusters is not due to the presence of the BODIPY moiety on the lipids. In addition, we report for the first time the presence of a previously uncharacterized hypsochromic shift of the fluorescence for the BODIPY labeled lipids that we attributed to BODIPY dimers. Finally, by adding cholesterol to the GUVs, we showed that the BODIPY dimers tend to favor the liquid ordered phase.

### The signaling lipid phosphatidylinositol 3,5 bis phosphate serves as a landmark for the TORC1 pathway.

N. Jin<sup>1</sup>, S. Park<sup>1</sup>, G. Tevzadz<sup>2</sup>, R. Loewith<sup>2</sup>, D. Bridges<sup>3</sup>, A. R. Saltiel<sup>3</sup>, L. S. Weisman<sup>1</sup>; <sup>1</sup>Departments of Cell and Developmental Biology, Life Sciences Institute, University of Michigan, Ann Arbor, MI, <sup>2</sup>Department of Molecular Biology, University of Geneva, Geneva, Switzerland, <sup>3</sup>Internal Medicine, Molecular and Integrative Physiology, Life Sciences Institute, University of Michigan, Ann Arbor, MI

The Target Of Rapamycin (TOR) is a Ser/Thr protein kinase that functions in multiple pathways and forms two distinct complexes, TORC1 and TORC2. TORC1 is a central regulator of cell growth and metabolism. In mammals, in response to amino acids, TORC1 moves to the lysosome membrane where it is activated. However, it has not been understood how mTORC1 or its activators are targeted to the lysosome membrane, and the significance of this localization is not yet known. Here we show that in the yeast *Saccharomyces cerevisiae* the signaling lipid phosphatidylinositol 3,5 bis phosphate (PtdIns(3,5)P<sub>2</sub>), plays a crucial role in the recruitment of TORC1 to the endosomal membrane. We show that Kog1, a yeast homologue of Raptor and a major regulator of TORC1, binds directly to PtdIns(3,5)P<sub>2</sub>. Moreover, PtdIns(3,5)P<sub>2</sub> is required for the proper localization of TORC1 to the yeast vacuole/endosomes. In addition, yeast

mutants with low levels of PtdIns(3,5)<sub>2</sub> display reduced TORC1 function. Furthermore, we found that a major substrate of TORC1 localizes on the vacuole membrane via binding PtdIns(3,5)P<sub>2</sub>. Together, these studies reveal that PtdIns(3,5)P<sub>2</sub> is required for TORC1 function via its role in recruitment of TORC1 to the vacuole membrane, and establish a novel link between the PtdIns(3,5)P<sub>2</sub> and TORC1 signaling pathways. In addition, the identification of Kog1 along with other novel unexpected candidates predicts that functions of PtdIns(3,5)P<sub>2</sub> extend beyond pathways currently known to be regulated by this lipid.

#### **A role for the PLD1 pathway in autophagosomal membrane dynamics and autophagy modulation.**

*C. Dall'Armi<sup>1</sup>, H. Hoga<sup>2</sup>, R. B. Chang<sup>1</sup>, K. A. Devereaux<sup>1</sup>, S. Guanghou<sup>3</sup>, M. R. Wenk<sup>3</sup>, A. M. Cuervo<sup>2</sup>, G. Di Paolo<sup>1</sup>; <sup>1</sup>Columbia University Medical Center, New York, NY, <sup>2</sup>Albert Einstein College of Medicine, New York, NY, <sup>3</sup>National University of Singapore, Singapore, Singapore*

Macroautophagy (simply referred to as autophagy) is an essential homeostatic process that entails the biogenesis of autophagosomes (APs), which sequester cytoplasmic substrates and undergo a maturation process before ultimately fusing with lysosomes, where the degradation of sequestered material occurs. While the autophagy process involves major alterations in membrane architecture, the lipid composition of the AP and changes underlying autophagosomal membrane dynamics are largely undetermined. We have previously reported that phospholipase D1 (PLD1), an enzyme producing bioactive lipid phosphatidic acid (PA), acts downstream of class III PI 3-kinase Vps34 during starvation-induced autophagy and positively regulates autophagy at both the biogenesis and maturation steps. However, the precise molecular mechanisms underlying the autophagic actions of PA and the specific role of this lipid in regulating mTOR in the context of autophagy are unknown. Here we tested the role of PLD1 in the acute amino acid activation of mTORC1 signaling following nutrient deprivation using a combination of pharmacological and genetic tools. Additionally, to better understand the role of PA in AP maturation, we performed cell-free heterotypic fusion assays using organelles purified from wild-type and PLD1-deficient mice. We found a decrease in fusion efficacy between PLD1-deficient APs and purified endosomes and lysosomes. A lipidomic analysis of these same organelles revealed a variety of lipid changes, which may contribute to the fusion defect phenotypes observed in the absence of PLD1. Overall, our studies clarify the lipid-based mechanisms controlling AP membrane dynamics and provide important clues on how PA intersects with the metabolism of other lipid families in the context of nutrient deprivation.

## **Establishing and Maintaining Organelle Structure I**

#### **Actin distribution in HepG2 cell-spheroids: A fluorescence microscopic study/**

*R. G. Aktas<sup>1</sup>, S. Karahuseyinoglu<sup>2</sup>, O. E. Tok<sup>3</sup>, M. Karabork<sup>1</sup>, D. Yucef<sup>4</sup>; <sup>1</sup>School of Medicine, Koc University, Istanbul, Turkey, <sup>2</sup>Embryology and Andrology Laboratories, Suleymaniye Research and Training Hospital, Istanbul, Turkey, <sup>3</sup>School of Medicine, Marmara University, Istanbul, Turkey, <sup>4</sup>School of Medicine, Acibadem University, Istanbul, Turkey*

HepG2 cells, human hepatocellular carcinoma cell line, are very popular for the studies of normal liver cells since they demonstrate numerous functions of normal human hepatocytes. Studies are continuing to produce a cell type which more resembles normal liver cells in 3D

environmental conditions. HepG2 cells tend to form spheroids in cultures instead of spreading over the surfaces. The current study aimed to investigate actin distribution in these spheroids. HepG2 cells (ATCC), were seeded on glass coverslips. They were grown in Minimum Essential Medium (ATCC) which contain 10% fetal serum bovine. Cells were labeled with fluorescent phallotoxins (Invitrogen). Labeling of the cells at the beginning of the formation of spheroids were compared with the labeling intensity of the cells which are seven days old after the formation of spheroid. Axioscope fluorescence microscope and Eclipse 90i Nikon confocal microscope were used for comparison of the location of actin. Antibodies which are specific for Golgi, mitochondria and endoplasmic reticulum were also used to investigate the changes of these organelle distribution during spheroid formation.

Results demonstrated that actin especially located on the cell membrane, between the adjacent cells in spheroids. Organells were also increasing during aggregate formation. There were no significant difference between the labeling density of the cells at the center of the spheroids and the cells which were located peripherally.

It has been concluded that spheroid formation stimulates adhesion between cells. Actin accumulation on cell plasma membrane is probably a sign of cell junction formation between the cells. More studies need to determine if the location of actin can also be a sign of newly formed bile ductuli between the cells as shown in different 3D culture models.

**SAS-6 coiled coil structure and interaction with SAS-5 suggests a mutual regulation in centriole assembly.**

*G. Dong<sup>1</sup>, R. Qiao<sup>1</sup>; <sup>1</sup>Max F. Perutz Laboratories, Vienna, Austria*

The centriole is a conserved microtubule-based organelle essential for both centrosome formation and cilium biogenesis. Five centriolar proteins have been identified in *Caenorhabditis elegans* and their homologues in other species have also been reported. Two of them, SAS-5 and SAS-6, physically interact with each other and are codependent for their targeting to procentrioles. However, it remains unclear how these two proteins interact at the molecular level and why the *C. elegans* centriole has a unique central tube that is absent in non-nematode centrioles. Here, we demonstrate that the SAS-5 C-terminal domain (CTD) specifically binds to the central region of the SAS-6 coiled coil. To further investigate their interaction, we have solved the crystal structure of the SAS-6 coiled-coil domain (CCD, residues 248-410) and established that the association of the SAS-6 CCD and the SAS-5 CTD is mediated by synergistic hydrophobic and electrostatic interactions. The crystal structure also shows a periodic charge pattern along the SAS-6 CCD which, in the absence of SAS-5, gives rise to an anti-parallel tetramer of its CCD. Electron microscopy studies of the SAS-5/SAS-6 complex suggest that the central tube of *C. elegans* centrioles is formed by SAS-5 circularly arranged on SAS-6; SAS-5 alone forms aggregates. Overall our findings establish the molecular basis of the specific interaction between SAS-5 and SAS-6, and suggest that both proteins individually adopt a self-associated conformation that is disrupted upon the formation of the hetero-complex to facilitate the correct assembly of the nine-fold symmetric centriole.

538

**Mechanisms of Tubular Recycling Endosome Biogenesis.**

*S. Panapakkam Giridharan<sup>1</sup>, B. Cai<sup>1</sup>, N. Vitale<sup>2</sup>, N. Naslavsky<sup>1</sup>, S. Caplan<sup>1</sup>; <sup>1</sup>Department of Biochemistry and Molecular Biology and Eppley Cancer Center, University of Nebraska Medical Center, Omaha, NE, <sup>2</sup>Institut des Neurosciences Cellulaires et Intégratives (INCI), UPR-3212 Centre National de la Recherche Scientifique & Université de Strasbourg, Strasbourg, France*

Endocytic recycling is a critical transport step that regulates the return of internalized receptors and membrane back to the cell surface. Over the last decade, our laboratory has focused on the function of the C-terminal Eps15 homology domain-containing (EHD) protein, EHD1. We and others have demonstrated that EHD1 is an ATPase that localizes to tubular recycling endosomes and regulates transport from the endocytic recycling compartment to the plasma membrane. However, the composition and function of these tubular endosomes to which EHD1 localizes has not been studied extensively, and their mode of biogenesis remains unknown. We have identified the molecular and atomic basis for the interaction between the EHD1 EH-domain and proteins containing the tripeptide asparagine-proline-phenylalanine (NPF), and we have identified a number of new EHD1 interaction partners that regulate endocytic events. One such protein is known as MICAL-L1, which associates with membranes through a C-terminal coiled-coil and recruits both EHD1 and Rab8a to the tubular membranes. To gain insight into the mode by which MICAL-L1 associates with membranes, we purified the coiled-coil and found that it is only one of a handful of proteins that selectively interacts with phosphatidic acid (PA). We have also discovered a novel interaction between a proline-rich domain of MICAL-L1 and the SH3 domain of the BAR-domain-containing protein, Syndapin2. Similar to MICAL-L1, Syndapin2 too showed a selective binding to PA. To determine whether PA comprises recycling tubule membrane in cells, we used a GFP-tagged version of the well-characterized yeast PA-binding protein, Spo20p. Indeed, PA could be identified as part of MICAL-L1-decorated tubules. Moreover, phospholipase D inhibitors that decrease PA synthesis severely impair the recycling of transferrin to the plasma membrane. Our data are consistent with a novel model by which PA recruits MICAL-L1 and Syndapin2 to membranes and facilitates the nucleation and biogenesis of recycling tubules that are required for optimal endocytic recycling.

**Identifying the members of the VPS16B and VPS33B complex in mammalian cells.**

*S. Chen<sup>1,2</sup>, D. Urban<sup>1,2</sup>, L. Li<sup>1</sup>, W. H. Kahr<sup>1,2,3</sup>; <sup>1</sup>Cell Biology, Hospital for Sick Children, Toronto, ON, Canada, <sup>2</sup>Biochemistry, University of Toronto, Toronto, ON, Canada, <sup>3</sup>Paediatrics, Hospital for Sick Children, Toronto, ON, Canada*

Platelets are small blood cells that initiate and coordinate blood clotting at wound sites, where they adhere, aggregate and secrete an assortment of molecules in the process of blood clotting. Platelets contain specialized granules that secrete their contents upon platelet activation and are required for platelet function. The two distinct types of platelet granules (alpha-granules and dense-granules), originate by non-redundant developmental pathways. We have shown that vacuolar protein sorting protein 33B (VPS33B), a member of the Sec1/Munc18 protein family predicted to interact with SNAP (Soluble NSF Attachment Protein) receptor (SNARE) proteins to facilitate docking and fusion of intracellular vesicles, is required for alpha-granule biogenesis. Recently we have identified another protein, VPS16B, which interacts with VPS33B. Our laboratory has also shown that VPS16B is required for platelet alpha-granule biogenesis. Using blue native gel analysis, we have determined that the VPS33B-VPS16B subunits exist as part of larger complexes (480 kDa and 720 kDa). My research entailed identifying additional components of the VPS33B-VPS16B complex and characterizing the role of these interactions in platelet alpha-granule formation. The identification of potential interacting proteins was done

through yeast hybrid assays combined with affinity purification and mass-spectrometry. Results from a Yeast-3-Hybrid assay using VPS16B as bait and VPS33B as the bridge indicated several interesting candidates that function within the Golgi-endosome trafficking pathway, such as COG1/5 (Conserved Oligomeric Golgi complex protein) and VPS52 (part of Golgi associated retrograde protein (GARP) complex). Further experiments are currently underway to confirm these interactions. Preliminary co-immunoprecipitation results indicate that VPS52 interacts with VPS16B in the 720kDa complex. Interestingly, blue native gel analysis of purified VPS33B-VPS16B complexes showed that the two proteins are capable of forming multimeric complexes by themselves (240 kDa and 480kDa). Further studies are currently underway to investigate the structure and function of these large complexes in alpha-granule biogenesis.

540

**Vacuole Size Scaling in Budding Yeast is Maintained by a Balance between Synthesis and Inheritance.**

Y-H. M. Chan<sup>1</sup>, W. F. Marshall<sup>1</sup>; <sup>1</sup>UC San Francisco, San Francisco, CA

Organelle size, including that of lysosomes, impacts function and is therefore regulated by the cell. However, relatively little is known about how lysosome size is kept in balance with the overall cell size. To address this question, we have developed a computational image analysis method to quantitatively measure the size of budding yeast vacuoles/lysosomes. Wild-type yeast show characteristic scaling trends when comparing vacuole and cell size. These trends are altered in membrane trafficking and inheritance mutants, showing that these are key pathways in determining vacuole size. The mutant *vac8Δ* is defective in normal inheritance of the vacuole from the mother to the bud during the cell cycle. Interestingly, even though daughters begin with smaller vacuoles, the population as a whole shows increased vacuole size scaling. Timecourse analysis reveals that vacuole is continuously generated in *vac8Δ* at rates comparable to wild-type despite the defect in delivery to the bud. Repeated cell cycles leads to accumulation of the generated vacuole in the mother and an age-dependence of vacuole-to-cell size scaling. These results are consistent with a model where wild-type organelle size scaling arises passively from consistent cell and vacuole growth patterns rather than through active regulatory mechanisms. Pulse-chase fluorescence labeling will be applied to determine the contributions of de novo synthesis and inheritance to determining vacuole size.

541

***Saccharomyces cerevisiae* Env7 is a palmitoylated serine/threonine kinase 16 (STK16)-related protein kinase and negatively regulates organelle fusion at the lysosomal vacuole.**

S. P. Manandhar<sup>1</sup>, F. Ricarte<sup>1</sup>, S. M. Cocca<sup>1</sup>, E. Gharakhanian<sup>1</sup>; <sup>1</sup>Biological Sciences, California State University, Long Beach, CA

Membrane fusion depends on conserved components and is responsible for organelle biogenesis and vesicular trafficking. Yeast vacuoles are dynamic structures analogous to mammalian lysosomes and serve as a model for membrane fusion and fission. Here we report that Env7 is a novel yeast palmitoylated protein kinase ortholog that negatively regulates vacuolar membrane fusion. Microscopic and biochemical studies confirm localization of tagged Env7 at vacuolar membrane via palmitoylation of N-terminal cysteine residues. Using custom prepared polyclonal anti-Env7 antibodies, we also show that wild-type Env7 is endogenously expressed at detectable levels and localized to vacuolar membrane. *in vitro* kinase assays of Env7 expressed in yeast as well as *E. coli* establish Env7 as a protein-kinase capable of autophosphorylation and phosphorylation of exogenous substrates. Site-directed mutagenesis

of Env7 'APE' motif Glu269 residue to Alanine (E269A) results in an unstable kinase-dead allele; Env7-E269A is stabilized and redistributed to detergent resistant fraction by interruption of proteasome system *in vivo*. Palmitoylation-deficient Cys13-15Ser mutant Env7 is cytoplasmic and lacks kinase activity suggesting that membrane association is necessary for Env7 kinase activity. Microscopic studies establish that *env7Δ* is defective in maintaining fragmented vacuoles during hyperosmotic response and in buds. *ENV7* function is not redundant with similar role of vacuolar membrane kinase Yck3 as the two do not share a common substrate, and *ENV7* is not a suppressor of *yck3Δ*. Bayesian phylogenetic analyses strongly support *ENV7* as an ortholog of human STK16, a Golgi protein kinase with undefined function. We propose that Env7 function in fusion/fission dynamics may be conserved within the endomembrane system and regulated by interplay of post-translational modifications.

542

**Lysosome tubules represent a more motile lysosome population and require the Arl8b and Rab7 GTPases for tubulation.**

A. Mrakovic<sup>1</sup>, J. Kay<sup>2</sup>, W. Furuya<sup>2</sup>, R. J. Botelho<sup>1</sup>; <sup>1</sup>Chemistry and Biology, Ryerson University, Toronto, ON, Canada, <sup>2</sup>Program in Cell Biology, Hospital for Sick Children, Toronto, ON, Canada

Lysosomes are essential organelles involved in many cellular functions including the breakdown of endocytic and biosynthetic cargo, pathogen killing, autophagy and even membrane repair. In most cells, lysosomes typically appear as small, punctate structures under the fluorescence microscope. By contrast, LPS-activated macrophages possess strikingly tubular lysosomes (TLs). TLs are suggested to play a role in phagosome maturation and retention of fluid-phase endocytic uptake in activated macrophages. In addition, LPS-activated dendritic cells form tubular MHC-II compartments, which are lysosome-related organelles and that may be involved in antigen presentation. However, remarkably little else is known about how TLs form and function. Therefore, we have initiated pioneering studies on the molecular requirements for lysosome tubulation in macrophage cell lines. Our work confirmed the requirement for microtubules as a template necessary for tubulation, along with both dynein and kinesin microtubule-dependent motors. In addition, we identified the first molecular components needed for lysosome tubulation; TL biogenesis required the concerted action of the Arl8b GTPase, along with its effector SKIP, a kinesin-adaptor protein, and the Rab7 GTPase, along with its effectors RILP and FYCO1, which are adaptor proteins for dynein and kinesin, respectively. Most importantly, we observed that TLs are highly dynamic structures that are almost always moving, whereas punctate lysosomes are conspicuously more static. We postulate that the more dynamic nature of TLs will lead to higher rates of endocytic content acquisition and lysosomal content exchange, which may have consequences for antigen delivery, sharing and processing within the lysosomal population.

543

**Rab11FIP1 interacts with the BLOC-1 complex to retrieve melanogenic proteins from the recycling pathway and a dominant negative mutation in *RAB11FIP1* causes Hermansky-Pudlak Syndrome Type 10 (HPS-10).**

A. R. Cullinane<sup>1</sup>, M. A. Merideth<sup>1</sup>, J. Pan<sup>1</sup>, J. A. Curry<sup>1</sup>, J. G. White<sup>2</sup>, M. Huizing<sup>1</sup>, W. A. Gahl<sup>1</sup>; <sup>1</sup>Medical Genetics Branch, NHGRI, NIH, Bethesda, MD, <sup>2</sup>Department of Laboratory Medicine, University of Minnesota, Minneapolis, MN

Hermansky-Pudlak Syndrome (HPS) is a genetically heterogeneous disorder of lysosome-related organelle (LRO) biogenesis and is characterized by oculocutaneous albinism and a bleeding diathesis. There are currently 9 known genes that cause HPS; all of whose protein

products function in the biogenesis of LROs. The Biogenesis of Lysosome related Organelle Complex 1 (BLOC-1) contains 8 subunits but relatively little is known about the intracellular function of the complex, although a role in endosomal protein sorting has been suggested. Using his-tagged BLOC-1 subunits expressed in HEK293 cells and mass spectroscopy, we discovered that Rab11FIP1 is a novel interacting protein of the BLOC-1 complex. *RAB11FIP1* encodes a Rab11a interacting protein that homo-dimerizes to interact with Rab11a. A yeast-2-hybrid assay showed that the Dysbindin subunit of BLOC-1 directly interacts with Rab11FIP1; this was confirmed by co-immunoprecipitation and confocal immunofluorescence microscopy in melanocytes. Here we report a girl who had previously been screened for mutations in HPS-1 through HPS-6 and all the genes encoding the BLOC-1 complex. No mutations were found, although the patient had typical signs and symptoms of HPS and a cellular phenotype mimicking that of BLOC-1, i.e., increased plasma membrane cycling and endosomal accumulation of a melanogenic protein, TYRP1. Whole exome sequencing revealed a *de novo* heterozygous frameshift mutation in *RAB11FIP1*. The short protein fragment from this allele was expressed and interacted with the full-length protein, resulting in a dominant negative effect. Known cargos of the BLOC-1 complex in melanocytes are TYRP1 and ATP7A. How these cargos traffic to LROs was unknown, but we discovered that GFP-TYRP1 traffics to the plasma membrane, is endocytosed and only then directed to LROs. We demonstrated that TYRP1 interacts with the AP-1, AP-2 and AP-3 complexes, allowing this trafficking to occur. ATP7A, however, appears to traffic directly to endocytic vesicles, where Rab11FIP1 and the BLOC-1 complex are required for retrieval to LROs. Taken together, these data suggest a function of the BLOC-1 complex in retarding protein recycling by forming a physical brake between early endosomes (through the BLOC-1 interactor, Syntaxin-13) and recycling endosomes (through the BLOC-1 interactor, Rab11FIP1). This would allow more time for proteins to be retrieved from the endosomal compartment (by the AP-3 complex) and directed to LROs.

### Establishing *Drosophila* S2 cells as a system for genetic studies of exosome/microvesicle biogenesis.

J-M. Yang<sup>1</sup>, S. J. Gould<sup>1</sup>; <sup>1</sup>Department of Biological Chemistry, Johns Hopkins University, Baltimore, MD

Animal cells secrete small, membrane-bound vesicles that have the same topology as the cell. These vesicles, termed exosomes/microvesicles (EMVs), mediate cellular signaling events with their capability to shuttle proteins, lipids, and RNAs among cells. EMVs are implicated in a wide variety of both normal biological processes and pathological conditions. However, despite their biomedical importance, little is known about the factors involved in EMV biogenesis. *Drosophila* S2 cells have emerged as an important experimental system for understanding basic cell biological processes, and here we report their use as a system to study EMV biogenesis. Using S2 cells that express two EMV cargo proteins, CD63-GFP and AcylTyA-GFP, we screened a variety of candidate genes for their roles in EMV biogenesis. Our results indicate that CD63-GFP budding is inhibited by the actin network, is independent of the endocytosis process, is ESCRT-independent, and is impaired by the depletion of Rab1, Rab6, and Fwd (a *Drosophila* PI4K) proteins. Similar results were also seen for the budding of AcylTyA-GFP. Taken together, these observations establish the usefulness of *Drosophila* S2 cells as a system for studying EMV biogenesis and provide novel insights on the EMV biogenesis pathway.

### Type II phosphatidylinositol 4-kinase regulates trafficking of secretory granule proteins in *Drosophila*.

C-I. J. Ma<sup>1,2</sup>, J. Burgess<sup>2,3</sup>, L. M. Del Be<sup>2,3</sup>, B. Barylko<sup>4</sup>, G. Polevoy<sup>2</sup>, J. Rollins<sup>5</sup>, J. P. Albanesi<sup>4</sup>, H. Krämer<sup>6</sup>, J. A. Brill<sup>1,2,3</sup>; <sup>1</sup>Institute of Medical Science, University of Toronto, Toronto, ON, Canada, <sup>2</sup>Program in Cell Biology, Hospital for Sick Children, Toronto, ON, Canada, <sup>3</sup>Department of Molecular Genetics, University of Toronto, Toronto, ON, Canada, <sup>4</sup>Department of Pharmacology, UT Southwestern Medical Center, Dallas, TX, <sup>5</sup>Division of Natural Sciences, The College of Mount Saint Vincent, Riverdale, NY, <sup>6</sup>Department of Neuroscience, UT Southwestern Medical Center, Dallas, TX

Type II phosphatidylinositol 4-kinase (PI4KII) is responsible for production of the lipid phosphatidylinositol 4-phosphate (PI4P), a crucial resident of Golgi membranes that regulates membrane trafficking events such as secretion. PI4KII function is required for normal development of the *Drosophila* larval salivary gland. In PI4KII mutants, mucin-containing glue granules were considerably smaller than in wild type. Furthermore, PI4KII formed dynamic tubular networks along microtubules. Portions of these tubules colocalized with late endosomes and lysosomes marked with YFP-Rab7 and GFP-LAMP, suggesting these PI4KII positive tubules were dynamic endosomal structures. In PI4KII mutants, these PI4KII positive tubular structures were absent and enlarged lysotracker positive endosomes were observed instead. These enlarged acidic late endosomes/lysosomes contained mucin cargo proteins as well as the glue granule associated SNARE SNAP24. Our data thus far suggested that PI4KII function is required for the proper trafficking of granule proteins, where mistrafficked granule proteins accumulated in the late endosome. To further examine the role of PI4KII in granule biogenesis, we employed a reverse genetic screen to identify potential genetic interactions using publicly available transgenic RNAi lines. A selection of candidate genes including Rabs, SNAREs, synaptotagmins, and BAR domain containing proteins were screened. Interestingly, RNAi directed against early endosome associated Rab5 resulted in a more severe phenotype, where the salivary glands were immature and granule protein expression was scarce. Although PI4KII partially colocalized with Rab7, Rab7 RNAi showed no changes in granule size. In contrast, early endosome associated SNARE Syntaxin13 (Syx13) RNAi generated a similar phenotype to PI4KII mutants. Our screen results suggest that PI4KII activity may affect how proteins are trafficked from the early endosome, leading to potential defects in vesicular homotypic fusion facilitated by the Syx13 SNARE complex.

### Dual role of the Arf1 exchange factor GBF1 in lipid and vesicular trafficking.

S. Bouvet<sup>1</sup>, M-P. Golinelli-Cohen<sup>1</sup>, C. L. Jackson<sup>1</sup>; <sup>1</sup>Institut Jacques Monod, CNRS - Université Paris Diderot-Paris7, Paris, France

Lipid droplets are dynamic organelles that interface with membrane trafficking pathways, and are involved in lipid homeostasis and signaling (Farese and Walther, 2012). The Arf1 exchange factor GBF1, its substrate Arf1 and effector COPI regulate trafficking both in the early secretory pathway, and in trafficking of a subset of LD resident proteins from the ER to the LD surface. In addition to their well-characterized localization to ER-Golgi intermediate compartment (ERGIC) and Golgi membranes, GBF1, Arf1 and COPI localize as well to the region surrounding LDs by fluorescence microscopy. We determined by thin section electron microscopy and tomography that bilayer ERGIC membranes are in close proximity to the LD surface (Soni et al., 2009). These results raise two interesting questions. First, do GBF1, Arf1 and COPI bind directly to the phospholipid monolayer of LDs, or are they only associated with bilayer ERGIC membranes in close proximity? Second, what localization determinants direct GBF1 either to LDs or to the

Golgi? We are exploring these questions using in vivo and in vitro approaches. We have identified a domain of GBF1 that binds directly to both liposomes and phospholipid monolayer droplets in vitro, and which localizes on its own to LDs in cells. This domain, called HDS1, is located downstream of the catalytic Sec7 domain. The N-terminal region of GBF1 upstream of the Sec7 domain is required for Golgi localization of GBF1. The Sec7 domain itself appears to be a major determinant for bilayer membrane localization, since the tandem Sec7-HDS1 does not localize to LDs, but rather to perinuclear membranes in cells.

**Hormone-sensitive lipase Ser660 phosphorylation is responsible for shrinking of lipid droplets in adipocytes.**

*M. Nagayama<sup>1</sup>, K. Shimizu<sup>2</sup>, T. Taira<sup>2</sup>, T. Uchida<sup>1</sup>, K. Gohara<sup>1</sup>; <sup>1</sup>Division of Applied Physics, Faculty of Engineering, Hokkaido University, Sapporo, Japan, <sup>2</sup>Primary Cell Co., Ltd., Sapporo, Japan*

Lipid droplet (LD) is the most characteristic organelle of adipocytes and is recognized as highly dynamic organelle that plays a crucial role in regulating energy homeostasis in living organisms. When adipocytes are stimulated with catecholamines, triglyceride stored in LDs is hydrolyzed (lipolysis) and released as free fatty acid and glycerol from the cells. To date, numerous studies on the complicated molecular processes involved in lipolysis have revealed that hormone-sensitive lipase (HSL), which possesses multiple phosphorylation sites, is the major rate-limiting lipase in the catecholamine-stimulated lipolysis. However, there are only few studies on the morphological changes of LDs in adipocytes during catecholamine-stimulated lipolysis. Thus, in the present study, we clarified the relationship between various phosphorylated forms of HSL and morphological changes such as shrinking of LDs.

The study used adipocytes differentiated from primary preadipocytes or 3T3-L1 cells in vitro. At first, we performed time-lapse observation of adipocytes stimulated with norepinephrine (NE) using a DIC microscope to investigate morphological changes of LDs. In 35% adipocytes, large LDs ( $\approx 10 \mu\text{m}$ ) shrunk from immediately to several hours after NE stimulation, and a part of them disappeared. We next performed immunofluorescence staining of HSL phosphorylated at either serine residues 563 (p-Ser563), 565 (p-Ser565), or 660 (p-Ser660). Without NE stimulation, p-Ser563 and p-Ser660 were hardly detected, while p-Ser565 was distributed throughout the cytoplasm. At 15 min after NE stimulation, the three phosphorylated forms were localized on the surface of LDs. At 6 h after the stimulation, p-Ser563 and p-Ser565 were hardly detected and dissociated from the LDs surface, respectively. On the other hand, marked localization of p-Ser660 on the surface of LDs was maintained even at 6 h after the stimulation, corresponding to the time course of LDs shrinking. In summary, these results suggest that the phosphorylation of HSL at serine residue 660 as well as translocation/localization of HSL on the LD surface is responsible for shrinking of LDs in adipocytes during catecholamine-stimulated lipolysis.

**Ldb16 associates with Fld1/seipin to control lipid droplet size in budding yeast.**C-W. Wang<sup>1</sup>, C-W. Wang<sup>1</sup>; <sup>1</sup>Institute of Plant and Microbial Biology, Academia Sinica, Taipei, Taiwan

The rare human disease congenital generalized lipodystrophy (CGL) is linked to mutations in BSCL2/seipin. While the molecular function of seipin is unknown, knocking-out the yeast seipin homolog FLD1 results in the accumulation of supersized lipid droplets (LDs) and altered lipid homeostasis. Here, we provide evidence for a protein termed Ldb16 that works in concert with Fld1 in yeast. Ldb16 null mutant accumulated supersized LDs and showed aberrant lipid profiling similar to that found in *fld1Δ*. Like Fld1, Ldb16 is a transmembrane protein localized to the endoplasmic reticulum (ER), and most importantly these membrane proteins assembled on the ER to mark a unique subdomain that makes contacts with LDs, a region that is believed to link neutral lipid synthesis and LD assembly. We found that Ldb16 interacts with Fld1 through its hydrophobic segments and the interaction is crucial for the control of LD morphology. Moreover, we revealed that Ldb16 is a natural substrate for ER-associated degradation (ERAD) and is stabilized when Fld1 is present. Together, our findings suggest for the first time that Fld1/seipin might regulate LD homeostasis through assembling together with other ER transmembrane protein like Ldb16 to scaffold the channel opening complex at the ER/LD contact site for the LD size control.

**Enhancer Mutagenesis Screen Yields Genetic Interactions between the BBSome and Transition Zone Complexes.**S. Henke<sup>1</sup>, S. Masyukova<sup>1</sup>, C. Williams<sup>2</sup>, D. Landis<sup>1</sup>, J. Pieczynski<sup>3</sup>, B. Yoder<sup>3</sup>; <sup>1</sup>Genetics and Genomics, University of Alabama at Birmingham, Birmingham, AL, <sup>2</sup>University of Michigan, Ann Arbor, MI, <sup>3</sup>CMDB, University of Alabama at Birmingham, Birmingham, AL

The cilium is a specialized signaling organelle essential for vertebrate development. Mutations disrupting its function result in a group of human diseases, termed *ciliopathies*. The cilium's signaling capabilities rely on maintaining a unique protein composition distinct from both the cell cytosol and membrane. To achieve this distinction, a diffusion barrier is believed to be established at the cilium's base. This subcellular region is called the transition zone (TZ) and is thought to help establish the cilia as a signaling compartment. Further evidence of this is found in ciliopathy mutations such as those observed in both Meckel-Gruber Syndrome (MKS) and Nephronophthisis (NPHP) which affect TZ proteins; emphasizing the importance of the sub-domain in which they localize. While TZ dysfunction is associated with disease its exact function remains elusive. *Nphp-4* is a well characterized TZ protein associated with NPHP; and unlike many ciliary proteins, the loss of this protein does not affect the ability for the ciliated sensory neurons of *C. elegans* to dye-fill. Here we utilize *C. elegans* in a mutagenesis screen to generate mutations that cause a dye-filling defective phenotype in a manner dependent on a background mutation in *nphp-4*. We aimed to identify novel TZ interactors to better understand the function of this sub-domain. The results uncovered exciting genetic interactions between *nphp-4* and proteins associated with both MKS and the ciliopathy Bardet-Biedl Syndrome (BBS). Thus, identification of genes from this screen has provided potential loci for human ciliopathies and new proteins that function with NPHP and MKS to establish the TZ.

**Regulated translocation of a cell surface membrane protein into the ciliary/flagellar membrane in *Chlamydomonas* relies on microtubule-dependent concentration at the flagellar base and is independent of intraflagellar transport.**

C. I. Hernandez-Lara<sup>1</sup>, O. Belzile<sup>1</sup>, Q. Wang<sup>1</sup>, A. Sahu<sup>1</sup>, W. J. Snell<sup>1</sup>; <sup>1</sup>Cell Biology, University of Texas Southwestern Medical Center, Dallas, TX

Key developmental pathways in multicellular animals depend on the cellular compartment created by the primary cilium/flagellum, yet we know little about the mechanisms that specify the membrane protein composition of this important sensory organelle. Intraflagellar transport (IFT), which carries soluble, axoneme-associated proteins to and from the cilium/flagellum, is implicated in regulating ciliary membrane protein composition, but whether cytoplasmic microtubules and anterograde IFT are essential for movement of membrane proteins from cell body plasma membrane into the flagellar membrane is unknown. Here, in immunolocalization/cell fractionation studies with an epitope-tagged form of the *Chlamydomonas* membrane protein SAG1, we report that a SAG1-derived polypeptide is homogeneously distributed on the cell body plasma membrane of resting gametes, and de-enriched in the flagellar membrane. Upon signaling triggered during fertilization, the cell body SAG1 polypeptide undergoes a striking and rapid (~ 5-10 min) redistribution to become concentrated in the cell membrane at the base of the flagella, followed by rapid translocation into the flagellar membrane. In a mechanism regulated by cell-cell interactions, the SAG1 polypeptide is shed into the medium in a novel flagellar membrane fraction that is de-enriched in known flagellar proteins, including the major membrane protein, FMG, and IFT complex proteins. Cytoplasmic microtubules facilitate SAG1 polypeptide translocation to the flagella and are required for SAG1 enrichment at the base of the flagella. Use of a conditional IFT kinesin 2 mutant indicates that both SAG1 polypeptide enrichment at the flagellar base and translocation into the flagellar membrane are independent of kinesin 2. Our work demonstrates that trafficking of a membrane protein between the cell body and the flagellum can be one-way; and that, unlike transport of most axoneme-associated proteins, translocation of an integral membrane protein into the flagellar membrane is independent of anterograde IFT.

551

**Comparative proteomics of half-length with full-length flagella reveals tip proteins required for flagellar assembly in *Chlamydomonas* and ciliogenesis in vertebrate cells.**

T. V. Tammana<sup>1</sup>, D. Tammana<sup>1</sup>, D. Diener<sup>1</sup>, J. Rosenbaum<sup>1</sup>; <sup>1</sup>Department of MCDB, Yale University, New Haven, CT

Ciliary tips are important hubs where IFT is re-structured from anterograde to retrograde trains, cargo is released for cilia assembly, motor exchange occurs and turnover products are picked up for return to the cell body. Also at the tip, structures of unknown function are inserted into the ends of A-tubules of the outer doublets, each with a filament linked to the ciliary membrane. To identify proteins that constitute these ciliary structures as well as proteins involved in IFT turnover at the tip we carried out quantitative, comparative proteomic analysis (iTRAQ) of half-length with full-length flagella in *Chlamydomonas*, based on the hypothesis that proteins localized at the flagellar tip will be enriched ca. two-fold in half-length flagella. Such a comparative study is possible only in *Chlamydomonas*, as isolation of intact half-length and full-length flagella can be easily done. The proof of principle for this approach is that CrEB1, a known flagellar tip protein in *Chlamydomonas*, is enriched two fold in half-length flagella. As proteins involved in flagellar assembly could be enriched in the flagellum during growth, we also found several known proteins like IFT polypeptides and motors with increased abundance in

short flagella. Localization studies on eleven candidate proteins that have close human homologues using mammalian antibodies were done in RPE1 cells in tissue culture. Five of these candidate proteins were localized to basal bodies and one, CEP104, localized to the ciliary tip and daughter centrioles. In actively growing RPE1 cells, CEP104 localizes at one end of each centriole throughout the cell cycle. Upon induction of ciliation by serum starvation, CEP104 from the mother centriole moves to the tip of the cilium. It remains at the ciliary tip during ciliary growth and resorption. The daughter centriole retains a cap of CEP104 during ciliary growth and centrosomal separation. Depletion of this protein using CEP104-siRNAs inhibits ciliogenesis in RPE1 cells. The *Chlamydomonas* homologue of CEP104, FAP256 also localizes to flagellar tips and an insertional mutant of FAP256, (Roc22) is defective in flagellar growth and regeneration, indicating its conserved role in flagellar assembly. Together, these results indicate that conserved tip proteins important for ciliogenesis in vertebrate cells can be identified through this proteomic approach in *Chlamydomonas*. Support-(NIH-GM14642)/JR

### **Eyespot Assembly in *Chlamydomonas reinhardtii* After Cell Division.**

T. M. Mittelmeier<sup>1</sup>, M. D. Thompson<sup>1</sup>, C. L. Dieckmann<sup>1</sup>; <sup>1</sup>Molecular and Cellular Biology, University of Arizona, Tucson, AZ

*Chlamydomonas reinhardtii* is a biflagellate unicellular green alga that uses an organelle known as the eyespot to sense light and direct phototaxis. The eyespot is a complex structure that requires coordinated contributions from the plasma membrane and chloroplast. The eyespot disassembles and forms *de novo* after each cell division at the equator of the cell, near the tip of the plus end of the daughter four-membered (D4) rootlet. The D4 rootlet is one of two highly acetylated rootlets that emanate from the region around each basal body at the anterior of the cell. Fluorescence microscopy with antibodies targeted against acetylated tubulin, photoreceptors ChR1 and ChR2, chloroplast envelope protein EYE2, and pigment granule protein EYE3, suggests that ChR photoreceptors are directed by the D4 rootlet to the equator of the cell where they interact with the other eyespot proteins to assemble an eyespot. The order of assembly of eyespot proteins is unknown, and is a focus of our current research. In dividing wild-type cells, ChR1/ChR2 and EYE2 patches are not observed at the position of eyespot formation until the D4 rootlet has extended to the equator of the cell. The patches of ChR1/ChR2 and EYE2 remain at the equator and enlarge as the D4 rootlet extends to the posterior of the cell and recedes back to the position of eyespot formation at the equator. In dividing *mlt1* (multi-eyed) mutant cells, an EYE2 patch positions properly in the absence of ChR1/ChR2, which accumulate at the anterior of the cell. These data suggest that ChR1/ChR2 do not regulate eyespot placement. Efforts are currently focused on: 1) isolating a double mutant defective in ChR1 and ChR2 (*cop3 cop4*), and, 2) identifying proteins that interact with EYE2. These approaches will help to more precisely define the role of these proteins in eyespot assembly and placement. Also under way is a screen designed to identify other potential regulators of eyespot assembly and/or placement.

553

### **Mitochondrial fission and fusion in *Dictyostelium discoideum*: a search for proteins involved in membrane dynamics.**

B. G. Schimmel<sup>1</sup>, G. W. Berbusse<sup>1</sup>, K. Naylor<sup>1</sup>; <sup>1</sup>Biology, University of Central Arkansas, Conway, AR

Mitochondrial morphology is maintained by two distinct membrane events -fission and fusion. Altering these conserved processes can disrupt mitochondrial morphology and distribution,

thereby disrupting the organelle's functionality and impeding cellular function. In higher eukaryotes, these processes are mediated by a family of dynamin-related proteins (DRP's). In the lower eukaryotes, for instance *Dictyostelium discoideum*, mitochondrial fission and fusion have been implicated but not yet established. To understand the overall mechanism of these dynamics across organisms, we developed an assay to identify fission and fusion events in *Dictyostelium* and to assess the involvement of the mitochondrial proteins, MidA, CluA, and two DRPs, DymA and DymB. Using laser scanning confocal microscopy to observe real time movement of fluorescently labeled *D. discoideum* mitochondria, we show, for the first time, that lower eukaryotes mediate mitochondrial fission and fusion. In *D. discoideum*, these processes are balanced, occurring approximately 1 event/minute. Quantification of the rates of fission and fusion in *midA*-, *cluA*-, *dymA*-, or *dymB*- strains established that MidA appears to play an indirect role in the regulation of fission and fusion, while the DRP's are not essential for these processes. Rates of fission and fusion were significantly reduced in *cluA*- cells, indicating that CluA is necessary for maintaining both fission and fusion. We have successfully demonstrated that *D. discoideum* mitochondria undergo the dynamic processes of fission and fusion. The classical mediators of membrane dynamics, the DRP's, are not necessary for these dynamics, whereas CluA is necessary for both processes. This work contributes to our overall understanding of mitochondrial dynamics and ultimately will provide additional insight into mitochondrial disease.

554

#### The formin INF2 mediates a novel actin-dependent step in mitochondrial fission.

F. V. Korobova<sup>1</sup>, V. Ramabhadran<sup>1</sup>, H. N. Higgs<sup>1</sup>; <sup>1</sup>Biochemistry, Geisel School of Medicine at Dartmouth, Hanover, NH

Mitochondrial fission is a fundamental process in cellular physiology, playing roles in cellular and mitochondrial health, apoptosis, and the proper function of many cell types such as neurons and cardiac muscle. Current understanding is that the dynamin-related GTPase Drp1 mediates fission, but the exact mechanism of mitochondrial division is unclear. In particular, the mechanism by which Drp1 is brought to the constriction site is unknown in mammals. A recent study showed that fission occurred at sites where mitochondria contacted endoplasmic reticulum (ER) and that, even in mammalian cells blocked for fission by a dominant-negative Drp1 construct, mitochondria still partially constricted at ER contact sites. Our results show that the ER-bound isoform of the formin INF2 (INF2-CAAX) is required for efficient mitochondrial fission in mammalian cells. Suppression of INF2-CAAX by siRNA results in a 2-fold increase in mitochondrial length, whereas expression of a dominant active INF2-CAAX construct (INF2-DA) results in a 2-fold decrease. Live-cell confocal microscopy shows that INF2-DA causes tight ER-mitochondria association, a decrease in mitochondrial motility, and an increase in fission events. INF2 does not interact with Drp1 but functions up-stream of Drp1, since the number of mitochondrially-associated Drp1 puncta correlate with INF2 expression levels and since dominant-negative Drp1 blocks INF2-DA's ability to decrease mitochondrial length. INF2's effects on mitochondria depend on its actin polymerization ability. The actin sequestering drug Latrunculin B or an actin polymerization-deficient INF2 mutant block the effects of INF2-DA on mitochondria size. Careful examination shows that actin filaments accumulate at mitochondrial constriction sites, between mitochondria and INF2-enriched ER membranes. These results lead to a model whereby INF2-induced actin filaments mediate initial constriction of the mitochondrial outer membrane. This initial constriction stimulates Drp1 accumulation at the constriction site, leading to a secondary, Drp1-dependent constriction and fission. Thus, we link for the first time actin polymerization with the mitochondrial fission process. This process has interesting

parallels to and differences with endocytic vesicle fission, which is also mediated by actin polymerization and a dynamin GTPase.

555

**Determining the role of CluA in mitochondrial distribution in *Dictyostelium discoideum*.**

C. McGee<sup>1</sup>, B. G. Schimmel<sup>1</sup>, A. Nsereko<sup>1</sup>, G. W. Berbusse<sup>1</sup>, K. Naylor<sup>1</sup>; <sup>1</sup>Biology, University of Central Arkansas, Conway, AR

Mitochondrial distribution in the social amoeba *Dictyostelium discoideum* is dependent upon CluA. Lack of CluA, or its homologs, produces mitochondrial clustering in various organisms. In budding yeast, mitochondrial fission defects result in highly interconnected mitochondria that cluster to one side of the cell. Therefore to clarify the function of CluA, we determined the rates of fission and fusion in *cluA*- cells. Unexpectedly, we observed that CluA is necessary for both fission and fusion with rates in *cluA*- cells about half that of a wild-type cell.

Studies of flies and plants suggest that CluA regulates mitochondrial movement along the cytoskeleton. In order to explore how CluA regulates both fission and fusion, we want to determine if the cytoskeleton is necessary to establish mitochondrial clusters. It is possible that in the absence of CluA the mitochondria are transported by the cytoskeleton improperly to a central location resulting in the clusters. Alternatively, electron microscopy has shown that the mitochondria in *cluA*- cells are interconnected; perhaps the cytoskeleton is necessary to complete the fission and fusion events in these cells. It has been theorized that movement along the cytoskeleton may complete fission or fusion of the organelles.

We will analyze mitochondrial morphology in *cluA*- cells treated with cholchicine and latrunculin-A. Using time-lapse confocal microscopy, we will also determine the dynamics, distance, and direction of mitochondrial movement in wild-type and *cluA*- cells, to see whether mitochondria move randomly or directionally, such as along cytoskeletal tracks in these cells. We expect that, if the cytoskeleton is necessary to establish this clustered phenotype, disruption of the cytoskeleton will allow the mitochondria to scatter throughout the cell. If the cytoskeleton is necessary to complete fission or fusion, we expect the clustered mitochondria to remain unchanged. The results from these experiments will provide insight into how CluA determines mitochondrial distribution either through a cytoskeletal dependent mechanism or by functioning as a novel regulator of both fission and fusion.

## **Nuclear Bodies and Dynamics**

556

**Temporal alteration of nuclear structure and stiffness accompany gene expression changes from force and cytokine treatment.**

S. T. Spagnol<sup>1</sup>, E. A. Booth-Gauthier<sup>1</sup>, K. N. Dahl<sup>1</sup>; <sup>1</sup>Chemical Engineering, Carnegie Mellon University, Pittsburgh, PA

Genome regulation requires delicately balanced temporal and spatial control for proper cellular homeostasis and adaptation. Although DNA is a linear genetic code, recent studies have illuminated that genome organization within the nucleus aids in regulation, and there is evidence that gene translocation within the nucleus leads to differential expression. The correlation of gene expression with gene position and movement in the mechanically stiff nucleus suggests there may be mechano-coupling impacting gene expression. We examine the effects of

extracellular mechanical and biochemical stimulation on nuclear organization. In addition to the cellular chemical signaling cascades that activate nuclear transcription factors leading to gene expression, we examine time-dependent reorganization of nuclear structures, altered chromatin condensation, gene movement and altered gene expression. We consider the response of endothelial cells to extracellular shear stress; we observe a dose-dependent response of the nuclear interior, with transition states at 30 minutes after the application of stress. We also consider chemical stimulation with VEGF on endothelial cells. These chemical treatments similarly result in an effective intranuclear softening. This effective softening correlates with chromatin decondensation and nuclear reorganization. This decondensation is coupled with increased motor protein-driven cytoskeletal stress on the nucleus. We suggest that these cytoskeletal stresses increase nucleoplasmic agitation to enhance DNA and protein diffusion and, thus, collision frequency to drive the favorable binding events necessary for transcriptional activation. We observe a time-dependent response with significant attenuation in the VEGF response after 2.5 hours. Endothelial cells exposed to shear following VEGF stimulation showed aspects of both stimulated responses, with an effective intranuclear softening that paralleled VEGF stimulation and the transition in the time-dependent response at 30 minutes from shear. Understanding genome organization within the nucleus and the mechanisms underlying stimulated cellular transition states are vital to elucidating genome function. Our results indicate that the large changes in gene expression associated with mechanical and VEGF stimulation of endothelial cells correspond to an effective nuclear softening and changes in global chromatin condensation, rather than a purely localized and gene-specific effect. Thus, our work fortifies the dynamic view of the genome, suggesting stimulated gene repositioning and implying a role for externally imposed nuclear stresses in stimulated changes in gene expression.

557

#### **A novel role for Protein Kinase C in nuclear size regulation.**

L. J. Edens<sup>1</sup>, D. L. Levy<sup>1</sup>; <sup>1</sup>University of Wyoming, Laramie, WY

Cell and nuclear size are tightly regulated amongst species, cell types, developmental stages and disease states. During *Xenopus laevis* early embryonic development the single fertilized cell (~1mm diameter) divides into several thousand 50µm diameter and smaller cells with concomitant reductions in nuclear size. From the cleavage stage embryo through gastrulation, there is an approximate 8-fold reduction in nuclear envelope surface area. These drastic nuclear size changes occur without changes in DNA content per cell, suggesting nuclear size is regulated by yet unknown cytoplasmic factors. In order to discover developmentally regulated proteins that control nuclear size during *X.laevis* embryogenesis, we developed an assay whereby large nuclei assembled in egg extract shrink in the presence of late embryo extract. We hypothesize that phosphorylation of lamins, an integral structural component of the nuclear envelope, may be responsible for nuclear size changes. We tested whether specific kinases were necessary for nuclear shrinking in this assay. Selective inhibition of protein kinase C (PKC) with chelerythrine, but not cyclin-dependent kinase with olomoucine, blocked shrinking. Interestingly, during time course immunofluorescence experiments it was observed that nuclei resuspended in buffer shrink and re-expand while nuclei in late embryo extract only shrink, suggesting that late embryo extract inhibits nuclear re-expansion. This inhibition of re-expansion is PKC-dependent as addition of chelerythrine promotes re-expansion. Furthermore, by depleting calcium and diacylglycerol, the most likely subfamily of PKC isozymes responsible for this activity has been identified. Future depletion or selective PKC isozyme inhibitor experiments will be performed to pinpoint a single isozyme that contributes to reducing nuclear size during developmental progression. We will use these data to alter nuclear size in a minimally invasive fashion in order to characterize the functional impacts of nuclear size modifications.

558

**Atomic force microscopy of the nucleus and nucleolus.**

L. F. Jimenez-Garcia<sup>1</sup>, L. T. Agredano-Moreno<sup>1</sup>, A. L. Zamora-Cura<sup>1</sup>, T. Nepomuceno-Mejía<sup>1</sup>, R. Lara-Martínez<sup>1</sup>, A. García-Senosiain<sup>1</sup>, G. Álvarez-Fernández<sup>1</sup>, R. J. Fragoso-Soriano<sup>1</sup>, M. Segura-Valdez<sup>1</sup>; <sup>1</sup>Cell Biology, UNAM, Mexico City, Mexico

Although nuclear structure, function and dynamics are well known by using different molecular and cellular approaches, few *in situ* studies have been done using atomic force microscopy. Here we present recent advances in this topic. We prepare samples of different sources as for transmission electron microscopy. Semithin sections are observed under atomic force microscopy. We have been able to recognize different substructures as chromatin, nucleolar dense fibrillar component and heterogeneous fibrillar centers. Also, Cajal bodies are seen under these conditions in some cells as tomato (*Lycopersicon esculentum*). In HeLa cells, interchromatin granule clusters were observed. Nanometric profiles of some nuclear territories as the nucleoplasm reveals zones similar to IGC. Nuclear structure of parasites as *Giardia lamblia*, *Entamoeba histolytica* and *Trypanosoma cruzi* are also shown. Discontinuities along nuclear envelope also indicates nuclear pores complexes (PAPIIT IN227810, CONACyT 180835, PAPIIME PE211412).

559

**New methods for quantitative immunolocalization reveal that stress and gold nanoparticles alter the functional organization of the nucleolus.**

M. Kodiha<sup>1</sup>, S. Boridy<sup>2</sup>, H. Mahboubi<sup>1</sup>, S. Shrivastava<sup>1</sup>, M. Frohlich<sup>1</sup>, S. Lee<sup>1</sup>, H. Su<sup>1</sup>, D. Maysinger<sup>2</sup>, U. Stochaj<sup>1</sup>; <sup>1</sup>Physiology, McGill University, Montreal, QC, Canada, <sup>2</sup>Pharmacology, McGill University, Montreal, QC, Canada

Nucleoli, the sites of ribosome biogenesis, are conspicuous compartments inside the nucleus that are composed of several thousand different proteins. Nucleoli are crucial for the proper execution of diverse cellular processes, many of which are directly relevant to human health. As such, nucleoli associate with key molecules that regulate cell cycle progression, apoptosis, the stress response and tumorigenesis. The molecular make up of nucleoli is highly dynamic and thus supports the rapid response to changes in cell physiology. This dynamic nature of nucleoli presents an obstacle to quantitative analyses of nucleolar proteins, and it demands powerful tools that measure the changes in composition and activities of the nucleolus under a wide variety of conditions. Although proteomics was indispensable to define the complexity of the nucleolar proteome, it is not efficient to examine those nucleolar processes that are highly dynamic or require large sample sizes. To achieve this goal, we developed novel quantitative immunofluorescence approaches that were combined with computer-based image analysis. These methods were used successfully to measure the association of fluorescent molecules with nucleoli. Our protocols provide robust, fast and reliable tools to analyze the functional organization of the nucleolus in a timely fashion. Importantly, these protocols are compatible with automated high throughput screening platforms, which permit simultaneous analyses of many of the biological processes that are located in nucleoli.

Here, we applied our protocols to define the effects of two different types of interventions on the functional organization of nucleoli. First, we selected heat shock as an environmental stress that is frequently experienced by living organisms. Second, we investigated the impact of gold nanoparticles, which have emerged as powerful tools for drug delivery, cellular imaging, biomedical diagnostics and therapeutics. Our results demonstrate that heat stress and gold nanoparticles alter the organization and function of the nucleolus. Furthermore, we show that the shape of gold nanoparticles is critical for their effect on the nucleolus.

Taken together, our research provides a novel platform to study the biology of the nucleolus. This platform combines quantitative immunofluorescence, computer-based image analysis and nanotechnology.

**Cohesin – A protein clip to fix the folds of the genome.**

*J. Zuin<sup>1</sup>, J. Dixon<sup>2</sup>, M. van der Reijden<sup>1</sup>, S. Thongjuea<sup>3</sup>, R. Brouwer<sup>4</sup>, G. van Cappellen<sup>5</sup>, W. van Ijcken<sup>6</sup>, B. Ren<sup>2</sup>, K. S. Wendt<sup>1</sup>; <sup>1</sup>Cell biology, Erasmus MC, Rotterdam, Netherlands, <sup>2</sup>Ludwig Institute for Cancer Research, La Jolla, CA, <sup>3</sup>Computational Biology Unit-Bergen Center for Computational Science and Sars Centre for Marine Molecular Biology, University of Bergen, Bergen, Norway, <sup>4</sup>Erasmus MC, Rotterdam, Netherlands, <sup>5</sup>Erasmus Optical Imaging Centre, Erasmus MC, Rotterdam, Netherlands, <sup>6</sup>Erasmus Center of Biomics, Erasmus MC, Rotterdam, Netherlands*

The cohesin complex is fundamental for all eukaryotes to ensure the stable transmission of the genome over numerous generations. To achieve this, cohesin tethers the replicates of the genome together to ensure proper identification and distribution of the copies during mitotic and meiotic cell divisions.

Starting with the genome-wide identification of cohesin-binding we realized that cohesin has more functions such as chromatin insulation (in cooperation with CTCF) [1] and transcriptional control and is important for chromosomal long-range interactions[2].

The chromatin fibre is organized in domains termed “fractal globules”[3] or “topological domains”[4] and CTCF is often found at the boundaries of these domains.

We aimed to investigate which role cohesin plays for the general organization of the chromatin fibre, especially whether cohesin is necessary to organize chromatin domains. To study this we have destroyed functional cohesin by protease cleavage which releases the cohesin complex from chromatin but not CTCF.

Using chromatin conformation capturing methods (4C and Hi-C) and 3D-FISH we have analyzed the impact of releasing cohesin from chromatin on chromatin structure genome-wide and in detail for the H19/IGF2 locus. By ChIP-sequencing and RNA-sequencing we will correlate these structural changes with altered cohesin binding and changes in gene activity. We will present the results of this study and discuss impact of our observations for the understanding of genome organization and cohesin function.

**Nucleography: Surveying the nuclear landscape.***K. V. Laster<sup>1</sup>, S. Kosak<sup>1</sup>; <sup>1</sup>Cell and Molecular Biology, Northwestern University, Chicago, IL*

In the mammalian nucleus, chromosomes are non-randomly organized in a cell-type specific manner. Using a murine hematopoietic progenitor cell model, our lab provided evidence that this cell-type specific chromosome organization is intimately correlated with gene expression. Specifically, we found that co regulated gene sets facilitate the establishment of emergent order in the nuclear architecture, suggesting that the differentiating nucleus functions as a self-organizing system. We have now extended our initial findings to human embryonic stem cells (hESCs), testing whether a similar phenomenon may underpin the loss of pluripotency during neuronal differentiation. Implementing a tendency based, bi-clustering algorithm on a multi-timepoint gene expression dataset, we observe that genomic order, as a function of entropy, is lost and regained over differentiation into committed neuronal precursor cells. This dynamic change in entropy is concomitant with phenotypic changes during the differentiation time course. We are investigating whether this modulation of gene expression at key timepoints is manifested in changes in global chromatin architecture utilizing a novel visualization technique. Using probe material generated from a micro-dissected nucleus, we expect to see increased variability in proximity of chromatin clusters at the entropic minima relative to the maxima. Additionally, we are examining the differential localization of specific genes involved in neuralization. These findings confirm that cellular differentiation is a highly dynamic process reflected at the level of genomic organization.

**Assistance of the SMN-complex component Unrip in snRNA 5' cap hypermethylation.***B. Boysen<sup>1</sup>, O. Gruss<sup>1</sup>; <sup>1</sup>DKFZ-ZMBH-Alliance, Heidelberg, Germany*

The survival of motor neurons (SMN) complex contributes to the biogenesis of small nuclear ribonucleoprotein particles (snRNPs). It binds snRNA and sm proteins in the cytoplasm and assembles the sm proteins in a ring-like structure around the snRNA. Afterwards it accompanies the snRNP on its import into the nucleus. Then the complex dissociates from the snRNP in the Cajal bodies. The SMN complex consists of nine different components, SMN, Gemin2-8 and Unrip. In contrast to other complex components Unrip dissociates at a certain step from the complex. It has been shown that Unrip leaves the SMN complex prior to accumulation of the SMN-snRNP-complex in nuclear Cajal bodies. However, whether Unrip dissociates prior or after nuclear import of the SMN-snRNP-complex is not yet fully clarified. Interestingly, loss of Unrip by RNAi causes an increase of nuclear as well as generation of cytoplasmic SMN foci. Here we show that Unrip is still part of the Snurportin-SMN import-complex and present our results about Unrip association with the complex. Furthermore fluorescence analysis upon Unrip knockdown reveals that the cytoplasmic foci depict an accumulation state of the SMN-snRNP-complex prior to 5' cap hypermethylation of the snRNA. Pulse-chase analysis indicates that loss of Unrip impairs 5' cap hypermethylation kinetics. Taken together our results show a contribution of Unrip in the process of snRNA 5' cap hypermethylation.

563

**Cell-Cycle-Dependent Structural Transitions in the Human CENP-A Nucleosome In Vivo.***M. Bui<sup>1</sup>, Y. Dalal<sup>1</sup>; <sup>1</sup>National Cancer Institute, National Institutes of Health, Bethesda, MD*

In eukaryotes, DNA is packaged into chromatin by canonical histone proteins. The specialized histone H3 variant CENP-A provides an epigenetic and structural basis for chromosome segregation by replacing H3 at centromeres. Unlike exclusively octameric canonical H3

nucleosomes, CENP-A nucleosomes have been shown to exist as octamers, hexamers, and tetramers. An intriguing possibility reconciling these observations is that CENP-A nucleosomes cycle between octamers and tetramers in vivo. We tested this hypothesis by tracking CENP-A nucleosomal components, structure, chromatin folding, and covalent modifications across the human cell cycle. We report that CENP-A nucleosomes alter from tetramers to octamers before replication and revert to tetramers after replication. These structural transitions are accompanied by reversible chaperone binding, chromatin fiber folding changes, and previously undescribed modifications within the histone fold domains of CENP-A and H4. Our results reveal a cyclical nature to CENP-A nucleosome structure and have implications for the maintenance of epigenetic memory after centromere replication.

#### **Nuclear Actin Filaments Inhibit Transcription.**

*L. Serebryanny<sup>1</sup>, M. Parilla<sup>1</sup>, C. J. Gottard<sup>2</sup>, P. de Lanerolle<sup>1</sup>; <sup>1</sup>Department of Physiology and Biophysics, University of Illinois: Chicago, Chicago, IL, <sup>2</sup>Department of Medicine, Northwestern University, Chicago, IL*

Why are there no actin filaments in the nucleus? Although the concentration of actin in the nucleus is above the critical concentration for polymerization, actin filaments are rarely detected in the normal interphase nucleus. Nevertheless, it has been established that nuclear actin has several important functions, including transcription by all three RNA polymerases, chromatin remodeling, and cell fate decisions. How actin performs these functions in the absence of filaments remains a mystery. Nuclear actin is thought to exist as monomers or in highly dynamic and short polymers, and the dynamic state of nuclear actin has been shown to be a crucial regulator of its nuclear functions. To more closely investigate the effects of nuclear actin dynamics on transcription, we have used several models to induce the formation of stable nuclear actin filaments and determined the effects of nuclear actin filaments on transcription. Targeting  $\alpha$ -catenin to the nucleus, or expressing V163M  $\alpha$ -actin, S14C  $\beta$ -actin or a sub-domain of supervillin results in the formation of nuclear actin filaments. Importantly, the presence of nuclear actin filaments strongly correlates with the accumulation of RNA polymerase II into large granules, a decrease in transcription, and alterations in chromatin structure. We are currently performing additional experiments to determine how G-actin impacts RNA polymerase II targeting in the nucleus. Our results provide insights into the function/polymerization relationship of nuclear actin and why, despite the propensity for actin to polymerize into filaments, it avoids doing so in the nucleus.

#### **Molecular dynamics of the survival of motoneuron (SMN) protein in the nucleus – mobilization of SMN in Cajal bodies.**

*B. Förthmann<sup>1,2</sup>, H. Brinkmann<sup>1</sup>, M. K. Stachowiak<sup>3</sup>, C. Grothe<sup>1,2</sup>, P. Claus<sup>1,2</sup>; <sup>1</sup>Neuroanatomy, Hannover Medical School, Hannover, Germany, <sup>2</sup>Center for Systems Neuroscience, Hannover, Germany, <sup>3</sup>Pathology and Anatomical Sciences, State University of New York, Buffalo, NY 14214, USA, Buffalo, NY*

The loss of survival of motoneuron (SMN) protein leads to Spinal Muscular Atrophy, a neurodegenerative disease affecting motoneurons. In the nucleus, SMN is associated with two types of nuclear bodies denoted as gems and Cajal Bodies (CBs). The 23 kDa isoform of Fibroblast growth factor-2 (FGF-2<sup>23</sup>) is a nuclear protein which binds to SMN and destabilizes the SMN-Gemin2 complex resulting in a decreased number of nuclear gems (Claus et al., 2003; Claus et al., 2004; Bruns et al., 2009). In the present study, we analyzed the effect of this FGF-2

isoform on CBs. We have shown that FGF-2<sup>23</sup> depletes SMN from CBs without affecting their general structure. FRAP analysis of SMN-EGFP in CBs demonstrated that the majority of SMN in CBs remained mobile and allowed quantification of fast, slow and immobile nuclear SMN populations. The potential for SMN release was confirmed by in vivo photoconversion of SMN-Dendra2, indicating that CBs concentrate immobile SMN that could have a specialized function in CBs. This is mechanistically regulated by a competition of coilin with FGF-2<sup>23</sup> for binding to SMN. These results demonstrate that FGF-2<sup>23</sup> promotes release of SMN from its immobile pool in the CB and further defines the function of this nuclear growth factor. Furthermore, FGF-2<sup>23</sup> caused snRNP accumulation in CBs. We propose a model in which Cajal bodies store immobile SMN that can be mobilized by its nuclear interaction partner FGF-2<sup>23</sup>, leading to U4 snRNP accumulation in CBs, indicating a role for immobile SMN in tri-snRNP assembly.

### Importin- $\beta$ and Ran regulate the passive permeability barrier in the nuclear pore complex.

J. H. Tang<sup>1</sup>, A. R. Lowe<sup>2,3,4</sup>, J. M. Yassif<sup>1</sup>, K. Weis<sup>3,5</sup>, J. T. Liphardt<sup>1,2,3,4,6</sup>; <sup>1</sup>*Biophysics Graduate Group, University of California - Berkeley, Berkeley, CA*, <sup>2</sup>*Dept. of Physics, University of California - Berkeley, Berkeley, CA*, <sup>3</sup>*QB3, University of California - Berkeley, Berkeley, CA*, <sup>4</sup>*Bay Area Physical Sciences - Oncology Center, Berkeley, CA*, <sup>5</sup>*Dept. of Molecular & Cell Biology, University of California - Berkeley, Berkeley, CA*, <sup>6</sup>*Physical Biosciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA*

The nuclear pore complex (NPC) is a large, multi-protein assembly that mediates the selective transport of molecules between the cytoplasm and nucleus in eukaryotic cells. While the proteins involved in the transport pathway have largely been identified, the physical mechanism by which this complex can support both efficient and selective molecular transport remains unclear. Using fluorescence microscopy and super-resolution imaging techniques, we have examined how nuclear transport receptors influence the permeability properties of the NPC for both active and passive transport processes. We find that importin- $\beta$  binding to the nucleoporin Nup153 significantly slows passive transport through the NPC; however, Ran in its GTP-bound form reverses this effect. FRAP studies reveal that RanGTP weakens the binding interaction of importin- $\beta$  to the NPC. Furthermore, STORM imaging of individual importin- $\beta$  localizations inside the NPC show that RanGTP dramatically changes the importin- $\beta$  distribution within the channel. These results suggest that importin- $\beta$  in conjunction with Nup153 is an integral component of the NPC permeability barrier which is regulated by RanGTP.

**Defining the mechanisms regulating selective mRNA export during heat shock-induced stress.**

B. J. Natalizio<sup>1</sup>, S. R. Wentz<sup>1</sup>; <sup>1</sup>Cell and Developmental Biology, Vanderbilt University School of Medicine, Nashville, TN

Eukaryotic cells respond to major environmental stresses through dramatic alterations in gene expression. An essential process during these events is the export of messenger RNA (mRNA) from the nucleus to the cytoplasm. As mRNA is synthesized, the transcript is packaged with proteins to form export competent messenger ribonucleoprotein particles (mRNPs). The protein composition of these mRNPs is highly dynamic, characterized by the association and dissociation of specific proteins that mediate efficient mRNA translocation through nuclear pore complexes. In the budding yeast *Saccharomyces cerevisiae* during the heat shock stress response, others have shown that the transcription and export of specific heat shock-induced mRNAs are upregulated. In contrast, non-heat shock-induced mRNAs are retained in the nucleus. This allows the translation machinery to be geared for the synthesis of heat shock proteins. However, the precise molecular determinants that control this selective mRNA export remain unresolved.

Previously, our laboratory demonstrated that the mRNA-binding proteins Nab2 and Yra1 colocalize to Mlp1-dependent intranuclear foci following exposure to heat shock stress conditions (Carmody et al. *Mol Cell Biol.* 2010 30(21):5168-79). To gain a better understanding of how mRNA export factors such as Nab2 are affected during heat shock stress, we employed a previously characterized nab2 mutant (*nab2-C437S*) that exhibits significantly reduced RNA-binding affinity and altered mRNP assembly (Tran et al. *Mol Cell.* 2007 28(5):850-9; Brockmann et al. *Structure.* 2012 20(6):1007-18). Surprisingly, using *in situ* hybridization analysis, we observed that poly(A) mRNAs were not retained in the nucleus following heat shock in the *nab2-C437S* mutant. This suggested a defect in the regulation of mRNA export. Moreover, colocalization of Nab2 and Yra1 to intranuclear foci upon heat shock stress was disrupted in the *nab2-C437S* mutant. We are currently analyzing the localization of non-heat shock and heat shock mRNAs in this mutant using single molecule RNA FISH. Recent evidence indicates that post-translational modifications of RNA binding proteins are important for the mRNA export mechanism. Our laboratory has previously shown that during heat shock stress Nab2 is phosphorylated by the mitogen-activated protein (MAP) kinase Sit2/Mpk1 (Carmody et al. *Mol Cell Biol.* 2010 30(21):5168-79). In addition, others have recently revealed that Yra1 is ubiquitinated by the E3 ligase Tom1 (Iglesias et al. *Genes Dev.* 2010 24(17):1927-38). We speculate that a potential role of these post-translational modifications may be to regulate selective mRNA export during stress responses. Our ongoing studies are focused on further characterizing the heat shock response in the *nab2-C437S* mutant and addressing this hypothesis. Together, these strategies aim to reveal the mechanism for selective mRNA export during the heat shock stress response.

**Traveling through the pore: dynamics and conformation of phenylalanine-glycine repeat domains inside the nuclear pore complex.**

R. Moussavi Baygi<sup>1</sup>, M. Mofrad<sup>1</sup>; <sup>1</sup>Bioengineering, UC Berkeley, Berkeley, CA

All kind of proteins and RNA transport across the nuclear envelope in eukaryotes is selectively regulated by nuclear pore complexes (NPCs). While the research field of the NPC is now entering its fifth decade, selective gating mechanism across the pore is still ambiguous. This

obscurity mainly stems from lack of accurate information on dynamics and conformations of the natively unfolded phenylalanine-glycine (FG) repeat domains that constitute about 30% of the of the NPC structure and are believed to be the main component of selective gating.

Due to their natively unfolded structure and extremely delicate nature, however, their functional state cannot be captured in vivo or in vitro. Indeed, FG-repeats are confined to the NPC central channel, and the compact architecture of the channel makes the investigation even more challenging. Thus, conformational behavior of the FG-repeats during transport has been the subject of speculation for the past 13 years, and still there is not a clear consensus that how these repeat domains form the selective barrier.

Nevertheless, there are extensive, and sometimes contradictory, data in the literature on structural and functional aspects of the FG-repeats. Currently, the time is truly ripe to gather this large pool of data and make a computational model to reveal dynamics and conformation of these repeat domains with high spatiotemporal resolutions.

Based on the available empirical data and following polymer physics principles, last year we published a computational 2D model of the whole NPC structure, which was validated against experimental results. In this study, we have focused on the mysterious central channel of the NPC to exclusively shed light on dynamics and conformation of the FG-repeat domains confined in the channel. To be able to mimic the real geometry of the pore, we have extended the model to the 3D version that capable of capturing true geometrical features of the channel. Our model suggests that FG-repeats form a layer of hydrophobic 'lubricant' on the channel wall and leave a central tube in the channel, but the formation of the channel-filling hydrogel is not feasible even at extreme pHs. Then we examined the same conditions for free, not confined, FG-repeats domains and found that they can form a hydrogel, both at the extreme and normal pHs. This indicates the essential role of the confined geometry of the NPC that has been neglected so far. Thermodynamic analysis reveals that for the hydrogel to form, 'enthalpic gain' must overcome 'entropic loss' of oppositely grafted FG-repeats in the channel.

569

### **The Nup-Imp $\beta$ affinity gradient of the nuclear pore complex is highly optimized to maximize import rate.**

*M. Azimi<sup>1</sup>, M. Mofrad<sup>1</sup>; <sup>1</sup>Department of Bioengineering, University of California Berkeley, Berkeley, CA*

**Background:** The nuclear pore complex (NPC) regulates transport between cytoplasmic and nuclear compartments of the cell. The mechanism of such transport is an active topic of debate and has lead to the suggestion of several theoretical models of transport. Among these is the affinity gradient model, which suggests that transport is based on the experimentally observed, steeply increasing affinity gradient across the pore. Although this model alone cannot account for transport, the observed affinity gradient likely plays a role.

**Objective:** Explore the effect of gradients in affinity between nucleoporins (Nups) and Importin- $\beta$  in the NPC on import rate and to determine the distribution of transport rates the range of experimentally observed affinities can support.

**Methods:** A 3D agent-based model (ABM) of the nuclear pore complex was constructed comprising static agents representing the NPC scaffold, nuclear basket, cytoplasmic filaments and nuclear envelope. Mobile agents were restricted to the cytoplasmic filament region, central channel and nuclear basket. Mobile agents consisted of Imp $\beta$ -binding (FG agents) and non-Imp $\beta$ -binding (non-FG agents); the quantity of the FG-agents being selected based on the number of FG-containing Nups within the NPC and the non-FG agents selected to represent the

volume of the channel occupied by Nups. Mobile agents representing Imp $\beta$  were present in the cytoplasmic region at a concentration of 3 $\mu$ M along with agents representing RanGTP in the nucleus at a concentration of 1 $\mu$ M. Imp $\beta$  agents were capable of translocating through the channel via a combination of diffusive events and binding/unbinding events with FG agents. The channel was partitioned into three regions consisting of cytoplasmic, central channel and nuclear basket. FG-Imp $\beta$  affinity was varied over a range of  $K_D=0.1$ nM to  $K_D=10$  $\mu$ M for all three regions and Imp $\beta$  transit rates were measured and averaged over 100 simulations per data point.

**Results:** Peak transport rate of Imp $\beta$  across the channel was observed for an affinity gradient of 1000nM, 200nM and 10nM in the cytoplasm, central channel and nucleus, respectively. The effect of cytoplasmic Nup affinity on transport rate peaked at  $K_D=1000$ nM with no appreciable increase in transport rate at higher values of  $K_D$ . Similarly, the effect of nuclear basket Nups on transport rate peaked at  $K_D=10$ nM with no noticeable increase at lower  $K_D$ . Adjusting central channel Nup affinity resulted in a biphasic behavior in transport rates with an observed maximum transport rate at  $K_D=200$ nM. Additionally, the transport rate for the optimal affinity gradient was approximately 23% greater than that of the most optimal channel lacking an affinity gradient.

**Conclusions:** The presence of an affinity gradient can increase Imp $\beta$  transport rates across the nuclear pore complex. Furthermore, our model and simulations predict that the transport rate reaches a maximum at optimum affinities for each nuclear pore region. Interestingly, these optimal values are in very near agreement to experimentally measured dissociation constants.

570

### Exploring the Potential Impact of the O-GlcNAcylation of Nucleoporins on Nucleocytoplasmic Transport.

*E. Bulat<sup>1</sup>, S. H. Mahboobi<sup>1</sup>, M. R. Mofrad<sup>1</sup>; <sup>1</sup>Departments of Bioengineering, Molecular and Cell Biology, and the Chemical Biology Graduate Program at the University of California, Berkeley, Berkeley, CA*

**Introduction:** O-GlcNAcylation, or the addition of *N*-acetylglucosamine (GlcNAc) to serine or threonine amino-acid residues in the nucleus and the cytosol, was discovered only several decades ago and has since garnered significant attention as a novel form of dynamic post-translational modification. While notable progress has been made in uncovering the role that O-GlcNAcylation may play in cellular processes such as transcription, translation, and signal transduction, very little is known about its potential role in nucleocytoplasmic transport (NCT).

The objective of this work is to study how the experimentally-validated O-GlcNAcylation of residues proximal to functionally-important phenylalanine-glycine (FG)-repeat domains on nucleoporin proteins (Nups) affects their interaction with hydrophobic patches on karyopherin proteins during NCT.

**Methods:** We have used the CHARMM molecular dynamics modeling package, along with CHARMM27 protein and CHARMM36 carbohydrate force fields, to generate multiple distinct O-GlcNAcylated peptides (glycopeptides) spanning 10-amino-acid sequences within the FG-repeat-rich portions of human Nup153 and Nup214. We then used VMD to solvate and ionize each glycopeptide in 139mM KCl, and NAMD to minimize and equilibrate them under periodic boundary conditions and an NPT ensemble. A crystal structure of human importin  $\beta$ 1 bound to the IBB domain of importin  $\alpha$ 2 (hImp $\beta$ 1/Imp $\alpha$ 2-IBB) was also minimized and equilibrated separately in identical conditions. Using VMD, we constructed systems involving each equilibrated peptide – either with or without the O-GlcNAc modification – separately replicated

around the equilibrated hImp $\beta$ 1/Imp $\alpha$ 2-IBB for temporal simulation of interaction and binding dynamics.

**Results and Conclusion:** Preliminary data suggest that glycosylated and unglycosylated peptides bind to the hImp $\beta$ 1/Imp $\alpha$ 2-IBB surface regions that are consistent with or in close proximity to some of the regions previously reported in the literature. The free energy change upon binding (FEB) that is attributed to van der Waals interactions between FG-repeat residues and hImp $\beta$ 1/Imp $\alpha$ 2-IBB is on the order of  $17.4 \pm 2.3$  and  $16.6 \pm 2.2$  kcal/mol for glycopeptides and peptides, respectively. In addition, where the GlcNAc is in the vicinity of the binding event, it contributes an additional  $9.8 \pm 1.3$  kcal/mol to van der Waals FEB. These observations may suggest that having O-GlcNAcylation near the FG-repeat domains of Nups contributes energetically to their association with Imp $\beta$ 1 as well as possibly other karyopherins.

571

**The impact of nuclear size on *Xenopus* early development.**

*P. Jevtic<sup>1</sup>, D. L. Levy<sup>1</sup>; <sup>1</sup>Molecular Biology, University of Wyoming, Laramie, WY*

Answering a fundamental question in cell biology like how nuclear size is regulated could shed light on understanding diseases associated with altered nuclear size, such as cancer. It has been previously shown that nuclear size in *Xenopus* can be either increased or decreased by altering the amounts of importin  $\alpha$ , Ntf2, and the nuclear import cargo lamin B. During early frog embryogenesis nuclear and cell size decrease with the nuclear to cytoplasmic volume ratio reaching a maximum at the midblastula transition (MBT). MBT is mainly characterized by embryonic transcription upregulation, longer cell cycles and cell division asynchrony. We hypothesize that MBT timing is determined by the nuclear to cytoplasmic volume ratio, which we can experimentally manipulate by altering nuclear size.

Our approach is to alter nuclear size in early *Xenopus* embryos by mRNA microinjection of one blastomere in a two-cell embryo to ectopically express nuclear scaling factors, enabling us to investigate the correlation between nuclear size and developmental progression. We monitor the molecular and cellular hallmarks of MBT in the two halves of the embryo by whole mount in situ hybridization and fluorescent time lapse microscopy. According to our preliminary data, increasing nuclear size in early embryos leads to a premature MBT indicated by earlier zygotic transcription, earlier onset of cell division asynchrony, and longer cell cycles in the injected half of the embryos. Conversely, decreasing nuclear size leads to a delayed MBT detected by later zygotic transcription, later onset of cell division asynchrony, and more cell divisions and smaller cells in the injected half of the embryo compared to the uninjected half.

Further we want to address the follow-up question: does altering nuclear size in early embryos affect development and differentiation in later stage embryos during gastrulation and organogenesis? Also it would be interesting to investigate the long-term effects of altering nuclear size in swimming tadpoles and beyond. This knowledge will provide insight into the link between nuclear size and normal embryonic development, cell function, physiology and morphology.

572

**Constructing Finite Element Models for Exportin Cse1p and Xpot.**

*M. Hu<sup>1</sup>, B. Kim<sup>1</sup>; <sup>1</sup>Mechanical and Industrial Engineering, University of Massachusetts Amherst, Amherst, MA*

Studying conformational dynamics of proteins is beneficial to understand their biological functions. Here, we utilized Finite Element Analysis (FEA), a mature engineering technique, to investigate the conformations of Cse1p and Xpot, two of the known transport factors, which play crucial roles in Nucleocytoplasmic Transport (NCT). Cse1p and Xpot are exportins, which

shuttle specific cargos from the nucleus to the cytoplasm by passing through the Nuclear Pore Complex (NPC). During the process, they are capable of adapting at least two different conformations to execute association and dissociation of cargos. Therefore, the flexibility of transport factors has been considered one of the most important characteristics of the NCT. A spring-loading hypothesis was proposed by another research group, which suggested that the Cse1p has a distorted conformation which may act like a loading spring after accommodating cargos in the nucleus. After passing through the NPC, conformational changes might be produced due to the strain stored in the complex structure, which allows the cargos to be released in the cytoplasm. In order to test this hypothesis, we first calculated the solvent-excluded surface (SES) of Cse1p's conformation in the nuclear/bound state. Second, we created an enclosed volume based on the SES, and then discretized the volume into a FEA model. Finally, a free-vibration analysis was carried out to obtain the nature vibrational modes of Cse1p that were found to be relevant to the mechanism of binding cargos. More precisely, a dominant mode was identified to have the most potential to form the unbound conformation in the cytoplasm. Furthermore, a distribution of strain/stress on Cse1p's FEA model was established, and the results indicated that Cse1p's distorted conformation in the nucleus did have stored strain/stress to facilitate the process of releasing cargos in the cytoplasm. In other words, we were able to quantitatively point out where the most flexible regions of Cse1p's complex structure were. The same procedure was applied on Xpot as well, and the results also revealed a dominant mode relevant to binding mechanism and a strain/stress distribution mapped to highly flexible regions of Xpot's bound conformation. In conclusion,, FEA can be a useful tool for exploring conformational dynamics of proteins and beneficial to understand their biological functions.

#### **Characterization of NLS2 from Influenza A virus nucleoprotein.**

*W. Wu<sup>1</sup>, N. Pante<sup>1</sup>; <sup>1</sup>University of British Columbia, Vancouver, BC, Canada*

Influenza A virus nucleoprotein (NP) is an abundant essential protein, participating in genome organization, nuclear trafficking, and RNA transcription and replication. Two nuclear localization sequences (NLSs) on NP are known to mediate the nuclear import of the influenza genome: NLS1 at the N-terminus of NP, and NLS2 spanning residues 198-216. Sequence alignment shows both NLSs on NP are highly conserved between different strains of influenza A virus, suggesting that these NLSs are ideal candidate for novel antiviral approaches. The functional role of NLS1 has been very well characterized in previous studies. Using chimera proteins fused to NLS2, we are characterizing the contribution of NLS2 to nuclear import and defining the amino acids that are important for NLS2's function. NLS2 has been previously classified as a classical bipartite NLS, containing two clusters of basic amino acids separate by a linker of 13 amino acids. Through sequence alignment, we found that there is one amino acid different in the second cluster of basic amino acid at position 17 on NLS2. Interestingly, with only this one basic amino acid difference (K:lysine to R:arginine) the NLS2 containing a K at position 17 (NLS2K) contributes stronger to the nuclear import of the chimera protein than the NLS2 containing an R at position 17 (NLS2R). To understand the nuclear import function differences between NLS2K and NLS2R, site-directed mutagenesis was performed to the basic clusters of each NLS2. Mutations in either cluster of NLS2K did not affect the nuclear accumulation of the chimera protein containing NLS2K, which corroborate that NLS2K is a classical bipartite NLS. In contract, mutagenesis of the first basic cluster of NLS2R yielded a significant decrease in the nuclear accumulation of a chimera protein containing NLS2R, and the same result was obtained when both amino acid clusters of NLS2R were mutated. This result indicates that NLS2R behaves as an unconventional monopartite NLS. We are now performing deletion mutants of the NLS2R-chimera protein to define this novel NLS. Together, these strategies aim to reveal

functional amino acids on NLS2 of influenza A virus NP that mediate the nuclear import of the viral genome.

**Elevated level of Human RPA Interacting Protein $\alpha$  (hRIP $\alpha$ ) in tumor cells is involved in cell proliferation through regulating RPA transport.**

S. Namkoong<sup>1</sup>, E-J. Lee<sup>2</sup>, I-S. Jang<sup>3</sup>, J. Park<sup>1</sup>; <sup>1</sup>Div. Biological Science and Technology, Yonsei University, Wonju, Korea, <sup>2</sup>Dep. Obstetrics and Gynecology, Chung-Ang University, Seoul, Korea, <sup>3</sup>Div Life Science, Korea Basic Science Institute, Taejeon, Korea

Replication protein A (RPA) is a eukaryotic single-stranded DNA binding protein that is essential for DNA replication, repair, and recombination, and human RPA interacting protein  $\alpha$ (hRIP $\alpha$ ) is the nuclear transporter of RPA. Here, we report the regulatory role of hRIP $\alpha$  protein in cell proliferation. hRIP $\alpha$  protein expression is often increased in human cervical tumor cells and hRIP $\alpha$  knockdown by siRNA inhibited cellular proliferation through deregulation of the cell cycle. In addition, overexpression of hRIP $\alpha$  resulted in increased clonogenicity. These results indicate that hRIP $\alpha$  is involved in cell proliferation through regulation of RPA transport.

**Control of gene expression through regulation of DEAD-box helicases.**

C. Regan<sup>1</sup>, Y. Li<sup>1</sup>, T. A. Bolger<sup>1</sup>; <sup>1</sup>Molecular and Cellular Biology, University of Arizona, Tucson, AZ

The mRNA life cycle is a fundamental cellular process comprised of a series of dependent steps from transcription to mRNA decay. During each step, the cohort of mRNA-associated proteins and the structure of the mRNA itself are constantly changing. The DEAD-box protein family is a major component of the machinery that facilitates these changes, "remodeling" mRNPs through the ability to both remove proteins bound to RNA and unwind structured mRNA. Importantly, appropriate control of DEAD-box protein activity and how DEAD-box proteins remodel RNP complexes are not fully defined. Only a small number of factors that affect DEAD-box protein activity have been identified. Among these is Gle1, which stimulates the activity of the DEAD-box protein Dbp5 in mRNA export. Our prior studies have revealed new functions of Gle1 in protein translation, acting both in initiation and termination. In termination, Gle1 likely activates Dbp5 as in export. In initiation, we found that Gle1 inhibits the activity of a different DEAD-box protein, Ded1. Because Gle1 is a multifunctional DEAD-box protein regulator (acting in nuclear export, translation initiation and translation termination), we suggest it is a key factor in regulating mRNP remodeling during these steps. Our current goals are to determine the mechanism and biological consequences of Gle1 regulation of Ded1 in translation initiation. This study will further our long-term goal of understanding how DEAD-box proteins and their regulatory factors direct the fate of mRNAs. In addition, the human homolog of Ded1, DDX3, has been implicated in several disease pathologies, including cancer development and HIV infection, and better understanding its cellular functions will be crucial in unraveling its roles in disease.

577

**Btf has functions unique from TRAP150 in regulating the subcellular distribution of mRNAs.**

S. Varia<sup>1,2</sup>, D. Potabathula<sup>2</sup>, Z. Deng<sup>1</sup>, A. Bubulya<sup>2</sup>, P. A. Bubulya<sup>2</sup>; <sup>1</sup>Biomedical Sciences PhD Program, Wright State University, Dayton, OH, <sup>2</sup>Biological Sciences, Wright State University, Dayton, OH

Transcription of protein-coding genes is coordinated with pre-mRNA processing as well as mRNP assembly and nuclear export in mammalian cells. Btf (BCLAF1) and TRAP150 are serine-arginine-rich (SR) proteins that share 39% sequence identity and 66% sequence similarity, but the extent of their functional overlap is not clear. Btf and TRAP150 were previously reported to associate with synthetic affinity-purified in vitro spliced mRNPs, and also as a part of the spliceosome complex, suggesting they are involved in pre-mRNA processing. We used a combined immunofluorescence/RNA-FISH approach to show that both Btf and TRAP150 localize at a constitutively active beta-tropomyosin (BTM) reporter minigene locus in HeLa cells. Both proteins also localize at a U2OS 2-6-3 reporter gene locus in a RNA polymerase II transcription-dependent manner. While Btf and TRAP150 showed some overlap with reporter RNA and other pre-mRNA processing factors at transcription loci, they showed the most extensive overlap with the exon junction complex (EJC) protein Magoh. Since EJC components have roles in nuclear export, we examined nuclear/cytoplasmic mRNA distribution by qRT-PCR. Depletion of Btf or TRAP150 did not alter splicing of BTM transcripts or the recruitment of other RNA processing factors to transcription sites. Specifically, Btf depletion (but not TRAP150 depletion) caused an increase of beta-tropomyosin minigene reporter transcripts in the cytoplasm. In addition, RNA-FISH using fluorescently tagged oligo-dT probes showed increased abundance of endogenous polyadenylated RNA in the cytoplasm of HeLa cells specifically following Btf depletion but not TRAP150 depletion. Since immunoblots revealed that Btf depletion resulted in increased expression of TRAP150, we prevented compensatory TRAP150 expression upon Btf depletion by adding limiting amounts of TRAP150 siRNA duplex to the siRNA mixture. Our experiments demonstrate that it is Btf depletion, but not compensatory TRAP150 upregulation, that leads to a global change in subcellular distribution of mRNA. We are currently mining our exon microarray data generated from Btf-depleted cells to identify mis-spliced endogenous mRNAs and to determine if incorrectly spliced transcripts reach the cytoplasm. In summary, our data suggests that Btf and TRAP150 have both redundant and distinct functions in human cells. We reveal that modulating the expression of a single protein, Btf, has global impact upon the nuclear/cytoplasmic distribution of mRNAs.

**Nucleolar localization signals interact electrostatically with nucleolar components.**

Y. R. Musinova<sup>1</sup>, D. M. Svistunova<sup>2</sup>, E. V. Sheval<sup>1</sup>; <sup>1</sup>Department of Electron Microscopy, A.N. Belozersky Institute of Physico-Chemical Biology, Moscow State University, Moscow, Russia, <sup>2</sup>Department of Bioengineering and Bioinformatics, Moscow State University, Moscow, Russia

The majority of nucleolar proteins are dynamically exchanged between the nucleolus and the surrounding nucleoplasm. How proteins are accumulated (sometimes in relatively high concentration) within such non-membrane-bound substructures remains unclear. One way of protein retention in the nucleolus is associated with the presence of specific short amino acid sequences – nucleolar localization signals (NoLSs). At present, the mechanism of their action is unknown. The analysis of published data showed that all described NoLSs are enriched with positively charged amino acids (~50% of the total amino acid content). One can suggest that the mechanism of interaction with the nucleolar components is electrostatic. To ascertain this

assumption, we used chimeric proteins containing EGFP and short tags containing different amounts (from 0 to 19) of positively charged amino acids – lysines or arginines (such tags were referred to as imitative NoLSs). We found that there was dependence between the charge of the imitative NoLSs and the level of EGFP accumulation inside nucleoli. The level of EGFP accumulation was inversely correlated with the speed of EGFP exchange between the nucleolus and the nucleoplasm. We found that the level of accumulation is higher in case of imitative NoLSs in which positively charged amino acids were not separated by uncharged amino acids. Also, we developed a method for the mapping of the NoLS boundaries. We mapped in detail the signals and their structure in two proteins. The presence of positively charged amino acids in close vicinity of the signal leads to the "blurring" the NoLS boundaries. In fact, in this case, the boundaries can be mapped only approximately. The results of this study confirm that NoLSs interact electrostatically with the nucleolar components.

**Structural basis for cell-cycle dependent nuclear import mediated by Kap121p in *Saccharomyces cerevisiae*.**

*J. Kobayashi<sup>1</sup>, Y. Matsuura<sup>1</sup>; <sup>1</sup>Nagoya University, Nagoya, Japan*

In all eukaryotes, precise regulation of the bidirectional transport of macromolecules between the nucleus and the cytoplasm is an essential aspect of many cellular processes, including gene expression, signal transduction, cell cycle progression, and differentiation. Nuclear transport occurs through nuclear pore complexes (NPCs) that form aqueous channels across the nuclear envelope, and altering the structure of NPCs is an emerging mechanism to control nuclear transport. The yeast nucleoporin Nup53p is a target of phosphorylation events in the final stages of mitosis. The phosphorylation of Nup53p alters the interactions of Nup53p with its neighbors during mitosis. This M phase specific molecular rearrangements in the NPCs allow Nup53p to bind the karyopherin Kap121p (also known as Pse1p) specifically during mitosis, slowing its movement through the NPCs and inducing cargo release. The M phase specific regulation of Kap121p-mediated nuclear import is required for normal progression through mitosis. Here we report crystal structures of Kap121p in isolation and also in complex with either its import cargos or Nup53p or RanGTP, which establish the structural basis for recognition of a novel nuclear localization signal (NLS), cargo-Nup53p competition and cargo-displacement by RanGTP. Kap121p has a superhelical structure composed of 24 HEAT repeats. Kap121p is almost exclusively  $\alpha$ -helical except for surface loops connecting the inner and outer helices of HEAT repeats and a large insert in HEAT15 that is folded into a small protruding domain involved in Ran-binding. The structures of the Kap121p-cargo complexes define a novel NLS that has a consensus sequence of **KV/IxKNxK/H**. The NLSs bind in the central portion of Kap121p on the inner concave surface of HEAT repeats 8 to 12 through multiple hydrogen bonds, electrostatic interactions and van der Waals contacts. The NLS- and Nup53p-binding sites are exactly the same, suggesting that Nup53p displaces import cargos by direct competition. The binding of cargos or Nup53p to Kap121p is not associated with conformational changes of Kap121p. By contrast, the binding of RanGTP drastically opens up the N-terminal arch of the Kap121p superhelix. Comparison of the NLS- and RanGTP-complexes revealed that RanGTP-mediated dissociation of import cargos involves both a global conformational change that locks the Kap121p superhelix into a cargo-incompatible conformation and a direct displacement by RanGTP.

## Endocytic Trafficking I

### Divergent modes for cargo-mediated control of clathrin-coated pit dynamics by signaling receptors.

A. Soohoo<sup>1</sup>, M. Puthenveedu<sup>1</sup>; <sup>1</sup>*Biological Sciences, Carnegie Mellon University, Pittsburgh, PA*

Clathrin-mediated endocytosis has long been viewed as being driven by core endocytic proteins, with the internalized proteins being passive cargo. Contrary to this, an emerging view suggests that signaling receptor cargo may actively control their own fate by regulating the dynamics of clathrin-coated pits (CCPs) that mediate their internalization. Despite its physiological implications, very little is known about such "cargo-mediated regulation" of CCPs by signaling receptors. Here, using multi-color TIR-FM imaging in live cells, we show that the mu-opioid receptor, a physiologically relevant G protein-coupled signaling receptor, delays the dynamics of a subset of CCPs in which it is localized. This delay is mediated by the interactions of two critical leucines on the receptor cytoplasmic tail, which regulate key components of CCP scission. These results identify a novel means for selectively controlling the endocytosis of distinct cargo that share common trafficking components, and indicate that CCP regulation by signaling receptors can operate via divergent modes.

### Exploring the Role of Protein-Protein Crowding in Clathrin Mediated Endocytosis.

J. Houser<sup>1</sup>, J. Jose<sup>1</sup>, C. C. Hayden<sup>2</sup>, E. M. Lafer<sup>3</sup>, J. C. Stachowiak<sup>1</sup>; <sup>1</sup>*Biomedical Engineering, University of Texas at Austin, Austin, TX*, <sup>2</sup>*Sandia National Laboratories, Livermore, CA*, <sup>3</sup>*Biochemistry, The University of Texas Health Sciences Center at San Antonio, San Antonio, TX*

Two major mechanisms of membrane bending during clathrin-mediated endocytosis have been investigated: bending by curved protein scaffolds such as the clathrin coat, and bending by insertion of wedge-like amphipathic helices into the membrane by adaptor proteins such as epsin1. Recently we have reported a third general mechanism – membrane bending by protein-protein crowding, where collisions between proteins bound densely to membrane surfaces drive bending (NCB 2012). Endocytic adaptor proteins frequently consist of a folded N-terminal membrane binding domain, and an unfolded C-terminal domain that binds clathrin and other proteins. Due to their lack of structure, unfolded protein domains have much larger hydrodynamic radii than folded protein domains of equal molecular weight. Therefore, based on the finding that molecular crowding can drive bending, we hypothesized that the unfolded portions of adaptor proteins might play an important role in curving membranes. In this study, we show that the unstructured epsin C-terminus can bend model membranes using 3-4 times fewer molecules than the structured epsin N-terminal homology (ENTH) domain, which has traditionally been thought to drive bending. These findings suggest that concentrating the unfolded domains of adaptor proteins at endocytic sites may have a previously unappreciated role in promoting membrane bending. Very recently, Dannhauser et al. (NCB 2012) have shown that clathrin can bend membranes in the absence of the ENTH domain, when recruited to the membrane surface by the epsin C-terminus. This result, in combination with our finding that the epsin C-terminus can drive bending by itself, points to two possible roles for clathrin in membrane bending: (i) clathrin could bend membranes directly through scaffolding, or (ii) it could bend membranes by locally concentrating adaptors and producing steric pressure between them. To investigate these possibilities, we are using epsin C-terminus to recruit

clathrin to the surface of giant unilamellar vesicles. We find that the presence of clathrin reduces the amount of epsin C-terminus needed to bend the membrane by a factor of approximately 2 and that the concentration of epsin on the membrane surface is locally increased by clathrin coats. The aim of our ongoing experiments is to reveal how clathrin and adaptor proteins work together to curve membrane surfaces.

**Live cell imaging of membrane topology during clathrin mediated endocytosis reveals regions of high curvature adjacent to growing pits.**

*S. T. Low-Nam<sup>1</sup>, J. Kerkvliet<sup>1</sup>, A. Cheng<sup>2</sup>, D. Drubin<sup>2</sup>, A. D. Hoppe<sup>1</sup>; <sup>1</sup>Chemistry and Biochemistry, South Dakota State University, Brookings, SD, <sup>2</sup>Molecular and Cell Biology, University of California, Berkeley, Berkeley, CA*

Induction of membrane curvature is a key feature in the classical model of vesicle formation during clathrin mediated endocytosis. Details of clathrin coated pit geometries and composition have been shown using electron microscopy, superresolution imaging and a suite of biochemical approaches. However, dynamic changes in membrane topology associated with clathrin assembly, pit formation and dynamin-mediated scission, remain poorly characterized. Furthermore, clathrin coated pits and invaginations are smaller (50-120 nm) than the resolving power of traditional fluorescence microscopes (approx. 250 nm). Improved techniques are required to monitor these sub-diffraction-limited objects in living cells. Polarized total internal reflection fluorescence (pol-TIRF) microscopy permits visualization of sub-resolution membrane curvature in cells labeled with lipophilic fluorophores that are oriented within the plasma membrane. We describe an approach to preferentially excite carbocyanine fluorophores (e.g. DiI) whose dipoles are oriented perpendicular or parallel to the glass substrate. A polarized laser beam is focused at orthogonal azimuthal positions in the back focal plane of a high numerical aperture lens to distinguish membrane curvature based on ratio imaging of the two excitation polarizations. Visualization of membrane topology with DiI in skin melanoma cells expressing endogenously-tagged GFP-dynamin permitted high spatiotemporal resolution imaging of clathrin mediated endocytosis. Unexpectedly, regions of high curvature were often observed adjacent to clathrin pits. The topology observed here is consistent with a role for membrane protrusions in the completion of endocytosis.

583

**Time-resolved electron tomography reveals how the plasma membrane is reshaped during endocytosis.**

*W. Kukulski<sup>1</sup>, M. Schorb<sup>1</sup>, M. Kaksonen<sup>1</sup>, J. A. Briggs<sup>1</sup>; <sup>1</sup>EMBL, Heidelberg, Germany*

Endocytosis, like many dynamic cellular processes, requires precise temporal and spatial orchestration of a complex protein machinery to mediate vesicle budding. To understand how the yeast plasma membrane is reshaped by the components of this machinery, we applied our recently developed correlated fluorescence microscopy and electron tomography procedure. This approach allows to directly correlate specific time windows, which are defined by the presence or absence of key protein pairs, with ultrastructure. Our analysis spans the time from recruitment of the early endocytic module, including Ede1, to the disassembly of the actin network, represented by Abp1. We systematically located 211 endocytic intermediates, assigned each of them to one of nine defined time windows during endocytosis, and reconstructed their ultrastructure in 3D. These reconstructions revealed flat membranes, invaginations of various depth and vesicles at endocytic sites. We then extracted parameters describing these membrane ultrastructures and performed a quantitative analysis of shape changes. The resulting virtual ultrastructural movie describes the protein-mediated membrane

shape changes during endocytosis. We find that clathrin is recruited to flat membranes and does not initiate curvature; membrane invagination only begins upon actin network assembly. Subsequently, approximately 3 s after initial bending and when invaginations are approximately 50 nm deep, amphiphysin binding to parallel membrane segments promotes elongation of the invagination into a tubule, which constricts into a neck at 1/3 of its depth. Scission occurs on average 9 s after initial bending, releasing non-spherical vesicles with 6'400 nm<sup>2</sup> mean surface area. These vesicles often retain the teardrop-shape of necked invaginations. In summary, our large, quantitative dataset reveals the sequence of changes in membrane shape occurring during endocytosis, and places them in the context of recruitment and disassembly of endocytic protein modules.

584

**Phosphorylation of clathrin light chain b regulates GPCR trafficking.**

*F. J. Ferreira<sup>1</sup>, M. Foley<sup>1</sup>, A. Cooke<sup>2</sup>, M. Cunningham<sup>2</sup>, G. Henderson<sup>2</sup>, E. Kelly<sup>2</sup>, S. Mundell<sup>2</sup>, E. Smythe<sup>1</sup>; <sup>1</sup>Biomedical Science, University of Sheffield, Sheffield, United Kingdom, <sup>2</sup>School of Physiology and Pharmacology, Bristol, United Kingdom*

Transmembrane receptors are involved in a myriad of physiological functions and disease can result if they are defective. G protein-coupled receptors (GPCRs) can signal at the cell surface as well as throughout the endocytic pathway and consequently the signal output may differ depending on cellular location. Regulation of the core endocytic machinery facilitates differential uptake of individual cargoes and ensures their appropriate trafficking. Clathrin-mediated endocytosis is a major entry portal into cells. Clathrin forms a lattice around invaginating pits that have captured cargo. Upon vesicle formation, regulated uncoating of components ensures efficient delivery to early endosomes.

We have investigated how clathrin regulates GPCR trafficking. In solution clathrin exists as triskelia composed of three molecules of clathrin heavy chain and associated clathrin light chains (CLC). We show that knockdown of both CLCs inhibits the endocytosis of GPCRs. Strikingly, phosphorylation of CLCb by G-protein-coupled receptor kinase 2 (GRK2) is required for efficient internalization of a subset of GPCRs. Overexpression of CLCb phospho-mutant inhibits uptake of GPCRs, whose internalization is GRK2-dependent. These results identify a new role for CLCb phosphorylation in the trafficking of a subset GPCRs.

585

**Girdin regulates endocytosis as a GAP of dynamin2.**

*L. Weng<sup>1</sup>, A. Enomoto<sup>1</sup>, M. Takahashi<sup>1</sup>; <sup>1</sup>Department of Pathology, Nagoya University Graduate School of Medicine, Nagoya, Japan*

Clathrin mediated endocytosis (CME) is the main pathway of endocytosis and large GTPase dynamin is a central player in this process. However, the regulation of dynamin GTPase activity is not completely understood. Here, we identified actin-binding protein Girdin interacts with dynamin2 through its NT domain, especially N2 domain. And dynamin2 GTPase and GED domain contain Girdin-binding site. In addition, Girdin-NT domain binds with dynamin2 GTP-form and increases dynamin2 GTPase activity in a dose and time dependent manner. Girdin-NT has no effect on dynamin2 self-assembly. All of these results strongly indicate Girdin as the GAP of dynamin2. In consist with Girdin's GAP function, knockdown of Girdin inhibits transferrin endocytosis, overexpression dynamin interacting domain (Girdin-NT or N2) also inhibits transferrin endocytosis, which indicates Girdin-dynamin interaction is essential for endocytosis. In conclusion, this study shows Girdin functions as a GAP for dynamin2 to regulate endocytosis.

586

### **Novel functional roles of non-muscle myosin II in clathrin-mediated endocytosis and synaptic transmission.**

*I. Chandrasekar<sup>1</sup>, J. E. Huettner<sup>2</sup>, Z. M. Goeckeler<sup>3</sup>, R. B. Wysolmerski<sup>3</sup>, S. G. Turney<sup>4</sup>, R. S. Adelstein<sup>5</sup>, P. R. Wang<sup>1</sup>, R. Jalalizadeh<sup>1</sup>, P. C. Bridgman<sup>1</sup>; <sup>1</sup>Anatomy and Neurobiology, Washington University School of Medicine, Saint Louis, MO, <sup>2</sup>Cell Biology and Physiology, Washington University School of Medicine, Saint Louis, MO, <sup>3</sup>Neurobiology and Anatomy, West Virginia University School of Medicine, Morgantown, WV, <sup>4</sup>Molecular and Cellular Biology, Harvard University, Cambridge, MA, <sup>5</sup>Molecular Cardiology, NHLBI, NIH, Bethesda, MD*

Clathrin-mediated endocytosis (CME) aids in nutrient uptake, receptor mediated signaling, and reabsorption in most cell types. It also plays a major role in synaptic vesicle recycling and therefore is important for sustaining normal synaptic transmission. From electrophysiology experiments on cultured hippocampal neurons isolated from myosin IIB (MIIB) knockout (KO) embryos we found that synaptic transmission was severely impaired compared to control neurons from wild type (Wt) embryos. FM1-43 dye uptake during K<sup>+</sup> depolarization showed abnormal accumulations in vacuolar structures in the KO neurons that also stained with an early endosomal antigen (EEA1) antibody, which lead us to classify them as recycling endosomes. This data and additional electrophysiology and EM experiments on the hippocampal neurons suggested that the impairment is at least partially due to a presynaptic defect in the synaptic vesicle recycling pathway that involves endocytosis. To obtain mechanistic insights into the role of MIIB we studied embryonic fibroblasts isolated from Wt and MIIB KO mice. We found CME was defective in MIIB KO fibroblasts especially during transferrin-mediated retrieval. Acute inhibition of MII using blebbistatin or knock down of MIIA or MIIB isoforms resulted in decreased uptake of fluorescent transferrin by the fibroblasts. TIRF microscopy of KO cells expressing YFP-clathrin light chain or GFP-dynamin revealed decreased coated pit dynamics. Exogenous expression of MIIB rescued the coated pit dynamics in the KO fibroblasts. Electron microscopy showed abnormally shaped coated pits in the KO fibroblasts. EM studies using HRP transferrin showed increased number of shallow and invaginated pits in KO and blebbistatin treated fibroblasts. In Wt cells, immuno EM detected MIIB in association with a network of actin filaments connected to coated pits. Taken together, our findings indicate MII is an important molecular player in CME and is involved in both development and maintenance of synaptic transmission.

587

### **Synaptojanin 1 plays a role in endocytic trafficking in zebrafish cone photoreceptors.**

*A. A. George<sup>1</sup>, S. Hayden<sup>1</sup>, L. Holzhausen<sup>1</sup>, S. E. Brockerhoff<sup>1</sup>; <sup>1</sup>Biochemistry, University of Washington, Seattle, WA*

Phosphoinositides (PIs) play key roles in regulating membrane trafficking and cells contain multiple PI kinases and phosphatases to regulate the location and levels of PI species. Synaptojanin 1 (SynJ1) is a polyphosphoinositide phosphatase that is involved in recycling of clathrin coated vesicles at synapses in neurons. We have previously identified a zebrafish mutant, no optokinetic response c (*nrc*), which lacks SynJ1. In zebrafish, this mutation results in vision defects and morphological and functional abnormalities at cone photoreceptor synapses. In addition to this expected role of SynJ1 at the photoreceptor synapse, we found that SynJ1 localizes to cone photoreceptor inner segments (IS) and that the loss of SynJ1 results in the accumulation of the synaptic vesicle protein VAMP2/synaptobrevin in the IS.

In this study, we characterized the IS phenotype of *nrc* cone photoreceptors. We found that the ribbon synapse protein ribeye also accumulates in the *nrc* cone IS, and colocalizes with mislocalized VAMP2/synaptobrevin. Using electron microscopy, we observed that the *nrc* cone IS contains large vesicular structures of unknown origin. These structures lack a clathrin coat and are much larger than the vesicles that accumulate at the synapses of neurons lacking SynJ1. In order to determine the origin of these vesicles, we created fluorescent protein markers for various subcellular organelles including the Golgi apparatus, the endoplasmic reticulum and multiple endocytic compartments. These markers were expressed in cones and zebrafish larvae were analyzed at 5 days post fertilization by confocal microscopy. We found that *nrc* photoreceptors contain disrupted Golgi and enlarged Rab5 positive endosomal compartments. Interestingly, the Golgi disruption is not caused by abnormal Golgi development. These results demonstrate a novel role for SynJ1 at the Golgi and in the regulation of early endosomal dynamics in zebrafish cone photoreceptors.

588

**One track, two destinations: Elucidating how the endosomal Retromer complex mediates distinct trafficking itineraries.**

*K. C. Varandas<sup>1</sup>, M. E. von Zastrow<sup>2</sup>; <sup>1</sup>Department of Cell Biology, University of California San Francisco, San Francisco, CA, <sup>2</sup>Department of Psychiatry, University of California San Francisco, San Francisco, CA*

To maintain the unique identities, compositions, and activities of organelles, divergent membrane trafficking routes for proteins and lipids must exist. The Retromer complex is known to mediate trafficking of cargo from endosomes to the trans-Golgi network (TGN), in a process known as retrograde transport. Interestingly, it was recently discovered that Retromer can also mediate the recycling of the  $\beta$ 2-adrenergic receptor ( $\beta$ 2-AR) from endosomes to the plasma membrane (PM). Using the  $\beta$ 2-AR as a model cargo for the recycling pathway and the Wnt transport receptor Wntless (Wls) as a model cargo for Retromer-dependent retrograde transport, it was determined that these cargos converge at a shared vesicular compartment in their trafficking itineraries when expressed in the same cell. Additionally, it was confirmed that the  $\beta$ 2-AR and Wls have distinct trafficking itineraries, as surface labeled  $\beta$ 2-AR traffics between the PM and intracellular vesicles, while surface labeled Wls traffics between the PM, intracellular vesicles, and the TGN. In the future, we plan to use this system to further elucidate how the Retromer complex is able to physically and biochemically segregate cargos between the recycling and retrograde transport pathways.

589

**Dopamine receptor D3 regulates endocytic sorting by a Prazosin-sensitive interaction with the coatomer COPI.**

*X. Zhang<sup>1,2,3</sup>, W. wang<sup>3</sup>, A. V. Bedigian<sup>1</sup>, M. L. Coughlin<sup>2</sup>, T. J. Mitchison<sup>2</sup>, U. Eggert<sup>1,2,4</sup>; <sup>1</sup>Dana-Farber Cancer Institute, Boston, MA, <sup>2</sup>Harvard Medical School, Boston, MA, <sup>3</sup>High Magnetic Field Lab, Chinese Academy of Sciences, HeFei, China, <sup>4</sup>King's College, London, United Kingdom*

Macromolecules enter cells by endocytosis and are sorted to different cellular destinations in early/sorting endosomes. The mechanism and regulation of sorting are poorly understood, although transitions between vesicular and tubular endosomes are important. We found that the antihypertensive drug Prazosin inhibits endocytic sorting by an off-target perturbation of the G protein-coupled receptor dopamine receptor D3 (DRD3). Prazosin is also a potent cytokinesis

inhibitor, likely as a consequence of its effects on endosomes. Prazosin stabilizes a normally transient interaction between DRD3 and the coatomer COPI, a complex involved in membrane transport, and shifts endosomal morphology entirely to tubules, disrupting cargo sorting. RNAi depletion of DRD3 alone also inhibits endocytic sorting, indicating a noncanonical role for a G protein-coupled receptor. Prazosin induces rigid sorting and recycling endosomal tubules and locks endocytic cargos in these tubules, which is different from Brefeldin A, another small molecule commonly used to disrupt membrane trafficking. Prazosin is therefore a powerful tool for rapid and reversible perturbation of endocytic dynamics.

590

**Ubiquitination and a Ser/Thr motif are required for internalization of an epsin-specific cargo.**

A. Sen<sup>1</sup>, D. Mukherjee<sup>1</sup>, M. E. Ramos-Miller<sup>1</sup>, C. B. Hanna<sup>1</sup>, R. C. Aguilar<sup>1</sup>; <sup>1</sup>Biological Sciences, Purdue University, West Lafayette, IN

The epsins are a conserved family of endocytic adaptors involved in Notch and RhoGTPase signaling. Although epsins participate in the endocytosis of several ubiquitinated transmembrane proteins, no epsin-specific cargo has been unequivocally identified to date.

Using a combination of genetics, biochemistry and cell biology, we determined that the endocytosis of the yeast Na<sup>+</sup>/H<sup>+</sup> antiporter ENa1 (Exitus Natru 1) exclusively depends on the presence of the epsin adaptor. In addition, our results indicate that epsin-mediated internalization requires ENa1 ubiquitination and the simultaneous presence of a Ser/Thr (ST) motif in its intracellular tail. Importantly, the ENa1 ST motif is required for epsin function but not for the transporter ubiquitination.

Specifically, we report that the internalization of GFP-ENa1 is abolished in double epsin knock-outs, but can be rescued by introducing either of the two yeast epsins, Ent1 or Ent2. Further, we established that the UIMs (Ubiquitin Interacting Motifs) of epsin are necessary for ENa1 internalization. Additionally, we have mapped crucial determinants present at the C-terminal intracellular tail of ENa1 that are required for its epsin-dependent internalization. First, we identified a requirement for Lys<sup>1090</sup> that can be bypassed by fusion of an in-frame ubiquitin in the C-terminal ENa1 tail. These observations suggest that ENa1 ubiquitination mediates UIM-mediated epsin recognition. Interestingly, although ubiquitination of the yeast GPCR, Ste3, is also required for its internalization, we verified that the endocytosis of this cargo is independent of epsin.

Therefore, we hypothesized the existence of other determinants responsible for conferring epsin specificity. Indeed, we determined the presence of an ST motif (S<sup>1076</sup>TST<sup>1079</sup>) essential for ENa1 internalization. Extensive mutational analysis suggested that this ST motif might be targeted for phosphorylation. However, this post-translational modification was not important for ubiquitination, but instead led to enhanced epsin binding as detected by in vitro binding assay. Indeed, both ubiquitination and integrity of the ST motif are simultaneously required for epsin-mediated internalization of ENa1.

In summary, we have identified the first epsin-specific cargo and are in the process of defining an epsin-specific recognition sequence. In addition, these findings set up the basis for more comprehensive studies of epsin function. Further, our results suggest the existence of sequence motifs in ubiquitinated cargo that contributes to the specificity for ubiquitin-binding endocytic adaptors.

**MICAL-L1 regulates the intracellular transport of c-Src.**

*J. Reinecke<sup>1</sup>, D. Katafiasz<sup>1</sup>, N. Naslavsky<sup>1</sup>, S. Caplan<sup>1</sup>; <sup>1</sup>Biochemistry and Molecular Biology, University of Nebraska Medical Center, Omaha, NE*

Increased activity of the non-receptor tyrosine kinase c-Src (Src) is found in numerous cancers including those of the breast, lung and colon. The intracellular trafficking of Src is intimately associated with its activation and function and the regulation of Src localization within the endocytic pathways is crucially important. Inactive Src localizes to the perinuclear endosomal recycling compartment (ERC). Upon activation, Src translocates from the ERC to the plasma membrane (PM). We have found that Src co-localizes with the endosomal regulatory protein Molecule Interacting with Cas Ligand Like-1 (MICAL-L1). Using immunofluorescence analysis, we demonstrate that MICAL-L1-depletion in HeLa cells leads to Src retention in the ERC. The Src-ERC accumulation is specially pronounced upon serum stimulation, following which Src normally is transported to the PM. By immunoblot analysis, there is a significant reduction in active Src in MICAL-L1-depleted cells. In addition, we find that loss of MICAL-L1 in human fibroblasts leads to accumulation of active Src in intracellular vesicles. Previous studies have shown that intracellular sequestration of Src in fibroblasts stabilizes focal adhesions, leading to defects in cell spreading and migration. In agreement with this, the number and size of focal adhesions in MICAL-L1-depleted fibroblasts is increased. A large number of cells display a singular broad lamella, suggestive of defects in cell spreading. In total, we provide novel data supporting a model in which MICAL-L1 is a crucial endocytic protein regulating the transport of Src, an intracellular kinase that is overactive in numerous cancers.

**Reciprocal regulation of fibroblast growth factor receptor signalling and trafficking mediated through Src and Eps8.**

*G. Auciello<sup>1</sup>, D. L. Cunningham<sup>1</sup>, J. K. Heath<sup>1</sup>, J. Z. Rappoport<sup>1</sup>; <sup>1</sup>Biosciences, University of Birmingham, Birmingham, United Kingdom*

Fibroblast growth factor receptors (FGFRs) regulate fundamental cellular processes, including proliferation, differentiation and angiogenesis and have emerged as growth factor receptors central to oncogenesis. We developed a live-cell assay system for studying FGFR endocytosis and trafficking by employing both confocal and total internal reflection fluorescence (TIRF) microscopy in cells expressing a previously characterised GFP-tagged FGFR2 construct. Our analyses have demonstrated that endocytosis of activated FGFR occurs through a dynamin dependent pathway which we have identified as clathrin-mediated endocytosis. While AP2 siRNA and Dynasore treatment completely inhibited FGFR endocytosis, caveolin1 siRNA had no effect. Additionally, following stimulation significant colocalization of FGFR and clathrin is observed, while no colocalization with caveolin1 was detected. Interestingly, FGF treatment also significantly increased the number of CCPs as well as the number of clathrin-mediated endocytic events. However, as FGF treatment did not increase transferrin uptake we hypothesize that these may represent a cargo specific population of clathrin-coated pits.

Recent proteomic studies have identified the multifunctional scaffolding protein Eps8 as a prominent target of Src kinase activity with potential roles in the regulation of the signalling and trafficking of FGFR. Our analysis shows that treatment of cells with the Src family inhibitor Dasatinib or depletion of Eps8, prevents the FGF induced increase in plasma membrane clathrin and reduces the internalization of FGFR. Following stimulation, FGFR passes through an Eps8 positive peripheral compartment en route to the peri-nuclear recycling compartment (PNRC). Both Src and Eps8 are required for receptor to exit from this EEA1 positive peripheral compartment into the Rab11 positive PNRC. Eps8 depletion also inhibits the early phases of

ERK activation in response to FGFR activation, placing this signalling event early in the trafficking pathway of the receptor. Thus, these results have identified the endocytic pathway for endocytosis of FGFR2 and described Eps8 and Src as a key mediator of the early phases of activated FGFR trafficking and signalling.

**Examining the Role of the ArfGAP Asap1 in Coupling Endocytosis and Actomyosin Downregulation during *Drosophila* Early Embryogenesis.**

*F. Rodrigues<sup>1</sup>, T. Harris<sup>1</sup>; <sup>1</sup>Department of Cell and Systems Biology, University of Toronto, Toronto, ON, Canada*

Plasma membrane structure is controlled by membrane trafficking and cytoskeletal activity. Arf small G proteins are major regulators of such events, and are activated by Arf GEFs (Guanyl Nucleotide Exchange Factors) and inactivated by ArfGAPs (GTPase Activating Proteins). Here we show the requirement of the ArfGAP Asap1 in the proper development of the *Drosophila* early embryo. Asap1 RNAi led to abnormal expansion of actomyosin-coated membranes at the tips of invaginating plasma membranes of cellularizing embryos. This actomyosin expansion was accompanied by the pinching and expulsion of nuclei from the embryo periphery. To determine the initial time point of actomyosin membrane expansion, we monitored actomyosin dynamics live and discovered the expansions arise during syncytial stages, prior to cellularization. Consistent with a role in membrane trafficking and endocytosis, Asap1 RNAi also inhibited the formation of Amphiphysin (Amph) positive tubules during early cellularization. Strikingly, RNAi of the ArfGEF Steppke (Step) or Arf1 also results in abnormal actomyosin network expansion and the inhibition of Amph positive tubules. This prompted us to pursue whether Asap1 might function with Step and Arf1. Co-expressed Asap1::GFP and mCherry::Step fusion proteins colocalized throughout the cortex of the forming epithelium and both were enriched at the tips of invaginating plasma membranes. Interestingly, co-expression of these proteins also led to an increase in the number of embryos with strong cortical mCherry::Step compared to the expression of mCherry::Step alone. We hypothesize that Asap1 may stabilize Step at the plasma membrane via Arf GTPase cycling and we are testing whether Step also affects cortical Asap1 levels. However, overall Asap1::GFP localization was unaffected with Step RNAi, suggesting other mechanisms may be involved in the proper placement of Asap1. To determine whether Asap1 localization is dependent on its activity towards Arfs, we generated a GFP::Asap1 fusion protein that lacks its GAP domain. Intriguingly, this deletion led to abnormal localization to Amph positive tubules, suggesting Arf binding may be somehow coupled to tubule regulation. Together, these data outline a regulatory system important for coupling endocytosis and actomyosin downregulation in the early *Drosophila* embryo.

594

**Dynein provides the mechanical force for membrane tubulation in clathrin-independent endocytosis.**

*C. A. Day<sup>1</sup>, K. R. Drake<sup>1</sup>, L. J. Kraft<sup>2</sup>, A. K. Kenworthy<sup>1,2,3</sup>; <sup>1</sup>Molecular Physiology and Biophysics, Vanderbilt School of Medicine, Nashville, TN, <sup>2</sup>Chemical and Physical Biology Program, Vanderbilt School of Medicine, Nashville, TN, <sup>3</sup>Cell and Developmental Biology, Vanderbilt School of Medicine, Nashville, TN*

The mechanisms responsible for inducing membrane curvature in the early stages of raft-dependent, clathrin-independent endocytic pathways remain poorly defined. Recent studies have identified a role for certain cargo molecules of these pathways, such as the glycolipid binding toxins Shiga toxin and cholera toxin, in mechanically deforming the plasma membrane

to produce tubular endocytic intermediates. However, it is currently unclear if cellular components also contribute to the process of membrane tubulation in this pathway. In the current study, we tested for a potential role of microtubules and microtubule motors in this process. As a model system, we visualized tubule formation in COS-7 cells labeled with fluorescent cholera toxin B-subunit (CTxB) under conditions previously shown to be permissive for tubule growth but that inhibit tubule scission. Pretreatment of cells with nocodazole prior to the addition of CTxB blocked tubule formation, indicating an intact microtubule network is required. In contrast, the number and length of tubules were unaltered when microtubules were stabilized with taxol, ruling out a role for microtubule dynamics in the tubulation process. Time lapse imaging revealed the tubules underwent complex motions including branching events and bi-directional movements, suggesting microtubule motors may also be important for tubule extension. Consistent with this, disruption of dynactin by expression of dynamitin or CC1, or direct inhibition of the ATPase activity of dynein using the small molecule inhibitor ciliobrevin A inhibited tubule formation. These findings suggest the microtubule motor dynein provides the primary mechanical force for membrane tubulation, thus defining a novel role for microtubule-based motility in early stages of clathrin-independent endocytosis.

595

**Endosomal Network Analysis identifies a role for the metabolic enzyme ATIC and the putative tyrosine phosphatase PTPLAD1 on insulin receptor (IR) regulation.**

*M. Boutchueng-Djidjou<sup>1</sup>, S. Fortier<sup>1</sup>, C. Landry<sup>2</sup>, R. Faure<sup>1</sup>; <sup>1</sup>Cellular Biology Laboratory, Chul/Crchuq, Quebec, QC, Canada, <sup>2</sup>Biologie, Institut de Biologie Intégrative et des Systèmes, Quebec, QC, Canada*

Following insulin binding at the cell surface of target cells, there is within seconds internalization of the activated complexes into the endosomal apparatus. At this intracellular locus, the IR is deactivated by the concerted action of several mechanisms including insulin dissociation at the intraluminal acidic pH followed by degradation of free insulin and rapid tyrosine dephosphorylation of IR regulatory phosphotyrosine sites. A proteome of a Golgi/endosomes (G/E) fraction prepared from the mouse liver was previously described by us. Bioinformatics analyses using Mouse Genome Informatics (MGI) facilities now show that they enriched for specific groups of proteins and depleted for others. Proteins identified in the G/E fraction can be grouped and linked according to their functional and molecular associations in the cell whereby they form tight and interconnected clusters. Altogether, these results can be now summarized as a network of functional links between proteins known to be involved in specific cellular functions and mechanisms. Among the yet to be characterized proteins associated with the internalized IR, the higher probability Mascot score was attributed to a metabolic enzyme, ATIC, a homodimeric enzyme implicated in the two final steps of the de novo purine biosynthesis pathway. We confirmed the association in hepatic endosomes and demonstrated that IR/ATIC binding can be dynamically reconstituted in vitro by using IR-loaded endosomes and that ATIC increases IR autophosphorylation activity. The association was not observed when the IR was replaced with the internalized epidermal growth factor receptor (EGFR). We also verified the IR/ATIC association in HEK293 cells partially depleted with ATIC and have confirmed the presence of IR/ATIC complexes and decreased IR tyrosine phosphorylation. The transmembrane protein PTPLAD1 was also detected in IR complexes. The deletion of PTPLAD1 in HEK293 cells induced IR hyperphosphorylation. The results indicates the presence of a mechanism whereby ATIC counteracts the IR tyrosine dephosphorylating activity of PTPLAD1 in endosomes.

**Cell surface GAPDH recruits Apo Tf to facilitate iron export in iron overloaded cells.**

*N. Sheokand<sup>1</sup>, H. Malhotra<sup>1</sup>, V. Tillu<sup>1</sup>, S. Kumar<sup>1</sup>, M. Raje<sup>1</sup>; <sup>1</sup>Cell biology and Immunology, Institute of Microbial Technology, Chandigarh, India*

Iron is an essential element for vital metabolic processes but is toxic in excess. Nature has evolved a delicately balanced system for its storage and recycling where the reticuloendothelial system plays an important role in maintaining this homeostasis. Though the mechanism of iron import into cells involving carrier proteins like transferrin and transferrin receptors is well characterized, iron export from cells still remains poorly understood. Till date ferroportin is the only known mammalian iron exporter and is highly expressed in duodenal enterocytes and macrophages. In the current study we report that cells (J774, differentiated THP1, primary splenic & peritoneal macrophages and hepatocytes) express the glycolytic enzyme glyceraldehyde -3-phosphate dehydrogenase (GAPDH) on their surface upon iron overload which results in increased Apo transferrin (Apo Tf) binding to their surface. Apo Tf is one of the best known biological chelators of iron and we hypothesize that cell surface GAPDH and Apo Tf assist cells to remove excess intracellular iron. GAPDH and Apo Tf interaction was confirmed by solid phase assays, co-immunoprecipitation, confocal microscopy colocalization and Förster resonance energy transfer (FRET). The equilibrium dissociation constant of GAPDH-Apo Tf interaction was found to be 5.3 nM by biacore analysis. The results were further confirmed in GAPDH knockdown THP1 cells which failed to present GAPDH to their surface upon iron overload and abolished the Apo Tf binding. Iron overload presented in form of erythrophagocytosis (in J774, differentiated THP1 and primary splenic macrophages) also resulted in surface presentation of GAPDH and increased Apo Tf binding. We further observed that this surface GAPDH interacts with ferroportin as confirmed by co-immunoprecipitation, confocal microscopy colocalization and FRET. By loading cells with radioactive iron we confirmed that addition of Apo Tf to cells facilitated the exit of iron. Our results demonstrate that upon iron overload cell surface GAPDH functions as high affinity receptor for Apo Tf increasing its local concentration in close proximity to cells so that iron released by ferroportin is quickly chelated by it to avoid any toxic effects of free iron. Collectively our findings provide a new dimension to the iron export mechanism where cell surface GAPDH recruits Apo Tf and facilitates the iron export in conjunction with ferroportin.

**Exit of the intracellular pathogen *Nematocida parisii* from *C. elegans* intestinal cells.**

*S. Szumowski<sup>1</sup>, K. Estes<sup>1</sup>, M. Smelkinson<sup>1</sup>, E. Troemel<sup>1</sup>; <sup>1</sup>Biological Sciences, University of San Diego California, La Jolla, CA*

Microsporidia comprise a diverse phylum of fungal-related pathogens that infect a broad range of hosts, including insects and humans. As obligate intracellular parasites, microsporidia are dependent on their hosts for replication. Although they likely usurp many host processes, very little is known about the mechanisms of pathogenesis used by these ubiquitous microbes. Recently we found that the microsporidia *Nematocida parisii* reorganizes the host *C. elegans* actin cytoskeleton and terminal web prior to making a non-lytic exit from host cells. We found that *N. parisii* spores exit from the apical side of intestinal cells into the lumen, and that they are free of host membrane after exit. By studying how *N. parisii* exits from cells while minimizing damage to the host we expect to learn about intestinal cell biology and intracellular trafficking as well as key mechanisms of microsporidia transmission. Our previous studies indicated that actin was required for *N. parisii* exit from intestinal cells, but we did not know the underlying mechanism. We now show that actin forms distinct "coats" on spores localized near the apical membrane. The number of actin coats in an animal is positively correlated with the number of

spores that are shed. In addition, animals with actin-coated spores are more contagious than animals without actin-coated spores. Thus, we believe that actin-coated spores are exiting from the host, and we are developing methods to image this process *in vivo*. A candidate RNAi screen of small GTPases revealed that members of the endocytic recycling pathway including *rab-5*, *rab-10*, *rab-11*, *cdc-42* and *ced-10* are required for efficient actin spore coat formation as well as spore exit. Furthermore, spore exit requires core components of the exocyst complex. So far, spore exit strongly resembles "kiss and coat" exocytosis, where membrane fusion is thought to trigger actin polymerization that stabilizes large cargo during the exit process. In this way, microsporidia appear to usurp host processes in order to proceed through their life cycle and exit non-lytically from host cells. These findings provide some of the first cell biological insights into microsporidia pathogenesis and may also offer insight into the fundamental biology of intestinal cells. Future work will focus on how microsporidia hijack the endocytic recycling pathway in order to traffic to the apical cell surface, as well as characterizing membrane topology during spore exit.

### **Adaptor protein Sorting Nexin 17 facilitates human papillomavirus trafficking and infection.**

*M. Bergant*<sup>1,2</sup>, *M. A. Ozbun*<sup>3</sup>, *S. K. Campos*<sup>4</sup>, *M. P. Myers*<sup>1</sup>, *L. M. Banks*<sup>1</sup>; <sup>1</sup>*International Centre for Genetic Engineering and Biotechnology, Trieste, Italy*, <sup>2</sup>*University of Nova Gorica, Nova Gorica, Slovenia*, <sup>3</sup>*University of New Mexico School of Medicine, Albuquerque, NM*, <sup>4</sup>*University of Arizona, Tuscon, AZ*

The Human Papillomavirus (HPV) L2 capsid protein plays an essential role during the early stages of viral infection, but the molecular mechanisms underlying its mode of action remain obscure. Using a proteomic approach we have identified the adaptor protein, Sorting Nexin 17 (SNX17) as a strong interacting partner of HPV-16 L2. This interaction occurs through NPxF/Y phosphotyrosine-binding domain, which is present in all papillomavirus (PV) types analysed. Using mutants of HPV-16 L2 defective for SNX17 interaction, or siRNA ablation of SNX17 expression we demonstrate that the interaction between L2 and SNX17 is crucial for viral infection. Furthermore, we show that SNX17 is essential for infection with multiple PV types from Alpha, Beta, Delta, Kappa and Pi genera, indicating an evolutionary highly conserved viral entry mechanism. Loss of the L2-SNX17 interaction results in enhanced turnover of the L2 protein and decreased stability of the viral capsids, and concomitantly there is a dramatic decrease in the efficiency with which viral genomes transit to the nucleus. Indeed, using a range of endosomal and lysosomal markers we show that capsids defective in their capacity to bind SNX17 transit much more rapidly to the lysosomal compartment. These results demonstrate that the L2-SNX17 interaction is essential for viral infection and facilitates the escape of the L2-DNA complex from the late endosomal/lysosomal compartments. Moreover, partial nuclear localisation of SNX17 during an HPV-16 infection suggests that SNX17 is also involved in the transport of the L2-DNA complex to the nucleus. These studies reveal a novel role for SNX17 in aiding viral infection processes, and raise the possibility that normal cellular recycling pathways are perturbed as a result of HPV infection.

### **A Nibbling Mechanism for the Clathrin-mediated Recycling of Secretory Granule Membrane after Exocytosis.**

*M. A. Bittner<sup>1</sup>, R. W. Holz<sup>1</sup>; <sup>1</sup>Pharmacology, University of Michigan, Ann Arbor, MI*

pTIRFM studies from our laboratory have revealed that most fused granule membranes do not undergo rapid endocytosis in chromaffin cells, but rather remain in the plasma membrane with varying degrees of curvature for many seconds. In this study we examine the subsequent fate of the chromaffin granule membrane. Immunocytochemistry of the granule membrane protein dopamine beta hydroxylase (DBH) revealed that DBH remained punctate on the surface for at least 30 minutes, but that the intensity of the puncta decreased over time. Other granule proteins (e.g., VMAT2, VAMP/synaptobrevin, synaptotagmin), some of which have clathrin-adaptor binding domains, also remained associated with these puncta. An analysis of the distribution of DBH puncta intensities over time suggested that the granule membrane components are gradually removed from the cell surface via a nibbling process, rather than via a single discrete event as in rapid endocytosis. Live cell TIRFM imaging of overexpressed GFP-labeled clathrin light chain or dynamin2 provided evidence that both proteins begin to accumulate at fusion sites within 10 seconds of release of granule contents. To directly demonstrate consummated endocytosis, a fixable fluid phase marker (Alexafluor cadaverine) was used to label endocytic vesicles in conjunction with antiDBH. In the absence of stimulation, cadaverine was taken up by constitutive endocytosis into vesicles which did not contain DBH. Following a 30 second depolarization, a second population of vesicles, containing both cadaverine and DBH, appeared. The presence of antiDBH did not alter constitutive cadaverine uptake. A role for endogenous dynamin in the nibbling process was demonstrated using the membrane-permeant dynamin GTPase inhibitor dyngo4a. Dyngo4a largely blocked the decrease in DBH puncta intensity over time, while having no effect on the constitutive uptake of cadaverine. In addition, overexpression of a GTPase-deficient mutant of dynamin2 (dyn2K44A) also prevented the loss of DBH puncta from the surface. We conclude that secretory granule membrane components remain associated on the plasma membrane following fusion and are internalized together in small increments via a clathrin- and dynamin-dependent process we term nibbling. These results explain the size mismatch between chromaffin granules (~300 nm diameter) and clathrin-coated vesicles (approximately 100 nm).

### **Endosomes, Lysosomes, and Lysosome-related Organelles**

600

#### **Lysosome-related organelle biogenesis protein complexes interact with the WASH complex.**

*P. V. Ryder<sup>1</sup>, R. Vistein<sup>2</sup>, A. Gokhale<sup>1</sup>, M. N. Seaman<sup>3</sup>, M. Puthenveedu<sup>2</sup>, V. Faundez<sup>1</sup>;  
<sup>1</sup>Department of Cell Biology, Emory University, Atlanta, GA, <sup>2</sup>Department of Biological Sciences, Carnegie Mellon University, Pittsburgh, PA, <sup>3</sup>Department of Clinical Biochemistry, University of Cambridge, Cambridge, England*

Biogenesis of lysosome-related organelles requires the targeting of specific membrane proteins and soluble cargoes to maturing organelles. One mechanism for this targeting is the recruitment and concentration of cargo into nascent vesicles by adaptor protein complexes, such as the

adaptor protein complex-3 (AP-3). Mutations to AP-3 and related protein complexes including the BLOC-1 complex cause the Hermansky Pudlak Syndrome, which is characterized by hypopigmentation, platelet dysfunction, and pulmonary fibrosis. Adaptor proteins are recruited to membranes from the cytosol in part by specialized phospholipids, making lipid kinases key regulators of membrane traffic. One such regulator is the phosphatidylinositol-4-kinase type IIa (PI4KIIa), which is known to bind and regulate the function of both AP-3 and BLOC-1 complexes. In order to search for upstream and downstream regulators of this pathway we designed an antibody that binds to PI4KIIa at its coat-interaction motif and thereby predominantly recognizes a subset of PI4KIIa that is not engaged in coat interactions. Using this antibody, we isolated PI4KIIa protein complexes by immunoaffinity chromatography coupled with *in vivo* isotope tagging of the cell proteome and mass spectrometry (SILAC). We identified several regulators of the actin cytoskeleton, including the WASH complex, an Arp 2/3 activator, and the RhoA guanine exchange factor RhoGEF1. We confirmed these interactions by independent immunoaffinity chromatography experiments, sucrose velocity sedimentation, and deconvolution immunofluorescent microscopy. We conclude that PI4KIIa, a key enzyme regulating cytosolic coats required for lysosome-related organelle biogenesis, interacts with RhoGEF1 and the WASH complex. Future work will test the hypotheses that the WASH complex is required for AP-3- and/or BLOC-1-dependent cargo sorting and vesicle fission for lysosome-related organelle biogenesis.

**Monoubiquitination of syntaxin 3 regulates its basolateral endocytosis and sorting to intraluminal vesicles in MDCK cells.**

A. J. Giovannone<sup>1</sup>, E. Reales-Rodriguez<sup>1</sup>, B. Pallavi<sup>1</sup>, T. Weimbs<sup>1</sup>; <sup>1</sup>Molecular, Cellular, & Developmental biology, University of California, Santa Barbara, Santa Barbara, CA

Syntaxins are a family of membrane fusion proteins involved in nearly all intracellular membrane trafficking pathways. In polarized epithelial cells, syntaxin 3 (Stx3) functions in apical membrane fusion. A small population of Stx3 is sorted to the basolateral membrane, only to be rapidly internalized. Stx3 also localizes to multivesicular bodies (MVBs) and lysosomes, although their trafficking to and function at these sites is currently unknown. In Madin-Darby canine kidney (MDCK) cells, we show that monoubiquitination at a conserved, polybasic, juxtamembrane region of Stx3 induces its internalization from the basolateral plasma membrane and subsequent trafficking to early endosomes. We use a Rab5 mutant to enlarge early endosomes and observe Stx3 in intraluminal vesicles (ILVs). We also show that Stx3 is present in exosomes purified from mammalian cell culture and human urine.

Trafficking of Stx3 to endosomes is prevented when lysine residues in the polybasic region are mutated to arginines and ubiquitination is prevented. We show that the Stx3-5R mutant is delayed in its rate of internalization from the basolateral plasma membrane and is also excluded from ILVs in enlarged early endosomes. Consequently, nearly none of Stx3-5R is found in exosomes isolated from mammalian cells expressing the mutant. Altogether, our data show that monoubiquitination on Stx3 is a signal for endocytosis and sorting to intraluminal vesicles. This suggests that ubiquitination on some SNARE proteins may be a general pathway for their distribution throughout the cell.

**Syndecan-syntenin-ALIX regulate exosome biogenesis.**

M. F. Baietti<sup>1,2</sup>, Z. Zhang<sup>1,2</sup>, E. Mortier<sup>1</sup>, A. Melchior<sup>1,2</sup>, G. Degeest<sup>1,2</sup>, A. Geeraerts<sup>1,3</sup>, F. Depoortere<sup>1</sup>, Y. Ivarsson<sup>1</sup>, C. Coomans<sup>1,2</sup>, E. Vermeiren<sup>1</sup>, P. Zimmermann<sup>1</sup>, G. David<sup>1,2</sup>; <sup>1</sup>Center of Human Genetics, KU Leuven, Leuven, Belgium, <sup>2</sup>Center for the Biology of Disease, VIB, Leuven, Belgium, <sup>3</sup>Dept. of Chemistry, KU Leuven, Leuven, Belgium

Syndecans are essential for fine-regulating signaling events between cells<sup>1</sup>. The extracellular heparan sulfate (HS) chains of the syndecans attract several signaling molecules, such as morphogens, to cell surfaces, but the mechanisms of their regulatory functions remain largely unknown.

Our work describes a new mechanism for exosome biogenesis and MVB formation. We have found that, through the PDZ protein syntenin<sup>2</sup>, a well-known syndecan cytoplasmic adaptor, syndecans are connected to ALIX<sup>3</sup>, an auxiliary component of the ESCRT machinery, implicated in vesicular budding, and marker of small signaling vesicles released by cells, known as 'exosomes'.

In the study, we explore whether the syndecan-syntenin-ALIX connection might regulate the biogenesis of exosomes, impacting on the cellular release of morphogen signals. The results obtained show that interfering with syndecan-syntenin-ALIX reduces exosome production by affecting the biogenesis of MVBs and that syndecan-syntenin-ALIX complexes control the composition of a specific population of exosomes, potentially transferring specific information between cells<sup>4</sup>.

The establishment of a direct link between syndecans and exosomes, as a novel mechanism of morphogen spreading, may help explain the role of HS in the diffusion of morphogenetic signals, in particular how lipid-modified morphogens travel long-range. Syndecan-syntenin exosomes might also participate in the biology of HS-associated pathological processes, including neurodegenerative and oncogenic diseases.

**Endo-lysosome trafficking is critical for maintaining membrane integrity in polarized retinal pigment epithelial cells.**

K. A. Toops<sup>1</sup>, J. Xu<sup>1</sup>, A. Lakkaraju<sup>1</sup>; <sup>1</sup>Ophthalmology & Visual Sciences, University of Wisconsin-Madison, Madison, WI

Rapid plasma membrane repair is a ubiquitous, highly conserved response crucial for cell survival. Pore-forming toxins or the terminal complement complex C5b-9 blast holes in membranes, induce calcium influx and activate signaling pathways that compromise cell function and can result in cell death. Assembly of sub-lytic C5b-9 membrane attack complexes (MAC) on the plasma membrane of retinal pigment epithelial (RPE) cells contributes to the pathogenesis of age-related macular degeneration (AMD), the most common cause of blindness in older adults. Mechanisms that limit sub-lytic MAC activity include: cell surface GPI-anchored complement regulatory proteins CD55 and CD59 that inhibit specific steps of MAC formation; elimination of assembled MAC by secretion into exosomes or by endocytosis and subsequent lysosomal degradation; and rapid resealing of pores by the exocytosis of late

endosomes and lysosomes. Here, we investigated how RPE membrane integrity is maintained after exposure to calcium ionophores (ionomycin), pore-forming toxins (streptolysin O) or sub-lytic C5b-9 deposition. Live imaging of polarized primary RPE cells using spinning disk/TIRF microscopy showed that a short exposure to ionomycin or sub-lytic MAC results in rapid exocytosis of late endosomes and lysosomes expressing GFP-CD63 or GFP-LAMP2, indicating that these organelles participate in RPE membrane repair. Pore formation induces endocytosis of CD55-GFP, suggesting that toxin and MAC removal from the plasma membrane occurs by internalization into endosomes that also contain complement regulatory proteins. Calcium influx also accelerates the secretion of sub-micron membrane vesicles called exosomes from RPE cells. We next investigated membrane repair in cells containing the retinal lipofuscin fluorophore A2E, a hallmark of AMD that causes cholesterol accumulation in late endosomes and lysosomes. Late endosomal cholesterol levels are critical for regulating organelle motility and for sorting GPI-anchored proteins. In RPE cells with A2E, surface biotinylation and immunofluorescence analyses show that recycling of CD59 to the plasma membrane is decreased. A2E also inhibits the tubulo-vesicular trafficking of GFP-CD63 and GFP-LAMP2, prevents lysosome exocytosis and alters exosome secretion in response to ionomycin or C5b-9. Our results indicate that membrane integrity in the RPE is maintained by the concerted actions of CD55, CD59 and late endosome-lysosome trafficking in both the exocytic and endocytic pathways. Lipofuscin/A2E interferes with membrane trafficking routes that involve late endosomes and lysosomes in the RPE. These data provide mechanistic insight into how lipofuscin accumulation decreases complement regulatory protein function and compromises the ability of the RPE to maintain membrane integrity, both of which likely contribute to a chronic inflammatory environment in the outer retina.

#### **Rules for ESCRT-mediated protein sorting.**

*S. Mageswaran<sup>1</sup>; <sup>1</sup>Biology, University of Utah, Salt Lake City, UT*

Multivesicular bodies (MVB) are mature endosomes that internalize a portion of the limiting membrane containing membrane proteins into the compartment, thus forming intraluminal vesicles (ILVs). This invagination process is catalyzed and directed away from the cytosol by cytosolic protein complexes called ESCRTs (Endosomal Sorting Complexes Required for Transport). Ubiquitin is the only well established signal for proteins to be sorted into ILVs by ESCRTs but there are reports of other sorting signals that are not well understood. The internalized lipids and proteins are turned over in the vacuole/lysosome. The ESCRT pathway is responsible for the downregulation of integral membrane proteins and for shutting down cellular signals by sequestering the signaling membrane proteins away from the cytosol. The pathway consists of several proteins that can be broadly divided into 2 categories; (1) the ESCRT-machinery proteins themselves and (2) the cargo proteins that get sorted into ILVs. ESCRTs and cargo proteins are very similar in many aspects (both get ubiquitinated and bind other ESCRT proteins) but unlike cargo proteins, ESCRTs predominantly stay outside the MVBs and are used for several rounds of vesicle formation. It is not clear how the ESCRT pathway differentiates between the ESCRT-machinery and the cargoes. It is even more surprising that ESCRTs don't enter MVBs considering the fact that they bind phosphatidylinositol-3-phosphate (PI-3P), a lipid that enters MVBs. Indeed, a few studies have reported sorting of ESCRTs into MVBs under special circumstances (regulated degradation of ESCRTs by sorting into MVBs; identification of ESCRTs in exosomes that are derived from MVBs; identification of ESCRTs in HIV virions that use ESCRTs to egress from the host cell plasma membrane; and packaging of the mutant ESCRT-I into MVBs in a strain lacking an ESCRT-I subunit, *mhb12*). From the

perspective of cargoes, it is not clear what the requirements are to be sorted into ILVs. In this study, we address two important questions; (1) what prevents ESCRTs from entering ILVs during normal MVB formation? and (2) what makes an efficient cargo for the ESCRT pathway. We used artificial fusion protein mimics for ESCRTs and cargoes to probe for the rules that govern their behavior. Our unbiased approach led us to conclude that cargo proteins have to; (1) associate with the endosomal membrane, (2) bind any ESCRT protein (including ESCRT-III that has no clear role in cargo sorting thus far) (3) and lose the interaction with ESCRTs before ILV formation. We also discovered a simple underlying mechanism that differentiates the ESCRTs from cargoes based on interaction strength. We propose a tug-of-war model where in ESCRTs get recycled back into cytosol by virtue of their strong interactions with other ESCRTs. When this inter-ESCRT interaction is weakened, their interaction with the membrane wins over to pull them into the ILVs.

**The yeast Alix homolog, Bro1, functions as an ubiquitin receptor for protein sorting into multivesiculated endosomes.**

*N. Pashkova<sup>1</sup>, L. Gakha<sup>2</sup>, L. Yu<sup>3</sup>, S. Winistorfer<sup>1</sup>, R. Piper<sup>1</sup>; <sup>1</sup>Molecular Physiology and Biophysics, University of Iowa, Iowa City, IA, <sup>2</sup>Carver College of Medicine Protein Crystallography Facility, University of Iowa, Iowa City, IA, <sup>3</sup>Carver College of Medicine NMR Facility, University of Iowa, Iowa City, IA*

Sorting of endocytosed membrane proteins into luminal vesicles of late endosomes/multivesicular bodies (MVB) is an important step for their vacuole/lysosomal degradation. This step is mediated by the ESCRT multicomponent apparatus as well as associated factors such as Vps4, the AAA-ATPase that catalyzes ESCRT complex disassembly and release, and the accessory protein Bro1 that recruits deubiquitinating enzyme Doa4 to ESCRT-III so that ubiquitin can be removed from cargo after cargo sorting. ESCRT-0, -I, and -II proteins contain ubiquitin-binding domains, which recognize ubiquitinated cargo to promote its entry into MVB luminal vesicles.

Here we show that Bro1 together with ESCRT-0 may work as a receptor for selective sorting of ubiquitinated cargos targeted for endosomal degradation. We found synthetic genetic interactions of BRO1 with ESCRT-0, arguing that Bro1 works at a step similar to ESCRT-0, which serves as a central ubiquitin receptor for MVB sorting. We found that Bro1 binds ubiquitin via its middle V-domain. In addition, the V-domains of other Bro1-like proteins including HD-PTP, Alix, and RIM20 could bind both K63-linked polyubiquitin and monoubiquitin. To understand structural basis of Bro1 V-domain interaction with ubiquitin, we solved the X-ray crystal structure of the protein complex. The yeast Bro1 V-domain was found to fold in a V-shaped two three-helix bundle, similar to the Alix V-domain. The structure revealed that the V-domain has a major ubiquitin-binding region centered along its N-terminal helix. The residues involved in interaction with ubiquitin were confirmed using a series of NMR paramagnetic relaxation experiments. Using both X-ray diffraction and NMR data, we built a model for how Bro1 V-domain binds ubiquitin that was confirmed with mutagenesis experiments. Mutants of Bro1 lacking the ability to interact with ubiquitin were defective in sorting ubiquitinated cargo membrane proteins, but only when combined with additional mutations in ESCRT-0 that compromised its biochemical interactions. Together these data suggest that Bro1 can work early in the MVB sorting process to recognize ubiquitinated cargo and implies that other Bro1 family members may perform a similar function.

606

### Vps9 drives the formation of class E compartments in yeast by causing hyper-activation of Vps21.

T. Shideler<sup>1</sup>, G. Odorizzi<sup>1</sup>; <sup>1</sup>MCDB, University of Colorado, Boulder, CO

Membrane trafficking through the endocytic pathway is regulated by Rab5 GTPases that promote fusion of incoming transport vesicles with early endosomes as well as homotypic fusion of early endosomes with one another. How Rab5 activity is regulated during the maturation of early endosomes into late endosomes is unknown. In *Saccharomyces cerevisiae*, Vps21 is the ortholog of human Rab5A. Vps21 is activated by the Guanine nucleotide Exchange Factor (GEF) Vps9. The aim of this study is to understand how Vps9 regulates Vps21 in the context of endosomal maturation.

Ubiquitinated transmembrane proteins targeted for lysosomal degradation are directed to endosomes, where they are sorted into intraluminal vesicles (ILVs) by the Endosomal Sorting Complexes Required for Transport (ESCRTs). The formation of ILVs occurs during endosomal maturation. Late endosomes filled with ILVs are known as multivesicular bodies (MVBs).

Disruption of ESCRTs in yeast blocks MVB biogenesis and, instead, leads to the formation of class E compartments, which consist of endosomes that have aberrantly flattened and stacked with one another. Recently, we showed that the formation of class E compartments is driven by hyperactive Vps21. Here we show that Vps9 is also required for class E compartment biogenesis, indicating that Vps9 is the GEF driving Vps21 hyperactivity in ESCRT-mutant cells.

Vps9 is composed of an unstructured N terminus, a conserved Vps9 domain, and a ubiquitin-binding CUE domain. We use confocal fluorescence microscopy to show that the CUE domain alone localizes to endosomes but is not necessary for endosomal localization of Vps9. By electron microscopy, we see that Vps9 lacking the CUE domain supports class E compartment formation. Therefore, we speculate that ubiquitin-binding reinforces Vps9 localization at endosomes but is not required for its activity toward Vps21.

The Vps9 ortholog in *C. elegans* is RABX-5, which appears to be down-regulated upon being displaced from endosomes by SAND-1. In yeast, the SAND-1 ortholog is Mon1. We see by confocal fluorescence microscopy that loss of Mon1 in yeast causes both GFP-Vps9 and GFP-Vps21 to accumulate at endosomes. By electron microscopy, we show that loss of Mon1 causes MVBs to enlarge, potentially as a consequence of continued Vps9 activation of Vps21. We propose a model where Vps9 is displaced by Mon1 after the completion of ILV cargo sorting by ESCRTs.

607

### Effects of ESCRT component knockout on MHCII compartments in dendritic cells.

A. De Mazière<sup>1</sup>, S. van Dijk<sup>1</sup>, J. Ma<sup>2</sup>, I. Mellman<sup>2</sup>, J. Klumperman<sup>1</sup>; <sup>1</sup>Department of Cell Biology, University Medical Center Utrecht, Utrecht, Netherlands, <sup>2</sup>Genentech, South San Francisco, CA

Major histocompatibility complex class II (MHCII) molecules of dendritic cells (DCs) present antigenic peptides to T-lymphocytes to generate a cellular immune response. In immature DCs, MHCII molecules are loaded with antigenic peptides by the assistance of the chaperone DM. This occurs in MHCII compartments (MIICs), which are specialized late endosomes/lysosomes. In MIICs, the majority of MHCII is localized on intraluminal vesicles, where it is destined for degradation. It has been hypothesized that the ESCRT complexes are responsible for sorting of ubiquitinated MHCII to the intraluminal vesicles of MIICs. Upon maturation of the DCs,

ubiquitination is downregulated and the large majority of the MHCII molecules accumulates at the plasma membrane.

In the present study, the role of Hrs (ESCRT-0), and of Tsg101 (ESCRT-I) in the localization of MHCII molecules was investigated by immunoelectron microscopy. In immature DCs derived from mice with a conditional knockout (KO) for either Hrs or Tsg101, MHCII was distributed as in wild type (WT) DCs, with, in the MIICs, a similar percentage of MHCII molecules present on the intraluminal vesicles. After maturation of the DCs by 16 h stimulation with LPS, the majority of MHCII molecules in the Hrs KO DCs shifted to the plasma membrane, similar as in WT cells. In the Tsg101 KO DCs this shift also occurred, however, part of the MHCII was found on aberrant clusters of membranes (vesicles and cisterns), resembling class-E compartments described in yeast and mammalian cells. The vesicles and cisterns were surrounded by a dense matrix, which sometimes showed periodic densities. They were accessible for endocytosed BSA-gold and positively labeled for Invariant chain (Ii), indicating an early endosomal origin. In addition, the vesicle clusters were positive for ubiquitin and p62, suggesting that they were involved in the process of autophagy. In conclusion, our results suggest that Hrs and Tsg101 are not necessary for the sorting of MHCII to the intraluminal vesicles of MIICs, but in stimulated cells the absence of Tsg101 gives rise to a class-E like compartment.

608

**Characterization of PCSK9 trafficking reveals a novel lysosomal transport complex.**

*R. M. DeVay<sup>1</sup>, D. L. Shelton<sup>1</sup>, H. Liang<sup>1</sup>; <sup>1</sup>Biology, Rinat-Pfizer, Inc., South San Francisco, CA*

Proprotein convertase subtilisin/kexin type 9 (PCSK9) interacts directly with the LDL receptor (LDLR) and targets it for lysosomal degradation. It has been shown that inhibiting PCSK9-LDLR interactions effectively blocks degradation of LDLR, thus, PCSK9 has emerged as a promising therapeutic target for lowering LDL cholesterol. Furthermore, it has been hypothesized that LDLR binding is required for PCSK9 internalization, making PCSK9 an ideal target for antibody therapeutics since there would be minimal expected target mediated clearance of anti-PCSK9 antibodies. We previously employed this reasoning to identify and develop an anti-PCSK9 antibody, J16, which completely blocks PCSK9 binding to LDLR. Surprisingly, these studies revealed that J16 is degraded in a PCSK9 dependent manner, suggesting that PCSK9 is internalized and trafficked to lysosomes regardless of its direct interaction with LDLR.

In this study, we confirmed that J16 does not alter PCSK9 trafficking, rather, exogenously added PCSK9 bound to J16 is still endocytosed and routed to lysosomes. Thus, a direct interaction with LDLR is not required for PCSK9 trafficking, and the mechanism by which PCSK9 diverts LDLR to lysosomes remained an important and open question. We hypothesized that lysosomal targeting of PCSK9 occurs via protein interactions on the luminal side of the membrane. We therefore sought to identify PCSK9 binding partners which could target PCSK9 to lysosomes. In doing so, we discovered a novel, pH dependent interaction between PCSK9 and the amyloid precursor-like protein 2 (APLP2). Interestingly, we found that PCSK9 and LDLR are trafficked along the same endo-lysosomal route as APLP2, and that recombinant LDLR and APLP2 can be complexed in a PCSK9 dependent manner at endosomal pH. Our data also indicate that APLP2 plays an active role in post-endocytic targeting of PCSK9 to lysosomes, thereby directly regulating PCSK9 trafficking and function.

Based on our observations, we propose that PCSK9 is involved in a novel lysosomal transport complex which would allow it to degrade multiple targets, including anti-PCSK9 blocking antibodies, by the same mechanism. Indeed, our data support a model in which PCSK9 bridges LDLR to APLP2, and APLP2 then mediates targeting of the trimeric complex to lysosomes.

Intriguingly, this system allows for a soluble messenger from either a local or distant source to modulate what has previously been considered a cell autonomous process.

**A Model System to Investigate Antibody Bipolar Bridging Mediated by gE-gI, a Herpes Virus Fc Receptor.**

*B. Ndjamen<sup>1</sup>, A. Farley<sup>2</sup>, S. E. Fraser<sup>3</sup>, P. J. Bjorkman<sup>1,4</sup>; <sup>1</sup>Division of Biology, 114-96, California Institute of Technology, Pasadena, CA, <sup>2</sup>Department of Architecture, MIT, Cambridge, MA, <sup>3</sup>Beckman Institute (139-74), California Institute of Technology, Pasadena, CA, <sup>4</sup>Investigator, HHMI, Pasadena, CA*

The Herpes Simplex Virus 1 (HSV-1) glycoproteins (gE and gI) bind the Fc region of human immunoglobulin G (hIgG), which allows HSV-1 infected cells to escape recognition by host Fc receptor-mediated effector functions. HSV-1 gE-gI can further undermine the immune system by participating in antibody bipolar bridging (ABB), a process by which the antigen binding fragments of the IgG bind an antigen while the Fc binds to gE-gI. The fate of a gE-gI/IgG/viral antigen ABB complex is unknown. In this study, we engineered an in vitro ABB system to determine whether a gE-gI/IgG/viral antigen complex is internalized and targeted for degradation in host cells. This system involves HeLa and HEK293T cells transiently expressing HSV-1 gE-gI and an HSV-1 antigen, gD, which is normally localized at the cell surface of HSV virions and infected cells. gD was fused to the Dendra2 fluorescent protein. We constructed two forms of a monoclonal anti-gD antibody: one in which the Fabs were fused to a hIgG1 Fc, which can bind to gE-gI via its Fc and to gD via its Fabs, and one in which the Fabs were fused to a mouse IgG2a Fc, which can bind to gD but not to gE-gI. A hIgG against an irrelevant antigen was used as a control. Using 4D-time-lapse confocal fluorescence imaging, we demonstrated that surface antigens such as HSV-1 gD are internalized only in ABB permissible conditions and internalization is dependent upon gE-gI. Internalized hIgGs, bound or not to a surface viral antigen, were targeted into lysosomal compartments, and analysis of enriched and immunopurified Dendra2 tagged lysosomal compartments show degraded HSV-1 gD.

These results suggest that gE-gI plays an active role in clearing the infected cell surface of both host IgG and viral antigens, providing HSV-1 with a mechanism to evade immune responses. Knowledge gained from this study can guide new strategies for development of HSV-1 based oncolytic virotherapies.

610

**Drebrin E, an actin binding protein, regulates post-endocytic fate of apical proteins in intestinal cells.**

*B. Vacca<sup>1</sup>, E. Bazellières<sup>2</sup>, R. Nouar<sup>3</sup>, D. Massey-Harroche<sup>1</sup>, A. Le Bivic<sup>1</sup>; <sup>1</sup>IBDML, Marseille, France, <sup>2</sup>IBEC, Barcelona, Spain, <sup>3</sup>CRO2, Marseille, France*

Intestinal epithelial cells are highly polarized and exhibit a complex architecture with a columnar shape, a specialized apical surface supporting microvilli organized in a brush-border. These microvilli are rooted in a dense meshwork of acto-myosin called the terminal web. We have shown recently that Drebrin E, an F-actin-binding protein, is a key protein for the organization of this terminal web and that Drebrin E is required for the columnar cell shape and the organization of microvilli in Caco-2/TC7 cells (human colonic cells) (Bazellières et al., J. Cell Sci., 2012). Now, to better understand how Drebrin E regulates the columnar epithelial phenotype we have investigated the levels of apical membrane proteins such as DiPeptidyl-Peptidase IV (DPPIV), Sucrase-Isomaltase (SI) or Alkaline Phosphatase (ALP) in Drebrin KD cells. All these apical proteins showed a marked decrease expression level while basolateral proteins do not, indicating that a specific step in apical membrane biogenesis or trafficking is affected. To

identify this step we have studied the subcellular localization of DPPIV, SI and ALP which was strikingly modified. Instead of being mostly present at the apical surface DPPIV, SI and ALP were accumulated inside a large sub-apical compartment and we showed, both by confocal and electron microscopy, that this compartment is related to lysosomes. Furthermore, by using endocytic assays we demonstrated that the enrichment of DPPIV in these lysosomes originates from apical endocytosis. We thus believe that Drebrin E is acting on the apical recycling pathway in intestinal epithelial cells to divert it to lysosomes. Interestingly, the phenotype observed in Drebrin E Caco-2/TC7 cells is reminiscent to a pathology called microvillar inclusion disease (MVID) which is mainly due to Myosin V mutations. We are now investigating the potential link between these two pathways with the hope to better understand this pathology.

611

### **Mapping interactions of Vps55 and Vps68 with trafficking machinery in *Saccharomyces cerevisiae*.**

*L. E. Thiele<sup>1</sup>, M. Davey<sup>1</sup>, E. Conibear<sup>1</sup>; <sup>1</sup>Department of Biochemistry and Molecular Biology, Centre for Molecular Medicine and Therapeutics, University of British Columbia, Vancouver, BC, Canada*

Vps55 and Vps68 mutants cause endosomal sorting defects and large-scale genomic data suggest functional ties to trafficking machinery, specifically Arf1 and Gcs1. However, it is not known how Vps55 and Vps68 interactions with trafficking machinery contribute to the overall function of the Vps55/Vps68 complex. We hypothesize that Vps55 and Vps68 bind to one another and to components of the trafficking machinery at separate sites. We aim to map these sites of interaction using a protein complementation assay, the Optimized yeast Cytosine Deaminase (OyCD) assay. This method utilizes a positive and negative selection technique to select for either interacting or non-interacting pairs. Thus, we can select mutants that have lost interactions with one protein but maintain interactions with another. This approach eliminates many mutants that perturb interactions due to global misfolding and identifies point mutants at the site of interaction. Thus far, we have shown that OyCD is a sensitive assay, which can show interactions and non-interactions between the proteins of interest (Vps55 and Vps68) and query proteins. Additionally, we have shown specific interactions with Arf1 and Gcs1 proteins, which supports the link to transport machinery. We are currently in the process of screening mutants to select Vps55 mutants that have lost interaction with Arf1 but maintain interaction with Vps68. These mutants will be used in further experiments to understand more fully how this interaction contributes to the function of the complex. By mapping sites of interaction, we hope to determine the role of Vps55 and Vps68, thereby gaining understanding of basic protein sorting, and the defects in this process that cause disease.

612

### **Regulating Sit1 Trafficking and Turnover by a Deubiquitinating Enzyme Ubp3.**

*E. Bogosian<sup>1</sup>, M. Zhu<sup>1</sup>, Y. Wang<sup>1</sup>; <sup>1</sup>Saint Louis University, Saint Louis, MO*

Sit1 is a yeast iron siderophore transporter that is translocated either to the plasma membrane in the presence of its substrate or to the vacuole in the absence of its substrate. Previous studies indicate that accurate intracellular targeting of Sit1 requires appropriate ubiquitination of the protein by Rsp5 ligase. Here, we examined the potential regulation of Sit1 trafficking by deubiquitinating enzymes. We find that disrupting either Ubp3 or its partner protein Bre5 resulted in mislocalization of Sit1. In the absence of substrate, Sit1 is mislocalized to the plasma membrane instead of vacuole in these mutants. Interestingly, Ubp3 interacts with Sit1 and ubiquitinated Sit1 is accumulated in the *ubp3Δ* mutants, suggesting the regulation of Sit1 by

Ubp3 may be direct. We propose that upon ubiquitination and subsequent internalization of Sit1 at the plasma membrane, further progression to the vacuole requires a deubiquitinating step carried out by the Ubp3-Bre5 complex.

613

### **Uptake and trafficking of opsonized and non-opsonized silica particles during silica induced cytotoxicity.**

*A. M. Goetjen<sup>1</sup>, G. N. Joshi<sup>1</sup>, D. A. Knecht<sup>1</sup>; <sup>1</sup>Department of Molecular and Cell Biology, University of Connecticut, Storrs, CT*

Silicosis is a fibrotic lung disease induced by prolonged exposure to silica dust. Alveolar macrophages clear inhaled silica particles by phagocytosis, but this causes the macrophages to die by apoptosis. One of the first abnormalities associated with silica uptake is the leakage of phago-lysosomal contents into the cytoplasm, which may be the trigger for activation of the apoptotic pathway. Our objective is to understand silica particle uptake into phagosomes, endo-lysosomal (EL) fusion, and how the resulting leakage causes subsequent apoptosis. Silica particles were coated with protein (non-opsonized) or antibody (opsonized) and added to cultured alveolar macrophages labeled with a variety of fluorescent probes. Alveolar macrophages internalize opsonized and non-opsonized particles within 10 to 15 minutes. The opsonized particles are phagocytosed specifically by the Fc-receptor-mediated pathway, but the rapid uptake of non-opsonized particles suggests the use of an alternative pathway. In order to demonstrate EL fusion with phagosomes, macrophages were loaded with FITC-dextran (FD) prior to particle addition. Vesicles loaded with FD fused with opsonized or non-opsonized particle phagosomes, and in both cases the dye started to appear in the cytoplasm 30 minutes later. The same vesicle fusion events are observed with latex particles, however there is no leakage or cell death. This data indicates that silica causes phagosomal membranes to become permeabilized soon after internalization. However, it is not until about 4-6 hours later that activation of apoptotic markers can be measured.

To further define the molecular requirements for phago-lysosomal leakage and toxicity of silica particles, we have utilized Cos7 fibroblasts. Cos7 cells only internalize 10% of particles within 2 hours and continue to gradually internalize particles over the next 48 hours. Cos7 cells expressing the Fc-receptor internalize 70% of opsonized particles within two hours, while uptake of non-opsonized particles is still slow. Fusion of EL compartments with phagosomes occurs much slower in Fc-Cos7s than in macrophages. While this process takes only 80 seconds to occur in macrophages, it takes over 70 minutes in Fc-Cos7s. We are currently testing whether phago-lysosomal leakage also occurs in Cos7 cells. Of particular importance is whether the cells subsequently undergo apoptosis as a result of leakage. This data will allow us to explore what key steps in the uptake and trafficking of particles are important for the cytotoxicity of silica.

614

### **Understanding the cellular mechanism of HDAC inhibitors for the treatment of NPC1 disease.**

*D. Gadi<sup>1</sup>, N. H. Pipalia<sup>1</sup>, F. R. Maxfield<sup>1</sup>; <sup>1</sup>Biochemistry, Weill Cornell Medical College, New York, NY*

Niemann-Pick type C type 1 disease (NPC1) is a rare but fatal neurodegenerative lysosomal storage disorder resulting in high levels of cholesterol accumulation in late endosomes (LE)/lysosomes (Ly) organelles in the cell. The NPC1 phenotype is caused by mutations in the

npc1 gene. Recently, histone deacetylase inhibitors (HDACi) have gained recognition in treating a number of non-cancer disorders. We have previously demonstrated that treatment with several HDACi significantly reduce cholesterol accumulation in the most commonly found I1061T mutation in the NPC1 patient derived cell lines (Pipalia et al., 2011). There are several cellular processes in NPC1 cells that may be affected by HDACi treatment. Our data indicates that NPC1 expression level is increased in the NPC1I1061T mutant cell line following HDACi treatment, and this might be responsible for correcting the NPC1 phenotype. However, the mechanism by which HDACi is enhancing NPC1 expression is not understood. We hypothesize that increased expression of NPC1 protein may be associated with protein folding chaperones in the endoplasmic reticulum (ER). It has also been reported previously that HDACi treatment causes induction of two chaperone proteins in a cancer cell line. We are currently testing the ER chaperones expression level after HDACi treatment in mutant NPC1 fibroblasts. We are determining the changes in expression level of Calnexin, BiP, HSF1, Hsp90, Hsp70, Hsp60, PDI and Hsp40 after HDACi treatment. Our preliminary results indicate that the expression levels of some of the ER chaperone proteins are altered after HDACi treatment. We are also measuring the NPC1 protein turnover rate in the absence and presence of one of the HDACi - suberoylanilide hydroxamic acid (SAHA) /Vorinostat. Determining how HDACi is correcting the NPC phenotype would lay the basis for targeted therapy based on genetic screening of NPC patients.

615

#### **Intracellular trafficking of human disease-causing prion protein mutants.**

*R. Victorova<sup>1</sup>, H. Sun<sup>1</sup>, R. Harrison<sup>1</sup>, A. Ashok<sup>1</sup>; <sup>1</sup>University of Toronto Scarborough, Toronto, ON, Canada*

Fatal, neurodegenerative, genetic prion diseases can be caused by specific mutations in the C-terminal globular domain (among other regions) of the human prion protein (PrP<sup>C</sup>). These mutations are hypothesized to lead to the cellular accumulation of misfolded PrP species (including the transmissible scrapie or PrP<sup>Sc</sup> form). We have previously described the generation of a sub-population of misfolded PrP conformers in cells expressing several naturally occurring, disease causing human PrP C-terminal mutations. While a unifying theme among the C-terminal PrP mutants appears to be an intracellular accumulation of the misfolded PrP sub-population, potentially in acidic compartments, there is little known about how these mutants are selectively sorted in post-ER compartments. In addition, it remains to be shown how intracellular accumulation of misfolded PrP species might then lead to the downstream phenotype of neurodegeneration that is seen in these human diseases. To address these two specific goals, we have carried out a series of imaging analyses to definitely identify the specific cellular compartments that harbour the misfolded PrP sub-populations generated upon expression of C-terminal PrP mutants. We have examined the localization of C-terminal PrP mutants, as well as wildtype (WT) PrP and hydrophobic-domain mutants, in neuroblastoma cells with respect to various cellular organelle marker proteins, such as EEA1, LAMP1, Rab5, Rab 7 and proteins in the trans Golgi. Our confocal image analyses and Pearson's coefficient calculations for co-localization clearly show overlap of all PrPs examined with Golgi proteins as expected for those proteins expressed within the secretory pathway. Interestingly, we were able to show a subtle, but consistent increase in co-localization between LAMP1 and a C-terminal mutant, H187R, as compared to either WT or hydrophobic domain mutants. Upon treatment with inhibitors of lysosomal acidification, we see a further increase in this co-localization between misfolded H187R and LAMP1. This confirms our previous findings that the misfolded PrP subpopulation does indeed get sorted to lysosomes and can accumulate there if lysosomal function were compromised. Our data also point to accumulation of the C-terminal mutants within other intracellular vesicles, which may represent trafficking intermediates in the delivery of

the misfolded sub-population from the secretory pathway to lysosomes. Our ongoing experiments are determining whether accumulation of these PrP misfolded species within lysosomes leads to compromised function of these organelles. Such experiments would then allow us to ascertain the perturbation in cellular homeostasis that leads to neurodegeneration in human genetic prion diseases.

616

### **Versatile roles of V-ATPase accessory subunit Ac45 in bone resorbing osteoclast formation and function.**

*T. S. Cheng<sup>1</sup>, A. Qin<sup>1,2</sup>, N. J. Pavlos<sup>1</sup>, Q. Jiang<sup>3</sup>, J. Xu<sup>4</sup>, K. R. Dal<sup>2,5</sup>, M. H. Zheng<sup>1</sup>; <sup>1</sup>School of Surgery - Centre for Orthopaedic Research, The University of Western Australia, Perth, Australia, <sup>2</sup>Department of Orthopaedics, Shanghai Jiao Tong University School of Medicine, Shanghai, China, <sup>3</sup>Model Animal Research Centre, Nanjing University, Nanjing, China, <sup>4</sup>School of Pathology and Laboratory Medicine, The University of Western Australia, Perth, Australia, <sup>5</sup>Laboratory of Orthopaedics Cellular & Molecular Biology, Shanghai Institutes for Biological Sciences Chinese Academy of Sciences, Shanghai, China*

Vacuolar-type H<sup>+</sup>-ATPases (V-ATPases) are multisubunit proton pumps that acidify intracellular cargos and deliver protons across the plasma membrane of a variety of specialized cells, including bone-resorbing osteoclasts. In osteoclasts, V-ATPases functions in extracellular acidification a process that initiates the dissolution of mineralized bone matrix and crucial for osteoclastic bone resorption. While the importance of V-ATPases in osteoclastic resorptive function is well-defined, whether V-ATPases facilitate additional aspects of osteoclast function and/or formation remains largely obscure. Our labs research focus has been on the identification and characterization of novel subunits of the V-ATPase which impacts osteoclast function and potential V-ATPase inhibitors for therapeutic applications. In line with this focus, we have recently reported that the V-ATPase accessory subunit Ac45 participates in both osteoclast formation and function. Using a siRNA-based approach, we demonstrate that targeted suppression of Ac45 impairs intracellular acidification and endocytosis, both are prerequisite for osteoclastic bone resorptive function in vitro. Interestingly, knockdown of Ac45 also attenuates osteoclast formation owing to a reduced fusion capacity of osteoclastic precursor cells. In an effort to gain more detailed insights into the functional role of Ac45 in osteoclasts, we attempted to generate osteoclast-specific Ac45 conditional knockout mice using a Cathepsin K-Cre-LoxP system. Surprisingly, insertion of the neomycin cassette in the Ac45-Flox<sup>Neo</sup> mice resulted in marked disturbances in CNS development leading to embryonic lethality thus precluding functional assessment of Ac45 in osteoclasts and peripheral bone tissues.

## **Vesicle Docking and Fusion**

617

### **N-ethylmaleimide sensitive factor hydrolyzes 12 ATP molecules to disassemble a single SNARE complex.**

*N. Shah<sup>1,2</sup>, K. N. Colbert<sup>1</sup>, W. I. Weis<sup>1,2</sup>; <sup>1</sup>Department of Structural Biology, Stanford University, Stanford, CA, <sup>2</sup>Department of Molecular and Cellular Physiology, Stanford University, Stanford, CA*

SNARE proteins anchored in the vesicle and target membranes are required for the fusion of intracellular membranes. The energy for this process is thought come from the association of the cytoplasmic region of SNAREs into a stable four helix bundle. N-ethylmaleimide sensitive

factor (NSF) is an AAA+ ATPase that hydrolyzes ATP to disassemble the post-fusion SNARE complex. The interaction between NSF and the SNARE complex requires an adaptor protein,  $\alpha$ SNAP. The mechanism by which ATP hydrolysis is coupled to SNARE disassembly is not known. The objective of this work is to understand how NSF utilizes energy to disassemble the SNARE complex.

Using spin columns to separate protein from radio-labeled nucleotides, we determined that NSF stably binds 12 ADP molecules in steady-state conditions, and that nucleotide hydrolysis is essential for this binding. We characterized the basic kinetics of NSF ATP hydrolysis, both in the absence and presence of  $\alpha$ SNAP and neuronal SNARE proteins. The ATPase rate and catalytic efficiency of NSF increase substantially during interaction with  $\alpha$ SNAP and the SNARE complex, indicating that the enzyme mechanism is altered during SNARE complex disassembly.

We used fluorescence-based methods to determine the rate at which NSF disassembles SNARE complexes, and by extension, the energy required for disassembly of a single SNARE complex. We determined that NSF hydrolyzes 12 ATP molecules to disassemble a single neuronal SNARE complex in pre-steady state conditions, and confirmed this value using catalytic constants determined from independent steady-state experiments.

Our findings demonstrate that sensitive measurements of nucleotide binding, hydrolysis and SNARE disassembly provide a greater understanding of the NSF mechanism, which may shed light on the modes of action of other members of the AAA+ ATPase family. Our findings offer detailed insight into the energy requirements of the membrane fusion process.

618

#### Single SNARE Complexes Zipper in Three Distinct Stages.

Y. Gao<sup>1</sup>, S. Zorman<sup>1</sup>, G. Gundersen<sup>1</sup>, Z. Xi<sup>1</sup>, L. Ma<sup>1</sup>, G. Sirinakis<sup>1</sup>, J. E. Rothman<sup>1</sup>, Y. Zhang<sup>1</sup>;  
<sup>1</sup>Cell Biology, Yale School of Medicine, New Haven, CT

With the help of optical tweezers we directly observe and quantify the long-sought SNARE assembly intermediate in which only the membrane-distal N-terminal half of the four helix bundle is assembled. Our finding provides clear proof of the zipper hypothesis with the important and unexpected modification that zippering proceeds through three sequential binary switches, not continuously, in the N- and C-terminal halves of the bundle and the linker domain. The half-zipped intermediate is transiently stabilized by externally applied force that mimics the repulsion between apposed membranes being forced to fuse. This intermediate then rapidly and forcefully zippers, delivering free energy of 36 kBT to drive fusion. Complexin can clamp SNARE zippering and synchronize neurotransmitter release by further stabilizing the half-zipped intermediate.

#### Regulation of SNARE complex assembly by the exocyst subunit Sec6.

M. L. Dubuke<sup>1</sup>, S. Maniatis<sup>1,2</sup>, K. M. Green<sup>1,2</sup>, S. A. Shaffer<sup>1,2</sup>, M. Munson<sup>1</sup>; <sup>1</sup>Biochemistry and Molecular Pharmacology, University of Massachusetts Medical School, Worcester, MA,  
<sup>2</sup>Proteomics and Mass Spectrometry Facility, University of Massachusetts Medical School, Worcester, MA

In eukaryotic cells, membrane-bound vesicles carry protein and lipid cargo between intracellular compartments, and between the cell surface and extracellular environment. A major unanswered question is how vesicle fusion is tightly controlled to prevent premature or

inappropriately localized membrane fusion. Two conserved families of proteins are required for correct vesicle fusion at the proper target membrane site – oligomeric tethering complexes and the SNARE proteins. The exocyst is the exocytic tethering complex that regulates polarized exocytosis, and is proposed to tether vesicles to their sites of fusion. Subsequently, the SNARE proteins mediate membrane fusion. Because SNARE proteins show little specificity for their binding partners, and are not always specifically localized to sites of membrane fusion, SNARE complex assembly must be highly regulated. Previous work from our laboratory demonstrated that, *in vitro*, the *Saccharomyces cerevisiae* exocyst subunit Sec6 directly binds the SNARE Sec9, and inhibits the formation of the Sec9-Sso1 SNARE complex. Sec6 and Sec9 also interact *in vivo*; therefore, we hypothesized that the interaction between Sec6 and Sec9 regulates the assembly of SNARE complexes, and is necessary for proper assembly of SNARE complexes at sites of exocytosis upon vesicle arrival. In order to elucidate the role of the Sec6-Sec9 interaction in SNARE complex assembly, we are selectively disrupting their interaction using the zero-length crosslinker EDC and mass spectrometry analyses to directly target the residues required for binding. We monitored the cross-linking reaction over a range of times, and quantification resulted in a rank ordered list of residues close to or in the binding site. A number of candidate residues were mutated, to either alanine or the opposite charge, and introduced into yeast as the sole copy of *SEC6* or *SEC9*. Mutations in several residues of both Sec6 and Sec9 resulted in temperature and media sensitive growth defects. Subsequent *in vitro* binding studies showed that an alanine substitution at one of the Sec9 sites caused only a modest decrease in the stability of the Sec6-Sec9 interaction, while the charge reversal mutation resulted in substantial destabilization of the Sec6-Sec9 complex. Therefore, a loss of interaction between the exocyst subunit Sec6 and the SNARE Sec9 leads to growth defects, likely due to a loss of SNARE complex assembly regulation.

### Structure of Vps33, a Key Regulator of Membrane Fusion.

R. W. Baker<sup>1</sup>, P. Jeffrey<sup>1</sup>, F. Hughson<sup>1</sup>, <sup>1</sup>Molecular Biology, Princeton University, Princeton, NJ

Intracellular trafficking involves the budding, directed movement, and fusion of vesicles with target membranes. SNARE proteins anchored in opposing membranes zipper into four-helix bundles, thereby exerting the force required to drive fusion between lipid bilayers. We have been interested in understanding how SNARE activity is regulated and enhanced *in vivo*. Many lines of evidence suggest that vesicle docking and fusion is orchestrated by a set of large protein complexes called MTCs (multisubunit tethering complexes). MTCs work in close collaboration with SNAREs and other elements of the vesicle trafficking machinery, notably Rab GTPases, which link trafficking to a regulated cycle of GTP hydrolysis, and a conserved family of SNARE binding proteins known as SM (Sec1-Munc18-like) proteins. Although several lines of evidence implicate MTCs as general regulators of fusion, they are large and complex, hampering efforts to understand their mechanisms of action. To address this deficiency, we have been studying an MTC called the HOPS (homotypic fusion and vacuole protein sorting) complex. Unusually, an SM protein, Vps33, is a stable subunit of the HOPS complex. HOPS binds the vacuolar Rab Ypt7, the Q-SNAREs Vam3 and Vam7, and both partially- and fully-formed SNARE complexes. These SNARE interactions are mediated by Vps33 and one or two other HOPS subunits. Through these and possibly other interactions, HOPS is able to tether opposing membranes and stimulate formation of *trans*-SNARE complexes, thereby promoting fusion. However, a molecular understanding of precisely how HOPS synthesizes so many inputs to produce a high-fidelity and physiologically competent fusion reaction remains elusive. As a first step toward characterizing the high-resolution structure of the HOPS complex, we have determined the x-ray structure of Vps33, and are using it as a blueprint to guide further structural and functional analysis.

**The Syntaxin1a N-peptide and LE 'open' mutation have no effect on the Munc18a-Syntaxin1a binding mode.**

*K. N. Colbert<sup>1</sup>, D. A. Hattendorf<sup>1</sup>, T. M. Weiss<sup>2</sup>, W. I. Weis<sup>1</sup>; <sup>1</sup>Structural Biology, Stanford University, Stanford, CA, <sup>2</sup>Stanford Synchrotron Radiation Lightsource, SLAC National Accelerator Laboratory, Stanford University, Menlo Park, CA*

In neurons, Soluble N-ethylmaleimide Sensitive Factor (NSF) Attachment protein Receptor (SNARE) proteins drive the fusion of synaptic vesicles to the plasma membrane through the formation of a four-helix SNARE complex. The neuronal protein Munc18a interacts with a closed conformation of the SNARE protein Syntaxin1a (Syx1a) and with assembled SNARE complex containing Syx1a in an open conformation. The N-peptide of Syx1a (1-24) has been implicated in the transition of Munc18a-bound Syx1a to Munc18a-bound SNARE complex, but the underlying mechanism is poorly understood.

Here, we report X-ray crystal structures of Munc18a bound to Syx1a with and without its native N-peptide (Syx1aΔN), and small-angle X-ray scattering data for Munc18a bound to Syx1a, Syx1aΔN, and Syx1a L165A/E166A (LE), a mutation thought to render Syx1a in a constitutively open conformation. We show that all three complexes adopt the same global structure, in which Munc18a binds a closed conformation of Syx1a. We also identify a possible allosteric connection between the Syx1a N-peptide and Munc18a domain 3a, providing mechanistic insight into the transition of closed-to-open Syx1a in SNARE complex assembly. While the role of the N-peptide in Munc18a-mediated SNARE complex assembly remains unclear, our results demonstrate that the N-peptide and LE mutation have no effect on the overall structure of the Munc18a-Syx1a complex.

**The birth of a membrane nanodomain - syntaxin clusters assemble from single molecules during secretory granule docking.**

*N. R. Ganasí<sup>1</sup>, S. Barg<sup>1</sup>; <sup>1</sup>Department of Medical cell biology, Uppsala University, Biomedical Centrum, Uppsala, Sweden*

Insulin is released by regulated exocytosis of secretory granules, and tethering/docking of the granules at the future release site is a critical step in this process. Granule docking depends on the plasma membrane t-SNARE syntaxin1a and its accessory protein munc18. Since syntaxin1a binds to granule proteins and forms clusters near docked granules, it may act as docking receptor for incoming granules. Here we used live cell imaging to test two simple predictions of this model: 1) syntaxin1a should cluster at the release site before a granule docks, and 2) syntaxin1a clusters should mark granules as docked and ready for exocytosis. Syntaxin1a formed small clusters near the majority of docked granules, which exhibited striking intensity variations with a period of a few seconds. The dynamic nature of the clusters was also evident from single molecule experiments indicating residence times of <1s at the cluster site. Surprisingly, when a granule arrived at the plasma membrane it did not dock at an empty syntaxin cluster. Instead, the cluster formed within seconds upon granule contact, and this correlated with the transition from a loosely tethered to a stably docked state. Conversely, spontaneous loss of the cluster predicted subsequent loss of the granule by undocking. All other tested proteins, including Munc13 and Munc18 arrived later than syntaxin1a. Granules did not recruit a deletion mutant of syntaxin1a that lacks the N-terminal Habc domain, and a soluble Habc fragment dose-dependently prevented cluster formation and granule docking. Stable

granule docking and association with syntaxin cluster was required for stimulation-evoked exocytosis, and sites of exocytosis were subsequently avoided by new granules attempting to dock. We conclude that granules induce the formation of their own docking site and that recruitment of syntaxin1a via its Habc domain is critical for docking. Syntaxin1a clusters form on a timescale consistent with rapid cellular signaling, which may be important for the short-term regulation of insulin secretion.

623

**Syntaxin binding protein 1 (STXBP1) modulates release of Weibel-Palade bodies from endothelial cells.**

*D. Van Breevoort<sup>1</sup>, M. Fernandez-Borja<sup>2</sup>, B. Snijders<sup>3</sup>, T. Carter<sup>4</sup>, J. Voorberg<sup>1</sup>, R. Bierings<sup>1,4</sup>; <sup>1</sup>Plasma Proteins, Sanquin Research, Amsterdam, Netherlands, <sup>2</sup>Molecular Cell Biology, Sanquin Research, Amsterdam, Netherlands, <sup>3</sup>Biomolecular Mass Spectrometry and Proteomics, MRC Clinical Sciences Centre, London, United Kingdom, <sup>4</sup>Physical Biochemistry, MRC National Institute for Medical Research, London, United Kingdom*

Vascular endothelial cells contain unique large rod-shaped granules, called Weibel-Palade bodies (WPBs). These granules function as storage organelles for various haemostatic and inflammatory components, such as von Willebrand factor (VWF), chemokines and P-selectin. Controlled release of these components into the vascular lumen through WPB exocytosis is essential for maintaining vascular homeostasis in response to vascular trauma or stress. Secretory granule exocytosis is tightly controlled by signalling pathways that are linked to G-protein coupled receptors. One of the final steps in exocytosis involves the assembly of the so-called SNARE-complex. SNARE-complexes are formed by zipper-like proteins, VAMPs (or v-SNAREs) on vesicles and syntaxins (or t-SNAREs) on the plasma-membrane. Formation of the SNARE-complex promotes fusion of secretory vesicles with the plasma membrane and subsequent release of granule content into the lumen. SNARE-complex formation is controlled by proteins belonging to the syntaxin binding protein (STXBP) family. In this study we investigate the possible role of syntaxin binding protein 1 (STXBP1), also known as Munc18-1, in WPB exocytosis. We show that STXBP1 is expressed in endothelial cells. Interestingly, STXBP1 was also picked up in a proteomic screen in endothelial cells for interactors of synaptotagmin-like protein 4-a (Slp4-a), a Rab27A effector that has recently been implicated as a positive regulator of WPB release. Using siRNA mediated knock-down of STXBP1 expression we show that STXBP1 depleted cells exhibited a decrease in Ca<sup>2+</sup>-stimulated VWF release. We speculate that STXBP1 regulates WPB release through its interaction with Slp4-a, thereby docking WPBs to the plasma membrane and facilitating the release of haemostatic, inflammatory and angiogenic cargo from these organelles.

624

**Characterisation of the Weibel Palade body fusion pore using optical and electrochemical techniques.**

*E. Cookson<sup>1</sup>, M. Hannah<sup>2</sup>, T. Carter<sup>1</sup>; <sup>1</sup>National Institute for Medical Research, London, United Kingdom, <sup>2</sup>Health Protection Agency, London, United Kingdom*

Regulated secretion of proteins and molecules from endothelial cells (ECs) is mediated by the exocytosis of secretory granules (SGs) called Weibel-Palade bodies (WPBs). Optical data indicate that WPBs can undergo a form of exocytosis that allows selective release of cargo molecules based on molecular size. Regulation of SG fusion pore dynamics is thought to underlie selective release of SG cargo, however the dynamics of the WPB fusion pore have not been quantitatively analysed. Using carbon fibre amperometry we have now determined the

properties and dynamics the WPB fusion pore during calcium-driven exocytosis. Initial biochemical and amperometric studies revealed that WPBs do not contain endogenous oxidisable molecules; therefore methods were developed to specifically load WPBs with suitable oxidisable molecules. Amperometry was performed in fura-2 loaded HUVEC expressing fluorescent WPBs to simultaneously monitor intracellular free calcium ion concentration changes and WPB exocytosis optically during stimulation. Current spikes were closely associated with WPB fusion events monitored optically. Current spike parameters comprised a 25-75% rise time, peak amplitude and decay time of  $1.77 \pm 1.37$  ms,  $49.24 \pm 34.17$  pA and  $7.26 \pm 7.75$  ms respectively (mean  $\pm$  SD,  $n = 617$  spikes). These values are comparable to those reported for SGs in other cell types (e.g. chromaffin cells), indicating that WPBs share similar processes controlling membrane fusion and mobilisation/release of oxidisable species. Approximately 50% of exocytotic events had pre-spike foot (PSF) signals indicating that a restricted fusion pore initially forms. In rare cases PSF signals showed step changes or fluctuations suggesting that during expansion the fusion pore may transition through different configurations before fully opening. Following characterisation of the WPB fusion pore under control conditions, factors which may affect the behaviour of the fusion pore were investigated, including the role of PM cholesterol. In line with previous studies, depletion of PM cholesterol led to a significant increase in the rate of fusion pore expansion from  $1.65 \pm 1.26$  ms ( $n = 409$ ) to  $1.41 \pm 0.92$  ms ( $n = 266$ ,  $p = 0.014$ ) and a significant decrease in the duration of the lifetime of the restricted fusion pore from  $5.41 \pm 9.26$  ms ( $n = 253$ ) to  $3.50 \pm 4.53$  ms ( $n = 184$ ,  $p = 0.025$ ), providing further evidence for the importance of cholesterol in shaping the exocytotic fusion pore.

625

### **SNARE Complex Phosphorylation is Altered Prior to Mouse Sperm Acrosomal Exocytosis.**

*S. Shah<sup>1</sup>, D. J. Miller<sup>1</sup>; <sup>1</sup>Animal Sciences, University of Illinois at Urbana-Champaign, Urbana, IL*

Phosphorylation can alter activity of phosphoproteins including all three core SNARE (soluble N-ethylmaleimide-sensitive-factor attachment protein receptor) proteins that have a critical role in intracellular membrane fusion events such as the acrosome reaction. During the final sperm maturation, known as capacitation, protein kinases and phosphatases are activated that may alter phosphorylation of SNAREs and other regulatory proteins. We hypothesize that during capacitation, SNARE protein phosphorylation changes, promoting SNARE complex formation in preparation for the acrosome reaction. To begin to test this hypothesis, we incubated mouse sperm in a specialized capacitating (dmKRBT) or non-capacitating (dmKRBT without BSA and – HCO<sub>3</sub>) medium and detergent-extracted sperm protein. To isolate formed SNARE complexes, sperm protein was immunoprecipitated with a syntaxin antibody and subsequently run on 12% SDS-PAGE gels, followed by immunoblotting with syntaxin antibody to verify that the complexes contained syntaxin. Samples were not boiled prior to SDS-PAGE to maintain the integrity of the SNARE complex. To detect changes in total phosphorylation of syntaxin-containing (SNARE) complexes, immunoprecipitated complexes were separated on an SDS-PAGE gel that was subsequently stained with Pro-Q Diamond. We observed phosphoprotein staining in 75, 100, and 150 and 230 KD protein complexes. Immunoblotting with a syntaxin antibody demonstrated that each complex contained syntaxin and was presumably a SNARE complex. Quantitation of SNARE complex phosphorylation showed that after 30 min of capacitation, overall phosphorylation was higher in the 75, 100 and 150 KD bands. To detect tyrosine phosphorylation of syntaxin and associated proteins, the anti-syntaxin immunoprecipitates were blotted with a phosphotyrosine antibody. Tyrosine phosphorylation of SNARE complexes decreased after 15 min of capacitation time. These data demonstrate SNARE complex phosphorylation is a dynamic process during capacitation and suggest that phosphorylation may

regulate SNARE complex formation during capacitation in preparation for the acrosome reaction. This work was partially supported by a fellowship from COMSATS Institute of Information Technology, Pakistan and the University of Illinois.

**Regulated exocytosis in the exocrine glands: the multiple roles of the actomyosin complex revealed by intravital microscopy.**

A. Masedunskas<sup>1</sup>, O. Milberg<sup>1</sup>, N. Porat-Shliom<sup>1</sup>, R. Weigert<sup>1</sup>; <sup>1</sup>National Institute for Dental and Craniofacial Research / OPCB/IMTU, National Institutes of Health, Bethesda, MD

The regulation and the dynamics of membrane trafficking events have been investigated primarily in in vitro models that often do not fully reflect the functional complexity found in a living multicellular organism. To address this issue we used intravital microscopy in the exocrine glands of live rodents (salivary glands, exocrine pancreas, and lacrimal glands) to investigate regulated exocytosis, a fundamental process in all the secretory organs. We found that upon stimulation of the appropriate GPCR, large secretory granules fuse with the apical plasma membrane, and gradually collapse without any evidence of compound exocytosis, as was previously described. Moreover, by using a series of selected transgenic mice, we showed that the driving force required to complete the collapse of the granules is provided by the sequential recruitment on the granule membranes of F-actin and two isoforms of nonmuscle myosin II, IIa and IIb. The recruitment is mediated by some membrane components of the apical plasma membrane and involved the small GTPase Septin 2. Our results provide information on the machinery controlling regulated secretion and show that intravital microscopy provides unique opportunities to address fundamental questions in cell biology under physiological conditions.

**FRET-based method to decipher the stoichiometry and structural assembly of bacterial ABC transporter involved in exporting endotoxins.**

M. M. Mohammad<sup>1</sup>, D. R. Singh<sup>2</sup>, S. Patowary<sup>2</sup>, J. A. Oliver<sup>3</sup>, V. Raicu<sup>2,3</sup>, L. Movileanu<sup>1,4,5</sup>; <sup>1</sup>Department of Physics, Syracuse University, Syracuse, NY, <sup>2</sup>Physics Department, University of Wisconsin-Milwaukee, Milwaukee, WI, <sup>3</sup>Department of Biological Sciences, University of Wisconsin-Milwaukee, Milwaukee, WI, <sup>4</sup>Structural Biology, Biochemistry, and Biophysics Program, Syracuse University, Syracuse, NY, <sup>5</sup>The Syracuse Biomaterials Institute, Syracuse University, Syracuse, NY

The ATP-binding-cassette (ABC) transporters are membrane protein machineries and common to all living cells. ABC transporters utilize the energy of ATP hydrolysis to transport a broad spectrum of solutes across the membrane. Wzm (the transmembrane component) and Wzt (the nucleotide binding component) proteins constitute an ABC transporter that translocates the endotoxic polysaccharides through the inner membrane of the pathogenic bacterium *Pseudomonas aeruginosa*. To gain insights into the subunit stoichiometry and structural assembly of this ABC transporter, we reconstituted the ABC transporter in CHO cell lines. We expressed Wzm and Wzt proteins fused with green fluorescent protein (GFP2) or its variant, yellow fluorescent protein (YFP). The three-dimensional cellular localization of the expressed ABC components were constructed by stacking images of different sections of the cells utilizing a newly developed and spectrally-resolved two-photon microscope. We next used Fluorescence Resonance Energy Transfer (FRET) to obtain a quantitative understanding of the interaction between the ABC components by calculating the apparent FRET efficiencies for single pixels. When Wzm-GFP2 and Wzm-YFP were co-expressed, our FRET analysis indicated that Wzm self-associates within the cell membrane as an oligomer. This correlates with our biochemical characterization of membrane-extracted Wzm. When Wzt-GFP2 and Wzm-YFP were co-

expressed, our FRET analysis indicated that Wzm and Wzt interact at the inner membrane surface. This correlates with our in vitro studies that show Wzm and Wzt interact with each other. The distribution of FRET efficiencies were compared when Wzt-GFP2 and Wzm-YFP or Wzt-YFP and Wzm-GFP2 were co-expressed to study the stoichiometry of Wzm and Wzt in the ABC transporter. Based on FRET analysis, wzt protein assembles into a rhombus-shaped tetramer in the absence of Wzm, but changes its assembly into a square-shaped tetramer when associates with Wzm. By contrast, Wzm assembles into a square-shaped tetramer irrelevant to its association with Wzt. Based on our work, we propose a model for the ABC complex assembly. The combination of FRET analysis and biochemical approaches will lead to a comprehensive investigation of the structural assembly and subunit composition of this ABC transporter and ultimately other transporters.

628

**Enhancement of SNARE-mediated membrane fusion by synaptotagmin II requires Ca<sup>2+</sup> and phosphatidylserine.**

*S. Tadokoro<sup>1</sup>, Y. Nagai<sup>1</sup>, H. Sakiyama<sup>1</sup>, N. Hirashima<sup>1</sup>; <sup>1</sup>Nagoya City University, Nagoya, Japan*

Mast cells play a pivotal role in allergic responses. Antigen stimulation causes the elevation of intracellular Ca<sup>2+</sup> concentration which triggers the exocytotic release of inflammatory mediators such as histamine. Recent researches revealed that SNARE (soluble N-ethylmaleimide-sensitive factor attachment protein receptor) proteins such as syntaxin-3, -4, SNAP-23 and VAMP-8 are involved in mast cells exocytosis. Although the exocytosis in mast cells is Ca<sup>2+</sup>-dependent, the target molecule of Ca<sup>2+</sup> is not clear. Synaptotagmin is a Ca<sup>2+</sup>-sensor and regulates exocytosis in neuronal cells. However, the role of synaptotagmin II, the most abundant isoform in mast cells, in the exocytosis is still controversial. In the present study, we investigated the role of synaptotagmin II by liposome-based fusion assay.

SNARE proteins (SNAP-23, syntaxin-3, VAMP-8) and synaptotagmin II were expressed in E.coli and purified as GST-tagged or His-tagged fusion proteins. These SNARE proteins were incorporated into liposomes by a detergent dialysis method. Membrane fusion between liposomes containing VAMP-8 and liposomes containing SNAP-23 and syntaxin-3 was monitored by fluorescence resonance energy transfer between fluorescent labeled phospholipids.

Ca<sup>2+</sup> did not show any effects on SNARE-mediated membrane fusion, but Ca<sup>2+</sup> enhanced the fusion in the presence of synaptotagmin II. Interestingly, synaptotagmin II inhibited SNARE-mediated membrane fusion in a dose-dependent manner in the absence of Ca<sup>2+</sup>. However, this inhibitory effect was lost by the addition of Ca<sup>2+</sup>, and the membrane fusion was induced depending on the Ca<sup>2+</sup> concentration. Next, we investigated the interaction of synaptotagmin II with phosphatidylserine (PS). PS-containing liposomes interacted with synaptotagmin II in the presence of Ca<sup>2+</sup>, whereas liposomes made from phosphatidylcholine only did not interacted with synaptotagmin II even in the presence of Ca<sup>2+</sup>. The enhancement of SNARE-mediated membrane fusion by Ca<sup>2+</sup>/synaptotagmin II required PS as a membrane component. These results suggest that synaptotagmin II regulates membrane fusion of SNARE-containing liposomes involved in exocytosis in mast cells, and this regulation is dependent on synaptotagmin II, Ca<sup>2+</sup>, and PS.

629

**The membrane association of the GEF Mon1p is regulated by its phosphorylation and binding to PI3P.***R. Fratti<sup>1</sup>, G. Lawrence<sup>1</sup>, C. Brown<sup>1</sup>, B. Flood<sup>1</sup>; <sup>1</sup>University of Illinois at Urbana-Champaign, Urbana, IL*

The maturation of early endosomes to late endosomes and lysosomes requires the exchange of several factors. Central to this conversion is the exchange of the early endosomal Rab5/Vps21p for the late endosomal Rab7/Ypt7p. This exchange is mediated in part by the nucleotide exchange factor Mon1p, which indirectly activates the GTPase activity of Rab5/Vps21 and subsequent removal from the membrane. Mon1p then aids in the recruitment of Ypt7p and activates it through the exchange of GDP for GTP. In this study, we investigated the recruitment and vacuole binding of the Mon1p-Ccz1p heterodimer. Initially, we found that Mon1p was reduced on vacuoles from strains lacking the phosphatidic acid phosphatase Pah1p. Vacuoles from *pah1Δ* strains also lacked Ypt7p, phosphatidylinositol 3-kinase Vps34p and its product phosphatidylinositol 3-phosphate (PI3P). Because the *C. elegans* homologue Sand-1 binds PI3P, we hypothesized that Mon1p-Ccz1p is recruited to vacuoles by PI3P. We found that Mon1p was competed off from vacuoles in the presence of the PI3P ligand FYVE. We also found that Mon1p is released from vacuoles over time and that the release is linked to its phosphorylation by the yeast casein kinase Yck3.

630

**Imaging the Intraciliary Dynamics of Signaling Receptors at Single Molecule Resolution.***F. Ye<sup>1,2</sup>, Q. Hu<sup>1</sup>, D. Breslow<sup>2</sup>, W. J. Nelson<sup>1</sup>, M. V. Nachury<sup>2</sup>; <sup>1</sup>Department of Biology, Stanford University, Stanford, CA, <sup>2</sup>Dept. of Molecular and Cellular Physiology, Stanford University School of Medicine, Stanford, CA*

Primary cilia participate in the sensing of extracellular stimuli by concentrating transmembrane receptors and signaling intermediates within a confined space. While several lines of evidence suggest that IntraFlagellar Transport (IFT) trains are essential for the transduction of mating signals in *Chlamydomonas*, the general relationship between the IFT machinery, the intraflagellar/intraciliary dynamics of signaling receptors and signaling output has remained largely unexplored. To characterize the dynamics of individual signaling receptors in the ciliary membrane, we set out to label individual Somatostatin Receptor 3 (SSTR3, a ciliary GPCR) molecules in live cells. Our approach relies on the site-specific biotinylation of an acceptor peptide fused to the extracellular domain of SSTR3 and on the application of fluorescently labeled monovalent streptavidin at low concentration onto cells. Using single molecule imaging of SSTR3, we have found that:

- 1- SSTR3 spends more than 90% of its time inside cilia diffusing rather than undergoing active transport. The diffusive movements are rapid and inhibition of IFT only reduces the effective diffusion coefficient of SSTR3 inside cilia by a modest amount.
- 2- Unlike IFT trains which move processively from one end of the cilium to the other, single SSTR3 molecules only display directed movements for limited distances. The latching of SSTR3 on IFT trains appears to be transient and rapidly reversible.
- 3- Immobilizing membrane proteins with the multivalent lectin WGA does not affect the movement of IFT trains (visualized as foci of GFP-IFT88 fluorescence) inside cilia.

Together, these studies suggest that the coupling between the IFT machinery and its cargoes is labile and dispensable for IFT train motility. Cargoes (at least transmembrane cargoes) behave as passengers randomly hopping on and off moving trains.

631

**Role of the small GTPase Cdc42 in renal ciliogenesis and cystogenesis.**

S. Choi<sup>1</sup>, L. Huang<sup>1</sup>, X. Zuo<sup>1</sup>, S. McKenna<sup>1</sup>, R. Burdine<sup>2</sup>, J. H. Lipschutz<sup>1</sup>; <sup>1</sup>University of Pennsylvania, Philadelphia, PA, <sup>2</sup>Princeton University, Princeton, NJ

**Background:** Primary cilia have been strongly implicated in the pathogenesis of autosomal dominant polycystic kidney disease (ADPKD), the most common potentially lethal genetic disorder, and cilia disruption results in large cysts that destroy the kidney. In renal tubule cells, we showed that the highly conserved eight-protein exocyst complex, which is involved in targeting and docking vesicles carrying membrane proteins, localized to, and was necessary for ciliogenesis (Zuo et al, Mol Biol Cell, 2009); that sec10 knockdown phenocopied pkd2 knockdown in zebrafish (Fogelgren et al, PLoS Genetics, 2011); and that the small GTPase Cdc42 interacted with exocyst Sec10 to regulate ciliogenesis in MDCK cells (Zuo et al, J Biol Chem, 2011).

**Methods:** Given the importance of Cdc42 for cell function, to study how cdc42 affects ciliogenesis and cystogenesis *in vivo*, we used two different animal models and techniques: antisense morpholinos (MOs) to knockdown cdc42 in zebrafish, and the Cre-Lox system to knockout Cdc42 in a kidney-specific manner in mice. Zebrafish embryos were injected with cdc42 start-site antisense MOs. Cdc42 renal tubule cell-specific knockout mice were generated by breeding Cdc42 floxed (fl) and Ksp-cadherin Cre (Cre<sup>ksp/+</sup>) mice.

**Results:** cdc42 morphants developed pericardial edema, short tail, small eyes, abnormal cilia, left-right patterning defects, and glomerular expansion that phenocopied sec10 and pkd2 morphants. Co-injection of small amounts of cdc42 and sec10 MOs, which individually had no effect, together resulted in an abnormal phenotype, suggesting that cdc42 and sec10 act in the same pathway. To generate Cdc42 kidney-specific knockout mice, female Cre<sup>ksp/+</sup> mice were first crossed with male Cdc42<sup>fl/fl</sup> mice. 7 female Cre<sup>ksp/+</sup>-Cdc42<sup>fl/+</sup> mice were then backcrossed against 2 male Cdc42<sup>fl/fl</sup> mice, and 55 pups were evaluated from P11 to P23. Of the 55 pups: 16 Cdc42<sup>fl/+</sup>, 20 Cdc42<sup>fl/fl</sup>, 18 Cre<sup>ksp/+</sup>-Cdc42<sup>fl/+</sup> living mice, and only 1 dead Cre<sup>ksp/+</sup>-Cdc42<sup>fl/fl</sup> (P18) kidney-specific knockout mouse, were identified by PCR genotyping. From E16.5 to P8, 41 pups were studied. Of the 41 pups: 17 Cdc42<sup>fl/+</sup>, 9 Cdc42<sup>fl/fl</sup>, 7 Cre<sup>ksp/+</sup>-Cdc42<sup>fl/+</sup>, and 8 Cre<sup>ksp/+</sup>-Cdc42<sup>fl/fl</sup> kidney-specific knockout mice were identified. By histology, there were increasing cysts identified from E16.5 to P8, with the kidneys of P8 Cre<sup>ksp/+</sup>-Cdc42<sup>fl/fl</sup> mice replaced by small cysts. The kidneys themselves were not grossly increased in size, and the cystic kidneys were reminiscent of a nephronophthisis phenotype.

**Conclusions:** In zebrafish, cdc42 knockdown results in a ciliary phenotype, and cdc42 acts synergistically with exocyst sec10. Cdc42 kidney-specific knockout in mice leads to an early postnatal death apparently due to kidney failure from polycystic kidney disease. Taken together, these data indicate that Cdc42 is essential for normal cilia function and nephrogenesis *in vivo*.

632

**A novel stimulatory activity for a Rab GTPase in membrane fusion.**

C. Stroupe<sup>1</sup>; <sup>1</sup>Molecular Physiology and Biological Physics, University of Virginia School of Medicine, Charlottesville, VA

Previous work has suggested that the principal function of the yeast vacuolar Rab GTPase Ypt7p is to recruit its effector, the HOPS/Class C Vps complex, to membranes. Here, it is demonstrated that Ypt7p has an activity beyond HOPS complex recruitment for membrane fusion. Reconstituted proteoliposomes made from lipid mixtures containing cardiolipin mix their lipids in a reaction that requires the HOPS complex, but not Ypt7p. Ypt7p is, however, required for lipid mixing of proteoliposomes lacking cardiolipin. Moreover, Ypt7p is still required for lipid

mixing even when the concentration of HOPS complex in lipid-mixing reactions is adjusted such that proteoliposomes with or without Ypt7p bind to equal amounts of HOPS. Ypt7p therefore must stimulate membrane fusion by a mechanism in addition to recruitment of HOPS to the membrane. This is the first report of such a stimulatory activity – that is, beyond bulk effector recruitment – for a Rab GTPase.

633

#### **Soluble SNAREs can function as transcription regulators.**

*C. Winterstein<sup>1</sup>, P. Bhattaram<sup>1</sup>, E. Reales<sup>1</sup>, S. Low<sup>1</sup>, J. Baggs<sup>2</sup>, J. Hogenesch<sup>2</sup>, T. Weimbs<sup>1</sup>;*  
<sup>1</sup>*Department of Molecular, Cellular & Developmental Biology, University of California Santa Barbara, Santa Barbara, CA,* <sup>2</sup>*Department of Pharmacology, University of Pennsylvania, Philadelphia, PA*

SNARE proteins are well established as the machines that accomplish membrane fusion in all intracellular membrane trafficking pathways in eukaryotes. Syntaxins, a conserved family of SNARE proteins, contain a C-terminal transmembrane anchor that is required for their membrane fusion activity. Here we show that syntaxin 3 (Stx3) functions as a nuclear regulator of gene expression in addition to its known function in membrane fusion at the plasma membrane. Stx3 undergoes proteolytic cleavage that releases it from the membrane. The cleavage site was identified as the most highly conserved residue among all eukaryotic syntaxins. In addition, we show that alternative splicing leads to a novel soluble isoform, termed Stx3S, that lacks the transmembrane anchor. These soluble forms of Stx3 bind to the nuclear import factor RanBP5 and target to the nucleus. Stx3S is endogenously highly expressed in human kidneys and several cell lines. A functional co-activator trap screen led to the identification of several transcription factors that interact with - and are regulated by - Stx3S. Among them is the ETS transcription factor ETV4 that is co-activated by Stx3S. Stx3S stimulates the expression of MMP-1, an endogenous ETV4 target gene. Stx2 and Stx4 undergo similar cleavage events as Stx3 suggesting that nuclear signaling by soluble syntaxins may be an ancient, conserved signaling pathway that may communicate information from cytoplasmic membrane trafficking events to the nucleus.

#### **Elucidating the Role of Phosphatidylcholine Transfer Protein (PCTP) in Tetrahymena Conjugation.**

*J. Cannon<sup>1</sup>, S. Rosenberg<sup>1</sup>, S. Guerrier<sup>1</sup>;* <sup>1</sup>*Biology, Carleton College, Northfield, MN*

The ability of membranes to fuse to one another is fundamental for many processes including tissue morphogenesis, virus transmission, and secretion. As a result, much work has sought to identify the molecular determinants that regulate membrane fusion. Membrane lipid content appears to play an important role in regulating membrane curvature during membrane fusion. Recently Kurczyk et. al, demonstrated that depletion of phosphatidylcholine (PC) (a curvature-resisting lipid) and increased levels of phosphatidylethanolamine (PE) (a high curvature-inducing lipid) coincided with the appearance of fusion pores during conjugation in *Tetrahymena Thermophila*. This data highlighted the potential role lipid mediated membrane curvature in fusion pore formation but these results also left many outstanding questions, including what are the mechanisms that might lead to rapid local changes in local PC or PE concentration in the specialized zone between conjugating cells. Using the *Tetrahymena* gene expression database, we identified a protein phosphatidylcholine transfer protein (PCTP), which has been shown to regulate PC transfer between the plasma membrane and endomembranes. Importantly, PCTP was expressed during the period in which fusion pores are being formed and PC is being

removed from the conjugation junction. We hypothesized that PCTP is required for the removal of PC during fusion pore formation and therefore proper conjugation. To test this hypothesis, we used a small molecule inhibitor (compound A1) of human PCTP on mating *Tetrahymena*. First, we found that compound A1 strongly inhibited the ability of *Tetrahymena* to form mating pairs (an early step in the conjugation process). This affect appeared to be due to the lack of clustering by adhesion receptors required for *Tetrahymena* pairing. Since pairing precedes fusion pore formation, we performed a time course to determine the specific effects of PCTP inhibition on fusion pore generation. We found that addition of compound A1 could inhibit pair formation both after adhesion receptors have clustered and more importantly could induce pairs to come apart if added immediately prior to the onset of fusion pore formation. Moreover, the ability of compound A1 to inhibit pairing diminished greatly if added two hours after mixing or more specifically, after fusion pores have been formed. This suggests that PCTP is required before and/or during pore formation but not after fusion pores have already been formed. Future experiments are aimed at determining the localization of PCTP using PCTP-GFP *Tetrahymena*. We are also in the process of generating PCTP knockout *Tetrahymena* to determine whether this will mimic the effects of compound A1. We believe these results provide a potential mechanism for the regulation of membrane lipid content during membrane fusion. Supported by ASCB-MAC, HHMI and the Consortium for Faculty Diversity at Carleton College.

## Signaling Networks Governing Cell Migration I

635

### LOV-TRAP: A broadly applicable, genetically encoded system to control protein activity with light through controlled sequestration at membranes.

H. Wang<sup>1</sup>, A. Winkler<sup>2</sup>, E. Hartmann<sup>2</sup>, R. A. Hallett<sup>3</sup>, B. Kuhlman<sup>3</sup>, I. Schlichting<sup>2</sup>, R. Liu<sup>4</sup>, K. M. Hahn<sup>1</sup>; <sup>1</sup>Department of Pharmacology, University of North Carolina Chapel Hill, Chapel Hill, NC, <sup>2</sup>Department of Biomolecular Mechanisms, Max Planck Institute for Medical Research, Heidelberg, Germany, <sup>3</sup>Department of Biochemistry and Biophysics, University of North Carolina Chapel Hill, Chapel Hill, NC, <sup>4</sup>Eshelman School of Pharmacy and Carolina Center for Genome Sciences, University of North Carolina Chapel Hill, Chapel Hill, NC

The kinetics and subcellular localization of protein activity is precisely controlled to regulate protein interactions and to create specific signaling networks. To study this important aspect of cell signaling, genetically encoded methods are being developed to control protein activity with light in living cells and animals (1-4). Here we describe a new approach that promises to be broadly applicable and is simple to apply. Through an in vitro selection from a protein domain library with more than  $10^{13}$  unique sequences using mRNA display, we developed Zdark, a small protein based on the Z domain (5) that binds only to the dark state of the LOV2 domain from *Avena sativa* phototropin (Figure 1). The LOV2 domain undergoes a large, reversible conformational change induced by light between 400 and 500 nm. Zdark binds to the dark state of LOV2 with a  $K_d$  of  $\sim 100$ nM, but shows no detectable binding to the lit state. In our new method (dubbed LOV-TRAP for LOV trapping and release of active protein) the LOV domain is anchored at an intracellular membrane (to date the mitochondrial and plasma membranes) and the protein of interest is fused to Zdark. In the dark, the Zdark-protein fusion is sequestered at a membrane where it cannot interact with its targets (here the mitochondria). Upon irradiation, LOV binding of the Zdark-protein conjugate breaks down, releasing the Zdark-protein fusion. Release is rapid ( $< 0.5$  secs) and reversible. We have demonstrated this for repeated light/dark cycles and have introduced mutations to vary the kinetics of return to the dark state. To date, we have completed caging of VAV2, Rac1 and RhoA. Progress with other targets will be

described, as will the use of the approach to control protein dimerization. Crystal structure and NMR data will be presented to illuminate the Zdark-LOV interaction. Applications of LOV-TRAP in studies of cell motility will be described.

#### **Rac1 induces PCK-dependent myosin IIA heavy chain phosphorylation to regulate association with focal adhesions and cell migration.**

*A. M. Pasapera<sup>1</sup>, R. S. Fischer<sup>1</sup>, S. V. Plotnikov<sup>1</sup>, T. Egelhoff<sup>2</sup>, C. M. Waterman<sup>1</sup>; <sup>1</sup>NHLBI, NIH, Bethesda, MD, <sup>2</sup>Cell Biology, Lerner Res Inst, Cleveland Clinic, Cleveland, OH*

Cell migration requires coordinated assembly of focal adhesions and contraction in the actomyosin cytoskeleton. The small GTPase Rac1 is critical to cell migration through its known functions in regulation of focal adhesion and actin cytoskeletal assembly dynamics, but its role in regulation of myosin II is not known. Myosin II dynamically assembles into minifilaments at the leading edge of migrating cells, and PKC-mediated phosphorylation in Ser 1916 in the non-helical tail is one of the main regulators. We hypothesized that Rac1 may regulate myosin II minifilament assembly dynamics during cell migration via downstream regulation of PKC and Ser 1916 phosphorylation. To test this, we analyzed the effects of Rac1 activation on the phosphorylation and dynamics of myosin IIA in U2OS cells. We found that transfection of active Rac1 (Rac1V12) induced PKC- and integrin-dependent myosin IIA phosphorylation on Ser 1916. Live cell imaging of GFP-myosin IIA revealed that Rac1 activation promotes rapid assembly, motion, and turnover of myosin IIA minifilaments, as well as perpendicular orientation to the leading edge, resulting in its accumulation specifically in focal adhesions. To determine the role of Ser 1916 phosphorylation on myosin IIA dynamics and localization, we expressed phosphomimetic (S1916D) and non-phosphorylatable mutants (S1916A) of myosin IIA. This showed that phosphorylation is critical to the Rac1-induced rapid assembly and turnover of myosin IIA minifilaments as well as to the focal adhesion association of myosin IIA. Thus, Rac1 acts as a master regulator of cell migration by coordinating actin assembly-mediated protrusion, adhesion, and actomyosin contraction dynamics.

#### **The small GTPase Rap1 promotes movement rather than strengthens cell-cell adhesion in cancer cells responding to insulin-like growth factor I.**

*M. A. Guvakova<sup>1,2</sup>, W. W. Lee<sup>2</sup>, D. K. Furstenau<sup>1</sup>, I. Prabakaran<sup>1</sup>, R. Hung<sup>1</sup>, D. C. Li<sup>1</sup>; <sup>1</sup>Surgery, University of Pennsylvania, Philadelphia, PA, <sup>2</sup>Microbiology, University of Pennsylvania, Philadelphia, PA*

It is widely assumed that the activation of the Ras oncoprotein-related protein 1 (Rap1) is necessary and sufficient to mediate its downstream signaling. However, how active Rap1 regulates seemingly opposite cellular processes from maintaining adhesion to promoting movement remains puzzling. Here we tested the hypothesis that the labile function of Rap1 is cell context-dependent. Rap1 was examined in MCF-7 human breast cancer cells either

hypersensitive to insulin-like growth factors (IGFs) due to overexpression of the wild type IGF-I receptor or insensitive to these cues due to expression of a dead kinase mutant of the IGF-IR. In the IGF-sensitive cells, IGF-I treatment induce the translocation of active Rap1 from E-cadherin based contacts to the actin-enriched motile protrusions in conjunction with relaxing adhesion and promoting movement of the cells. The pretreatment of cells with cAMP-Epacs activators of Rap1 (forskolin and 8-pCPT-2'-O-Me-cAMP) did not rescue the loss of intercellular adhesion induced by IGF-I. At the biochemical level, transient rather than sustained activation of Rap1 by IGF-I appeared to be critical for the onset of cell movement. Ligand-bound autophosphorylated IGF-IR signaled to C3G, CRK SH3-binding guanine nucleotide exchange factor (GEF) to excite GTP-loading (activation) of Rap1. Subsequent internalization of the IGF-IR coincided with the gradual hydrolysis of the bound GTP leading to inactivation of Rap1. Blocking receptor-mediated endocytosis with dansylcadaverine and dynasore prolonged Rap1 activation but did not trigger cell movement. Moreover, expression of the constitutively active mutant V12Rap1 by itself was insufficient to induce movement in IGF-insensitive cells. When IGF-IR signaling was "off", basal activity of Rap1 was required to hold up cell adhesion. Forcing sustained inactivation of Rap1 by over expressing RapGTPase activating protein (RapGAP) or silencing C3G had a detrimental effect on filamentous actin and adhesion in all cells regardless of their sensitivity to IGF. Our novel findings reveal previously unidentified role of C3G-Rap1 signaling in the IGF-IR – actin axis promoting cell movement. We conclude that the ability of Rap1 to promote cell movement is critically dependent on IGF-IR signaling. Whether this mechanism can be extended to other receptor tyrosine kinases remains to be seen.

**Myopodin-induced cell migration is regulated by a non-canonical RhoA/ROCK-dependent and myosin-independent pathway.**

*F. Kai<sup>1</sup>, R. Duncan<sup>1</sup>; <sup>1</sup>Dalhousie University, Halifax, NS, Canada*

More than 80% of patients with invasive prostate cancer have deletions within their myopodin gene, suggesting that myopodin is a reliable predictive marker of prostate cancer metastasis. Five human myopodin (hMYO) splicing variants, each with a unique amino and/or carboxy-termini, have been identified. Biochemical studies have also revealed that myopodin is an actin-binding protein. Since actin rearrangement is an essential process involved in cell migration, it has been postulated that myopodin might affect cancer metastasis by modulating the actin cytoskeleton. However, this hypothesis has not been directly tested and there is no information on the role of the different myopodin isoforms in cancer cell migration. To address these deficits, we ectopically expressed the myopodin isoforms in invasive prostate cancer cells (PC3). Results indicate that all isoforms enhance the chemokinetic activity of PC3 cells, a form of non-directional cell migration. Immunohistochemical studies revealed that the myopodin isoforms induced distinct actin structures in the cell body, and disruption of these structures by genetic or chemical means significantly impaired cell migration, suggesting the myopodin-induced actin structures are directly involved in cell migration. Cell migration requires myosin-mediated actin fiber contraction in order to retract the trailing edge and propel the cell body forward. Interestingly, knockdown of myosin or inhibition of myosin contractibility with blebbistatin did not affect myopodin-induced cell migration, indicating myopodin enhances cell migration via a myosin-independent pathway. However, myopodin-induced migration requires the activation of the upstream effectors of myosin, i.e. RhoA and ROCK. Furthermore, myopodin rescued the tail-retraction defect in myosin-knockdown PC3 cells. Taken together, our data suggest that myopodin may functionally replace myosin to promote cell migration through its ability to induce actin bundles and via a non-canonical RhoA/ROCK-dependent, myosin-independent pathway.

**Rnd3/RhoE is down-regulated in hepatocellular carcinoma and controls cellular invasion.**

*F. Grise<sup>1</sup>, S. Sena<sup>1</sup>, A. Bidaud-Meynard<sup>1</sup>, J. Baud<sup>2</sup>, J-B. Hiriart<sup>1</sup>, K. Makki<sup>1</sup>, N. Dugot-Senant<sup>3</sup>, C. Staedelf<sup>2</sup>, P. Bioulac-Sage<sup>1</sup>, J. Zucman-Rossi<sup>4</sup>, J. Rosenbaum<sup>1</sup>, V. Moreau<sup>1</sup>; <sup>1</sup>Inserm U1053, Bordeaux, France, <sup>2</sup>Inserm U869, Bordeaux, France, <sup>3</sup>Bordeaux University, IFR66, Bordeaux, France, <sup>4</sup>Inserm U674, Paris, France*

Hepatocellular carcinoma (HCC) is the main primary malignancy of the liver and one of the most common and aggressive cancer worldwide, causing 500,000 to 1 million deaths annually. HCC diagnosis is often done at advanced stages of the disease when curative solutions, mostly based on surgery, can no more be proposed. Therefore the development of new molecular targets for therapy, drugs and treatment strategies are needed.

From micro-array data analysis, we noticed the significant down-regulation of Rnd3 expression in HCC. Rnd3, also called RhoE, belongs to the RhoGTPase family and is atypical, since in contrast to other GTPases, it is always in its active GTP-bound form. Here, we address the role of Rnd3 in HCC development.

Rnd3 down-regulation was validated by quantitative real time PCR in a hundred independent tumors. Moreover, Rnd3 down-expression was confirmed using immunohistochemistry on tumor sections and Western blot on human tumor and cell line extracts. Rnd3 expression was significantly lower in invasive tumors with satellite nodules. Overexpression and silencing of Rnd3 in Hep3B cells led to decreased and increased 3D cell motility, respectively. The siRNA-mediated down-regulation of Rnd3 expression induced loss of E-cadherin at cell-cell junctions that was linked to epithelial-mesenchymal transition through the up-regulation of the zinc finger E-box binding homeobox protein ZEB2 and the down-regulation of miR-200b and miR-200c. We further analyzed the pathways involved in Rnd3 knockdown-induced invasion and found that tumor hepatocyte invasion occurred in an MMP-independent, and Rac1- and Cdc42-dependent manner.

In conclusion, Rnd3 down-regulation provides an invasive advantage to tumor hepatocytes suggesting that RND3 might represent a metastasis suppressor gene in hepatocellular carcinoma.

**Scaffold proteins coordinate small GTPase activation in HGF stimulated motility.**

*M. A. Attar<sup>1</sup>, J. C. Salem<sup>1</sup>, L. C. Santy<sup>1</sup>; <sup>1</sup>Biochemistry and Molecular Biology, Pennsylvania State University, University Park, PA*

Epithelial cells are largely immotile under normal circumstances, but become motile during development, repair of tissue damage and during cancer metastasis. Both normal and pathologic epithelial migration is stimulated by growth factors. Hepatocyte growth factor (HGF) induces many epithelial cells lines to begin moving. A number of small GTPases that are activated downstream of HGF and are required for HGF-induced movement. We have found that two scaffold proteins, CNK3 and GRASP, coordinate the activation of ARF6 and Rac in response to HGF. CNK3 binds to the ARF-GEF cytohesin 2/ARNO and is required for the activation of ARF6 in response to HGF. GRASP binds directly to both cytohesin 2 and to the Rac-GEF Dock180. This interaction promotes the activation of Rac 1 in response to ARF6. Knockdown of either scaffold inhibits HGF stimulated migration of MDCK cells. These two scaffolds work together to build a ARF-to-Rac signaling module that stimulates epithelial migration.

**Distinct spatiotemporal coordination of Rac1 and RhoA activities in migrating carcinoma cells revealed by experimental multiplexing of FRET sensors.**

*T. Yin<sup>1</sup>, Y. I. Wu<sup>1</sup>; <sup>1</sup>Center for Cell Analysis and Modeling, University of Connecticut Health Center, Farmington, CT*

Cell migration consists of cycles of protrusion and adhesion at the front, and detachment and retraction at the rear. Signaling crosstalk among different Rho GTPases is thought to play a significant role in coordinating these cellular behaviors spatially and temporally. Previously, genetically-encoded, Förster resonance energy transfer (FRET)-based biosensors were employed to study such dynamics, but left much to be desired specifically in better dynamic range and precise quantification. Here we report the result of coupling of activation-dependent effector binding with dimerization of fluorescent proteins in a new set of sensors of Rho GTPases, namely Dimerization-Optimized Reporters for Activation (Dora) of Rho GTPases. To provide an instrument-independent comparison, the FRET efficiencies of Dora sensors were determined to be 0.80/0.16, 0.68/0.14, and 0.69/0.20 (on/off) for Rac1, cdc42, and RhoA respectively, significantly improved from the published Raichu-Rac1 (0.50/0.28) and FLAIR-RhoA (0.54/0.46). Furthermore the Dora design of sensors were extended with dimerizing orange and red-emitting FRET pair of fluorescent proteins, and to broader signaling targets such as H-Ras, Rab11, and Protein Kinase A. These technical breakthroughs enabled us to experimentally resolve the spatiotemporal dynamics of Rac1 and RhoA activations in the same cell. In contrast to what was reported in mouse embryonic fibroblasts, MCF-7 breast cancer cells showed closer temporal correlation of protrusion with Rac1 activation, with RhoA activation lagging behind. Rac1 activation was absent from retracting tails. Rather than promoting it, RhoA activation appeared to stall or slow down protrusion at the front where it spatially overlapped with Rac1 activation. This occurred synchronously with transient, marked activation of RhoA and retraction at the rear. Blocking downstream signaling of RhoA with the Rho kinase inhibitor Y27632 disrupted the polarized distribution of active Rac1 and resulted in the rapid activation of Rac1 peripheral to active RhoA, indicating that RhoA antagonizes Rac1 at the front.

Hudson<sup>2</sup>, L. A. Sklar<sup>1</sup>; <sup>1</sup>Pathology, University of New Mexico, Albuquerque, NM, <sup>2</sup>Pharmaceutical Sciences, University of New Mexico, Albuquerque, NM, <sup>3</sup>Cancer Center, University of New Mexico, Albuquerque, NM, <sup>4</sup>Specialized Chemistry Center, Kansas University, Lawrence, KS, <sup>5</sup>Medicine, University of New Mexico, Albuquerque, NM, <sup>6</sup>Medicinal Chemistry, Kansas University, Lawrence, KS*

Cdc42 activation controls key cellular process including cytoskeletal remodeling, cell division, signal transduction, and vesicular transport. Dysregulated Cdc42 activity contributes to sporadic and genetic diseases ranging from cancer to immunologic disorders. We report the characterization of the first known small molecule inhibitor of Cdc42. The compound was identified through high throughput screening (HTS) of the Molecular Libraries Screening Center Network library of over 200,000 compounds. The compound acts as an allosteric guanine nucleotide binding inhibitor in a dose-dependent manner both in vitro and in cell based assays. The compound was highly specific for Cdc42 with no inhibitory activity against Rho and Rac GTPases. Structure activity analyses identified key structural determinants required for specific

Cdc42 binding. Cell based studies show the inhibitor is not cytotoxic, prevents GTPase activation, and blocks Cdc42-dependent filopodia formation and cell migration. Disease relevant applications are illustrated through the inhibition of hantavirus infection and integrin activation. Together the data identify a novel, allosteric Cdc42 specific inhibitor with utility for studies of in vitro mechanism and cell-based function.

643

### **Regulation of CXCR4 Receptor Trafficking, Signaling, and Function by Arf6.**

*J. Freed<sup>1</sup>, D. Ezdon<sup>1</sup>, J. L. Benovic<sup>2</sup>, C. C. Moore<sup>1</sup>; <sup>1</sup>Department of Pharmacology, Philadelphia College of Pharmacy, University of the Sciences, Philadelphia, PA, <sup>2</sup>Department of Biochemistry and Molecular Biology, Kimmel Cancer Center, Thomas Jefferson University, Philadelphia, PA*

CXCR4, a chemokine receptor essential for select neuronal, cardiovascular, and hematopoietic cell migration in response to stromal cell-derived factor-1a (SDF, CXCL12), has emerged as a critical player during breast cancer cell metastasis. Dysregulated CXCR4 on nonmotile primary tumor cells confers an aberrant migratory capacity and promotes the invasive homing to distal SDF-expressing organs. This has led to the vigorous pursuit of factors that regulate the SDF-CXCR4 axis. We demonstrate here that ADP-ribosylation factor 6 (Arf6) regulates cell surface levels of CXCR4 specifically upon activation with SDF. Expression in HEK293 cells of either wild type Arf6 or an active GTPase-deficient Arf6 mutant (ARF6-QL) maintains CXCR4 at the cell surface upon SDF stimulation, whereas an inactive GDP/GTP exchange-deficient Arf6 mutant (ARF6-TN) or Arf6 siRNA promotes CXCR4 loss from the cell surface. Consistent with these data, receptor cell surface levels are similarly altered following modulation of endogenous Arf6 by EFA6, an Arf6-selective guanine nucleotide exchange factor (GEF), or by ACAP1, an Arf6-selective GTPase activating protein (GAP). In addition to regulating SDF-dependent CXCR4 cell surface levels, Arf6 is activated downstream of CXCR4 and regulates SDF-dependent ERK signaling in both HEK293 cells expressing heterologous CXCR4 and MDA-MB-361 metastatic breast cancer cells expressing endogenous CXCR4. Specifically, Arf6 modulates agonist-dependent ERK activity in membranes and in response to SDF gradient stimulation. Furthermore, Arf6 modulates SDF gradient-dependent migration of highly invasive MDA-MB-231 metastatic breast cancer cells. Taken together, these data demonstrate Arf6 regulation of the SDF-CXCR4 axis, and have implications on the dysregulation of CXCR4 observed in breast cancer metastasis.

644

### **The role of an R-Ras/ARF6 signaling module in hepatocyte growth factor (HGF) dependent migration**

*J. C. Salem<sup>1</sup>, L. E. Goldfinger<sup>2</sup>, L. C. Santy<sup>1</sup>; <sup>1</sup>Biochemistry and Molecular Biology, Penn State University, University Park, PA, <sup>2</sup>Temple University School of Medicine, Philadelphia, PA*

In response to hepatocyte growth factor (HGF), epithelial cells show increased migration, as well as display branching morphogenesis in 3D matrices. ARF6 is one small GTPase that acts downstream of HGF leading to cortical actin rearrangements. It is known that ARF guanine nucleotide exchange factor (GEF) cytohesin-2/ARNO binds to scaffold IPCEF1. Upon transfection of Madin Darby canine kidney (MDCK) epithelial cells, ARNO causes a motility phenotype very similar to cells treated with HGF. We recently found that IPCEF1 is actually the C-terminal half of a scaffolding protein called CNK3 [1]. We also showed that the C-terminal CRAC domain of CNK3 associates with ARNO and is required for ARF6 activation downstream of HGF [1]. CNKs have been shown to be involved in signaling downstream of Ras GTPases. A unique R-Ras effector, RLIP76 has been shown to associate with ARNO and links R-Ras to

ARF6 activation [2]. Here, we show that CNK3 associates with RLIP76 via its C-terminal half. In addition, the RhoGAP domain of RLIP76 is needed for co-immunoprecipitation with CNK3. Immunofluorescence staining shows that CNK3 and RLIP76 co-localize. Using split-Venus bimolecular fluorescence complementation microscopy, we show that CNK3 is a shared partner between ARNO and RLIP76 suggesting that they could be apart of the same complex. Finally, we provide evidence that R-Ras does not modulate the interaction between CNK3 and RLIP76. We hypothesize that the interaction between CNK3/RLIP76 is required for HGF-dependent ARF6 activation and migration. Assessing the degree to which the RLIP76/CNK3 module promotes HGF-dependent migration is an important step in understanding the machinery cells need become motile. Elucidating HGF-induced motility can help us grasp developmental processes, epithelial mesenchymal transition (EMT), and metastasis.

**Microenvironment for hypoxia and interaction with endothelial cells control homing activity of placenta-derived mesenchymal stem cells via alpha4 integrin and Rho signaling.**

*J. Choi<sup>1</sup>, J. Jung<sup>1</sup>, Y. Yoo<sup>1</sup>, W. Heo<sup>2</sup>, G. Kim<sup>1</sup>; <sup>1</sup>CHA university, Seoul, Korea, <sup>2</sup>KAIST, Daejeon, Korea*

Mesenchymal stem cells (MSCs) are powerful source for cell therapy in the degenerative diseases. The homing activity of MSCs is one of important factors to enhance the therapeutic effect when they are transplanted into target tissues or organs. The characteristic capable of homing of MSCs is similar to invasion of cancer. Rho family, which is a migration factors, has been known to be regulated by integrin family in several cancers. However their mechanisms in MSCs were not known. Therefore, the objectives of this study were to compare the expression of markers related to integrins signaling in normal fibrotic cell (WI-38) and placenta-derived mesenchymal stem cells (PDMSC) depend on normoxia and hypoxic conditions. In addition, the correlation between homing activity of MSCs and alpha4 integrin and Rho signaling was evaluated. The invasion activities of PDMSCs exposed to hypoxic condition were significantly increased those of WI-38 and those of normoxia ( $p < 0.05$ ) by Transwell invasion assay. Expressions of integrin  $\alpha 4$  were increased both in WI-38 and PDMSCs under hypoxic condition compared to normoxia. Down-regulation of integrin  $\alpha 4$  by siRNA in PDMSCs and WI-38 were shown to decrease their invasion activities. Interestingly, Rho family-related makers such as Rho A and ROCK1 were significantly increased in PDMSCs under hypoxic condition compared to normoxia ( $p < 0.05$ ). Furthermore, the invasion activity of PDMSCs was decreased by Rho kinase inhibitor treatment (Y-27632) and by co-cultured with human umbilical vein endothelial cells (HUVEC) in ex vivo system; otherwise, invasion ability of WI-38 was not changed excepting WI-38 co-cultured with HUVEC under hypoxia. Although there are no difference in invasion ability of WI-38 in normoxia by Y-27632 treatment, invasion abilities of PDMSCs co-cultured with HUVEC were significantly increased ( $p < 0.05$ ). Taken together, alterations of alpha4 integrin and Rho signaling by hypoxia and interaction with endothelial cells could be regulating the homing activity of PDMSCs.

**Role of microtubules in neutrophil polarity and migration in live zebrafish.**

S. Yoo<sup>1</sup>, P-Y. Lam<sup>1</sup>, M. R. Eichelberg<sup>1</sup>, L. Zasadil<sup>1</sup>, W. Bement<sup>1</sup>, A. Huttenlocher<sup>1</sup>; <sup>1</sup>University of Wisconsin Madison, Madison, WI

Microtubules control cell motility by positively regulating polarization in many cell types. However, how microtubules regulate leukocyte migration is not well understood, particularly in living organisms. Here we exploited the zebrafish system to study the role of microtubules in neutrophil migration *in vivo*. The localization of microtubules was visualized in motile neutrophils using various bioprobes, revealing that, in contrast to *in vitro* studies, the microtubule organizing center is positioned in front of the nucleus in motile neutrophils. Microtubule disassembly impaired neutrophil wound attraction but enhanced F-actin polarity based on the distribution of stable and dynamic F-actin. Microtubule depolymerization inhibited polarized PI(3)K activation at the leading edge and induced rapid, PI(3)K independent motility. Finally, we show that microtubules exert their effects on neutrophil polarity and motility at least in part by the negative regulation of both Rho and Rac activity. These results provide new insight into the role of microtubules in neutrophil migration in a living vertebrate and show that the motility of these professional migratory cells are subject to distinctly different rules than those established for other cell types.

**Semaphorin3A and Ephrin-A1 Suppress the NGF-Enhancing Effects on Breast Epithelial Cell Migration.**

M. D. Wallace<sup>1</sup>, S. Gehler<sup>1</sup>; <sup>1</sup>Biology Department, Augustana College, Rock Island, IL

The vast majority of all cancer deaths are a consequence of tumor metastases to other regions of the body. However, the molecular mechanisms underlying metastases are not well understood. In some cancers, neurotrophins and axon guidance molecules, all of which were originally characterized in the nervous system, have been shown to have varying effects on cell motility. We demonstrate that nerve growth factor (NGF) selectively enhances the migration of malignant, but not normal, breast epithelial cells, consistent with previously published results (Dolle et.al, 2003). Secondly, using a scratch assay, both semaphorin3A (Sema3A) and ephrin-A1 inhibit malignant breast epithelial cell migration by approximately 25% and 29%, respectively. However, there was no change in cell proliferation following exposure to either Sema3A or ephrin-A1. In the nervous system, Sema3A and NGF have been found to share common signaling pathways to regulate nerve cell growth and growth cone dynamics (Dontchev and Letourneau, 2002; Ben-Zvi et al., 2008). Since breast cancer cells have been shown to respond to NGF, Sema3A, and ephrin-A1 through paracrine and autocrine signaling mechanisms *in vitro* and *in vivo* (Dolle et.al, 2003; Pan et al., 2009; Wykosky and Debinski, 2008), we sought to determine whether Sema3A or ephrin-A1 could suppress the NGF-enhancing effects on breast epithelial cell migration. While NGF enhanced migration by approximately 62%, simultaneous treatment with Sema3A + NGF inhibited migration by 60%, similar to Sema3A treatment alone. Similar effects were observed with simultaneous treatment using ephrin-A1 + NGF. These results indicate Sema3A and ephrin-A1 were able to overcome the enhancing effects of NGF, and suggest Sema3A, ephrin-A1, and NGF share common signaling pathways to regulate motility of breast epithelial cells. Understanding the interactions between these molecules *in vitro* will lead to a better understanding of the complexities of tumor cell motility mechanisms *in vivo*.

**CSPG4-NEDD9 interaction promotes migration, invasion, and growth of breast cancer cells.**

*J. Iida<sup>1</sup>, J. Dorchak<sup>1</sup>, R. Clancy<sup>1</sup>, C. Luo<sup>2</sup>, Y. Chen<sup>2</sup>, H. Hu<sup>2</sup>, R. J. Mura<sup>3</sup>, C. D. Shriver<sup>4</sup>; <sup>1</sup>Cell Biology, Windber Research Institute, Windber, PA, <sup>2</sup>Biomedical Informatics, Windber Research Institute, Windber, PA, <sup>3</sup>Windber Research Institute, Windber, PA, <sup>4</sup>Surgery, Walter-Reed National Military Medical Center, Bethesda, MD*

Triple negative (TN) breast cancers are defined by a lack of expression of estrogen, progesterone, and HER2 receptors. It is widely recognized that TN breast cancers have a poorer prognosis than any other subtype of breast cancers. Given the lack of effective targeted therapies for TN breast cancer patients, understanding of the mechanisms of growth and invasion of these tumors will provide insight into developing novel approaches to lower the mortality from TN breast cancer. CSPG4 (chondroitin sulfate proteoglycan 4) gene is expressed on various cell types including breast cancer and melanoma cells and promotes cell migration and invasion. In this study, we demonstrated that statistical analysis (ANOVA) of The Cancer Genome Atlas (TCGA) project gene expression data (<https://tcga-data.nci.nih.gov/>) suggests that tumors from patients with basal subtype breast cancer had significantly higher CSPG4 expression than tumors from patients with other subtypes. Since TN subtype is generally overlapping with basal subtype, these results support the notion of CSPG4 as a key molecule for promoting TN breast cancer invasion and metastasis. We further demonstrated that NEDD9 was co-immunoprecipitated with CSPG4 but not with CD44 or  $\beta$ 1-integrin in MDA-MB-231 cells, suggesting that CSPG4 and NEDD9 form a molecular complex for facilitating tumor migration, invasion, and growth. Overexpression of NEDD9 in a TN breast cancer cell line, HCC38, significantly enhanced migration and invasion. Conversely, suppression of NEDD9 expression by siRNA significantly inhibited migration and invasion of MDA-MB-231 cells, suggesting that NEDD9 plays a key role in promoting invasion and metastasis of TN breast cancer cells. These results provide key insights for not only understanding mechanisms of TN breast cancer progression but also suggest the CSPG4-NEDD9 complex as a potential drug-target for patients who develop this subtype of breast cancer. The views expressed in this article are those of the author and do not reflect the official policy of the Department of Defense, or U.S. Government.

**GnRH Induces RUNX2 Expression Via ERK And AKT Signaling: Possible Involvement In The Regulation Of Trophoblast Invasion?**

*B. Peng<sup>1</sup>, H. Zhu<sup>1</sup>, P. C. Leung<sup>1</sup>; <sup>1</sup>Dept of Obstetrics & Gynaecology, Child & Family Research Institute, Vancouver, BC, Canada*

Gonadotropin-releasing hormone (GnRH) is expressed in first trimester placenta and exerts pro-invasive effects on extravillous trophoblast cells *in vitro*. The RUNT-related transcription factor RUNX2 has been reported to regulate matrix metalloproteinase (MMP)2/9 as well as an integrin ligand osteopontin expression and is often associated with invasive phenotypes. Thus, our aim was to investigate the effects of GnRH on RUNX2 expression and examine the role of RUNX2 in regulating trophoblast invasiveness.

GnRH receptor, RUNX2, MMP2/9 and osteopontin were detected at invasion sites of human first-trimester placenta by immunohistochemistry. RunX2 and osteopontin are co-expressed in the invasive extravillous trophoblastic cells. Treatment of an immortalized human extravillous trophoblast cell line (HTR-8/SVneo) with GnRH resulted in time- and concentration-dependent increases in RUNX2 mRNA and protein levels. Pre-treatment with the GnRH receptor antagonist Antide attenuated the effects of GnRH on RUNX2 mRNA and protein levels.

Treatment with GnRH elevated phospho-ERK and phospho-Akt protein levels in HTR-8/SVneo cells. Moreover, GnRH-induced increases in RUNX2 protein levels were attenuated by co-treatment with a MEK inhibitor (PD98095) or a phosphoinositide 3-kinase inhibitor (LY294002). Small interfering RNA (siRNA) was used to examine the contributions of RUNX2, MMP2, MMP9 and osteopontin to HTR-8/SVneo cell invasiveness. Transwell Matrigel or collagen I mediated HTR8/SVneo cell invasion was reduced following knockdown of RUNX2, MMP2, MMP9 and osteopontin. Importantly, down-regulation of RUNX2 alone significantly reduced basal MMP2, MMP9 and osteopontin mRNA and protein levels.

Our results suggest that GnRH acts via its receptor to induce ERK and Akt phosphorylation which contributes to elevated RUNX2 expression. GnRH-induced RUNX2 expression may enhance the invasive capacity of trophoblasts by modulating the expression of MMP2, MMP9 or osteopontin.

### **Effect of pituitary tumor transforming gene -1 (PTTG1) on the activities for invasion and proliferation of trophoblast cells.**

*S. Lim<sup>1</sup>, J. Choi<sup>1</sup>, J. Jeon<sup>1</sup>, H. Lee<sup>1</sup>, G. Kim<sup>1</sup>; <sup>1</sup>CHA University, Seoul, Korea*

Pituitary tumor transforming genes (PTTGs), which are isolated from pituitary tumor cells play important roles in malignant transformation as well as several biological process such as cellular growth, development, DNA repair, metabolism and invasion. Invasion of trophoblast is a pivotal role in placentation, decidualization and successful implantation. It is regulated by numerous factors including growth factors, adhesion molecules, matrix metalloproteinases (MMPs), and hypoxia. However, role of the PTTG1 in trophoblast was unknown. Therefore, the objectives are to analyze the expression of PTTG1 in trophoblast and the effect of PTTG1 on activities for invasion and proliferation of trophoblast. Also, the function of PTTG1 in trophoblast was evaluated by the down-regulation of PTTG1 using siRNA. Expression of PTTG1 in trophoblast was localized into nucleus of the cells. Their expressions were significantly decreased in dose dependently when they were exposed to siRNA-PTTG1 treatment for 48 hours ( $p < 0.05$ ). In addition, the numbers of invasive cells were significantly decreased in trophoblast treated with siRNA-PTTG1 compared to control ( $p < 0.05$ ). Especially, invasion abilities of HTR-8 were significantly decreased by 200 and 400pM/ml of siRNA-PTTG1 ( $p < 0.05$ ). Furthermore, down-regulated PTTG1 in trophoblast induced to change the expressions of markers related to adhesion molecules such as integrins and Rho signaling. However, there are no difference proliferations of trophoblast by FACS analysis. These results suggest that alteration of PTTG1 could be regulate invasion of trophoblast.

### **Dynamin 2 Potentiates Migratory Tumor Cell Invasion through a Novel Stabilization of the Oncogenic Rac1 GEF, Vav1.**

*G. L. Razidlo<sup>1</sup>, Y. Wang<sup>1</sup>, J. Chen<sup>1</sup>, D. D. Billadeau<sup>1</sup>, M. A. McNiven<sup>1</sup>; <sup>1</sup>Mayo Clinic, Rochester, MN*

Metastatic invasion represents a complex synergy of cell motility, adhesion, and matrix remodeling. A cytoskeletal enzyme recently implicated in neoplastic invasion is the large GTPase Dynamin 2 (Dyn2). Dyn2 is markedly upregulated in pancreatic cancer, is a potent activator of metastatic migration, and is required for Rac1-mediated formation of lamellipodia. However, the mechanisms by which Dyn2 participates in these processes are unclear. Here we demonstrate that Dyn2 promotes Rac1 activation in pancreatic cancer cells through a direct interaction with the Rac1 guanine nucleotide exchange factor (GEF) Vav1. Vav1 is ectopically

expressed in over half of human pancreatic cancers to increase tumor cell survival and invasion. Disruption of the Dyn2-Vav1 interaction impairs Rac1 activation and subsequent lamellipodia formation and cell migration. Surprisingly, inhibition of the Dyn2-Vav1 interaction results in a dramatic reduction in Vav1 protein stability, resulting in diminished Rac1 activation. In the absence of Dyn2 binding, Vav1 is targeted to the lysosome for degradation via an interaction with the cytoplasmic chaperone Hsc70. Importantly, a specific mutation of Vav1 near its Dyn2-interactive C-terminal SH3 domain prevents Hsc70 binding, resulting in a stabilization of Vav1 levels. Thus, Dyn2 binding prevents the interaction of Vav1 with the Hsc70 chaperone and thus prevents the targeting of this oncogenic GEF to the lysosome. The effects of Dyn2 on Vav1 protein levels and Rac1 activation are independent of Dyn2 enzymatic activity and function in endocytosis. These findings represent a completely novel function for both Dynamin and Vav1. The fact that these proteins are aberrantly co-expressed at high levels within a majority of pancreatic tumors supports the concept that these proteins interact to increase Vav1 stability and subsequently promote an oncogenic outcome. Supported by NCI RO1 CA104125 to MAM.

### **Arpin, a Novel Protein that Inhibits the Arp2/3 Complex at the Leading Edge, Steers Cell Migration.**

*I. Dang<sup>1</sup>, R. Gorelik<sup>1</sup>, C. Sousa<sup>1</sup>, J. Linkner<sup>2</sup>, T. Chypisheva<sup>3</sup>, V. Ermilova<sup>3</sup>, C. Guérin<sup>4</sup>, M. Nemethova<sup>5</sup>, E. Derivery<sup>1</sup>, G. Lakisic<sup>1</sup>, V. Small<sup>6</sup>, L. Blanchoin<sup>4</sup>, A. Alexandrova<sup>3</sup>, J. Faix<sup>2</sup>, A. Gautreau<sup>1</sup>; <sup>1</sup>Laboratoire d'Enzymologie et Biochimie Structurales, CNRS, Gif-sur-Yvette, France, <sup>2</sup>Hannover Medical School, Hannover, Germany, <sup>3</sup>N. N. Blokhin Cancer Research Center, Moscow, Russia, <sup>4</sup>CEA, Grenoble, France, <sup>5</sup>Institute of Molecular Biotechnology, Vienna, Austria*

The Arp2/3 complex generates branched actin networks that power protrusion of the leading edge in migrating cells. The small GTPase Rac controls Arp2/3 activation at the leading edge through the Wave complex. Here we present the identification of a novel protein that inhibits the Arp2/3 complex and its role in steering cell migration. By bioinformatics, we retrieved an uncharacterized protein containing an Acidic motif at its C-terminus, a characteristic motif of Arp2/3 activators. A combination of in vitro assays, revealed, however, that this protein inhibits the Arp2/3 complex by competing with the activators. We called this protein Arpin as a tribute to A.G.'s PhD supervisor and as a good mnemonic for Arp2/3 inhibition. Surprisingly, the Arp2/3 inhibitory protein Arpin localizes to the leading edge of migrating cells, where actin is polymerized. Rac activates Arpin and RNAi-mediated depletion of Arpin induces lamellipodia to protrude faster, consistent with its inhibitory role on Arp2/3 complex activity. Arpin depleted cells generated from an invasive breast carcinoma cell line, as well as Dictyostelium discoideum amoeba inactivated for the orthologous Arpin gene, migrated more than the controls, because of increased directionality. To confirm this role, we performed a gain-of-function experiment in fish keratocytes, which migrate in a persistent manner. Microinjection of purified zebrafish Arpin into keratocytes resulted in lamellipodial instability and in a turn of the migration direction. The function of the Arp2/3 inhibitory protein Arpin in steering cell migration is thus conserved and is likely to be important for cancer progression and metastasis formation. Indeed, an immunohistochemical analysis of human breast samples revealed that Arpin is well expressed in breast epithelia but that its expression is lost in most invasive carcinoma.

**Regulation of collective cell migration and intercellular force transmission by cell-cell junction proteins.**

*E. Bazellères<sup>1</sup>, X. Serra-Picamal<sup>1</sup>, R. Vincent<sup>1</sup>, V. Conte<sup>1</sup>, M. Bintanel<sup>1</sup>, X. Trepas<sup>1</sup>; <sup>1</sup>IBEC, Barcelona, Spain*

In a wide variety of migratory processes, including embryonic morphogenesis, wound healing, and some forms of epithelial tumor invasion, cells migrate collectively. Collective motion of epithelial cell sheets involves physical forces that are generated by the actomyosin cytoskeleton and transmitted across intercellular junctions. The physical network of adhesion proteins that supports force transmission between motile cells remains poorly understood, however. To identify the proteins that are involved in intercellular force propagation and to study their regulation of collective cell migration within an epithelial cell sheet (MCF10A), we used siRNAs to target 20 genes encoding for structural proteins of cell-cell junctions. By using polydimethylsiloxane (PDMS) cell micropatterning combined with Traction force Microscopy, Monolayer Stress Microscopy and Particle Image Velocimetry, we systematically mapped the effect of depleting cell-cell adhesion proteins on cell-matrix forces, cell-cell forces and cell velocities. Our data show that cell velocities and intercellular forces are regulated not only by Cadherin-Catenin complexes, as commonly assumed, but also by proteins traditionally associated with tight junctions. By combining mechanical and gene expression data we provide a mechano-genetic network that captures the regulation of collective cell migration by intercellular adhesion proteins.

**Visualizing and manipulating focal adhesion kinase regulation in live cells.**

*M. Ritt<sup>1</sup>, J-L. Guan<sup>1,2</sup>, S. Sivaramakrishnan<sup>1,3</sup>; <sup>1</sup>Cell and Developmental Biology, University of Michigan, Ann Arbor, MI, <sup>2</sup>Internal Medicine, University of Michigan, Ann Arbor, MI, <sup>3</sup>Biomedical Engineering, University of Michigan, Ann Arbor, MI*

Focal Adhesion Kinase (FAK) is essential for cell migration, and plays an important role in tumor metastasis. However, the complex inter-molecular and intra-molecular interactions that regulate FAK activity at the focal adhesion remain unresolved. Recent studies using conformational FRET sensors to probe an important regulatory interaction between the FERM and kinase domains of FAK have yielded conflicting results. Here, we report on FAK FRET sensors using a new technique termed Systematic Protein Affinity Strength Modulation (SPASM). SPASM involves the expression of a single polypeptide with two proteins or protein domains separated by a modular ER/K linker. Changes in affinity between the proteins are quantitatively measured using a genetically encoded FRET pair on either side of the ER/K linker and manipulated by varying the length of the helix. We demonstrate that SPASM FRET sensors are more consistent in reporting changes in the strength of the FERM-kinase interaction than conformational sensors. Further, changes in the ER/K linker length were used to systematically vary the strength of the FERM-kinase interaction. Systematic control of the FERM-kinase interaction both *in vitro* and at live cell focal adhesions was evident in measurements of FRET, kinase activity, and Y397 phosphorylation in multiple cell lines. Control of this key phosphorylation event translated directly into control over cell migration in wound-healing assays. Our findings suggest that the FERM-kinase interaction is spatially patterned *in vivo*, in line with a recent report on the layered architecture of the focal adhesion. We also report on the use of our toolbox of SPASM FAK sensors to understand the impact of the tumor microenvironment on the FERM-kinase interaction. Specifically, cancer cells have been shown to maintain an alkaline intracellular pH (~ 7.5) compared to normal cells (6.8-7.2). SPASM FAK sensors reveal that the FERM-kinase interaction is sensitive to pH, with an enhanced auto-inhibitory interaction

between the FERM and kinase domains at acidic pH. The use of the SPASM technique quantitatively demonstrates, for the first time, a pH dependent change in a protein interaction at a macromolecular structure in live cells. The FERM-kinase interaction was weakest at pH 7.5 with a steady increase at lower pH, peaking at a 3-fold increase at pH 5.8. The enhanced FERM-kinase interaction at acidic pH in live cells was accompanied by reduced Y397 phosphorylation. Our findings provide a potential mechanism for enhanced FAK activity in the tumor microenvironment.

**Cytoskeletal SPECC1L is a novel modulator of cell adhesion, cell motility, actin stability and PI3K-AKT signaling.**

N. R. Wilson<sup>1</sup>, A. J. Olm-Shipman<sup>1</sup>, E. Kosa<sup>1</sup>, L. Pitstick<sup>2</sup>, B. C. Bjork<sup>2</sup>, A. Czirok<sup>1</sup>, I. Saadi<sup>1</sup>;  
<sup>1</sup>Department of Anatomy and Cell Biology, University of Kansas Medical Center, Kansas City, KS, <sup>2</sup>Department of Biochemistry, Northwestern University, Downers Grove, IL

Orofacial clefts are among the most frequent birth defects, affecting one child in eight hundred, in the U.S. alone. Previously, we identified *SPECC1L* (sperm antigen with calponin homology and coiled-coil domains 1-like) as the first gene mutated in oblique facial clefts (ObFC). *SPECC1L* is a novel cytoskeletal 'crosslinking' protein, which interacts with both the actin and microtubule cytoskeletons. *SPECC1L* deficiency in *Drosophila*, zebrafish and mammalian cells results in migration and adhesion defects, revealing a potential mechanism underlying ObFCs [Saadi *et al.*, AJHG 2011]. We now report that *SPECC1L*-knockdown (kd) cells show cell-adhesion (HEK-293T and U2OS osteosarcoma) and cell migration (U2OS) changes **only upon confluence**. While confluent 293T kd cells fail to adhere to any extracellular matrix (ECM), confluent U2OS kd cells show a more selective defect by not adhering to poly-D-lysine substrate. In addition, the *SPECC1L*-kd cells appear drastically elongated upon reaching confluence, in contrast to cuboidal control cells. The average length/width ratio for *SPECC1L*-kd cells (2.94) compared to control cells (1.99) is significantly longer ( $p < 10^{-8}$ ,  $n=100$ ). More important, our initial results using live-imaging and Particle Image Velocimetry analysis indicate that, upon confluence, kd cells move faster **individually**, but are less coordinated **collectively** with the correlation length of sheet motion being 52  $\mu\text{m}$  vs 45  $\mu\text{m}$  for control and kd cells, respectively ( $p < 0.0005$ ). Thus, our previous report of poor performance of *SPECC1L*-kd cells in wound-repair assays is not due to lack of individual motility, but rather their **inability to move collectively**. We are now extending analysis to mixed populations of cells, to test whether kd cells change shape and move less coordinately when surrounded by control cells and vice versa. At the molecular level, antibody array and Western blot analyses of lysates from *SPECC1L*-kd 293T and U2OS cells show a down-regulation of PI3K-AKT signaling, which plays a central role in mediating signals from the ECM, growth factors and cytokines. Several members of the pathway, including pan-AKT, FAK, GSK3 $\beta$ , p53 and cofilin are down-regulated, while the p120 inhibitory subunit of PI3K is up-regulated. Reduced expression in kd cells of cofilin, which is required for actin turnover, also explains the marked increase in F-actin staining in *SPECC1L*-kd U2OS cells. Lastly, preliminary data from transient transgenic shRNA-based kd of *Specc1l* in mouse shows a range of embryonic developmental defects. We will now confirm whether PI3K-AKT signaling and neural crest cell migration are perturbed in these embryos. Together, these findings begin to explain the cellular and molecular role of *SPECC1L* in facial morphogenesis and malformation.

657

**Mechanism of integrin mediated Arg kinase activation.**

*M. A. Simpson<sup>1</sup>, W. D. Bradley<sup>1</sup>, D. Harburger<sup>2</sup>, D. Calderwood<sup>2</sup>, A. Koleske<sup>1</sup>; <sup>1</sup>Molecular Biophysics and Biochemistry, Yale University, New Haven, CT, <sup>2</sup>Pharmacology, Yale University, New Haven, CT*

Abl family kinases, which include the mammalian Abl and Arg, act downstream of integrin receptors to coordinate changes in cell shape and movement. Although integrin-mediated adhesion to the extracellular matrix stimulates Abl and Arg kinase activity, the mechanism by which integrins interface with and activate these kinases is unclear. Abl family kinases are held in an inactive auto-inhibited conformation, in which the SH3 and SH2 domains form an inhibitory lock on the kinase domain. It is believed that activators of these kinases disrupt this configuration, allowing the kinase to assemble into a kinase-active configuration. We provide evidence that integrin beta1 directly activates Arg via a multistep mechanism that includes: 1. An initial, direct binding event between the Arg kinase domain and a lysine-rich region of the beta1 cytoplasmic domain, 2. A subsequent phosphorylation event at the membrane proximal tyrosine residue of beta1 mediated by Arg, 3. A stabilizing interaction between the phosphorylated beta1 cytoplasmic domain and the Arg SH2 domain. Together, these interactions act to robustly activate Arg kinase activity.

658

**Phosphorylation of the actin bundling protein L-plastin by Mst1 regulates T cell polarization and migration.**

*X. Xu<sup>1</sup>, S. C. Morley<sup>2</sup>, Y. H. Huang<sup>1</sup>; <sup>1</sup>Pathology and Immunology, Washington University, Saint Louis, MO, <sup>2</sup>Pediatrics, Washington University, Saint Louis, MO*

A mouse forward genetics screen using ENU mutagenesis was performed to identify genes critical for T cell function. One mutant line was found to have T cell lymphopenia due to a recessive mutation in the sterile 20-like S/T kinase Mst1. In drosophila and non-immune cells, Mst (hippo) activity regulates organ size by promoting apoptosis and restricting proliferation. However, Mst1 deficiency in mice results in inefficient migration of mature T cells, attributed to defective integrin clustering and adhesion. Mst1 has been defined to be a downstream effector of the small GTPase Rap1. Through association with the adapter RapL, Mst1 is recruited to active Rap1 in proximity to integrins. The ability of Mst1 to activate and phosphorylate integrins or components of the inside-out signaling cascade remains an open and important question. We used phosphoproteomics of T cell receptor (TCR) and chemokine stimulated primary CD4 helper T cells to identify Mst1 substrates. Here, we report Mst1-mediated phosphorylation of the actin bundling protein L-plastin (L-fimbrin), a regulator of actin cytoskeletal rigidity. Using TIRF microscopy, we show that Mst1 phosphorylation directly alters F-actin bundling by L-plastin. Given that L-plastin deficiency in T cells resembles Mst1 deficiency, we propose that L-plastin is a major Mst1 effector in the establishment of T cell polarity and migration in response to TCR and chemokine stimulation, required for thymic egress. Future studies will evaluate the ability of L-plastin containing phospho-mimetic substitutions to rescue L-plastin or Mst1 deficiency in T cell function.

## Chemotaxis and Directed Migration I

### Priming of Natural Killer cells following Transendothelial Migration mediated by specific Cytokines and Chemokines.

*S. Mukherjee<sup>1</sup>, E. Brown<sup>1</sup>, B. W. Butler<sup>1</sup>; <sup>1</sup>Texas Tech University, Lubbock, TX*

Natural Killer (NK) cells must undergo transendothelial migration to locate and kill cancer or virally infected cells. This process is mediated in part by chemokines and cytokines that once secreted at the site of inflammation or tumorigenesis, activate the vascular endothelial cells, thus creating a homing signal for the NK cells. We have observed that when NK cells undergo transendothelial through vascular endothelial cells that have been activated with specific cytokines (TNF- $\alpha$  and TGF- $\beta$ ) and the chemokine (SDF-1 $\alpha$ ), the NK cells become primed. This priming results in a more rapid response with respect to signaling downstream of the NK activation receptor, NKG2D and the integrin LFA-1. This priming effect also promotes a more rapid response by the actin and microtubule cytoskeletons during NK-mediated cytolytic activity. Taken together, transendothelial migration that is mediated by specific cytokines and chemokines serves as a priming mechanism for Natural Killer cells and thus leads to enhanced and more rapid cytotoxicity.

660

### The diabetic environment induces stable intrinsic changes in inflammatory cells that alter migratory responses.

*P. Bannon<sup>1</sup>, K. A. Mace<sup>1</sup>; <sup>1</sup>Faculty of Life Sciences, University of Manchester, Manchester, United Kingdom*

Inflammatory cell migration is critical to efficient tissue repair and regeneration. Chronic inflammation is characterized by excessive numbers of inflammatory cells present in the injured tissue and is a common characteristic of diabetes-induced non-healing wounds. Although inflammatory cells are present in wound tissue of diabetic patients and mouse models in excessive numbers, it is not clear whether this is due to altered chemotaxis-induced recruitment or aberrant retention of these cells. In order to model wound-induced recruitment and migration, we performed in vitro assays to analyse these behaviors in diabetic-derived versus non-diabetic derived primary monocyte/macrophages and granulocytes. Here we show that CCR2 and CxCR2 chemokine receptors are dysfunctional in diabetic-derived inflammatory cells. Interestingly, although diabetic-derived inflammatory cells express similar levels of these receptors, they display attenuated chemotactic responses. Moreover, diabetic-derived cells show abnormal cell polarization. To determine whether this may reflect a more general migratory defect, we performed scratch wound assays and analysed migration into the 'wound' zone using live imaging. Although diabetic-derived macrophages migrated randomly, they failed to close the 'wound' due to a lack of persistent directionality. In addition, several lines of evidence demonstrate that these defects persist outside of the diabetic environment, indicating the induction of stable cell-intrinsic changes.

661

**Role of iPLA2 in the regulation of the endosomal recycling of integrin and chemotactic motility of microglia.**S-H. Lee<sup>1</sup>, N. Sud<sup>1</sup>, N. Lee<sup>1</sup>, C. Y. Chung<sup>1</sup>; <sup>1</sup>Pharmacology, Vanderbilt University Medical Center, Nashville, TN

Microglia are the immune effector cells that are rapidly activated in response to even minor pathological changes in the central nervous system. It has been reported that microglial activation is accompanied by the alteration of integrin expression. Inflammatory cytokines increased expression of  $\alpha 4\beta 1$ ,  $\alpha 5\beta 1$ , and Mac-1 integrins on microglia but changes of integrin expression upon ADP (a chemoattractant for microglia) stimulation remain unknown. We, in this study, investigated if ADP can induce the alteration of integrin species on cell surface, leading to changes in chemotactic ability on different ECM. FACS scans and surface biotinylation assays showed that ADP stimulation induced a significant increase in the expression of  $\alpha 6$  integrin, but not  $\alpha 5$  on the surface of microglia cells. Examination of microglia motility on different ECM revealed that cells have greater motility on laminin than fibronectin upon ADP stimulation, presumably due to the increased expression of  $\alpha 6$  integrin. Our recent study demonstrated that knock-down of Ca<sup>++</sup>-independent phospholipase A2 (iPLA2) specifically inhibits the trafficking of c-Src through recycling endosomes. Given that iPLA2 activity is required for the regulation of recycling endosome trafficking, we tested if there is any change of the expression level of integrin subunits in iPLA2 knock-down cells. Integrin endocytosis assay revealed that iPLA2 activity is required for the recycling of  $\alpha 6$  integrin back to the plasma membrane. Time-lapse microscopy also clearly revealed the essential role of iPLA2 activity for the recycling of  $\alpha 6$  integrin from the endosomal recycling complex to the plasma membrane via recycling endosomes. The alteration of integrin-mediated adhesion may regulate the extent of microglial infiltration into the site of damage by controlling their chemotactic ability.

662

**Role of Cortactin Homolog HS1 During Transendothelial Migration of Natural Killer Cells.**S. Mukherjee<sup>1</sup>, O. Mooren<sup>1</sup>, J. A. Cooper<sup>1</sup>; <sup>1</sup>Cell Biology and Physiology, Washington University School of Medicine in St. Louis, St. Louis, MO

Natural killer (NK) cells provide immune protection by recognizing and killing target cells that lack MHC class I protein, often including cancer cells and virus infected cells. However, before NK cell can perform its functions, it has to traverse the barrier of endothelial cells lining the blood vessel wall. The process of transendothelial migration is complex and poorly understood in NK cells. NK cell motility is initiated by environmental signal, which promotes its attachment to the vascular endothelial layer and subsequent trans-cellular migration. Mechanism of transendothelial migration involves tight regulation of adhesion molecules, chemokines and cytoskeletal regulators. Thus, the molecules, which can integrate between signaling pathways and cytoskeletal regulation, may play essential function in this process.

We hypothesize that HS1 is a potential candidate in regulating NK cell transmigration as it is involved in signaling and actin assembly in NK cell and T cell activation. Our data indicate that depletion of endogenous HS1 protein by siRNA or shRNA technique in NK cells diminishes its ability to transmigrate across the endothelial cell monolayer during transendothelial migration assay and this transmigration event can be rescued by transfecting with shRNA insensitive HS1 construct. It has been established that, in NK cells, phosphorylation of HS1 Tyr residue at position 397 is required for adhesion to the integrin ligand ICAM-1, whereas phosphorylation of Tyr378 is important for chemotaxis. Moreover, a recent study has reported that phosphorylation of HS1 Tyr222, Tyr378 and Tyr397 is required for its interaction with Arp2/3 and efficient

chemotaxis in neutrophil. Currently we are investigating the role of phosphorylation on all of these Tyr residues in NK cell transendothelial migration.

663

**Loss of Arp2/3 complex does not inhibit fibroblast chemotaxis, but does trigger an NF- $\kappa$ B-dependent secretion of chemokines and growth factors with autonomous and non-autonomous effects on migration.**

C. Wu<sup>1</sup>, S. Asokan<sup>1</sup>, E. M. Haynes<sup>1</sup>, J. E. Bear<sup>1</sup>; <sup>1</sup>cell biology and physiology, UNC-chapel hill, chapel hill, NC

Chemotaxis is critical for numerous physiological processes such as wound healing, morphogenesis, and immune response, as well as being important for diseases such as metastatic cancer. While this process has been intensively studied in amoeboid cells, it is much less well understood in mesenchymal cells such as fibroblasts. Recently, our group showed that fibroblasts depleted of the Arp2/3 complex showed normal chemotactic responses, but were deficient in the ability to respond to gradients of extracellular matrix cues (haptotaxis). In these experiments, PDGF- a physiological chemoattractant for fibroblasts was used. Contrary to these results, another group recently showed that the Arp2/3 complex is required for EGF chemotaxis in fibroblasts. We repeated the chemotaxis assay with our depleted cells using EGF and observed that chemotaxis to this ligand was also intact. To address whether RNAi depletion was sufficient to completely abrogate Arp2/3 function, we tested the chemotaxis of fibroblasts derived from a conditional knockout mouse for the Arpc2 (p34) subunit of Arp2/3 and observed that these cells had intact chemotactic responses. One possible explanation for these differences is the design of the microfluidic chemotaxis chamber used by each group. Our chamber has continuous media exchange, while the Ibidi chamber used by the other group was sealed. Based on RNA-seq-based expression profiling of our Arp2/3-depleted cells, we discovered that loss of Arp2/3 leads to the up-regulation of many genes encoding secreted proteins such as chemokines, growth factors and proteases. Using immunofluorescent staining and ELISA, we have confirmed this up-regulation at protein level for a subset of these genes. Interestingly, most of the up-regulated secretory factors are regulated through the NF- $\kappa$ B pathway. Indeed, we have found that the NF- $\kappa$ B activity in Arp2/3-depleted cells was up-regulated and that inhibiting NF- $\kappa$ B reversed the increased expression of secreted factors. To test whether the secreted factors produced by the Arp2/3-depleted cells could affect chemotaxis through signaling crosstalk, we repeated these experiments using conditioned media in our continuous flow chambers. Conditioned media harvested from Arp2/3-depleted cells blocked EGF chemotaxis, but conditioned media from control cells did not. Thus, our findings indicate that Arp2/3 loss does affect chemotaxis, but in an indirect way involving altered NF- $\kappa$ B dependent gene expression. We have also identified the upstream signaling events leading from Arp2/3 loss or inhibition to NF- $\kappa$ B activation involving the canonical MEKK3-IKK pathway.

**Reconstitution of *in vivo* macrophage-tumor cell pairing and streaming motility on one-dimensional micro-patterned substrates.**

V. P. Sharma<sup>1,2</sup>, A. Patsialou<sup>1</sup>, B. T. Beaty<sup>1</sup>, H. Liu<sup>3</sup>, M. Clarke<sup>4</sup>, D. Cox<sup>1,2</sup>, J. Condeelis<sup>1,2</sup>, R. Eddy<sup>1</sup>; <sup>1</sup>Anatomy and Structural Biology, Albert Einstein College of Medicine, Bronx, NY, <sup>2</sup>Gruss Lipper Biophotonics Center, Albert Einstein College of Medicine, Bronx, NY, <sup>3</sup>Ben May Department for Cancer Research, University of Chicago, Chicago, IL, <sup>4</sup>Institute for Stem Cell Biology and Regenerative Medicine, Stanford School of Medicine, Stanford, CA

In mammary tumors, intravital imaging techniques have uncovered an essential role for macrophages during tumor cell invasion and metastasis mediated by an epidermal growth factor

(EGF) / colony stimulating factor-1 (CSF-1) paracrine loop. It was previously shown that tumor cells in mammary tumors in mice exhibit high velocity migration on extracellular matrix (ECM) fibers. These cells form paracrine loop-dependent linear assemblies of alternating host macrophages and tumor cells known as “streams”. Here, we confirm by intravital imaging that similar streams form in close association with ECM fibers in mammary tumors derived from a highly metastatic patient-derived primary tumor cell, TN1 and in mammary tumors derived from MDA-MB-231, a human breast cancer cell line. To understand the *in vivo* cell motility behaviors observed in streams, an *in vitro* model of fibrillar tumor ECM utilizing adhesive 1D micropatterned substrates was developed and imaged by time-lapsed wide field microscopy. MTLn3 breast carcinoma cells on 1D fibronectin or type I collagen substrates migrated with higher velocity than on 2D substrates and displayed enhanced lamellipodial protrusion, cell velocity and persistence upon local interaction and pairing with bone marrow-derived macrophages (BMMs). Inhibitors of EGF or CSF-1 signaling disrupted this interaction and reduced tumor cell velocity and protrusion, validating the requirement for an intact paracrine loop. Both MTLn3 and MDA-MB-231 cells were capable of co-assembling into linear arrays of alternating tumor cells and macrophages that resembled streams *in vivo*, suggesting the stream assembly is cell autonomous and can be reconstituted on 1D substrates. Our results validate the use of 1D linear micropatterned substrates as a simple and defined approach to study fibrillar ECM-dependent cell pairing, migration and relay chemotaxis with high spatial resolution as a complementary assay to imaging of tumors in the living animal by intravital microscopy. Potential future applications include high-throughput screening for novel motility-related anti-metastasis drugs.

**Dynamic myosin II organization regulates front-rear coupling, cell shape determination, and efficient chemotaxis in neutrophil-like HL60 cells.**

T. Y-C. Tsai<sup>1,2,3</sup>, S. Collins<sup>1</sup>, M. Davidson<sup>4</sup>, T. Meyer<sup>1</sup>, J. E. Ferrell Jr.<sup>1</sup>, J. A. Theriot<sup>2,3</sup>;

<sup>1</sup>Chemical and Systems Biology, Stanford University, Stanford, CA, <sup>2</sup>Biochemistry, Stanford University, Stanford, CA, <sup>3</sup>Howard Hughes Medical Institute, Stanford, CA, <sup>4</sup>Florida State University, Tallahassee, FL

Myosin contraction at the rear is known to be necessary for proper cell migration, though little is known about how myosin dynamics at the rear are coupled to protrusion at the leading edge. Here, we study migration of neutrophil-like HL60 cells expressing fluorescently labeled myosin II with high spatiotemporal resolution, both in uniform environments and in light-induced gradients of chemoattractant.

We find that the degree of rearward polarization of myosin II is determined by cell speed and myosin diffusivity. As the cell accelerates, myosin molecules are swept backward to concentrate at the rear in the cell frame of reference. Hyperphosphorylation of myosin II light chain decreases the average myosin mobility and leads to enhanced rearward polarization. Cells with rearward-polarized myosin II have a more convex shape of the rear and switch polarity less frequently than cells where myosin II is evenly distributed. The shape determination of the rear can be explained by a “Graded Radial Retraction” model.

In addition, myosin II localization is highly dynamic and correlates with changes in whole-cell movement. In a persistently moving cell, cycles of protrusion at the front are tightly coupled to simultaneous contraction at the rear, followed 10 seconds later by transient local increases in myosin II and F-actin concentration. In a turning cell, these myosin II “flashes” localize at the outside of the cell and correlate with left-right shape asymmetry and with periods of increased

angular velocity. The dynamics we observe are consistent with a model of self-reinforcing recruitment of contracting myosin II followed by myosin-triggered F-actin disassembly.

Finally, we demonstrate that proper phosphoregulation of myosin light chain is important for efficient chemotaxis in HL-60 cells. Using both siRNA and pharmacological perturbations, we find that hypophosphorylation of myosin II leads to front-rear decoupling, a long tail phenotype, reduced speed and frequent switching of polarity. Conversely, hyperphosphorylated myosin II becomes less dynamic and less efficient to reorient the cells in a light-controlled switching gradient of chemoattractant.

666

#### **Cooperative dynamics of actin nucleators in epithelial cell protrusion.**

*K. Lee<sup>1</sup>, H. Elliott<sup>1</sup>, A. Besser<sup>1</sup>, E. Gutierrez<sup>2</sup>, A. Groisman<sup>2</sup>, G. Danuser<sup>1</sup>; <sup>1</sup>Cell Biology, Harvard Medical School, Boston, MA, <sup>2</sup>Physics, University of California San Diego, La Jolla, CA*

Arp2/3 and several members of the formin family of actin nucleators have been shown to coexist at the leading edge of migrating cells where they drive cell protrusion by promoting actin filament assembly. Although their individual biochemical functions are well studied, the functional interactions between these various types of nucleators are poorly understood because of the spatiotemporal heterogeneity and transience of actin dynamics during cell migration events like protrusion. Here, in order to characterize the coordination of several actin nucleators *in situ*, we develop a novel local image sampling and 'event-averaging' approach. We measure the local fluorescence of HaloTag fusions to actin nucleators in small sampling windows moving with the leading edge. These local fluorescence time series data are then aligned using protrusion events such as protrusion onset or maximal protrusion velocity as common timing references. This allowed us to average the fluorescence over many sampling windows and extract from highly heterogeneous and noisy signals systematic trends in the kinetics of protein recruitment and further molecular variables. Our analysis shows that the formin mDia1 is recruited to the leading edge before protrusion onset along with components of nascent adhesions whereas Arp2/3, the formin mDia2, and VASP, and cofilin increase the rate of actin assembly after protrusions. Concurrently, we observe a steady increase in local traction forces, which are initiated at the cell edge with the formation of nascent adhesions and translocate backwards with adhesion maturation. Formin inhibition leads to significant reduction of lamellipodial Arp2/3. Our data is consistent with a model where mDia1-activation leads the way into a new protrusion, while Arp2/3 binds to mDia1-mediated actin filaments and nucleates actin filament growth in branched networks. Further analysis of the system dynamics using Arp2/3 inhibitor suggest that the reinforced actin polymerization by Arp2/3 and other actin regulators after protrusion onset supports edge advancement against increasing tension from the cell boundary.

#### **Directional persistence of migrating cells requires Kif1C-mediated stabilisation of trailing adhesions.**

*U. Theisen<sup>1</sup>, A. Straube<sup>1</sup>; <sup>1</sup>Centre for Mechanochemical Cell Biology, University of Warwick, Coventry, United Kingdom*

Directional cell migration requires the establishment and maintenance of long-term differences in structure and function between the front and rear of a cell. Many cell types require the microtubule cytoskeleton to support cell polarity and guide directional migration. To do this, microtubules themselves are arranged asymmetrically in migrating cells with the majority

growing towards the front of the cell, thereby supporting front-biased processes. Cell migration is viewed as a cyclic process of protrusion at the cell front and retraction of the cell rear, with protrusion towards an attractant determining migration direction of the cell. In the absence of external guidance cues, however, symmetry breaking occurs at the rear.

Here we show that the cell rear is also important for directional stability of cell migration. We find that the microtubule motor Kif1C contributes to directionally persistent cell migration primarily through stabilization of an extended cell rear. Kif1C accumulates at the tip of cell tails shortly after tail formation and dispersal of Kif1C correlates to tail retraction. We find that Kif1C-mediated transport of  $\alpha 5\beta 1$ -integrins is required for the proper maturation of trailing focal adhesions and resistance to tail retraction. Tail retraction correlates to and precedes changes in migration direction. Furthermore, stabilisation of cells tails through inhibition of myosin II activity suppresses the Kif1C depletion phenotype and results in longer-lived tails and higher directional stability of migrating cells. Taken together these findings indicate that the maintenance of an extended, tense cell tail facilitates directional persistent cell migration. We propose a rear-steering mechanism whereby the counterforce originating from a well-anchored tail serves to maintain directionality of the force-generating leading edge of the cell.

668

### **Chemotaxing amoeboid cells migrate by switching between modes with distinct adhesion and contractility dynamics.**

*E. E. Bastounis<sup>1</sup>, R. Meill<sup>2</sup>, B. Álvarez-González<sup>3</sup>, J. C. del Álamo<sup>3</sup>, J. C. Lasheras<sup>3</sup>, R. Firtel<sup>2</sup>;*  
<sup>1</sup>Bioengineering, UCSD, San Diego, CA, <sup>2</sup>Section of Cell and Developmental Biology, UCSD, San Diego, CA, <sup>3</sup>Mechanical and Aerospace Engineering, UCSD, San Diego, CA

Chemotaxis, or directed cell migration, is involved in a broad range of biological phenomena, ranging from the metastatic spreading of cancer to the active migration of neutrophils during wound healing or in response to bacterial infection. Chemotaxing Dictyostelium cells adapt their morphology and speed to external conditions such as the stiffness and adhesive properties of their substrate. The mechanism, by which they control both their shape and speed, still remains largely unknown. Using Fourier Traction Force Microscopy (FTFM) to measure the spatiotemporal evolution of shape and traction stress dynamics during migration, we construct traction tension kymographs. The kymographic representation of the traction stresses allows us to determine, for the first time, how the formation and disassembly of adhesions are coupled with the generation of axial and lateral traction stresses. We show that wild-type cells control their motility by switching between two motility modes with distinct adhesion and contractility dynamics. In the “Stepping-Stepping” mode, the adhesion sites remain stationary while the body moves forward by periodic axial contractions. The back adhesions break after new frontal adhesions are formed. In the “Stepping-Gliding” mode, the cell reduces the magnitude of the traction stresses, increases the frequency of axial contractions and its migration speed, and keeps the frontal adhesion stationary while sliding the back adhesion forward. These two modes are not conserved when cells move on highly adhesive poly-L-lysine coated substrates, where cells alternate between a “Nearly Stationary” mode, characterized by strong lateral contractions and extremely low migration speed and a “Gliding-Gliding” mode where multiple weak and transient adhesions are formed, which are gliding forward as the cell moves by barely adhering at the substrate. Finally, we found that cells with cytoskeletal crosslinking defects (*mhcA* and *abp120* cells), move by developing increased lateral contractility implementing distinct motility modes, which slightly differ from those observed in wild-type cells.

669

### ForC lacks formin activity but is required for chemotaxis and multicellular development of *Dictyostelium* cells.

A. Junemann<sup>1</sup>, B. Nordholz<sup>1</sup>, L. Eichinger<sup>2</sup>, R. Gräß<sup>3</sup>, J. Faix<sup>1</sup>; <sup>1</sup>Institute for Biophysical Chemistry, Medical School Hannover, Hannover, Germany, <sup>2</sup>Center for Biochemistry, University of Cologne, Cologne, Germany, <sup>3</sup>Institute für Biochemie und Biologie, University of Potsdam, Hannover, Germany

Diaphanous-related formins (DRFs) are known to drive nucleation and elongation of unbranched actin filaments downstream of Rho GTPase signaling pathways. They are characterized by the Diaphanous inhibitory domain (DID) in their N-terminal region and its counterpart – the Diaphanous auto regulatory domain (DAD) at the C-terminus. *Dictyostelium discoideum* ForC qualifies for this class of formins, but in spite of the presence of DID and DAD homology domains, it lacks the canonical proline-rich formin homology domain 1 (FH1) that recruits profilin-actin complex for subsequent filament assembly by the FH2 domain. Of note, ForC is not a pseudo gene since the genetic knockout of ForC strongly impairs late development. The phenotype of the mutant is characterized by the presence of aberrant fruiting bodies, as opposed to control, which forms single-stalked structures. Immunoblotting with specific antibodies revealed that ForC is absent in vegetative cells, becomes detectable after 4-5 h of starvation, which is defined as the onset of early aggregation, and peaks around 9-12 h. Fluorescence microscopy of cells expressing a GFP-tagged N-terminal ForC fragment showed that ForC transiently accumulates in the leading edge, suggesting that ForC may play a role in cell migration. Consistent with the expression profile, we observed no defects in random migration of vegetative mutant cells. Strikingly, however, chemotaxis towards a source of cAMP after 6 h of starvation was entirely abolished. Time-lapse phase contrast microscopy revealed though, that ForC-null cells can still aggregate albeit strongly delayed. Moreover, we observed an entire failure of phototaxis. Together, this suggests ForC to be critically involved in migration at the single cell level as well as multicellular aggregates during *Dictyostelium* development. Since ForC cannot be expressed in *E. coli* for biochemical analyses, we purified a C-terminal half of ForC containing the putative FH2 domain from *Dictyostelium* cells. Of note, ForC-FH2-C did neither inhibit nor stimulate actin polymerization as assessed by actin pyrene assays, suggesting that ForC lacks formin activity. Thus, ForC may have evolved from a genuine formin to become a developmentally expressed modulator of the actin cytoskeleton regulating cell migration.

### Model of Capping Protein and Arp2/3 Complex Turnover in the Lamellipodium Based on Single Molecule Statistics.

L. M. McMillen<sup>1</sup>, M. B. Smith<sup>1</sup>, D. Vavylonis<sup>1</sup>; <sup>1</sup>Physics, Lehigh University, Bethlehem, PA

Capping protein (CP) and Arp2/3 protein complex regulate actin polymerization near the leading edge of motile cells. They assemble near the edge of the lamellipodium, undergo retrograde flow, and dissociate into the cytoplasm as single subunits or as part of actin oligomers. To better understand this cycle, we modeled the kinetics of CP and Arp2/3 complex in the lamellipodium using data from prior single molecule microscopy experiments [Miyoshi et al. JCB, 2006, 175:948]. In these experiments speckle appearance and disappearance events corresponded to assembly and dissociation from the F-actin network. We used the measured dissociation rates of Arp2/3 complex and CP (0.048/s and 0.58/s, respectively) in a Monte Carlo simulation that includes particles in association with F-actin and diffuse in the cytoplasm. We explored the effect of slowly diffusing cytoplasmic pool to account for a big fraction of CP with diffusion coefficients as slow as 0.5  $\mu\text{m}^2/\text{s}$  measured by single molecule tracking [Smith et al. Biophys. J.,

2011,101:1799]. These slowly diffusing species could represent severed actin filament fragments. We show that such slow diffusion coefficients are consistent with prior FRAP experiments by Kapustina et al. [Cytoskeleton, 2010, 67:525] who fitted their data using larger diffusion coefficients. We also show that the single molecule data are consistent with FRAP experiments by Lai et al. [EMBO J., 2008, 28:986] who found that the Arp2/3 complex recovers more quickly at the front of the lamellipodium as compared to the back. We discuss the implication of disassembly with actin oligomers and suggest experiments to distinguish among mechanisms that influence long range transport.

**Mathematical modelling of protrusion generation and dynamics.**

*J. Zimmermann<sup>1</sup>, M. Falcke<sup>1</sup>; <sup>1</sup>Max Delbrück Center for Molecular Medicine, Berlin, Germany*

Many cells generate protrusions repeatedly or even in an oscillatory manner. At the same time, existing lamellipodia may exhibit shape oscillations with an amplitude comprising almost the whole protrusion depth. We investigate the mechanism of this type of dynamics by mathematical modelling. We use a model which has been verified by explaining the force velocity relation of fish keratocytes. We find an oscillation mechanism agreeing with recent experimental observations. With that mechanism, oscillations of the signaling pathways upstream of nucleation promoting factors or other actin binding molecules are not required to obtain oscillatory protrusions.

672

**Actin filament elasticity and retrograde flow shape the force-velocity relation of motile cells.**

*J. Zimmermann<sup>1</sup>, C. Brunner<sup>2</sup>, M. Enculescu<sup>1</sup>, A. Ehrlicher<sup>2</sup>, M. Goegler<sup>2</sup>, J. Käs<sup>2</sup>, M. Falcke<sup>1</sup>; <sup>1</sup>Max Delbrück Center for Molecular Medicine, Berlin, Germany, <sup>2</sup>Division of Soft Matter Physics, University of Leipzig, Dept. of Physics, Leipzig, Germany*

Cells migrate through a crowded environment during processes such as metastasis or wound healing, and must generate and withstand substantial forces. The cellular motility responses to environmental forces are represented by their force-velocity relation, which has been measured for fish keratocytes but remains unexplained. We present a mechanism quantitatively explaining the cell's force-velocity relation; and its changes upon application of drugs that hinder actin polymerization or actomyosin based contractility. Even pN opposing forces slow down lamellipodium motion by three orders of magnitude. At larger opposing forces, the retrograde flow of actin accelerates until it compensates for polymerization, and cell motion stalls. Subsequently, the lamellipodium adapts to the stalled state. Elastic properties of filaments close to the lamellipodium leading edge and retrograde flow shape the force-velocity relation. Our results shed new light on how these migratory responses are regulated, the relation of polymerization forces to elastic and viscous forces in the lamellipodium, and on its mechanics and structure.

## Signaling Scaffolds and Microdomains

673

### Signal molecules anchoring of proliferation and differentiation genes by A-Kinase Anchoring Protein (AKAP) 95.

*T. Kuntziger<sup>1</sup>, P. Collas<sup>1</sup>; <sup>1</sup>Stem Cell Epigenetics Laboratory, Institute of Basic Medical Sciences, Oslo, Norway*

A-kinase anchoring protein 95 (AKAP95) is a DNA-binding zinc finger protein that in addition to binding cAMP-dependent protein kinase, binds other signaling molecules such as protein phosphatase 1. AKAP95 is a nuclear matrix protein and also interacts with chromatin modifiers such as histone deacetylase (HDAC) 3, suggesting it may contribute to functionally compartmentalize chromatin and orchestrate fundamental nuclear processes such as replication or transcription. We are testing the hypothesis that AKAP95 constitutes an anchoring platform integrating information from signaling pathways involved in proliferation and differentiation with regulators of gene expression such as transcription factors and chromatin remodeling factors. To this end, we characterize by genome-wide approaches genomic sites occupied by AKAP95 in human mesenchymal stem cells (MSCs) and their transformed counterparts, using for this mesoderm-derived osteosarcoma U2OS cells. We focus our attention on proximal and distal regulatory sequences for cell cycle control and differentiation genes. We intend to identify co-occupying gene regulatory factors and address the role of AKAP95 in recruiting and maintaining these factors at the AKAP95 occupancy sites. We expect to characterize chromatin regulating complexes anchored by AKAP95 at genomic loci involved in oncogenic transformation and establish a new role for the major nuclear AKAP, AKAP95, in the regulation of proliferation-associated chromatin processes.

674

### P2Y receptors trigger loss of cortical gravin/PKA localization through calcium and PKC mediated signaling.

*M. Schott<sup>1</sup>, B. Maliske<sup>2</sup>, B. Grove<sup>1</sup>; <sup>1</sup>Anatomy and Cell Biology, Univ. of North Dakota, Grand Forks, ND, <sup>2</sup>Univ. of North Dakota, Grand Forks, ND*

Gravin (AKAP12), a multivalent A-kinase anchoring protein, anchors PKA and likely other signaling proteins to the plasma membrane through a subcellular targeting domain which includes N-myristoylation and three downstream polybasic regions rich in positively charged amino acids. Although gravin is postulated serve as a scaffold for diverse signaling complex at the plasma membrane, reports demonstrate that pharmacological activation of PKC or  $[Ca^{2+}]_i$  increase causes the loss of cortical gravin through its translocation into the cytosol. However, the signaling effects exerted by gravin redistribution are not understood, nor has this response been demonstrated to occur through receptor mediated signaling. We postulate that receptor mediated signaling events which trigger PKC and/or  $[Ca^{2+}]_i$  consequently alter subcellular PKA activity through the translocation of gravin. To assess this, we examined the effect of  $Ca^{2+}$ -elevating agents on gravin and gravin-dependent PKA distribution in cells expressing EGFP- or EYFP-tagged gravin constructs. Ionomycin and thapsigargin each initiated rapid gravin redistribution into the cytosol, an event which was inhibited by  $Ca^{2+}$  chelation using BAPTA-AM. Treatment of cells coexpressing gravin-EYFP and PKA RII-ECFP with  $Ca^{2+}$ -elevating agents also resulted in PKA redistribution, but only when gravin was present. Consistent with this, treatment with ATP in a  $Ca^{2+}$  free medium also resulted in rapid gravin redistribution in concert with a rise in  $[Ca^{2+}]_i$ , suggesting that this change is mediated by purinergic P2Y receptors. ATP also caused PKA redistribution in cells coexpressing gravin and PKA constructs. However,

inhibition studies using BAPTA-AM and bisindolylmaleimide indicated that PKC activation also contributed to ATP mediated changes in gravin distribution. Our studies confirm that receptor mediated signaling events involving activation of PKC and  $[Ca^{2+}]_i$  increase causes gravin redistribution and support the hypothesis that these changes alter subcellular PKA activity. For future studies, we have developed an assay for measuring real-time changes in PKA activity with a FRET biosensor known as A-Kinase Activity Reporter 3 (AKAR3). Both membrane-localized and cytosolic AKAR3 are now being used to understand the role of AKAP12 translocation in compartmentalized PKA signaling.

675

**14-3-3 $\zeta$  is required for glucose homeostasis, lipid metabolism, and adipogenesis.**

G. E. Lim<sup>1</sup>, M. Piske<sup>1</sup>, H. S. Ramshaw<sup>2</sup>, M. A. Guthridge<sup>3</sup>, A. F. Lopez<sup>2</sup>, J. D. Johnson<sup>1</sup>;

<sup>1</sup>University of British Columbia, Vancouver, BC, Canada, <sup>2</sup>Centre for Cancer Biology, Adelaide, Australia, <sup>3</sup>Monash University, Melbourne, Australia

Insulin is a critical hormone that regulates metabolism through multiple signaling pathways. It has been proposed that molecular adaptors, such as members of the 14-3-3 family, coordinate and integrate signaling cues to facilitate insulin's effects on cell survival, adipogenesis, lipid metabolism, and glucose uptake. However, this hypothesis has not been tested in vivo. To examine the in vivo role of 14-3-3 proteins in metabolism, we utilized knockout (KO) mice lacking 14-3-3 $\zeta$ , an isoform, which we and others have implicated in insulin signaling in vitro. 14-3-3 $\zeta$  KO mice were significantly smaller than littermate controls at weaning, but were indistinguishable from wildtype mice by 12 weeks. 14-3-3 $\zeta$  KO mice showed a significant delay in their ability to clear a glucose load (2g/kg). This glucose intolerance was due to significant insulin resistance, as assessed by insulin tolerance tests (1.5U/kg). Insulin resistance in 14-3-3 $\zeta$  KO mice was associated with 2-fold increases ( $p < 0.05$ ) in fasting and random-fed insulin levels and 1.5-fold increased  $\beta$ -cell mass. Serum triglycerides were significantly higher in KO mice, and analysis of lipogenic genes in white adipose tissue showed significantly decreased transcript expression of hormone-sensitive lipase, fatty acid synthase, and acetyl-CoA carboxylase. Together, these in vivo data indicate that 14-3-3 $\zeta$  KO mice have many of the hallmarks of early type 2 diabetes. To further investigate the molecular mechanisms by which 14-3-3 proteins regulate insulin signaling, NIH3T3 fibroblasts were first transfected with a plasmid containing difopein, a pan 14-3-3 inhibitor. Loss of 14-3-3 function did not affect insulin-stimulated Akt phosphorylation, but attenuated activation of the MAPK signaling pathway. siRNA-mediated knockdown of 14-3-3 $\zeta$  recapitulated the effect of difopein on insulin signaling. As loss of 14-3-3 $\zeta$  was associated with altered lipid homeostasis, we next examined if the  $\zeta$  isoform was involved in adipogenesis. siRNA-mediated knockdown of 14-3-3 $\zeta$  in 3T3-L1 pre-adipocytes resulted in a dramatic block of differentiation, as measured by Oil Red-O staining. Quantitative PCR analysis demonstrated that 14-3-3 $\zeta$  was required for expression of mature adipocyte markers, such as Ap2, PPAR $\gamma$ , GLUT4, hormone-sensitive lipase, fatty acid synthase, AND SREBP-1c. Taken together, these findings demonstrate, for the first time that 14-3-3 $\zeta$  isoform is required for insulin signaling and glucose homeostasis in vivo. Furthermore, the  $\zeta$  isoform is required for adipogenesis and may explain the defects in lipid metabolism observed in the knockout mice. These data suggest the possibility of modulating insulin sensitivity and obesity by targeting 14-3-3 adapter proteins.

676

**Pseudopodial pyruvate kinase M2 regulates senescence via the RhoGEF Tiam1 in metastatic cancer cells.**

*J. Shankar<sup>1</sup>, N. Stoynov<sup>2</sup>, L. J. Foster<sup>2</sup>, I. R. Nabi<sup>1</sup>; <sup>1</sup>Cellular and Physiological Sciences, Life Sciences Institute, Vancouver, BC, Canada, <sup>2</sup>Department of Biochemistry and Molecular Biology, Centre for High-Throughput Biology, Vancouver, BC, Canada*

Epithelial mesenchymal transition (EMT) promotes cancer cell invasion and metastasis and also overrides cellular senescence, a failsafe mechanism that limits cellular transformation. How cellular transformation, an early event in cancer progression, is controlled by a late stage process such as EMT remains unclear.

Here we identify 13 pseudopod-enriched proteins, including the YWHAE 14-3-3 $\epsilon$  scaffolding protein and pyruvate kinase M2 (PKM2), a key regulator of cancer cell metabolism, and show that all are required for tumor cell migration and invasion. While knockdown of five pseudopod-enriched proteins in metastatic human cancer cells induce expression of epithelial markers (i.e. E-cadherin), knockdown of the eight other pseudopod proteins (including PKM2 and YWHAE) increase cell spreading and expression of senescence markers (p53, p16, SA- $\beta$ -Gal). Pseudopod protein reversal of EMT is associated with reduced RhoA activity, increased Rac1 activity and increased expression of the RhoGEF, Tiam1, while induction of senescence is associated with reduced Rac1 activation and loss of Tiam1 expression. The EMT- and senescence-associated pseudopod proteins form distinct complexes and senescence-associated YWHAE interacts directly with both PKM2 and TIAM1. Peroxide-induced senescence induces selective loss of senescence-associated pseudopod proteins and Tiam1, but not EMT-associated pseudopod proteins. Furthermore, expression of a constitutively active form of Tiam1 prevents senescence induced by either peroxide treatment or knockdown of senescence-associated pseudopod proteins. This suggests that pseudopod protein control of Tiam1 maintains the balanced RhoA and Rac1 activity that limits senescence and promotes EMT.

PKM2 regulation of senescence via Tiam1 control of Rho GTPase activity defines a novel role for this cancer-associated metabolic enzyme in cancer progression. Based on the critical role described for pseudopod proteins, acquisition of motile and migratory ability therefore represents a common mechanism linking senescence override and EMT in cancer progression.

Supported by the Cancer Research Society Inc. JS is the recipient of a Strategic Fellowship under the Mitacs Elevate program (MITACS Inc.).

**Proteins of the Ubiquitin Proteasomal System regulate the function of the MAPK1/2 pathway scaffold - Shoc2.**

*P. Shi<sup>1</sup>, M. Jeoung<sup>1</sup>, E. Galperin<sup>1</sup>; <sup>1</sup>University of Kentucky, Lexington, KY*

The mitogen-activated protein kinases (MAPK1/2) signaling pathway is critical in normal human development as it controls cell proliferation, differentiation, migration and apoptosis. When these processes are perturbed, malignant transformations, cardiovascular pathologies and RASopathies (genetic syndromes) can develop. The MAPK1/2 pathway is a complex signaling interconnected network with large numbers of dynamic protein interactions and diverse biological outcomes. A significant part of how biological specificity is generated depends on scaffold proteins. Scaffold proteins are key players that control protein-protein interactions, compartmentalize incoming MAPK1/2 signals at particular cellular locations, and regulate accessibility to substrate, thereby delivering signaling specificity. Hence, scaffold proteins not

only have a huge impact on the biological behavior of the MAPK1/2 pathway, but they essentially determine the functional outcome of the signaling.

While studying the mechanisms of MAPK1/2 signal propagation, we discovered that the Ras-RAF binding scaffold protein Shoc2 is recruited to the surface of late endosomes. Shoc2 is a critical MAPK1/2 pathway regulator that accelerates MAPK1/2 signaling. Moreover, germline deletion of Shoc2 in mice results in early embryonic lethality due to severe defects in heart development. We showed that Shoc2 interacts with several proteins of the Ubiquitin Proteasomal System (UPS), and PSMC5 is among them. PSMC5 is an AAA (ATPase Associated with various cellular Activities) ATPase and a part of the 19S proteasomal subunit. In this study, we identified the functional properties of PSMC5 and the key structural elements mediating the interaction between Shoc2 and PSMC5. RNAi depletion of PSMC5 resulted in increased levels of Shoc2 protein and subsequent increase in MAPK1/2 activity upon EGFR activation. This suggests that interaction of Shoc2 with PSMC5 plays an important role in Shoc2 function as a positive regulator of MAPK1/2 signaling. We also demonstrated that fluorescent protein-tagged Shoc2 and PSMC5 expressed in cells are recruited to a subset of multi-vesicular bodies (MVB)/late endosomes containing Rab7. Moreover, increased translocation of Shoc2 to MVB affected Shoc2 protein levels and its function as a MAPK1/2 signal modulator.

In this study, we identified a novel non-proteolytic function of PSMC5 in regulating MAPK1/2 signaling. We determined that PSMC5 interaction with Shoc2 is part of the cellular machinery by which Shoc2 is targeted to the endocytic compartment. Our results suggest that spatio-temporal mechanisms regulating the MAPK1/2 pathway involve recruitment of Shoc2 to the MVB/LE compartment.

#### **Identification of a Novel Function of the Clathrin-Coated Structure at the Plasma Membrane in Facilitating GM-CSF Receptor-Mediated Activation of JAK2.**

*P-H. Chen<sup>1</sup>, F-C. Chien<sup>2</sup>, S-P. Lee<sup>3</sup>, W-E. Chan<sup>4</sup>, I-H. Lin<sup>1</sup>, C-S. Liu<sup>1</sup>, F-J. Lee<sup>5</sup>, J-S. Lai<sup>4</sup>, P. Chen<sup>2</sup>, H-F. Yang-Yen<sup>3</sup>, J. J. Yen<sup>1</sup>; <sup>1</sup>IBMS, Academia Sinica, Taipei, Taiwan, <sup>2</sup>Research Center for Applied Sciences, Academia Sinica, Taipei, Taiwan, <sup>3</sup>IMB, Academia Sinica, Taipei, Taiwan, <sup>4</sup>Department of Biologic Drugs, Development Center for Biotechnology, Taipei, Taiwan, <sup>5</sup>Institute of Molecular Medicine, College of Medicine, National Taiwan University, Taipei, Taiwan*

It is well known that ligand-binding to the high-affinity GM-CSF receptor (GMR) activates JAK2. However, how and where this event occurs in a cellular environment remains unclear. Here, we demonstrate that clathrin-, but not lipid raft-mediated endocytosis is crucial for GMR signaling. Knockdown expression of clathrin heavy chain or intersectin 2 (ITSN2) attenuated GMR-mediated activation of JAK2, whereas inhibiting clathrin-coated pits or plaques to bud off the membrane by the dominant negative mutant of dynamin enhanced such event. Moreover, unlike the wild-type receptor, an ITSN2-non-binding mutant of GMR defective in targeting to clathrin-coated pits or plaques (collectively referred to as clathrin-coated structures [CCSs] here) failed to activate JAK2 at such locations. Additional experiments demonstrate that ligand treatment not only enhanced JAK2/GMR association at CCSs, but also induced a conformational change of JAK2 which is required for JAK2 to be activated by CCS-localized CK2. Interestingly, ligand-independent activation of the oncogenic mutant of JAK2 (JAK2V617F) also requires the targeting of this mutant to CCSs. But JAK2V617F seems to be constitutively in an open conformation for CK2 activation. Together, this study reveals a novel functional role of CCSs in GMR signaling and the oncogenesis of JAK2V617F.

**Caveolin-1 expression attenuates PKC activation in human melanoma cells.**A. V. Phan<sup>1</sup>, R. W. Baer<sup>1</sup>; <sup>1</sup>Physiology, A. T. Still University, Kirksville, MO

Caveolin-1 (cav-1) is a membrane protein that is involved in structural integrity, vesicle transportation, and signal transductions. Depending on the type of cancer, cav-1 may have either a pro- or anti-metastatic effect. In melanoma, cav-1 is believed to be anti-metastatic. Our goal was to characterize possible mechanisms by investigating the effects of increasing cav-1 expression on PKC-alpha (PKC) activation and activation of putative pro-metastatic, downstream, proteins (ERK, JNK and AKT). Wild-type BLM and 1205Lu melanoma cells were each transfected to create corresponding stable, cav-1 expressing lines. BLM and 1205Lu wild-type and BLM and 1205Lu cav-1 expressers were treated with 10 ng/ml PMA to stimulate PKC. After 0, 1, 5, 15, 30, 60, and 120 min of treatment, 50 µg of each whole cell extract was run on SDS page gels and subjected to immunoblotting for analysis of total and phosphorylated proteins using IR detection (Licor Odessey). Time courses for each cell line were repeated at least in triplicate. In the BLM cell line, PMA stimulation caused an increase in PKC phosphorylation that peaked at 5 min. Peak phosphorylation of ERK subsequently occurred at 30 min and JNK's at 120 min. In the BLM cav-1 expressers, PMA treatment caused little stimulation of PKC phosphorylation over the 2 hr period, and the overall PKC activity was 36% less than wild-type. ERK's peak activity did not occur until 120 min, and JNK activity or activation was no longer detectable. AKT activity did not change with PMA stimulation in either wild-type or cav-1 expressers, but basal activity was 172% more in cav-1 expressers than wild-type. In the 1205Lu cell line, PMA stimulation caused little additional PKC phosphorylation over 2 hr. Peak phosphorylation of ERK occurred at 5 min, and peak phosphorylation of JNK occurred at 30 min. In the 1205Lu cav-1 expressers, PKC activity remained constant; but overall PKC activity was 42% less than wild-type. Peak phosphorylation of ERK occurred at 60 min and JNK activity or activation was also no longer detectable. AKT activity did not exhibit an activation curve in either wild-type or cav-1 expressers, but basal activity was 167% more in cav-1 expressers than wild-type. The decreased PKC activity with cav-1 expression is consistent with cav-1 being an anti-metastatic protein. Peak phosphorylation of ERK and JNK follows peak phosphorylation of PKC-alpha suggesting that their increased activation is in part related to PKC activation. We conclude that cav-1 expression decreases PKC protein activity, and the activation of putative pro-metastatic downstream proteins. PKC inhibition is one probable mechanism by which cav-1 expression induces anti-metastatic behavior in melanoma.

**Reconstitution of PSD-95 Scaffolding Activity Suggests Anomalous Diffusion at the Membrane.**U. B. Choi<sup>1</sup>, M. E. Bowen<sup>1</sup>; <sup>1</sup>Physiology & Biophysics, Stony Brook University, Stony Brook, NY

Scaffold proteins organize signal transduction by binding multiple partners within a signaling pathway. This shapes the output of signal responses as well as providing specificity and localization. The Membrane Associated Guanylate Kinases (MAGUKs) are scaffold proteins at intracellular junctions where they localize cell surface receptors and link them to downstream signaling enzymes. Much of what we know about MAGUK scaffold protein function has been inferred from the binding sites discernible in their primary sequence. Distinguishing physiological binding partners has proved challenging. Observational studies of the MAGUK PSD-95 have identified more than 50 different ligands for a protein that only contains five binding sites. Understanding scaffolding is complicated by the molecular diversity of different protein isoforms functioning together in vivo, which stymies knock out approaches. Reconstitution provides a

simplified system where inferred knowledge can be put to the test. We have achieved the first in vitro reconstitution of multi-protein scaffolding using purified components. We have recapitulated the native geometry of cellular junctions by using single molecule approaches to watch protein interactions at a membrane surface with video microscopy. As expected from theory, scaffolding activity is highly dependent on the scaffold concentration. We found that the scaffold becomes self-competitive at high concentration. Although pairwise interactions with the scaffold are weak and transient, a soluble scaffold is able to raise the effective concentration of other soluble proteins near the membrane surface. Our results suggest that scaffolds may not function by creating stable multi-protein complexes as expected. Instead, scaffolding may simply increase the probability of two proteins being in close proximity without them interacting directly. The scaffold presents a kinetic trap that hampers free diffusion away from the target receptor. This may be sufficient to achieve proper localization without locking any individual components in place.

**Reconstruction of MAPK signaling cascades using PDZ-based synthetic scaffold proteins.**

*J. Ryu<sup>1</sup>, S-H. Park<sup>1</sup>; <sup>1</sup>Seoul national university, Seoul, Korea*

Department of Biological Sciences and Research Center for Functional Cellulomics, Seoul National University, Seoul, Korea, 151-742

Scaffold proteins are thought to play a critical role in flux control of signaling pathways by tethering signaling proteins into active complexes. However, the mechanism by which scaffold proteins trigger designated signaling responses is still unclear. As a bottom-up approach, we designed synthetic scaffolds to replace Ste5 scaffold for rewiring of the mating MAPK pathway in the budding yeast, *Saccharomyces cerevisiae*. The synthetic scaffolds based on PDZ domains with binding affinities for Ste11 (MAPKKK), Ste7 (MAPKK), Fus3 (MAPK), and plasma membrane led to the assembly of kinase complexes at plasma membrane, which is sufficient to trigger the mating MAPK responses. We also found that signaling plasticity is still manifested at the upper tier of MAPK pathway and the signaling specificity is determined in part by scaffold assembly. Modular characteristics of Ste5 and the synthetic scaffold complexes, and the plasticity of mating signaling suggest that signaling pathways might have evolved via recombination of simple yet modular protein domains. Artificial rewiring of signaling pathways using synthetic scaffolds allows for engineering of cell signaling pathways with noble physiological properties.

**Fas-associated factor 1 activates c-Jun N-terminal kinase to promote oxidative stress-induced necrotic cell death.**

*C. Yu<sup>1,2</sup>, K. Seo<sup>1,2</sup>, T. Jang<sup>1,2</sup>, M-Y. Park<sup>1</sup>, E. Kim<sup>1,2,3</sup>; <sup>1</sup>College of Biological Sciences and Biotechnology, Chungnam National University, Daejeon, Korea, <sup>2</sup>BK21 Daedeok R&D Innopolis Bio Brain Center, Chungnam National University, Daejeon, Korea, <sup>3</sup>Graduate School of New Drug Discovery and Development, Chungnam National University, Daejeon, Korea*

Oxidative stress-induced necrotic cell death is implicated in the pathogenesis of various diseases. However, its signaling pathway is yet to be clearly defined. In this study, we investigated FAF1's role in the oxidative stress-induced necrotic cell death. FAF1-deficient mouse embryonic fibroblast (MEF) cells were resistant to necrotic cell death elicited by H<sub>2</sub>O<sub>2</sub>. Moreover, restoration of FAF1 in FAF1-deficient MEF cells recovered their sensitivity to H<sub>2</sub>O<sub>2</sub>.

These data indicate that FAF1 is essential for oxidative-stress induced necrotic cell death. FAF1 activated JNK, a key regulator of oxidative stress-induced necrosis, via physical interaction with upstream regulators of JNK signaling, RIP1 and TRAF2, upon oxidative stress. Furthermore, depletion of FAF1 markedly suppressed sustained PARP-1 activation, a downstream phenomenon of JNK activation. Finally, we examined severity of pancreatic tissue damage in the mouse acute pancreatitis model. Pancreatic tissue damage was significantly attenuated in FAF1-deficient mice when compared with that of the wild type mice. Taken together, our data implicate FAF1 as a key mediator of oxidative stress-induced necrosis. [This research was supported by the grant (KDDF-201202-10) from the Korea Drug Development Fund, and by the grant (2011-0031223) from the National Research Foundation at the Ministry of Education, Science and Technology in Korea.]

#### **Role of monocytic thrombomodulin in inflammation.**

*H-L. Wu<sup>1</sup>, C-Y. Ma<sup>1</sup>, G-Y. Shi<sup>1</sup>; <sup>1</sup>Department of Biochemistry and Molecular Biology, College of Medicine, National Cheng Kung University, Tainan, Taiwan*

**Objective:** This study aims at investigating whether monocytic thrombomodulin (TM) mediates lipopolysaccharide (LPS)-induced signaling pathways and inflammatory response.

**Methods:** Biotinylated LPS pull-down assay was used for investigating the binding of LPS and monocytic TM. LPS-induced inflammatory response was analyzed in TM-knockdown monocytic cells. Coimmunoprecipitation and immunofluorescence assays were used for evaluating the interaction between TM and CD14/Toll-like receptor 4 (TLR4)/myeloid differentiation factor-2 (MD-2) complex in primary macrophages. We also established the myeloid-specific TM-deficient mice for investigating the role of TM in experimental sepsis models.

**Results:** TM knockdown in human monocytic cells attenuated LPS-induced signaling pathways and cytokine production. Coimmunoprecipitation and immunofluorescence assays showed that monocytic TM interacted with the LPS receptors, CD14 and TLR4/MD-2 complex, indicating that it binds to LPS and triggers LPS-induced inflammatory response by interacting with the CD14/TLR4/MD-2 complex. The myeloid-specific TM-deficient mice displayed improved survival which resulted from the attenuation of septic syndrome, including reduced systemic inflammatory response and less bacterial dissemination after *Klebsiella pneumoniae* infection or cecal ligation and puncture surgery.

**Conclusion:** We conclude that monocytic TM is a novel component in the CD14/TLR4/MD-2 complex and participates in the LPS-induced signaling pathways and inflammatory response.

#### **Identification of IF4γ2 as a Novel Contributor to Anthrax Toxin Entry into Cells.**

*R. Jimenez<sup>1</sup>, J. Chaudry<sup>1</sup>; <sup>1</sup>University of Texas at San Antonio, San Antonio, TX*

Anthrax toxin endocytosis is mediated by two receptors, tumor endothelial marker 8 (ANTRX1/TEM8) and capillary morphogenesis gene 2 protein (ANTRX2/CMG2). The receptor-binding component of the toxin is protective antigen (PA), and the toxic components are edema factor (EF, an adenylyl cyclase) and lethal factor (LF, a metalloprotease). To harm cells, EF raises cAMP to abnormal levels, and LF cleaves certain mitogen-activated protein kinase kinases. PA has the central role of delivering EF and LF to cytosol, and is therefore pivotal in anthrax toxin intoxication. Here we report identification of initiation factor 4 gamma 2 (IF4γ2) as

an accessory player in anthrax toxin entry. We identified IF4 $\gamma$ 2 by the yeast two-hybrid system as a candidate protein that may interact with the cytoplasmic domain of CMG2. The relevance of IF4 $\gamma$ 2 to anthrax toxin entry was assessed by cytotoxicity assays following siRNA-mediated down-regulation of IF4 $\gamma$ 2. These studies revealed that reduced IF4 $\gamma$ 2 levels result in a degree of resistance to the toxin. Further, Western blotting with anti-PA antibody revealed that cells expressing less IF4 $\gamma$ 2 show reduced PA binding. Binding studies with fluorescently labeled PA gave similar results. These studies show that IF4 $\gamma$ 2 is a player in anthrax toxin entry into cells, and that it influences toxin endocytosis at the level of PA binding to receptors.

### Normal CFTR inhibits a pro-inflammatory IL-1R-TACE-EGFR pathway in airway epithelial cells.

S. Kim<sup>1</sup>, B. A. Beyer<sup>1</sup>, C. Lewis<sup>2</sup>, J. A. Nade<sup>2</sup>; <sup>1</sup>Portland VA Medical Center, Oregon Health and Science Univ., Portland, OR, <sup>2</sup>Univ. of California San Francisco, San Francisco, CA

Objective: Cystic fibrosis (CF) airway cells lack normal CF transmembrane conductance regulator (CFTR) protein and produce increased amounts of the potent neutrophil chemokine interleukin (IL)-8. Multiple stimuli have been shown to induce IL-8 production via metalloprotease TACE-dependent activation of an epidermal growth factor receptor (EGFR) signaling pathway. Here we propose the novel hypothesis that lack of normal CFTR increases constitutive IL-8 production via a TACE-EGFR pathway. Methods/Results: We examined this hypothesis in airway epithelial (NCI-H292, NHBE) cells containing normal CFTR treated with the CFTR-selective inhibitor CFTR-172, and in airway cells containing mutant CFTR (IB3 cells) versus matched cells containing wild-type CFTR (C38 cells). CFTR-172 induced IL-8 production markedly in the NCI-H292 and NHBE cells. Pretreatment with the EGFR inhibitor AG1478, an EGFR neutralizing antibody, or with the TACE inhibitor TAPI-1 suppressed CFTR-172-induced IL-8 production completely in both cell types. In the NCI-H292 cells, CFTR-172 induced two phases of EGFR phosphorylation (EGFR-P) that involved TACE: the first EGFR-P led to the production, release and subsequent binding of IL-1 $\alpha$  to IL-1R on the cell surface, stimulating the second EGFR-P and downstream IL-8 production. Ligand binding to IL-1R also contributed to CFTR-172-induced IL-8 production in the NHBE cells, indicating that IL-1R leads to CFTR-172-induced IL-8 production in multiple cell types. In CF (IB3) cells, IL-8 production and steady state EGFR-P levels were greater than in wild-type CFTR (C38) cells. Pretreatment with AG1478, an EGFR neutralizing antibody, or with TAPI-1 decreased IL-8 and EGFR-P levels in both the IB3 and C38 cells, but IL-1R blockade decreased these responses only in the IB3 cells, indicating that IL-1R activates TACE-dependent EGFR-P and IL-8 production in IB3 cells but not in C38 cells. Conclusions: The lack of normal CFTR increases constitutive IL-8 production in airway cells via IL-1R-dependent activation of a TACE-EGFR signaling pathway. These findings suggest novel targets for the treatment of airway neutrophilic inflammation in diseases characterized by decreased or abnormal CFTR expression.

### Conformational Coupling Across the Plasma Membrane in Activation of the EGF receptor.

N. F. Endres<sup>1,2</sup>, R. Das<sup>1,2</sup>, A. Smith<sup>3</sup>, A. Arkhipov<sup>4</sup>, E. Kovacs<sup>1,2</sup>, Y. Huang<sup>1,2</sup>, J. Pelton<sup>1</sup>, Y. Shan<sup>4</sup>, D. E. Shaw<sup>4,5</sup>, D. Wemmer<sup>1,3,6</sup>, J. Groves<sup>3,6,7</sup>, J. Kuriyan<sup>1,3,6,7</sup>; <sup>1</sup>QB3, UC Berkeley, Berkeley, CA, <sup>2</sup>Department of Molecular and Cell Biology, UC Berkeley, Berkeley, CA, <sup>3</sup>Chemistry, UC Berkeley, Berkeley, CA, <sup>4</sup>D.E. Shaw Research, New York, NY, <sup>5</sup>Center for

*Computational Biology and Bioinformatics, Columbia University, New York, NY, <sup>6</sup>Physical Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA, <sup>7</sup>Howard Hughes Medical Institute, Berkeley, CA*

How the epidermal growth factor receptor (EGFR) activates is incompletely understood. The intracellular portion of the receptor is intrinsically active in solution, and to study its regulation we measured autophosphorylation as a function of EGFR surface density in cells. EGFR escapes inhibition only at high surface densities, but deletion of the extracellular module shows that the transmembrane helix and the intracellular module suffice for constitutive activity at low densities. The intracellular module is inactivated when tethered on its own to the plasma membrane and fails to dimerize, as determined by fluorescence cross-correlation spectroscopy. NMR and functional data indicate that activation requires an N-terminal interaction between the transmembrane helices, which promotes an antiparallel interaction between juxtamembrane segments and release of inhibition by the membrane. We conclude that EGF binding removes steric constraints in the extracellular module, allowing activation through N-terminal association of the transmembrane helices.

**Intracellular sodium fine-tunes EGFR trafficking by a HDAC6 and tubulin acetylation-mediated feedback loop.**

*S. Lee<sup>1</sup>, S. A. Langhans<sup>1</sup>; <sup>1</sup>NCCCR, Al duPont Hospital for Children, Wilmington, DE*

Epidermal growth factor (EGF) regulates proliferation and/or migration in diverse cells by triggering molecular cascades including cytoskeletal reorganization, cell cycle progression and gene expression. It is well known that endocytosis of activated EGF receptor (EGFR) and its subsequent delivery to specific endocytic compartments through a microtubule-dependent process are required to terminate EGF signaling. Here we show that intracellular trafficking of EGFR vesicles is regulated by the acetylation status of microtubules and that EGF-induced sodium influx modulates this process. EGF treatment of DAOY cells induced tubulin acetylation which was significantly delayed under low-sodium conditions. Similarly, increased sodium influx induced by ionophores or by blocking the Na,K-ATPase activity resulted in increased tubulin acetylation. Blocking sodium influx by low-sodium conditions not only altered tubulin acetylation but also the EGF-induced turnover of EGFR and the trafficking of EGF-positive vesicles suggesting that intracellular sodium might be involved in modulating EGFR signaling. Moreover, increased intracellular sodium reduced the activity of HDAC6, the predominant HDAC family member that regulates tubulin acetylation. Knockdown of HDAC6 reversed the effects of sodium replacement in EGF-treated cells indicating that HDAC6 inactivation by sodium influx may be involved in modulating tubulin acetylation and EGFR trafficking. Together our data suggest a novel pathway by which EGF modulates EGFR trafficking through sodium influx/HDAC6 inactivation/tubulin acetylation.

### Cell shape can dynamically process information during signal flow in regulatory pathways.

*P. Rangamani<sup>1,2</sup>, A. Lipshtat<sup>3</sup>, E. Azeloglu<sup>2</sup>, R. C. Calizo<sup>4</sup>, S. Scarlata<sup>4</sup>, S. Neves<sup>2</sup>, R. Iyengar<sup>2</sup>;*  
<sup>1</sup>Molecular and Cell Biology, Univ of California Berkeley, Berkeley, CA, <sup>2</sup>Department of Pharmacology and Systems Therapeutics, Mount Sinai School of Medicine, New York, NY, <sup>3</sup>Gonda Brain Research Center, Ramat Gan, Israel, <sup>4</sup>Stony Brook University, Stony Brook, NY

Shape is often an indicator of cell health. The role of cell shape in signaling is not well understood. We determined if cell shape could process information during signal transduction at the plasma membrane. Using analytical approaches and numerical simulations we studied elliptical shapes since neoplastic transformation often results in cells that are spindle shaped. Mathematical analyses showed that with increasing eccentricity of the cell, receptors diffusing evenly in the plane of the membrane accumulate transiently at regions of high curvature upon binding ligand. This inhomogeneous distribution of activated receptors is periodic and follows the Mathieu function. This transient inhomogeneity arises from local balance between reaction and diffusion of the soluble ligand and membrane-bound diffusion of the receptor. Numerical simulations for the receptor pathways show that these transient microdomains of activated receptors in the membrane amplify signals to downstream protein kinases. For the growth factor receptor pathway, change in cell shape from circle to ellipse results in a nearly two-fold increase in activated MAP-kinase in the nucleus.

The model predictions were tested experimentally using patterned cells. Experimental measurements of receptor density and diffusivity show that the EGF receptor activation and diffusion is dependent on the local curvature. Additionally, elliptical cells show a transient spatial inhomogeneity in the activation of signaling components when compared to circular cells in vitro.

Thus, cell shape and growth factor signaling can form a multi-scale positive feedback loop that could contribute to the maintenance of the transformed state.

689

### Regulation of Na,K-ATPase $\beta$ -subunit in TGF- $\beta_2$ -mediated epithelial-to-mesenchymal transition in human retinal pigmented epithelial cells.

*S. Mony<sup>1</sup>, S. Lee<sup>1</sup>, J. F. Harper<sup>2</sup>, S. P. Barwe<sup>1</sup>, S. A. Langhans<sup>1</sup>;* <sup>1</sup>NCCCR, Al duPont Hospital for Children, Wilmington, DE, <sup>2</sup>Biochemistry and Molecular Biology, University of Nevada, Reno, Reno, NV

Proliferative vitreo retinopathy (PVR) is associated with extracellular matrix membrane (ECM) formation on the neural retina and disruption of the multilayered retinal architecture leading to distorted vision and blindness. During disease progression in PVR retinal pigmented epithelial cells (RPE) lose cell-cell adhesion, undergo epithelial-to-mesenchymal transition (EMT), and start to deposit ECM leading to tissue fibrosis. The EMT process is mediated via exposure to vitreous cytokines and growth factors such as TGF- $\beta_2$ . Previous studies have shown that Na,K-ATPase is required for maintaining a normal polarized epithelial phenotype and that decreased Na,K-ATPase function and subunit levels are associated with TGF- $\beta_1$ -mediated EMT in kidney cells. In contrast to the basolateral localization of Na,K-ATPase in most epithelia, including kidney, Na,K-ATPase is found on the apical membrane in RPE cells. We now show that in RPE cells EMT is as well associated with altered Na,K-ATPase expression. TGF- $\beta_2$  treatment of ARPE-19 cells resulted in a time-dependent decrease in Na,K-ATPase  $\beta_1$  levels while Na,K-ATPase  $\alpha_1$  levels, Na,K-ATPase activity, and intracellular sodium levels largely remained unchanged. Knockdown of Na,K-ATPase  $\beta_1$  was associated with a change in cell morphology

from epithelial to mesenchymal and induction of EMT markers such as  $\alpha$ -SMA and fibronectin, suggesting that Na,K-ATPase  $\beta_1$  may be a potential contributor to TGF- $\beta_2$  -mediated EMT in RPE cells. Na,K-ATPase  $\beta_1$  subunit was down regulated at the RNA level during TGF- $\beta_2$  signaling and this effect was independent of its known transcriptional regulator, Snail. Analysis of the 1141bp Na,K-ATPase  $\beta_1$  promoter revealed a putative hypoxia response element (HRE). HIF-1 $\alpha$  levels were upregulated by TGF- $\beta_2$  even under normoxic conditions. HIF-1 $\alpha$  bound to the Na,K-ATPase  $\beta_1$  promoter and blocking HIF-1 $\alpha$  binding to HRE blocked the TGF- $\beta_2$  mediated Na,K-ATPase  $\beta_1$  decrease suggesting that HIF-1 $\alpha$  may play a potential role in Na,K-ATPase  $\beta_1$  regulation during EMT in RPE cells.

**The physical basis behind achondroplasia, the most common form of human dwarfism.**

*K. Hristova<sup>1</sup>; <sup>1</sup>Johns Hopkins University, Baltimore, MD*

Fibroblast growth factor receptor 3 (FGFR3) is a receptor tyrosine kinase that plays an important role in long bone development. The G380R mutation in FGFR3 transmembrane domain is known as the genetic cause for achondroplasia (ACH), the most common form of human dwarfism. Despite many studies, there is no consensus about the exact mechanism underlying the pathology. To gain further understanding into the physical basis behind the disorder, we use quantitative imaging FRET to characterize the dimerization of wild-type FGFR3 and the ACH mutant in plasma membrane-derived vesicles. We demonstrated a small, but statistically significant increase in FGFR3 dimerization due to the ACH mutation. We also measured the activation of wild type and mutant FGFR3 in mammalian cells using Western blots, and analyzed the activation within the frame of a physical-chemical model describing dimerization, ligand binding and phosphorylation probabilities within the dimers. The data analysis demonstrated that FGFR3 activity in achondroplasia is increased due to increased dimerization and increased probability for phosphorylation of the unliganded mutant dimers. As achondroplasia is a heterozygous disorder, we also investigated the formation of FGFR3 heterodimers in cellular membranes. We accomplished that by designing an FGFR3 construct that lacks the kinase domain, and we monitored the formation of inactive heterodimers between this construct and wild-type and mutant FGFR3. The formation of the inactive heterodimers depleted the pool of full-length receptors capable of forming active homodimers and ultimately reduced their phosphorylation. By analyzing the effect of the truncated FGFR3 on full-length receptor phosphorylation, we demonstrated that FGFR3 WT/G380R heterodimers form with lower probability than wild-type FGFR3 homodimers at low ligand concentration. These results further our knowledge of FGFR3-associated bone disorders.

**Spatial Organization of EphA2 and its effects on internalization and signaling in living cells.**

*A. C. Greene<sup>1,2</sup>, S. J. Lord<sup>2,3</sup>, J. T. Groves<sup>2,3</sup>; <sup>1</sup>Howard Hughes Medical Institute, Department of Chemistry, Department of Molecular and Cell Biology, The University of California Berkeley, Berkeley, CA, <sup>2</sup>Physical Biosciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA, <sup>3</sup>Howard Hughes Medical Institute, Department of Chemistry, The University of California Berkeley, Berkeley, CA*

Our research focuses on the spatial reorganization of receptors and ligands that occurs at the cell-cell interface during juxtacrine signaling. We have developed a unique experimental

platform in which live cells are interfaced with supported lipid bilayers to create a simplified and controllable system that recapitulates essential aspects of the cell-cell contact. To probe how protein organization in the membrane influences signaling in the cell, we pattern supported lipid bilayers into microscale corrals that restrict membrane protein oligomerization to microclusters and then measure changes in cell signaling. For instance, when MDAMB231 breast cancer epithelial cells expressing the receptor tyrosine kinase EphA2 are placed on a supported lipid bilayer containing the EphA2 ligand, ephrinA1, the receptors bind the ligands and the complex reorganizes into large clusters. Applying spatial perturbations to disrupt the reorganization of EphA2-ephrinA1 clusters results in alterations of downstream signaling events. In particular, we found that recruitment of the metalloprotease ADAM10 to the clusters is inhibited, indicating that EphA2 signaling is sensitive to perturbations in the spatial organization of the ligand. ADAM10 has been implicated in the cleavage and subsequent endocytosis of other ephrin ligands, suggesting that ADAM10 may be necessary for the efficient endocytosis of EphA2-ephrinA1. Therefore, our research is currently probing the role of endocytosis in context of how EphA2 is spatiomechanically sensitive. Here, we report that the spatial organization of EphA2-ephrinA1 does alter the internalization of the receptor and ligand. We also found that Pitstop2, a small molecular inhibitor of clathrin-mediated endocytosis (CME), negatively effects ephrinA1 endocytosis, indicating that CME is important in EphA2-ephrinA1 internalization. The implications of these observations for spatial regulation of EphA2 signaling will be further discussed.

692

### **Soluble MerTK release helps regulating POS phagocytosis by Retinal Pigment Epithelial cells.**

*E. F. Nandrot<sup>1,2,3</sup>, C. Parinot<sup>1,2,3</sup>, J. Chatagnon<sup>1,2,3</sup>, A-L. Law<sup>1,2,3</sup>; <sup>1</sup>Inserm, U968, Paris, France, <sup>2</sup>UPMC Univ Paris 06, UMR\_S 968, Institut de la Vision, Paris, France, <sup>3</sup>CNRS, UMR\_7210, Paris, France*

In the eye, cells from the retinal pigment epithelium (RPE) exert a daily rhythmic phagocytic function that is essential for retinal health and vision by photoreceptor cells. Mer tyrosine kinase (MerTK) receptors at the apical surface of RPE cells are activated at the time of the morning phagocytic peak and required to internalize bound photoreceptor outer segments (POS). When alphavbeta5 integrin receptors and their ligands MFG-E8 are absent, retinal phagocytosis loses its rhythm but is still present, thus implying that MerTK can be activated independently from this pathway. We previously showed that a soluble form of MerTK (sMerTK) is released in the conditioned media (CM) of mouse J774 macrophages and rat RPE-J cells during phagocytosis. Moreover, in vivo sMerTK levels slightly fluctuate along the light:dark cycle peaking just before and after phagocytosis in the interphotoreceptor matrix (IPM). In addition, MerTK ligands Gas6 and Protein S are both present in the IPM but their in vivo role is still debated. Therefore, we investigated the influence of known ligands on RPE phagocytosis and examined if sMerTK could downregulate POS uptake by RPE cells in vitro. We challenged J774 and RPE-J cells with POS in serum-free medium with various doses of either ligand alone or in combination. We then analyzed sMerTK protein levels present in the CM of RPE cells using immunoblots and quantified the corresponding phagocytic activity using FITC-labeled POS. All MFG-E8 doses increased phagocytosis and amplified MerTK cleavage. Protein S had a similar effect in a dose-dependant manner albeit to a lower extent. In contrast, increasing doses of Gas6 decreased phagocytosis and exerted an antagonist effect even when used in combination. Interestingly, these effects seem RPE-specific as J774 macrophages sharing the same phagocytic machinery responded moderately and equally to all ligand/s. Next, we tested if sMerTK could impede POS phagocytosis using 2 approaches. First, POS resuspended in CM did not change RPE cells phagocytic intake. Then, we stimulated sMerTK release from the cell surface by preincubating

cells with POS or LPS, shown to stimulate sMerTK release in macrophages. In these conditions, both POS binding and uptake were decreased, the effect being more marked when protein neosynthesis was blocked using cycloheximide. Last, RPE phagocytic activity slightly increased when MerTK cleavage was blocked using an inhibitor specific for the potential MerTK protease Adam17. Taken together, these data strengthen our hypothesis that MerTK is implicated in controlling RPE circadian phagocytic activity aside from its internalization role.

693

**5-lipoxygenase plays a central role in TLR4-mediated monocyte adhesion to endothelial cells through an increased expression of Mac-1 on monocytes.**

S-J. Lee<sup>1,2</sup>, E-K. Choi<sup>1,2</sup>, Y-S. Lee<sup>1,2</sup>, K-W. Seo<sup>1,2</sup>, C-D. Kim<sup>1,2</sup>; <sup>1</sup>Pharmacology, School of Medicine, Pusan National University, Yangsan, Korea, <sup>2</sup>MRC for Ischemic Tissue Regeneration, Pusan National University, Pusan, Korea

Recent evidence has demonstrated an important role of toll-like receptors (TLRs) in atherogenesis. In particular, TLR4 has been shown to participate in the pathogenesis of atherosclerosis by the increased formation of macrophage foam cells as well as by monocyte activation. However, the role of this pathway in monocyte adhesion to vascular endothelial cells, an early event in macrophage foam cell formation, is still unclear. To investigate the underlying mechanisms involved in the TLR-mediated adhesion of monocytes to endothelial cells, we determined the expression of adhesion molecules on monocytes stimulated with the TLR4 agonist, lipopolysaccharide (LPS). Among the various adhesion molecules on monocytes, the Mac-1 expression were exclusively increased, which subsequently led to the increased adhesion of monocytes to endothelial cells. Moreover, the role of Mac-1 in LPS-induced monocyte adhesion to endothelial cells was confirmed by blocking antibody with Mac-1. Furthermore, The LPS-induced expression of Mac-1 and monocyte adhesion were attenuated by the inhibition of 5-lipoxygenase (5-LO) pathways with MK886, a 5-LO inhibitor, and U-75302, a LTB4 receptor antagonist as well as in monocytes from 5-LO<sup>(-/-)</sup> mice. Moreover, an en face immunohistochemistry of endothelial surface revealed a marked increase in monocyte adhesion to the aortic endothelium in LPS-treated mice. This was also significantly attenuated in 5-LO<sup>(-/-)</sup> mice treated with LPS, confirming a role of 5-LO in monocyte adhesion to endothelial cells induced by TLR4 activation in in vivo study. These results suggest a potential role of 5-LO-derived leukotrienes in TLR4-mediated monocyte adhesion to endothelial cells through Mac-1 expression. Collectly, these data suggest that 5-LO plays a central role in TLR4-mediated monocyte adhesion to endothelial cells through the increased expression of Mac-1 on monocytes, thus contributing to the initiational process of atherosclerosis.

**Oxysterols are allosteric activators of the oncoprotein Smoothed.**

S. Nachtergaele<sup>1</sup>, L. K. Mydock<sup>2</sup>, K. Krishnan<sup>2</sup>, J. Rammohan<sup>3</sup>, P. H. Schlesinger<sup>3</sup>, D. F. Covey<sup>2</sup>, R. Rohatgi<sup>4</sup>; <sup>1</sup>Biochemistry, Stanford University, Stanford, CA, <sup>2</sup>Developmental Biology, Washington University, St. Louis, MO, <sup>3</sup>Cell Biology and Physiology, Washington University, St. Louis, MO, <sup>4</sup>Medicine/Oncology, Stanford University, Stanford, CA

Oxysterols are a class of endogenous signaling molecules that can activate the Hedgehog pathway, which has critical roles in development, regeneration and cancer. Though the majority of small molecule Hedgehog modulators identified to date appear to bind to overlapping sites on the seven-pass transmembrane protein Smoothed, oxysterols do not show this behavior. A complicating factor in identifying the mechanism by which oxysterols activate Hedgehog signaling is that as amphipathic molecules, they can transduce cellular signals directly through a

protein target or indirectly through effects on membrane properties. To answer this question, we took a chemical approach and synthesized the enantiomer and an epimer of the most potent oxysterol, 20(S)-hydroxycholesterol. Using these molecules, we show that the effects of oxysterols on Hedgehog signaling are exquisitely stereoselective, consistent with the hypothesis that they function through a specific protein target. Pharmacological analysis and affinity chromatography with a novel oxysterol analog suggest that these molecules target Smo at a site distinct from the canonical site that binds inhibitors such as cyclopamine and agonists such as SAG. Our work suggests that Smo may be susceptible to regulation by small molecules at multiple binding sites and provides a generally applicable framework for probing sterol signaling mechanisms.

**Visualizing the efficacy of GPCR signaling in live cells.**

R. Malik<sup>1</sup>, S. Sivaramakrishnan<sup>1,2</sup>; <sup>1</sup>Cell and Developmental Biology, University of Michigan, Ann Arbor, MI, <sup>2</sup>Biomedical Engineering, University of Michigan, Ann Arbor, MI

G-protein coupled receptors (GPCRs) bind a variety of ligands to initiate a diverse array of cellular responses. Several recent structural and biophysical studies have shown that the same GPCR can adopt distinct structural conformations in response to different ligands. However, these structural conformations exhibit subtle differences that do not explain the different signaling efficacies of distinct ligands acting on the same GPCR. In this report, GPCR efficacy in live cells was captured using a new genetically encoded technique termed systematic protein affinity strength modulation (SPASM). SPASM involves the expression of a single polypeptide with two proteins or protein domains and a FRET pair separated by a modular ER/K linker. Varying the length of the ER/K linker systematically controls the effective concentration of the interaction. SPASM allows for expression of GPCR and G $\alpha$  (domains) in equal amounts and at an engineered effective concentration. We report on the application of SPASM to two prototypical GPCRs, opsin and  $\beta$ 2-adrenergic receptor ( $\beta$ 2-AR). SPASM was used to measure the interaction between each GPCR and either full length G $\alpha$  or a peptide derived from the G $\alpha$  c-terminus ( $\alpha$ 5 helix). Active conformations of both GPCRs, that are known to initiate downstream signaling, showed an enhanced affinity for the c-terminus of the primary G $\alpha$  (Gat – opsin; Gas –  $\beta$ 2-AR). Activity state was altered using agonist ( $\beta$ 2-AR – isoproterenol (ISO); opsin – maturation with 9-cis-retinal), mutagenesis (opsin – K296A and E113Q;  $\beta$ 2-AR – D130N and CAM) or inverse agonist ( $\beta$ 2-AR – metoprolol or ICI118,551 (ICI)). The gain in affinity of the active GPCR for the primary G $\alpha$  c-terminus was directly reflected in measurements with G $\alpha$  chimeras (Gas/t and Gat/s). Sensor readout was a direct measure of the efficacy of the ligand in precipitating a known downstream cellular response. Specifically, live-cell ISO dose stimulation curves of the  $\beta$ 2-AR- $\alpha$ 5 sensors showed a characteristic sigmoidal FRET response with an EC50 consistent with the low affinity state of  $\beta$ 2-AR in the ternary complex model. Competition of ISO with ICI showed sigmoidal inhibition of FRET with EC50 consistent with ICI binding affinity. Sensors that probe the GPCR interaction with the G $\alpha$  c-terminus reported ligand efficacy more consistently than those with full-length G $\alpha$ . As an independent measurement of GPCR activation, FRET measurements directly correlated with rate of second messenger (cAMP) accumulation. Further, varying ER/K linker length systematically controlled the rate of cAMP accumulation without the need for site-directed-mutagenesis of either GPCR or G $\alpha$ . Taken together, our studies strongly support the use of SPASM to examine signaling efficacy and selectivity of any GPCR.

696

**Dynamic monomer-dimer equilibrium as a general property of the class A GPCR: detection by single-molecule imaging.**

R. S. Kasai<sup>1</sup>, T. K. Fujiwara<sup>2</sup>, A. Kusumi<sup>1,2</sup>; <sup>1</sup>Institute for Frontier Medical Sciences, Kyoto University, Kyoto, Japan, <sup>2</sup>Institute for Integrated Cell-Material Sciences (WPI-iCeMS), Kyoto University, Kyoto, Japan

Class-A G-protein-coupled receptor (GPCR) includes about 85% of GPCR or ~700 different GPCRs. Previously, by developing new methods based on single-molecule imaging, we succeeded in fully characterizing the two-dimensional (2D) dimer-monomer equilibrium of a class-A GPCR, formyl peptide receptor (FPR) (Kasai et al. JCB 2011). This was the first determination ever of the dissociation equilibrium of any molecules in the membrane. Here, we applied this method to another prototypical class-A GPCR, beta2-adrenergic receptor (B-AR), and found that B-AR also undergoes similar dynamic monomer-dimer equilibrium, with a 2D monomer-dimer equilibrium constant of 1.6 (3.6) copies/square micron, a dimer dissociation rate constant of 12.6 (11.0) /s [dimer lifetime of 80 (90) ms], and a dimer formation rate constant of 7.9 (3.1) /[copies/square microns]/s (FPR values in parentheses). Physiological expression levels of B-AR (FPR) have been reported to be 16 -260 (2.1) copies/square micron [46,000 - 740,000 (6,000) copies/cell]. Using the determined equilibrium constant, it is expected that, at any moment, 75 -92% of B-AR would exist as dimers, whereas ~42% of FPR would. However, it is critically important to realize that these are transient dimers of 80-90-ms lifetimes, and the difference comes from their monomer lifetimes due to different expression levels, i.e., 0.49 -8 ms for B-AR and 154 ms for FPR. These results suggest that class A GPCRs are under comparable dynamic monomer-dimer equilibrium and this might play a role in signal transduction and/or its regulation. Previously, Hern et al. (PNAS, 2010) reported rapid dimer dissociation of M1 muscarinic receptor, another class-A GPCR. Taken together, these results suggest that class-A GPCRs generally undergo dynamic equilibrium between monomers and homo-dimers. Because no homology exists between different GPCRs, this infers that each GPCR is individually evolved to be capable of forming transient dimers, suggesting the dynamic interconversion between monomers and dimers may be critical for the function of class-A GPCRs.

697

**Global GPCR dimerization screening using AdBiFC assay system in human cells.**

Y. Song<sup>1</sup>, C. Park<sup>1</sup>, E. Cho<sup>2</sup>, D. Seer<sup>2</sup>, J-Y. Jeong<sup>3</sup>, W-K. Huh<sup>1</sup>; <sup>1</sup>School of Biological Sciences, Seoul National University, Seoul, Korea, <sup>2</sup>BRN Science Inc, Seoul, Korea, <sup>3</sup>Marine Biotechnology Research Group, Korea Institute of Ocean Science & Technology, Seoul, Korea

G protein-coupled receptors (GPCRs) are the largest class of cell surface receptors that mediate numerous physiological responses to various extracellular stimuli. GPCRs are believed to exist as monomers, but emerging evidences suggest that GPCRs may form dimers (or higher-order oligomers) leading to an alteration of their signals. Here, we developed an adenovirus-based bimolecular fluorescence complementation (AdBiFC) assay system, combining a gateway-compatible high-throughput technology and an adenovirus-mediated gene delivery system, to visualize protein-protein interactions in living human cells. To identify and profile the GPCR dimerization, we generated recombinant adenovirus libraries in which 164 of individual GPCR are C-terminally tagged with either the N- or the C-terminal fragment of a yellow fluorescent protein variant Venus, and performed a large-scale BiFC assay using a high-content screening analyzer. From this binary interaction assay, we identified over 1,200 GPCR dimeric combinations including 26 homodimerizations. Furthermore, we developed a  $\beta$ -arrestin

recruitment assay using AdBiFC technique to monitor GPCR activation, which can be readily adapted to potential drug screening in living cells. Overall, our AdBiFC assay system provides a platform for analyzing global GPCR interactions and may prove highly useful for studying the pathophysiology of GPCR dimerizations.

698

**A single Lys residue on the first intracellular loop modulates the ER export and cell-surface expression of  $\alpha$ 2A-adrenergic receptor.**

Y. Fan<sup>1</sup>, C. Li<sup>1</sup>, G. Wu<sup>1</sup>; <sup>1</sup>Pharmacology and Toxicology, Georgia Health Sciences University, Augusta, GA

Export from the ER represents an initial step in intracellular trafficking of G protein-coupled receptors (GPCRs). However, the underlying molecular mechanisms remain poorly understood. We have previously demonstrated that a highly conserved Leu residue on the first intracellular loop (ICL1) is required for exit of several GPCRs from the ER. Here we found that, in addition to Leu64 residue in the ICL1, the neighboring positively charged residue Lys65 also modulates the cell-surface transport of  $\alpha$ 2A-adrenergic receptor ( $\alpha$ 2A-AR). Mutation of Lys65 to Ala, Glu and Gln significantly attenuated, whereas mutation of Lys65 to Arg strongly augmented  $\alpha$ 2A-AR expression at the cell surface. Consistent with the effects on the cell-surface expression of  $\alpha$ 2A-AR, mutation of Lys65 to Ala and Arg produced opposing effects on  $\alpha$ 2A-AR-mediated ERK1/2 activation. Furthermore, confocal microscopy revealed that the  $\alpha$ 2A-AR mutant K65A displayed a strong intracellular expression pattern and was extensively co-localized with the ER marker DsRed2-ER, suggestive of ER accumulation. These data provide the first evidence indicating an important function for a single Lys residue on the ICL1 in the ER export and cell-surface expression of  $\alpha$ 2A-AR. These data also suggest that the ICL1 may possess multiple signals that control the cell-surface targeting of GPCRs via distinct mechanisms.

**Identification of Ubiquitin-binding domain containing proteins that regulate trafficking and signaling of the yeast G-protein Gpa1.**

G. Dixit<sup>1</sup>, M. Torres<sup>2</sup>, H. Dohlman<sup>1</sup>; <sup>1</sup>Biochemistry and Biophysics, University of North Carolina, Chapel Hill, Chapel Hill, NC, <sup>2</sup>School of Biology, Georgia Institute of Technology, Atlanta, GA

G-proteins and their associated receptors form the largest class of proteins that receive and transduce chemical and sensory signals. Regulation of G-proteins therefore, is critical to appropriate cellular responses. G Proteins are comprised of three subunits-  $\alpha$ ,  $\beta$  and  $\gamma$ . The yeast G $\alpha$  subunit, Gpa1 is subject to both poly and mono-ubiquitination. Each modification is carried out by different ubiquitinating enzymes and has different consequences for G-protein activity. While polyubiquitination is a signal for Gpa1 degradation, monoubiquitination results in Gpa1 endocytosis and delivery to the vacuole.

However, the specific ubiquitin binding domain (UBD) containing protein machinery that targets monoubiquitinated Gpa1 and mediates its endocytosis and trafficking is not known. We conducted a microscopy-based screen of 40 UBD gene deletion mutants to identify those in which Gpa1 trafficking to the vacuole was impaired. We also performed a parallel screen to identify UBD gene deletion mutants that disrupt endocytosis and trafficking of the monoubiquitinated receptor. Comparing the results from the two screens, we identified four UBD proteins that are needed specifically for proper trafficking and endocytosis of the Gprotein but not of the receptor. These four UBD's had no effect on trafficking of a Gpa1 mutant that cannot be ubiquitinated. Our analysis reveals novel G protein-binding proteins and, more broadly, the functional consequences of G protein monoubiquitination and endocytosis.

**sFRP1 Potentiation vs. Inhibition of Wnt3a/[beta]-catenin Signaling: Mechanistic and Structure-Function Analysis.**

*C. P. Xavier<sup>1</sup>, M. Melikova<sup>1</sup>, S. Saffo<sup>1</sup>, J. S. Rubin<sup>1</sup>; <sup>1</sup>NCI, Laboratory of Cellular and Molecular biology, Bethesda, MD*

Wnt signaling regulates a variety of cellular processes including proliferation, motility and polarity. Many of these activities are mediated by the Frizzled (Fzd) family of seven-pass transmembrane receptors, which bind Wnts via a conserved cyteine-rich domain (CRD). Secreted Fzd-related proteins (sFRPs) contain an amino-terminal, Fzd-like CRD and a carboxyl-terminal, heparin-binding netrin-like domain (NTR). Previous studies identified sFRPs as soluble Wnt antagonists that bind directly to Wnts and prevent their interaction with Fzds. However, subsequent observations suggested that sFRPs and Fzds can form homodimers and heterodimers via their respective CRDs, and that sFRPs can stimulate signal transduction. Here, we present evidence that sFRP1 either inhibits or potentiates the Wnt3a/[beta]-catenin pathway, depending on its concentration and the cellular context. sFRP1 has biphasic activity in a SuperTopFlash (STF) reporter assay in HEK293/STF cells. The potentiating effect in HEK293/STF cells was mimicked by CRDsFRP-1, while CRDsFRP-1 did not inhibit Wnt3a activity even at micromolar concentrations. In contrast, sFRP1 only inhibited Wnt3a/[beta]-catenin signaling in L929 fibroblasts. Interestingly, when L cells were engineered to stably express Fzd5 but not Fzd2 or Fzd4, sFRP1 enhanced Wnt3a/[beta]-catenin signaling at nanomolar concentrations. Future experiments will explore the molecular mechanisms responsible for potentiation vs. inhibition of Wnt/[beta]-catenin signaling by sFRP1.

**Mapping spatial approximations between residues contributing to the helix N-capping motif of secretin and distinct residues within each of the extracellular loops of its receptor using cysteine trapping.**

*M. Dong<sup>1</sup>, D. I. Pinon<sup>1</sup>, L. J. Miller<sup>1</sup>; <sup>1</sup>Mayo Clinic, Scottsdale, AZ*

Secretin family peptides contain key determinants for biological activity and receptor specificity in their amino-terminal regions, however current understanding of how this region interacts with its receptor is unclear. Within the peptide amino terminus is a helix N-capping motif that has been postulated to contribute directly to its biological activity, while also stabilizing the carboxyl-terminal helical region of the peptide that docks within the receptor amino-terminal domain. This helix-helix interaction is poised to direct the peptide amino terminus toward the receptor core. In secretin, the N-capping motif includes residues Phe<sup>6</sup>, Thr<sup>7</sup> and Leu<sup>10</sup>. The current work was designed to use the powerful cysteine trapping approach to systematically explore spatial approximations for each of these residues with those of the secretin receptor. Probes were developed in which cysteines were incorporated into each of these positions within secretin. Each of these analogues was a full agonist for cAMP, although it bound with lower affinity than the natural hormone. For the targets, secretin receptor mutants were prepared in which natural residues in each of 61 positions throughout the tops of transmembrane segments and extracellular loop (ECL) regions were also replaced with cysteines, and these were expressed in COS cells. After ligand binding under conditions permitting spontaneous formation of disulfide bonds, the patterns of covalent labeling were distinct for each of the three probes. The position 6 probe predominantly labeled multiple residues in the carboxyl-terminal half of ECL2 and amino-terminal half of ECL3, while the position 7 probe only labeled a single residue within the carboxyl-terminal region of ECL2 and another residue at the beginning of ECL3. The position 10 probe did not efficiently label any of the residues in any of these regions. Sites of disulfide formation were quite distinct for these N-capping motif residues than for analogous experiments

recently performed with position 2 and 5 probes. Utilizing this battery of spatial approximation data is helpful to orient the amino-terminal region of secretin toward its receptor and to provide new insights into the molecular basis for specificity and biological activity.

702

**Desensitization of Melanin-concentrating Hormone-Mediated ERK Signaling Despite Poor MCHR1 Internalization.**

*A. E. Goodspeed<sup>1</sup>, J. I. Moden<sup>1</sup>, S. Wicks<sup>1</sup>, L. B. Cook<sup>1</sup>; <sup>1</sup>Biology, The College at Brockport, SUNY, Brockport, NY*

Melanin-concentrating hormone (MCH) receptor 1 knockout mice have limited incidence of diet-induced obesity. This makes the MCH signaling pathway a potential pharmacological target to fight human obesity. MCHR1 is a G-protein coupled receptor (GPCR) that activates multiple signaling pathways, including ERK phosphorylation. Overstimulation of GPCR signaling is a hallmark of many diseases. Likewise, inadequate desensitization of MCH signaling could potentiate the obese phenotype. GPCR desensitization typically involves agonist-induced internalization of activated receptors, and subsequent degradation or receptor recycling. Our initial aim was to determine whether MCH signaling desensitizes. In order to measure this we maximally stimulated MCHR1-transfected BHK-570 cells with 100 nM MCH for 10 min, then following three washes in serum-free media and a 30 min recovery period, cells were stimulated again. Western blots of lysates for phosphorylated-ERK and total ERK were performed. ImageJ was used to normalize activation levels. MCH was unable to signal a second round of ERK signaling unless we waited 70 minutes, indicating that the MCH signaling pathway is desensitized during this period. We hypothesized that MCHR1 internalization was responsible, however when MCH was added to cells, no visible redistribution of MCHR1 was detectable using fluorescence microscopy. We tried a more sensitive assay, a cell-based ELISA, and only measured a 15% loss of surface MCHR1 after 30 min of MCH treatment. Live-cell experiments conducted with rhodamine-MCH and MCHR1-eYFP transfected cells support these conclusions. We tested the hypothesis that beta-arrestins and/or GRKs were limiting factors in preventing agonist-mediated endocytosis of MCHR1. Only overexpression of beta-arrestins-1 and -2 showed significant gains. We conclude that MCHR1 can undergo receptor-mediated endocytosis, but the fraction of available receptors on the plasma membrane does not account for the extensive loss of ERK signaling observed. This suggests that MCHR1 mediated ERK signaling desensitizes while MCHR1 is at the plasma membrane, rather than via removal of the receptor from the cell surface. Future experiments are aimed at determining whether this desensitization is homologous or heterologous.

703

**Melanin-concentrating Hormone Receptor 1 in CHO-K1, SH-SY5Y and 3T3-L1 Cells: A Pathway to Primary Cilia.**

*B. H. Pratt<sup>1</sup>, N. N. Covello<sup>1</sup>, L. B. Cook<sup>1</sup>; <sup>1</sup>The College at Brockport, SUNY, Brockport, NY*

Obesity results when caloric intake exceeds metabolic needs over an extended period of time. The condition predates heart disease and diabetes – two pathologies that diminish the quality of life and increase risk of premature death. Melanin-concentrating hormone (MCH) acts via a G protein-coupled receptor on the plasma membrane of neurons to stimulate appetite, and adipocytes to stimulate feedback secretion of leptin. Dysregulation of MCH signaling is hypothesized to be a contributing factor in select appetite disorders. Little is known about how cells regulate MCH receptor signaling however plasma membrane localization of MCHR1 has been implicated as a contributing factor. We previously reported that caveolae enhance MCH

signaling in CHO cells. This, together with recent reports of MCHR1 localization to primary cilia in hypothalamic neurons led us to hypothesize that organization of MCHR1 in the plasma membrane might be important to MCH function in other cell types as well. When VSVg-tagged MCHR1 is transiently expressed in CHO-K1 cells, receptor can be found on the plasma membrane, but occasionally localizes to two punctate dots near the nucleus, particularly after serum deprivation. We next studied two endogenously-expressing cell lines: human SH-SY5Y neuroblastoma cells and murine 3T3-L1 pre-adipocytes, which both responded to MCH by activating ERK. Using immunostaining, diffuse plasma membrane-localized MCHR2 was detected in SH-SY5Y cells. Although MCHR1 plasma membrane expression was confirmed in both SH-SY5Ys and 3T3-L1s, both cell types harbored distinctive MCHR1 patterning; SH-SY5Ys had clusters of MCHR1-positive vesicles and 3T3-L1 cells revealed MCHR1-positive primary cilia during differentiation. Together, these results suggest trafficking of MCHR1 to a centrosomal-location prepares receptor for entry into primary cilia, and that a role for primary cilia in the regulation of receptor signaling may be more widespread than originally thought. Future experiments will be aimed at determining the role that this localization plays in the regulation of MCH signaling.

#### **G Protein-coupled Receptor Kinase 2 Promotes CCR7 Internalization.**

*C. T. Winebrenner<sup>1</sup>, K. H. Boxberger<sup>1</sup>, B. Kaiser<sup>1</sup>, C. A. Bill<sup>1</sup>, L. Kilgore<sup>1</sup>, T. P. Welch<sup>1</sup>, H. D. Cunningham<sup>1</sup>, C. M. Vines<sup>1</sup>; <sup>1</sup>Microbiology, Molecular Genetics & Immunology, University of Kansas Medical Center, Kansas City, KS*

C-C Chemokine Receptor 7 (CCR7) plays central roles in targeting T cells, breast tumors and activated dendritic cells to the lymph nodes during an immune response. Two ligands, CCL19 and CCL21 activate CCR7 and are thought to regulate this migration. To migrate, cells must sensitize/desensitize in response to differing ligand gradients. Others and we have shown that in human T cells, CCR7 rapidly desensitizes by internalizing 80% of the surface CCR7 in response to stimulation with CCL19, but not to CCL21. In addition, we have shown that activated CCR7 promotes redistribution of arrestin-3, a protein that binds to phosphorylated G protein-coupled receptors, to the nucleus. To determine the mechanism regulating the internalization and arrestin-3 redistribution we examined the roles of G protein-coupled receptor kinases human embryonic kidney (HEK-293T) cells. We found that comparing the four ubiquitously expressed GRKs, only GRK2 and GRK3 promoted differential internalization of CCR7 or redistribution of arrestin-3 to the nucleus. In addition, the kinase function of GRK2 mediated arrestin re-localization. Since GRK function is cell type dependent, we examined CCR7 internalization in primary wild-type (WT), GRK2<sup>+/-</sup>, and GRK3<sup>-/-</sup> T cells. WT cells internalized 36% of CCR7/CCL19 and 11% of CCR7/CCL21, while GRK2<sup>+/-</sup> T cells internalized 57% of CCR7 in the presence of either CCL19 or CCL21. GRK3<sup>-/-</sup> cells failed to internalize CCR7 in the presence of either ligand. To define a physiological significance of GRK regulation we characterized the effect of GRK2 and GRK3 on T cell migration. We found that WT murine T cells migrated to both CCR7 ligands, GRK2<sup>+/-</sup> cells only migrated in the presence of CCL19, and GRK3<sup>-/-</sup> cells failed to migrate to either ligand. Taken together, these results indicate CCL21- and CCL19-induced internalization of CCR7 and redistribution of arrestin-3 is dependent upon the expression of GRK2 and GRK3, and that T cell migration to CCR7/CCL21 or CCR7/CCL19 is dependent on GRK3.

## Rho-Family GTPases

### Toward unraveling the structure and molecular basis of ferrous iron transport of feo from *klebsiella pneumonia*.

K-W. Hung<sup>1</sup>, J-Y. Tsa<sup>2</sup>, T-H. Juan<sup>1</sup>, Y-L. Hsu<sup>1</sup>, C-D. Hsiao<sup>2</sup>, T-H. Huang<sup>1,1</sup>; <sup>1</sup>Inst. Biomed. Sci., Academia Sinica, Taipei, Taiwan, <sup>2</sup>Inst. Mol. Biol., Academia Sinica, Taipei, Taiwan

Feo from *K. pneumoniae* is a unique type of ferrous iron transporter for bacteria. It consists of three proteins, FeoA, a small SH3-domain like protein; FeoB, a large protein consisting of a cytosolic N-terminal G-protein domain and a C-terminal transmembrane domain that may serve as a Fe<sup>2+</sup> permease; and FeoC, a small putative transcriptional factor. The objective of the present study is to unravel the molecular basis of Fe<sup>2+</sup> transport by Feo. Using X-ray crystallography and NMR we have solved the structure of *Kp*FeoA, the intracellular domain of *Kp*FeoB (*KpN*FeoB), *Kp*FeoC and *KpN*FeoB/*Kp*FeoC complex. In the structures, a canonical G-protein domain (G domain) is followed by a helical bundle domain (S-domain), which despite its lack of sequence similarity between species is structurally conserved. In the nucleotide-free state, the G domain's two switch regions point away from the binding site. This gives rise to an open binding pocket whose shallowness is likely to be responsible for the low nucleotide - binding affinity. Nucleotide binding induced significant conformational changes in the G5 motif which in the case of GMPPNP binding was accompanied by destabilization of the switch I region. In addition to the structural data, we demonstrate that Fe<sup>2+</sup>-induced foot printing cleaves the protein close to a putative Fe<sup>2+</sup>-binding site at the tip of switch I, and we identify functionally important regions within the S-domain. Moreover, we showed that *Kp*FeoC assumed a winged-helix structure and it forms a tight complex with *KpN*FeoB. The crystal structure of *KpN*FeoB/*Kp*FeoC complex suggests that *Kp*FeoC may function as a regulator, in addition to its proposed role as a transcriptional regulator.

### Signaling Events in Protection of Insulin-Secreting Cells from Glucotoxicity-Induced Apoptosis during Knockdown of p21-Activated Kinase-1.

G. Li<sup>1</sup>, J. Zhang<sup>1</sup>, R. Luo<sup>1</sup>, Y-M. Bee<sup>2</sup>; <sup>1</sup>Dept of Clinical Research, Singapore General Hospital, Singapore, Singapore, <sup>2</sup>Dept of Endocrinology, Singapore General Hospital, Singapore, Singapore

The major cause for various cardiovascular complications in diabetes is the chronic hyperglycemia which is called as glucotoxicity resulting in damage to many tissues including islet  $\beta$ -cells. We found that knockdown of p21-activated kinase-1 (PAK1), a downstream effector of the small G-protein Rac1, did not mediate the adverse effects of Rac1 suppression on cytoskeletal organization and glucose-stimulated insulin secretion in INS-1  $\beta$ -cells. By contrast, PAK1 knockdown reduced  $\beta$ -cell demise during glucotoxicity. Exposure of INS-1 cells to high (20 or 30 mM) glucose for 2-3 days activated PAK1, while knockdown of PAK1 by siRNA transfection could protect INS-1 cells from glucotoxicity-induced apoptosis, as assessed by flow cytometry and activation of caspases. Glucotoxicity caused subdiploidy apoptosis by shifting INS-1 cells from G1 to sub-G1 phase due to DNA fragmentation and diminished cyclin D1 protein mass. Meanwhile, an increase of caspase-8 and -9 activities occurred, followed by

marked caspase-3 activation peaking at 48 h, as assessed by the cleavage of specific fluorogenic substrates. PAK1 knockdown significantly attenuated glucotoxicity-induced caspase activation and apoptosis. Chronic high glucose also activated p38 mitogen-activation protein kinase (MAPK) and JNK but not p44/42 MAPK. However, PAK1 knockdown only reversed p38 MAPK activation upon glucotoxicity. Additionally, chronic high glucose markedly increased thioredoxin-interacting protein (TXNIP) which might protect against glucotoxicity-induced  $\beta$ -cell apoptosis. However, PAK1 knockdown did not enhance, rather modestly reduced TXNIP (assessed by immunoblotting) upon glucotoxicity. Furthermore, inhibition of p38 MAPK by a specific inhibitor of 10  $\mu$ M SB203580 could protect INS-1 cells from glucotoxicity-induced apoptosis and reduce the activation of caspases in INS-1 cells exposed to high glucose for 2-3 days. SB203580 also slightly diminished glucotoxicity-induced increase in TXNIP, similar to the effect of PAK1 knockdown. Our studies have demonstrated that PAK1 may play an important role in glucotoxicity-induced apoptotic death of insulin-secreting cells. Such protective effect seems not to be mediated by TXNIP; rather it is through attenuation of activation of p38 MAPK and subsequent activation of caspases.

### **Comparative Responses to Stress Caused by Ionizing Radiation (Gamma and Ultraviolet) in HeLa Cells: Studying New Roles for Rac1 GTPases.**

*J. H. Osaki<sup>1</sup>, G. T. Espinha<sup>1</sup>, F. L. Forti<sup>1</sup>; <sup>1</sup>Biochemistry, Institute of Chemistry, University of Sao Paulo, Sao Paulo, Brazil*

Rac1 is a member of the family of small GTPases related to Ras, and comprise a group of signaling molecules acting as switches (from GDP to GTP state) to control a number of essential cellular functions (proliferation, migration, formation of lamellipodia, membrane ruffles and adhesion). This protein is overexpressed in tumorigenic cells as lung, breast and colon, and the variant constitutively active of Rac1, Rac1b, is naturally expressed in colon and breast cancer. Ionizing radiation causes several types of DNA lesions, like single and double strand breaks, pyrimidine dimers and 6-4 photoproducts usually repaired by homologous recombination, non-homologous end-joining, nucleotide excision, base excision and mismatch repair mechanisms. Thus, the overexpression of Rac1 in human cervical cancer cells associated to their radiosensitivity against different types of DNA damages, prompted us to this study, where we compare HeLa cells (human cancer cervix), mutants expressing dominant negative Rac1 (HeLa-Rac1-N17) and constitutively active Rac1 (HeLa-Rac1-V12) as to cell migration, survival, proliferation and DNA damage response after exposition to low doses of gamma radiation (0.5; 2 and 5Gy) and ultraviolet radiation types A (50 KJ/m<sup>2</sup>), B(80 J/m<sup>2</sup>) and C (4 J/m<sup>2</sup>). From survival and proliferation assays we observed that the dominant negative clone HeLa-Rac1-N17 was more sensitive to different doses of gamma radiation and the same was observed in treatments with the three types of ultraviolet radiation, despite of the fact that HeLa-Rac1-N17 showed a delayed DNA repair rate compared to HeLa-Rac1-V12 clone and HeLa cells. The constitutively active clone HeLa-Rac1-V12 was significantly even faster than HeLa cells in relation to DNA repair after exposition to ionizing radiation. The migration studies showed that cells with higher Rac1 activity migrate more than dominant negative clone after radiation treatments. In conclusion, these results demonstrate that Rac1 protein very likely plays important roles in DNA damage responses and repair mechanisms in human cancer cervix cells, and molecular mechanisms underlying cell death and survival are under investigation to explain these differential responses after damage caused by gamma and ultraviolet radiation. **Signaling in Context: Rac1 Activation Encodes for Increased Survival in 3D.**

G. Ou<sup>1,2</sup>, C. Frantz<sup>1</sup>, M. Rubashkin<sup>1,2</sup>, J. Friedland<sup>3</sup>, J. Lakins<sup>1</sup>, J. Chernoff<sup>4</sup>, L. C. Santy<sup>5</sup>, C. Chen<sup>3</sup>, M. A. Schwartz<sup>6</sup>, V. Weaver<sup>1,2</sup>; <sup>1</sup>University of California, San Francisco, San Francisco, CA, <sup>2</sup>University of California, Berkeley, Berkeley, CA, <sup>3</sup>University of Pennsylvania, Philadelphia, PA, <sup>4</sup>Fox Chase Cancer Center, Philadelphia, PA, <sup>5</sup>Penn State University, University Park, PA, <sup>6</sup>Yale University, New Haven, CT

Survival of single cells in a three dimensional (3D) environment is crucial for the formation of embryonic bodies and infiltration of tissues by isolated tumor cells. While it has been established that cells on two-dimensional (2D) substrates undergo higher rates of apoptosis compared to those in 3D, most studies on the mechanisms regulating cell survival have been performed on spread cells in 2D environments. To investigate the molecular mechanisms underlying enhanced cell survival in 3D, we assessed the effect of cell shape, matrix ligation, and integrin-dependent adhesion on the survival of isolated mammary epithelial cells (MECs) in compliant 2D and 3D environments. We found that apoptosis in 2D is linked to Rac1 binding of NADPH oxidase, which increases production of reactive oxygen species (ROS) and leads to matrix metalloproteinase (MMP) activation. In contrast, increased  $\alpha 6 \beta 4$  integrin ligation of laminin in 3D environments leads to enhanced Arf6 activity through two guanine exchange factors (GEFs), ARNO and GEP100. Arf6 activity then promotes membrane and actin cytoskeletal remodeling, altering Rac1 activity in concert with increased EGF-mediated activation of Rac1 to reduce NADPH-mediated ROS production and to favor apoptosis resistance signaling through Pak1. These data suggest that matrix dimensionality enhances cell survival in 3D by acting through changes in cell shape, membrane tension, and cytoskeletal organization that in turn affect intracellular signaling. This work illustrates the importance of matrix dimensionality in determining cell behavior and fate and highlights the necessity of contextualized study of molecular signaling.

**Ypk1/2 kinases, yeast TORC2 effectors, regulate Rho1 GTPase via controlling phospholipid composition.**

R. Hatakeyama<sup>1</sup>, S. Yoshida<sup>1</sup>; <sup>1</sup>Brandeis University, Waltham, MA

The conserved target of rapamycin kinase complex 2 (TORC2) regulates cell polarity via Rho GTPases. However, the precise mechanism by which TORC2 regulates Rho is obscure. Because it has recently been shown that TORC2 is activated in response to plasma membrane (PM) stretching, uncovering the molecular link between TORC2 and Rho is critical to understand how cell polarity is maintained under membrane-stressed condition. Here we demonstrate that yeast Ypk1/2 kinases, major effectors of TORC2, regulate localization of Rho1 GTPase possibly via controlling phospholipid composition at inner leaflet of PM.

We found that overexpression of Rho1 rescues temperature-sensitive growth of *ypk1/2* (*ypk-ts*) mutant, suggesting Rho1 as a major downstream target of Ypk1/2. Rho1 controls cytoskeleton at growing bud cortex, whereas this localization was impaired in *ypk-ts* cells. Thus Ypk1/2 seem to promote Rho1 function by targeting it to growth sites.

How do Ypk1/2 recruit Rho1? We hypothesized that Ypk1/2 promote accumulation of phosphatidylserine (PS) at inner leaflet of bud PM, which in turn recruits Rho1, based on following known facts. (1) Ypk1/2 negatively regulate Dnf1/2-Lem3 phospholipid flippase complex. (2) In *LEM3* deleted cells, via unknown mechanism, PS accumulates at inner leaflet of growth sites. (3) PS recruits Cdc42, another member of Rho GTPases, to bud cortex.

We asked if PS recruits Rho1. Indeed, deletion of *CHO1* PS synthase resulted in impaired Rho1 localization at bud cortex. On the other hand, artificial accumulation of inner PS by *LEM3* deletion caused enhanced bud localization of Rho1. Thus PS accumulation is necessary and sufficient for Rho1 targeting to bud cortex. Possible mechanisms by which PS recruits Rho1 will be discussed.

In unstressed condition, phosphatidylinositol (4,5)-biphosphate ( $PIP_2$ ) also plays an important role for Rho1 tethering to PM at growth sites. However, it has been shown that  $PIP_2$  is downregulated when cells are exposed to membrane stresses such as hypo-osmotic shock or inhibition of sphingolipid biosynthesis, the conditions where TORC2 activation occurs. Therefore Rho1 targeting by TORC2-Ypk1/2 pathway via PS might be a compensation mechanism for  $PIP_2$  loss. Consistent with this idea, *LEM3* deletion rescued Rho1 mislocalization in  $PIP_2$  deficient mutant cells.

Based on these results, we propose that TORC2-Ypk1/2 pathway let PS substitute for  $PIP_2$  in Rho1 recruitment to maintain cell polarity under membrane stress.

**Human rhinovirus activates of the small G-protein Rac attenuating the TLR3/IFN- $\alpha$  pathway while promoting the p38 pathway in human monocyte-lineage cells.**

*D. J. Hall<sup>1</sup>, B. Schuler<sup>1</sup>, L. Li<sup>1</sup>, M. T. Schreiber<sup>1</sup>; <sup>1</sup>Chemistry, Lawrence University, Appleton, WI*

Rhinoviral infections are a major cause of asthma exacerbations. Though productive rhinovirus infection occurs predominantly in the bronchial epithelial cells of the upper airway, monocytic-lineage cells are implicated in establishing the inflammatory microenvironment observed during rhinoviral asthma exacerbation. Human rhinovirus (HRV) is unique in that nearly genetically identical viruses bind either the intercellular adhesion molecule (ICAM)-1 or low-density lipoprotein (LDL) receptor. Within minutes of binding to its cellular receptors, HRV is capable of eliciting a signaling response in both epithelial cells and monocyte-derived macrophages. It is unclear whether this signaling response is important to the subsequent release of inflammatory mediators, particularly in cells not capable of supporting viral replication. We show here that the small molecular-weight G-protein Rac is activated in macrophages following the binding of HRV to either ICAM-1 or LDL-R. Following this observation, we sought to determine whether Rac activation during HRV exposure is merely a byproduct of receptor attachment or is a key player in mediating the inflammatory response. We demonstrate that inhibiting Rac resulted in the upregulation of toll-like receptor 3 (TLR3) in macrophages exposed to major- and minor-group HRV and resulted in increased release of interferon- $\alpha$ . Furthermore, inhibiting Rac in HRV-exposed macrophages attenuated activation of the stress kinase p38 and release of the proinflammatory cytokine CCL2, but inhibiting Rac did not affect release of the proinflammatory cytokine CCL5. These findings suggest that Rac is an important regulator in establishing the inflammatory microenvironment that is initiated in the human airway upon exposure to rhinovirus.

711

**Regulation of the Rac activator Tiam1 by aPKC phosphorylation.**

*T. Watanabe<sup>1</sup>, K. Matsuzawa<sup>1</sup>, S. Wang<sup>2</sup>, T. Matsui<sup>1</sup>, M. Kakeno<sup>1</sup>, K. Kaibuchi<sup>1</sup>; <sup>1</sup>Nagoya University, Nagoya, Japan, <sup>2</sup>Mie University, Tsu, Japan*

The establishment and maintenance of cell polarity is fundamental to many biological processes, both physiological and pathological. It is now understood that the Rho family GTPases with several groups of evolutionarily conserved polarity proteins, such as the Par complex, comprise the core of the intrinsic cell polarization machinery. We, and others, have shown that the Par complex, consisting of Par3, Par6 and aPKC, functionally interacts with the

Rac activator Tiam1, by direct interaction through Par3, to control cell polarization in various cell types and contexts. However, it remains unknown how the Par complex regulates Tiam1. Here, we report that Tiam1 is a substrate of aPKC. Phosphorylation sites were mapped to the inhibitory N-terminal region of Tiam1. We also found that this N-terminus binds to the adjacent PHnCCEx as well as the DPH domains in the C-terminus, which are responsible for Par3-binding and GEF activity, respectively; these interactions were abrogated by aPKC-mediated phosphorylation of Tiam1. In N1E-115 cells, overexpression of phosphomimetic mutants induced formation of dorsal ruffles more efficiently than either WT or non-phosphorylatable mutants. Additionally, Tiam1 phosphorylation was necessary for Cdc42-dependent lamellipodia formation requiring the interplay between Tiam1 and the Par complex. Further, Tiam1 is phosphorylated by aPKC during growth factor signaling in multiple cell types in a timecourse consistent with Rac activation. Thus, it is attractive to consider regulated intramolecular associations as a regulator of Tiam1 activity.

712

**A naturally occurring dominant-negative splice variant regulates the responsiveness of Galphaq-regulated RhoGTPase activators.**

*L-L. Li<sup>1</sup>, S. Tossavainen<sup>1</sup>, T. Church<sup>1</sup>, V. Redai<sup>1</sup>, M. J. Courtney<sup>1</sup>; <sup>1</sup>Neurobiology, A. I. Virtanen Institute for Molecular Sciences, University of Eastern Finland, Kuopio, Finland*

RhoGTPases have a powerful influence on cell behavior and fate via regulation of transcription and cytoskeleton. Small GTPases such as members of Rho family are activated by exchange of bound GDP for GTP, which is mediated by guanine-nucleotide exchange factors (GEFs). Extracellular signals activate RhoGTPases via G protein coupled receptors. Galpha12/13-regulated GEFs are well studied, whereas less is known about the Galphaq-regulated neuronally-enriched GEFs implicated in schizophrenia and other diseases. We have found and characterized a novel Galphaq-regulated GEF splice variant. This variant is expressed in different cells and tissues. This variant is inactive as a Rho activator, but it also acts as a dominant negative inhibitor of related GEFs. Deletion analysis identifies the region sufficient for inhibition, which we reveal possesses an unexpected yet strong homophilic interaction which may be responsible for the inhibitory action. We propose a model whereby activation of Galphaq-regulated GEFs renders them competent to interact in trans with the inhibitory region of the variant. The variant may selectively target the activated GEF population, thereby sharpening the response curve to activation signals to generate a more all-or-none character than would otherwise occur.

713

**Fission yeast Rga7 is a Rho2 GAP that regulates cell integrity and morphology.**

*R. Martín-García<sup>1</sup>, P. M. Colf<sup>2</sup>, J. Cansado<sup>3</sup>, P. Perez<sup>1</sup>; <sup>1</sup>Instituto de Biología Funcional y Genómica, Consejo Superior de Investigaciones Científicas, Salamanca, Spain, <sup>2</sup>Microbiología y Genética, Universidad de Salamanca, Salamanca, Spain, <sup>3</sup>Genética y Microbiología, Universidad de Murcia, Murcia, Spain*

Rho GTPase-activating proteins (GAPs) are negative regulators that inactivate Rho GTPases. Rho GAPs are involved in the regulation of critical biological responses in eukaryotic cells such as cellular morphogenesis. Rga7 is one of the nine GAPs present in fission yeast. Rga7 localizes to the cell division site and to the cell tips. Mutant cells lacking Rga7 display aberrant morphology: cells are wider than wild-type, they have cytokinesis defects with higher percentage of cells having one or more septa and a percentage (13%) of dead cells in the population. We have found that Rga7 is a GAP for Rho2-GTPase which acts upstream of Pmk1, a MAPK involved in the regulation of fission yeast cell integrity and cell separation. However,

elimination of Rho2 only partially suppresses the cell death observed in cells lacking Rga7 and does not affect the cytokinesis phenotype. On the other hand, elimination of Pmk1 almost completely suppresses cell death caused by the lack of Rga7 and increases the proportion of cells with separation defects during cytokinesis. Two hybrid screening detected physical interaction between Rga7 and Rho2 and between Rga7 and Pek1, the MAPK kinase which acts as an activator of the Pmk1 MAPK signaling. All together, these data suggest that the function of Rga7 in fission yeast integrity and cytokinesis is performed through the modulation of the MAPK pathway, in both Rho2 dependent and independent ways.

714

### **Investigating Rho GTPase Pattern Formation During Single-Cell Wound Healing: The Role of RhoGAP1/8.**

*N. Davenport*<sup>1</sup>, *W. Bement*<sup>1,2,3</sup>; <sup>1</sup>Graduate Program in Cellular and Molecular Biology, University of Wisconsin-Madison, Madison, WI, <sup>2</sup>Department of Zoology, University of Wisconsin-Madison, Madison, WI, <sup>3</sup>Laboratory of Cell and Molecular Biology, University of Wisconsin-Madison, Madison, WI

The ability to respond to physical damage is an essential and evolutionarily conserved feature of single cells and tissues. The Rho family of GTPases has been shown to coordinate the cytoskeletal rearrangements needed to reestablish the integrity of the plasma membrane and underlying cortex in response to cell damage. The precision with which Rho and Cdc42 are activated and maintained in distinct activity zones throughout the healing process suggests the involvement of multiple Rho GTPase regulators at the wound. To date, a candidate screen for guanine nucleotide exchange factors (GEFs) and GTPase activating proteins (GAPs) involved in regulating Rho GTPase activity at the wound has identified a single wound regulator, Abr. By continuing the candidate screen, we have identified two additional GAPs, RhoGAP1 and RhoGAP8, as potential wound regulators. eGFP-tagged RhoGAP1 localizes between the zones of active Rho and Cdc42 in wounded *Xenopus laevis* oocytes where it may be acting as an enzymatic barrier to prevent Rho GTPase activity zone mixing during wound healing. Targeting is mediated by its C-terminal region which contains both a GAP domain and a proline-rich region. Further, overexpression of RhoGAP1 results in a reduction in active Rho at wounds. We have also discovered that RhoGAP1 and RhoGAP8 colocalize at wounds which, in addition to previously reported evidence of their interaction, suggests they may form a complex to regulate Rho GTPase activity.

### **DLC1 regulation by PP2A and Mek2 alters its RhoGAP activity.**

*A. Ravi*<sup>1</sup>, *C. Q. Pan*<sup>1,2</sup>, *A. Ravichandran*<sup>2</sup>, *B. C. Low*<sup>1,2</sup>; <sup>1</sup>Department of Biological Sciences, National University of Singapore, Singapore, Singapore, <sup>2</sup>Mechanobiology Institute Singapore, Singapore, Singapore

Actin remodelling is essential to many dynamic cellular processes such as morphogenesis, motility, differentiation and endocytosis. These changes are controlled by Rho GTPases that cycle between the active GTP- and inactive GDP-bound forms, which in turn are tightly regulated by guanine nucleotide exchange factors (GEFs), GTPase activating protein (GAPs) and the guanine nucleotide dissociation inhibitor (GDIs). Deleted in Liver Cancer-1 (DLC1), is a bona fide tumor suppressor GTPase activating protein (GAP) acting preferentially on Rho. It is a multi-domain protein, consisting of N-terminal SAM domain, C-terminal START domain and the catalytic RhoGAP domain. This allows for its interaction with diverse cellular proteins, including FAK, Tensins and Talin, all of which are focal adhesion-associated proteins, as well as other scaffolding, regulatory proteins such as 14-3-3, EF1A1, and S100A10. As such, the tumor

suppressive function of DLC1 can be mediated in a GAP-dependent or GAP-independent manner. Interestingly, DLC1 also contains a serine-rich region which is a phosphorylation hot-spot and is thought to be modified downstream of several potential kinases such as Akt, RSK and PKC/PKD. Despite all these, the nature of DLC1s activation and inactivation remains largely unknown. Here we show that PP2A and Mek2, which are ubiquitous for regulation of many growth-related kinase signalling, can regulate the activation and inactivation of DLC1. Specifically, DLC1-PP2A interaction follows for a unique Mek2-dependent binding profile accompanied by changes in the active RhoA levels. The physiological significance and impacts on cell spreading and migration will be discussed.

**Analysis of a Rho GTPase centered interactome reveals complex regulation of neurite outgrowth.**

*L. M. Fusco<sup>1</sup>, M. Bagonis<sup>2</sup>, G. Danuse<sup>2</sup>, O. Pertz<sup>1</sup>; <sup>1</sup>Department of Biomedicine, University of Basel, Basel, Switzerland, <sup>2</sup>Cell Biology, Harvard Medical School, Boston, MA*

Rho GTPases are key regulators of the actin, adhesion, and microtubule dynamics that allow complex morphogenetic events such as neurite outgrowth to occur. Rho GTPases are molecular switches that cycle between an active and an inactive state, which is regulated by two protein families: the guanine nucleotide exchange factors (GEFs) and the GTPase activating proteins (GAPs). Upon activation, Rho GTPases interact and regulate the activity of different effector proteins contributing to cellular responses. Classical loss of function experiments, using dominant negative (DN) constructs, have suggested that the Rho GTPases Rac1 and Cdc42 regulate neurite extension, whereas RhoA controls growth cone collapse and neurite retraction. Based on our recent analysis of the neurite proteome (1), we used a bioinformatic approach to identify a potential Rho GTPase centered, neurite-localized interactome. This interactome consisted of a surprisingly high number of GEFs, GAPs and effectors as well as upstream and downstream interactors (220 proteins total). To explore the significance of this complexity we performed an RNA interference screen. Intriguingly, loss of function of different components of this interactome led to more subtle phenotypes as compared to Rho GTPase DN mutants. A more complete understanding of these phenotypes required timelapse analysis of the neurite outgrowth dynamics and high resolution analysis of the F-actin and microtubule cytoskeleton. For example, RhoA knock down (KD) leads to longer neurites because of loss of growth cone collapse events. High resolution, quantitative analysis of the growth cone also reveals that RhoA loss of function leads to an increase in F-actin content in filopodia. Surprisingly, Cdc42 loss of function also leads to a loss of growth cone collapse, but unlike RhoA, exhibits diminished F-actin content in filopodia. Loss of function in response to KD of different GEFs, GAPs and effectors affected specific morphodynamic cell behaviors (neurite initiation, elongation, collapse, etc.), but also had an impact on subtle filopodium function (F-actin content, filopodia number, etc). These results are consistent with a scenario in which different signaling modules consisting of specific GEFs, GAPs, Rho GTPases and effectors co-operate to regulate specific neurite subfunctions in time and space to fine tune the neurite outgrowth process. This is in accordance with the complexity of spatio-temporal Rho GTPase signaling recently uncovered using FRET biosensors (2). Quantitative computer vision techniques will be necessary to appropriately analyze these complex phenotypes and have the potential to produce integrated models of spatio-temporal Rho GTPase signaling.

**Central role of the exchange factor GEF-H1 in TNF- $\alpha$ -induced sequential activation of Rac, ADAM17/TACE and RhoA in tubular epithelial cells.**

*F. Waheed<sup>1,2</sup>, Q. Dan<sup>1</sup>, Y. Zhang<sup>1</sup>, P. Speight<sup>1</sup>, A. Kapus<sup>1,2</sup>, K. Szaszi<sup>1,2</sup>; <sup>1</sup>Li Ka Shing Knowledge Institute, St. Michael's Hospital, Toronto, ON, Canada, <sup>2</sup>Surgery, University of Toronto, Toronto, ON, Canada*

The Rho family small GTPases, RhoA and Rac, are key regulators of the cytoskeleton, and affect a variety of vital cellular functions, including growth, adhesion, polarity and migration. We have previously shown, in tubular epithelial cells, that the pleiotropic pro-inflammatory cytokine Tumour Necrosis Factor- $\alpha$  (TNF- $\alpha$ ) activates RhoA through the Guanine Nucleotide Exchange Factor GEF-H1. Activation of GEF-H1 requires phosphorylation on its Thr 678 residue by the Extracellular Signal Regulated Kinase (ERK). ERK in turn is stimulated by TNF- $\alpha$ -induced transactivation of the Epidermal Growth Factor Receptor (EGFR), which is a key step in mediating RhoA activation, and cytoskeleton and junction remodelling. The aim of the current study was to explore the mechanisms through which TNF- $\alpha$  activates the EGFR.

We performed our studies in the proximal tubule epithelial cell line LLC-PK1. Using an enzyme activity assay with a fluorogenic substrate we show that TNF- $\alpha$  stimulates TACE/ADAM17. TACE silencing using specific siRNA prevented TNF- $\alpha$ -induced activation of the EGFR/ERK pathway. In search for the underlying mechanism, we found that TACE activation is mediated by the MAP kinase p38, which in turn is activated through the small GTPase Rac. Using affinity pull down assays to follow Rac and GEF-H1 activation (GST-PBD and GST-Rac (G15A) pull downs, respectively), we found that TNF- $\alpha$  activates Rac through the exchange factor GEF-H1. Thus, TNF- $\alpha$  stimulates both Rac and RhoA through the exchange factor GEF-H1. However, although EGFR and ERK-dependent phosphorylation at the T678 site of GEF-H1 is a prerequisite for stimulation of RhoA, it is not required for Rac activation. In contrast, GEF-H1 mediated-Rac activation is upstream from the TACE/EGFR/ERK pathway and requires phosphorylation at the S885 site on GEF-H1. Thus, the Rac- and RhoA-specific exchange activities of GEF-H1 are regulated through different phosphorylation sites. Moreover, GEF-H1-mediated Rac activation controls the EGFR/ERK pathway and the downstream RhoA activation. Together these findings provide a novel mechanism to explain the hierarchical activation of Rac and RhoA by TNF- $\alpha$ . Such a mechanism could be key in coordinating GEF function and fine-tuning Rac and RhoA activation.

718

**High-Content Combinatorial RNAi Screens Reveal the Regulation of Cytokinesis by Rho-family GTPase Signalling Networks in Drosophila.**

*L. Evans<sup>1</sup>, C. Bakal<sup>1</sup>; <sup>1</sup>The Institute of Cancer Research, London, United Kingdom*

There is currently little understanding of the architecture and dynamics of the signalling networks that coordinate the dramatic cytoskeletal rearrangements underpinning cytokinesis. While classical genetic screens have identified several core cytokinesis regulators, signalling networks are robust to single genetic perturbations, suggesting more genes can be discovered. We have shown that double RNAi screens can be used to identify novel regulators of diverse cellular processes that are not apparent in single genetic screens (Bakal et al, 2008; Arias-Garcia et al, 2012). Here I have developed a quantitative, high-throughout combinatorial screen to isolate novel regulators of cytokinesis.

In *Drosophila* cells, inhibition of the Rho-family GTPase Rho1 or its upstream activators (RacGAP50C and Pebble) results in cytokinesis failure and the generation of multinucleate cells

due to defects in contractile ring assembly and ingression. I have completed double RNAi screens using libraries targeting *Drosophila* Rho-family GTP Exchange Factors (GEFs) or GTPase Activating Proteins (GAPs), as well as kinases/phosphatases in wild type cells or those sensitised with Rho1, RacGAP50C, or Pebble RNAi, totalling 3,264 genetic combinations. Within the screens each gene is targeted in duplicate or quadruplicate by 2-5 independent dsRNA amplicons. High throughput microscopy collects 40-160 images (30-90 cells per image) per treatment, and image analysis algorithms are used to assign a quantitative multidimensional signature describing cell shape to each combination. Measurement of multiple (9) morphology features allows regulators of cell shape to be identified independent of cytokinesis defects.

Here I will discuss how using combinatorial screening I have identified RhoGAP16F and RhoGAP54D as putative regulators of cytokinesis. Neither RhoGAP16F or RhoGAP54D was identified in single knockdown screens as contributing to cytokinesis. However inhibition of RhoGAP16F increased the number of multinucleate cells in Pebble or RacGAP50C deficient backgrounds. Conversely, knockdown of RhoGAP54D weakly suppresses the cytokinesis failure that occurs following inhibition of Pebble or RacGAP50C by RNAi. Both genes are poorly characterized, but we have previously used computational methods to predict that RhoGAP16F and RhoGAP54D are GAPs for Rac-type GTPases (Nir et al., Genome Res 2010). We hypothesize that these genes may normally play a role in regulating Rac-driven cortical tension whose inhibition impacts cytokinesis only when Rho1 levels are suppressed (Loria et al, 2012).

Analysis of kinase/phosphatase screen data is ongoing. Extensive genetic and biochemical validation of all screen hits will then be performed. Finally, one goal of these studies is to generate a comprehensive network model describing the architecture and dynamics of signalling during cytokinesis.

### **Rho A signaling contributes to simvastatin-induced osteogenesis in bone marrow mesenchymal stem cells.**

*I-C. Tai<sup>1,2</sup>, Y-H. Wang<sup>2</sup>, J-K. Chang<sup>2,3</sup>, M-L. Ho<sup>2,4</sup>; <sup>1</sup>Graduate Institute of Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan, <sup>2</sup>Orthopaedic Research Center, College of Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan, <sup>3</sup>Department of Orthopedics, Kaohsiung Municipal Ta-Tung Hospital, Kaohsiung, Taiwan, <sup>4</sup>Department of Physiology, College of Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan*

Statins, 3-Hydroxy-3-methylglutaryl-coenzyme A (HMG-CoA) reductase inhibitors, reduce cholesterol synthesis and prevent cardiovascular disease. They also have been found to inhibit prenylation of Rho proteins in recent decade. Previous reports showed that statins inhibited protein prenylation and decreased the active form of RhoA in osteoclasts. Others reports indicated that statins inhibited protein prenylation but increased the active form of RhoA in human erythroleukemia cells. Therefore, the role of statins regulates RhoA activity remains unclear. Rho GTPases act as molecular switches to regulate mesenchymal stem cell differentiation. Previous study showed that transfected constitutively active-form of RhoA into human mesenchymal stem cells (hMSCs) which leded osteogenesis. On the other hand, dominant negative RhoA leded adipogenesis. Rho GTPases play a significant role in regulating cytoskeletal dynamics and have been shown to be crucial for cell proliferation and differentiation. According to the description above, we want to investigate whether simvastatin (SIM) induced osteogenesis through RhoA signaling and further altering the actin cytoskeleton contributes and increasing the cellular tension within BMSCs. For all experiments, mesenchymal stem cells, D1, were treated with or without simvastatin (SIM) in osteo-induction

medium. The SIM 0.5 and 1uM appeared to alter cytoskeletal organization at day 2. And SIM 1uM enhanced the osteogenic gene expressions of Runt-related transcription factor 2 (Runx-2), bone morphogenetic protein 2 (BMP-2), Alkaline phosphatase (ALP), osteocalcin (OC) and dose-dependently increased the mineralization at day 5 in D1cells culture. We further found that SIM 1uM sustainably increased active-form RhoA level at day2 and day3. In order to investigate the role of RhoA in osteogenesis, we transfect the constitutive active and dominate negative form RhoA in D1 cells. After transfect the constitutive active form RhoA increased the effect of mineralization rather than transfect dominate negative form RhoA. Blebbistatin, selectively inhibits the ATPase function of nonmuscle myosin II, 10uM significantly decreased the SIM-induced mineralization at day 5 in D1cell culture. We summarized that SIM enhanced osteogenesis through activation of RhoA signal. And tension released by Blebbistatin significantly inhibited SIM-induced osteogenesis. We suggest RhoA signaling might contribute to SIM-enhanced osteogenesis in mBMSCs

### **Mechanical Force on ICAM-1 Leads to RhoA-Mediated Cytoskeletal Changes in Endothelial Cells.**

*E. C. Lessey<sup>1</sup>, R. Superfine<sup>2</sup>, K. Burridge<sup>1</sup>; <sup>1</sup>Department of Cell Biology & Physiology, University of North Carolina at Chapel Hill, Chapel Hill, NC, <sup>2</sup>Department of Physics and Astronomy, University of North Carolina at Chapel Hill, Chapel Hill, NC*

RhoA-mediated cytoskeletal rearrangements in endothelial cells (ECs) play an active role in transendothelial cell migration (TEM), a normal physiological process in which leukocytes are recruited from the blood circulation into tissues. While much has been learned about RhoA signaling pathways downstream from ICAM-1 in ECs, little is known about the consequences of the tractional forces that leukocytes generate on ECs as they migrate over the surface before TEM. We have found that after applying mechanical forces to ICAM-1 clusters, there is enhanced RhoA signaling and cellular reinforcement compared to ICAM-1 clustering alone. Using the RhoA activity assay, we have determined ICAM-1 clustering alone leads to ~1.75 fold increase in RhoA activity over untreated cells, whereas the addition of force leads to ~2.5 fold higher RhoA activation over control. There is a ~21.5 fold increase in myosin light chain phosphorylation with force over control compared with a ~1.5 fold increase over control with clustering alone. We observe a 26% increase in RhoA-dependent cellular stiffening measured by pulling on ICAM-1 clusters with magnetic tweezers. We have confirmed the cytoplasmic tail of ICAM-1 is required for the observed findings. These changes may assist in downstream leukocyte TEM. Further exploring how ECs respond to forces generated by leukocytes on ICAM-1 will contribute to our understanding of inflammatory diseases where leukocyte TEM correlates with disease progression, such as atherosclerosis, ischemic cardiomyopathy, and ischemia reperfusion injury.

### **Rho/Rho kinase signaling is involved in cAMP-regulated amylase release in rat parotid acinar cells.**

*T. Narita<sup>1</sup>, H. Tsuchiya<sup>1</sup>, T. Konno<sup>1</sup>, H. Sugiya<sup>1</sup>; <sup>1</sup>Lab of Veterinary Biochemistry, Nihon University College of Bioresource Sciences, Fujisawa, Japan*

Rho family of proteins is a member of Ras superfamily and functions as molecular switches cycling between a GDP-bound inactivated state and GTP-bound activated state. The active Rho has been demonstrated to be involved in cell functions including migration, growth and differentiation. In rat parotid acinar cells, stimulation of  $\beta$ -adrenergic receptors provokes an

increase in intracellular cAMP level followed by the activation of protein kinase A (PKA) without an increase in intracellular  $\text{Ca}^{2+}$ , resulting in exocytotic release of amylase. We investigated the involvement of Rho in cAMP-dependent amylase release. A protein band ADP-ribosylated by *Clostridium botulinum* C3, a well known inhibitor of Rho function via ADP-ribosylation of Rho, was detected in rat parotid acinar cells. The same protein band was crossreacted with anti-RhoA antibody. C3 exoenzyme blocked the cAMP-induced amylase release in streptolysin O-permeabilized acinar cells. RhoA was activated by the  $\beta$ -agonist isoproterenol in a time-dependent manner. The isoproterenol-induced RhoA activation was inhibited by the inhibitor of PKA. The inhibitor of Rho kinase, which is activated by active Rho, Y-27632, partially inhibited the isoproterenol-induced and dibutyryl cAMP-induced amylase release. F-action coating of secretory granules observed in isoproterenol-stimulated cells was disturbed by the treatment of Y-27632. These observations suggest that RhoA/ROCK signaling is involved in exocytosis of amylase induced by  $\beta$ -adrenergic receptor activation in rat parotid acinar cells.

## Regulatory and Noncoding RNAs

722

### Identification and Characterization of Novel Genes Required for miRNA Activity in *Drosophila melanogaster*.

J. Erickson<sup>1</sup>, C. Gillmore<sup>1</sup>, C. A. Reinke<sup>1</sup>; <sup>1</sup>Biology, Linfield College, McMinnville, OR

MicroRNAs (miRNAs) are small (~22nt), non-coding RNAs essential for homeostasis and development in plants and animals. Primary miRNAs are transcribed from genomic DNA and sequentially processed into single-stranded mature miRNAs. Mature miRNAs interact with the miRNA-induced silencing complex (miRISC) and bind to the 3'UTR of target mRNAs via Watson-Crick base pairing, to silence target messages. Functional mature miRNAs are regulated at multiple stages of biogenesis and maturation. While several key molecules in the miRNA pathway have been elucidated, identification and characterization of regulatory and downstream factors is ongoing.

To discern the molecular mechanisms of miRNA function *in vivo*, a forward genetic screen was conducted using *Drosophila melanogaster* to identify novel genes required for miRNA activity. EMS mutagenesis was followed by the isolation of mutants with disrupted miRNA activity as visualized by a change in the expression of an eye-specific GFP reporter fused to the 3'UTR of the *Bearded* gene, which is regulated by multiple miRNAs in the *Drosophila* eye. Mitotic clones were generated in the *Drosophila* eye using FLP/FRT, and mutants with altered levels of GFP fluorescence relative to background (and hence putative altered miRNA activity) were recovered. The screen yielded 25 novel alleles of core components of the miRNA pathway, including alleles of *Drosha*, *Pasha*, *Dicer-1* and *Ago1*. The isolation of previously characterized miRNA pathway genes demonstrates the efficacy of our approach. Additional sensors of miRNA activity reveal unique requirements for sensor silencing. In addition to the identification of 25 novel alleles of core components of the miRNA pathway, ~20 mutant lines demonstrating altered miRNA sensor expression were isolated. Our lab is identifying genes whose alteration leads to the disruption of miRNA-mediated silencing using a combination of recombination mapping with molecularly defined P-element insertions and deficiency mapping. The role of these genes in miRNA activity will be characterized through the analysis of miRNA pathway intermediates in our mutant lines.

723

**MvU620 plays a role in the release of transcripts from storage and prevention of degradation during development of the male gametophyte of *Marsilea vestita*.**C. M. Van der Weele<sup>1</sup>, S. M. Wolniak<sup>1</sup>; <sup>1</sup>Cell Biology & Molecular Genetics, University of Maryland-College Park, College Park, MD

The male gametophyte of *Marsilea vestita* starts its development from a single cell stored as a dried microspore. Upon hydration the gametophyte initiates a spatially and temporally precise developmental program that first goes through a division phase in 4 hours to make 7 sterile cells and 32 spermatids. When the divisions are completed, development switches to a maturation phase in which each spermatid forms a complex motile apparatus. The development of the gametophyte is completed in 10-11 hours with the release of multiciliated male gametes. Previous research has shown that development in the gametophyte does not rely on new transcription but utilizes RNA that is stored in the dry microspore and that RNA processing is necessary for translation essential for development. Furthermore, the polyamine spermidine was shown to play a role in the release of transcripts from storage, and uncontrolled release caused aberrant development. MvU620 is a RNA binding protein with a single RRM1 domain that binds to U1A/U2B and has sequence homology to Rbp1. In RNAi knockdowns, a dominant phenotype is the lack of proper maturation after the division phase has ended. A reduction of acetylated alpha tubulin, lack of a microtubule ribbon, fewer and mislocalized basal bodies as well as misshapen or collapsed nuclei are indicative of a multifaceted role for MvU620 in post-transcriptional regulation. MvU620 has at least 4 splice forms, and RT analysis, morphological analysis after RNAi knockdowns, and *in situ* hybridizations with probes for shared or isoform-specific sequences showed temporal and spatial differences in abundance and distribution among isoforms. QPCR analysis on RNAi knockdowns showed that one of the shorter isoforms is regulating the presence of a longer isoform, perhaps through alternative splicing. QPCR analysis of several transcripts affected by MvU620 proteins showed an increase in abundance in the knockdown at 2 hours but reduction at 4 hours, which indicates an early release from storage but also precocious degradation. PCR analysis on RNA isolates showed the presence of antisense DNA matching these transcripts. Deep sequencing analysis of untreated spores at different times suggest that this antisense DNA becomes detectable with the appearance of MvU620 transcript isoforms. MvU 620 encodes a small family of RNA-binding proteins that play multiple roles in the post-transcriptional regulation of development in these rapidly maturing spermatids. Supported by NSF grant 0842525 to SMW.

**Alternative polyadenylation of Hsp70.3: Identification of regulatory RNA binding proteins.**L. Smith<sup>1</sup>, W. Paulding<sup>2</sup>, A. Roessler<sup>1</sup>, A. Gabanic<sup>1</sup>, M. Kelley<sup>1</sup>, L. Haar<sup>3</sup>, M. McGuinness<sup>3</sup>, W. K. Jones<sup>3</sup>, M. Tranter<sup>1</sup>; <sup>1</sup>Division of Cardiovascular Diseases, University of Cincinnati College of Medicine, Cincinnati, OH, <sup>2</sup>Dept. of Biology, Xavier University, Cincinnati, OH, <sup>3</sup>Dept. of Pharmacology & Cell Biophysics, University of Cincinnati College of Medicine, Cincinnati, OH

Heat shock protein 70.3 (Hsp70.3) expression increases in response to cellular stress and plays a cytoprotective role. It has been shown that increased expression of Hsp70.3 in the heart is protective against ischemia/reperfusion injury (myocardial infarction). Recent work by our lab shows that Hsp70.3 expression is controlled through coordinated post-transcriptional regulation by miRNAs and alternative polyadenylation (APA). APA-mediated shortening of the Hsp70.3 3'-untranslated region (3'UTR) facilitates increased protein expression following cell stress via enhanced mRNA stability, removal of regulatory miRNA binding sites, and enhanced polyribosome loading. In this work, we sought to identify the RNA binding proteins (RBPs) that mediate APA of Hsp70.3 through interactions with the 3'UTR of the Hsp70.3 mRNA. To do this,

the 3'UTR sequence of Hsp70.3 mRNA was randomly biotinylated using in vitro transcription and incubated with protein extract from HL-1 cardiac myocyte cells following control or treatment with one hour heat shock (HS); a condition shown to induce APA Hsp70.3 as observed in the in vivo heart. RNA bound proteins were then co-precipitated with the biotinylated RNA using avidin coated magnetic beads and identified using mass spectrometry. Our results identified a total of 45 known RBPs interacting with the Hsp70.3 3'UTR. Of these, 26 RBPs were found to associate with the Hsp70.3 3'UTR during both control and HS conditions, including RBPs previously indicated to play a role in APA and/or mRNA degradation as well as RBPs whose function remains unknown. In addition, 9 unique RBPs were found to bind only under control conditions, whereas 10 unique RBPs were found to bind only after HS stress. These results represent an important first step in characterizing the proteins that associate with the Hsp70.3 3'UTR and allow for ongoing and future investigation into the functional role of the identified RBPs in APA and post-transcriptional control of Hsp70.3 gene expression. A mechanistic understanding of how these RBPs contribute to the regulation of Hsp70.3 gene expression will enhance our understanding of APA as a global modulator of gene expression.

#### Identification and validation of miRNA-directed cleavage targets using omics approach.

J. Park<sup>1</sup>, J-W. Nam<sup>2</sup>, S. Ahn<sup>3</sup>, S. Kim<sup>1</sup>, J. Lee<sup>3</sup>, C. Shin<sup>1</sup>; <sup>1</sup>Department of Agricultural Biotechnology, Seoul National University, Seoul, Korea, <sup>2</sup>Department of Biology, Massachusetts Institute of Technology, Whitehead Institute for Biomedical Research, Cambridge, MA, <sup>3</sup>School of Biological Sciences, Research Center for Functional Cellulomics, Institute of Molecular Biology and Genetics, Seoul, Korea

MicroRNAs (miRNA), discovered in *C. elegans*, are short non-coding RNAs that bind and regulate the expression of target mRNAs in plants and animals. *C. elegans* miRNAs bind to partially complementary sequences in the 3' untranslated region of the target mRNA, which results in translational repression through mRNA destabilization. The high-throughput sequencing of RNA cleavage fragments was performed to directly detect cleaved miRNA targets in *C. elegans*. Based on this analysis, *mir-249* was identified as a potential miRNA that regulates a *zk637.6* that is paralogous to *asna-1* (*zk637.5*) by cleavage mechanism with extensive, evolutionary conserved complementarity. Additionally, we validated *mir-249* directed cleavage of the *zk637.6* by a gene-specific 5' rapid amplification of cDNA ends and observed notable difference in expression of *zk637.6* in wild-type versus *mir-249* mutant *C. elegans* by quantitative real-time PCR. Furthermore, the expression of *zk637.6* was strongly dependent on the expression of *mir-249*, that is, the higher expression of *mir-249* in early stage results in stronger repression of *zk637.6* expression. These findings may lead to a better understanding of the biological roles of miRNAs in *C. elegans*. Funding Source: This work was supported by Basic Science Research Program through the National Research Foundation of Korea (NRF) funded by the Ministry of Education, Science and Technology (2010-0022096), Republic of Korea. #### Expression of microRNAs 96 and 210 is associated with the production of fetal hemoglobin.

R. Ferreira<sup>1</sup>, C. Lanaro<sup>1</sup>, K. Y. Fertrin<sup>1</sup>, M. A. Bezerra<sup>2</sup>, A. S. Araújo<sup>2</sup>, F. F. Costa<sup>1</sup>, D. M. Albuquerque<sup>1</sup>; <sup>1</sup>Hematology and Hemotherapy Center, University of Campinas, Campinas, Brazil, <sup>2</sup>Hematology and Hemotherapy Center of Pernambuco, Recife, Brazil

Beta thalassemia (BT) is an inherited hematologic disease characterized by reduced or absent synthesis of  $\beta$ -globin chain with compensatory  $\gamma$ -globin chain production resulting in higher fetal

hemoglobin (HbF), excess of  $\alpha$ -globin chains, hemolysis and ineffective erythropoiesis. MicroRNAs (miRs) have been described to participate in globin switching and can modulate transcriptional erythroid-specific regulators. Expression analyses of miRs 96 and 210 were performed on peripheral blood CD34<sup>+</sup> cell cultures from healthy controls (CON, n=4) and nontransfused BT intermedia patients (n=4). Cells were cultured in a liquid system stimulating erythropoiesis and collected after 7, 10 and 13 days for extraction of miR, transcription to cDNA and analysis by q-PCR. During BT erythroid differentiation, overall expression of miR-96 was decreased, reaching significance on day 13 when compared to CON cultures (0.316 $\pm$ 0.042 vs. 0.051 $\pm$ 0.030, respectively, p<0.05). Expression of miR-210 increased during erythroid differentiation in both cultures, and on day 13 this expression was significantly higher in BT than in CON cultures (0.996 $\pm$ 0.086 vs. 1.970 $\pm$ 0.130, respectively, p <0.05). This data suggest that miR-96 and miR-210 could be associated with increased levels of HbF observed in BT patients, agreeing with studies showing that knockdown of miR-96 and overexpression of miR-210 are associated with increased production of  $\gamma$ -globin. We performed in silico analysis and found that miR-210 targets two regions of the *KLF1* mRNA, a critical transcription factor involved in globin switching by directly activating  $\beta$ -globin and indirectly repressing  $\gamma$ -globin gene expression (free energy miRNA:mRNA hybridization = -31.7 and -30.1 kcal/mol, significance threshold under -20kcal/mol). Interestingly, in our BT cultures, *KLF1* expression was lower on days 10 and 13 when compared to CON cultures (1.159 $\pm$ 0.608 vs. 0.164 $\pm$ 0.087 and 1.360 $\pm$ 0.966 vs. 0.217 $\pm$ 0.081, respectively, p<0.05). A previous study showed that increased levels of *KLF1* can decrease  $\gamma$ -globin gene expression by inhibiting the interaction between the LCR (locus control region) and the  $\gamma$ -globin gene. Our data showing concurrent decrease of *KLF1* and miR-96 along with upregulation of miR-210 suggest that this regulatory mechanism may affect  $\gamma$ -globin expression. Taken together, these findings contribute to the understanding of HbF production and to the development of new therapeutic strategies for hemoglobinopathies. #### **An association between microRNA-155 and the Hp genotype in patients with sickle cell anemia.**

M. N. Santos<sup>1</sup>, R. Ferreira<sup>2</sup>, D. M. Albuquerque<sup>2</sup>, R. T. Oliveira<sup>1</sup>, M. A. Bezerra<sup>3</sup>, C. Lanaro<sup>2</sup>, T. R. Zaccariotto<sup>1</sup>, A. S. Araújo<sup>3</sup>, F. F. Costa<sup>2</sup>, M. H. Blotta<sup>1</sup>, M. F. Sonati<sup>1</sup>; <sup>1</sup>Department of Clinical Pathology, School of Medical Sciences, University of Campinas - Unicamp, Campinas, Brazil, <sup>2</sup>Hematology and Hemotherapy Center of Campinas, University of Campinas - Unicamp, Campinas, Brazil, <sup>3</sup>Hematology and Hemotherapy Center of Pernambuco, Recife, Brazil

Sickle cell anemia (SCA) is characterized by chronic inflammation with a very variable immune response that depends on multiple genetic and environmental factors. Haptoglobin (Hp) is an acute-phase protein with immunomodulatory and antioxidant properties whose basic function is to bind to free hemoglobin in the plasma and protect blood vessels from its oxidative effects. Two codominant alleles (HP1 and HP2) result in three main genotypes/phenotypes (Hp1-1, Hp2-1 and Hp2-2), which correspond to proteins with distinct physical, chemical and functional characteristics. MicroRNAs (miRs) are post-transcriptional modulators of gene expression and their role in infection, inflammation and cell differentiation, proliferation and apoptosis has been investigated. miR-155 is involved in red blood cell differentiation and also plays an important role in inflammation and immunity; however, there is a dearth of information in the literature about the expression of these molecules in SCA. The aim of this study was to investigate the expression profile of miR-155 in granulocytes and determine plasma levels of cytokines IL-1 $\beta$ , IL-6, IL-8 and TNF- $\alpha$  in SCA patients classified according to Hp genotype (Hp1-1, Hp2-1 and Hp2-2). Twelve patients of each Hp genotype (determined by allele-specific PCR), in steady state, were selected for the study. Cytokine plasma levels were determined by ELISA, and miR-

155 expression profile by q-PCR. The results showed that the miR-155 expression rate in granulocytes from patients with the Hp1-1 genotype was greater than the expression rate in Hp2-1 patients, which in turn was greater than that in Hp2-2 patients. The difference between the expression rates for Hp1-1 and Hp2-2 patients was statistically significant ( $p=0.002$ ). Interestingly, plasma TNF- $\alpha$  levels were higher in the Hp1-1 group than in the others but did not reach statistical significance. There were no statistically significant differences in plasma IL-1 $\beta$ , IL-6 and IL-8 levels between the different Hp genotypes. miR-155 is considered important for inflammatory activation of human myeloid cells and, when overexpressed in CD14<sup>+</sup> cells in peripheral blood, can lead to down-regulation of SHIP-1, an inhibitor of inflammation, and an increase in production of proinflammatory cytokines such as IL-6 and TNF- $\alpha$ . In agreement with this, our results suggest that miR-155 may be related to Hp genotype and may play a role in the inflammatory response in SCA patients. Financial support: FAPESP/CNPq/CAPE

### Regulation of Human Growth Hormone Receptor Expression by MicroRNAs.

S. Elzein<sup>1</sup>, C. G. Goodyer<sup>1</sup>; <sup>1</sup>Experimental Medicine, McGill University, Montreal, QC, Canada

MiRNAs are small (19-21nt) noncoding RNAs that play an important role in regulating gene expression primarily through targeting the 3'UTR of mRNAs and enhancing their degradation or inhibiting translation. In the last decade, a critical role for miRNAs has been demonstrated in many chronic diseases, including cancer.

The pleiotropic actions of Growth Hormone (GH) result from activation of its receptor (GHR) on target cells and the subsequent stimulation of multiple intracellular signaling pathways, leading to changes in gene expression, differentiation and metabolic activity. Clinical studies have associated over- or under-expression of GHR with effects on childhood growth, obesity, cancer and diabetes suggesting that GHR levels must be tightly regulated at every stage of life. Our previous studies have focused on 5'UTR (promoter) regulation of *GHR* gene expression. In the present study, we are mapping functional miRNA binding sites in the *GHR* 3'UTR.

We used multiple *in silico* prediction tools based on different algorithms to define putative miR-binding sites within the *GHR* 3'UTR and prioritized a subset based on conservation across several species, hybridization energy, published reports that link specific miRNAs to GHR-related physiological or pathophysiological activities, and the presence of parallel sites in GH/IGF axis-related genes. To test these sites, we created a Luc-*GHR* 3'UTR luciferase reporter vector and screened for miRNA activity: miR-16 ( $p<0.05$ ), miR-202 ( $p<0.01$ ), miR-129-5p ( $p<0.01$ ) and miR-142-3p ( $p<0.01$ ) showed significant inhibitory effects. Studies are ongoing to determine the specificity of their sites (site-directed mutagenesis) as well as to examine their effects on endogenous *GHR* mRNA (qPCR) and protein (western blot) expression levels. Future goals are to determine the role of these miRNAs in GHR-related pathophysiology and their potential use as therapeutic agents.

### Target RNAs Promote Release of Guide RNAs from Human Ago2.

N. De<sup>1</sup>, I. MacRae<sup>1</sup>; <sup>1</sup>The Scripps Research Institute, La Jolla, CA

Argonaute proteins bind small guide RNAs to form the functional core of RNA induced silencing complexes (RISCs), which mediate the silencing of complementary target RNAs. The details of small RNA biogenesis and mechanisms for loading into Argonaute proteins are well-studied,

however much less is known about how small RNAs are removed from Argonaute and degraded. Here we show that highly complementary target RNAs induce the release of guide RNAs from human RISC by destabilizing the interaction between Argonaute2 (Ago2) and the bound guide strand. This “unloading” activity can be enhanced by mismatches between the target and the 5' of the guide RNA and attenuated by mismatches to the 3' end of the guide. The introduction of 3' mismatches leads to more potent silencing of abundant mRNAs in mammalian cells. These findings may help to explain why the 3' ends of mammalian microRNAs (miRNA) rarely match their targets, suggest a mechanism for sequence-specific small RNA turnover and offer mechanistic insight for design of improved siRNAs.

### **The Crystal Structure of Human Argonaute2.**

*N. T. Schirle<sup>1</sup>, I. J. MacRae<sup>1</sup>; <sup>1</sup>The Scripps Research Institute, La Jolla, CA*

At the core of every RNA-Induced Silencing Complex (RISC) is an Argonaute protein that mediates RNA interference (RNAi) in eukaryotes. The 2.3Å crystal structure of human Argonaute2 (Ago2), the human “slicer” enzyme, bound to a heterogeneous pool of guide RNAs reveals a bilobed architecture with the guide RNA cradled in a hydrophilic central cleft between the two lobes. Nucleotides 2-6 of the guide RNA are arranged in an A-form configuration exposed to solvent for target recognition. An isoleucine intercalates between bases 6 and 7 to introduce a kink that disrupts helical stacking, which may facilitate product release or target recognition. Tandem tryptophans bound in two binding pockets located within the PIWI domain represent a likely interaction surface for tryptophan rich cofactors. These studies provide valuable insight into the mechanisms of eukaryotic RNAi.

731

### **Cyanobacterial DEAD-box RNA helicase: Autoregulation, RNA maturation and sRNA metabolism.**

*A. R. Rosana<sup>1</sup>, D. Chamot<sup>1</sup>, J. Georg<sup>2</sup>, W. Hess<sup>2</sup>, G. Espie<sup>3</sup>, G. Owttrim<sup>1</sup>; <sup>1</sup>Department of Biological Sciences, University of Alberta, Edmonton, AB, Canada, <sup>2</sup>Faculty of Biology, University of Freiburg, Freiburg, Germany, <sup>3</sup>Department of Biology, University of Toronto, Mississauga, ON, Canada*

DEAD-box RNA helicases are ubiquitous enzymes found in all domains of life that rearrange RNA secondary structure. They function in every aspect of RNA metabolism, frequently in response to abiotic stress. In the cyanobacterium *Synechocystis* sp. PCC 6803, expression of the cyanobacterial RNA helicase gene, *crhR*, is regulated in response to temperature fluctuation. Physiologically, CrhR inactivation dramatically affected the photosynthetic capacity and morphology of the mutant cells in response to temperature downshift. Analysis of the expression profile of the *crhR* dicistronic operon in wild type and Δ*crhR* cells indicated that CrhR autoregulates its own expression through a combination of transcript processing and temperature-dependent mRNA and protein stabilization mediated by dramatic temperature- and mutant-induced alteration of half-life. *crhR* inactivation resulted in unregulated accumulation of both transcript and protein while multiple transcripts detected in the mutant suggested defects in RNA processing and/or degradation. 5' RACE-RCA and immunoprecipitation analysis are ongoing to establish processing sites and potential RNases (RNase II/R, E, J) involved in transcript turnover and maturation. Furthermore, tiling arrays revealed that CrhR controls expression of a subset of small RNAs in *Synechocystis*. A model integrating the ability of CrhR in unwinding and annealing RNA with a role in gene regulation during environmental acclimation involving autoregulatory pathways and small regulatory RNAs will be presented.

## Epigenetics and Chromatin Remodeling

732

### Promoting neocentromere assembly in human cells.

L. P. Valente<sup>1</sup>, L. E. T. Jansen<sup>1</sup>; <sup>1</sup>Epigenetic Mechanisms Laboratory, Instituto Gulbenkian de Ciência, 2780-156 Oeiras, Portugal

In almost all eukaryotes, centromeres are propagated epigenetically. In order to understand how local sequence and chromatin features of the mammalian genome affect the creation and maintenance of a centromere we flanked a human centromere with loxP site-specific recombination sites by gene targeting. These sites are embedded within inactive selective markers that will be activated only upon successful Cre-mediated excision of the endogenous centromere of chromosome 4, creating a 170 megabase acentric chromosome. Stringent selection will allow for the recovery of centromere-depleted cells and for tracking the fate of the acentric chromosome. We anticipate one outcome to be the formation of neocentromeres. We will discuss the overall strategy and initial results of this assay in which we aim to determine the impact of chromosome context in the nucleation of human neocentromeres and to identify the key players involved in this process.

733

### The Sex-Determining Factor SRY Functions as a Male-Specific Genetic Modifier by Interacting and Modulating the Activities of Other Transcription Factors.

Y. Li<sup>1</sup>, C. Y-F. Lau<sup>1</sup>; <sup>1</sup>VA Medical Center, University of California San Francisco, San Francisco, CA

The SRY gene on the Y chromosome is responsible for switching on the male sex development during embryogenesis. SRY is a dual-function transcription factor capable of simultaneously repressing and activating genes involved in ovarian and testicular differentiation respectively. Numerous SRY interactive proteins, capable of forming transcription complexes with different transcriptional regulatory functions, have been identified. Although SRY is normally expressed at the time of sex determination in the embryonic gonad, its ectopic expression in non-gonadal tissues has been documented. Hence, it could modulate the gene expression program and exert a male-specific effect(s) on the development and physiology of affected tissues.

Using proteomic and promoter characterization strategies, we demonstrated that SRY is capable of interacting with a variety of transcription factors, such as SP1, SF1, PAX3 and NKX2-1, in vitro and in vivo. Domain mapping showed that the HMG box of SRY is responsible for such interactions with various domains of these transcription factors. To evaluate the effects of such SRY interactions, we demonstrated that SRY is capable of stimulating the transcriptional activities of SP1 and SF1 on MAOA and SOX9 gene respectively. SRY interactions with PAX3 and NKX2-1 result in suppression of their transactivation of the RET promoter in cultured cells. Hence, SRY is capable of stimulating or repressing the transactivation of its interacting transcription factors; thereby modulating the latter's gene regulatory programs. Significantly, SRY is a member of a family of SRY-box containing (SOX) transcription factors, which harbor a conserved HMG box, a presumed DNA-binding domain. Our observations suggest that the HMG box could also function as a protein-protein interacting domain. Importantly, SRY could compete with other SOX transcription factors, via such protein-interacting domain, in their complex formation. Indeed, we demonstrated that SRY could compete with SOX10 on its binding with PAX3 and NKX2-1, and inhibit SOX10 exacerbation of the transcriptional activities of these transcription factors. The present observations, collectively, suggest that the Y-encoded SRY can serve as a genetic modifier capable of

modulating the activities of other transcription factors and their respective gene regulatory programs, thereby exerting a male-specific effect(s) on the development and physiology of the affected tissues.

734

**The Mof Acetyltransferase is Required for JIL-1 H3S10 Kinase Stability in *Drosophila* Males.**

Y. Li<sup>1</sup>, W. Cai<sup>1</sup>, C. Wang<sup>1</sup>, H. Deng<sup>1</sup>, X. Bao<sup>1</sup>, W. Zhang<sup>1</sup>, J. Girton<sup>1</sup>, J. Johansen<sup>1</sup>, K. M. Johansen<sup>1</sup>; <sup>1</sup>Roy J. Carver Department of Biochemistry, Biophysics & Molecular Biology, Iowa State University, Ames, IA

Mof is a histone H4K16 acetyltransferase in both *Drosophila* and mammals. Mof, is a key component of the MSL (male specific lethal) dosage-compensation complex on the X-chromosome. However, Mof is also a member of the NSL (non-specific lethal) complex that is present in both sexes. The JIL-1 kinase localizes specifically to euchromatin interband regions of polytene chromosomes, is the kinase responsible for phosphorylation of histone H3S10 at interphase, and is up-regulated on the male X chromosome. However, it is not known how this localization is regulated or what causes JIL-1 to be enriched on the male X chromosome. To begin to address these issues and to study JIL-1's functional relationship to Mof we performed various combinations of double labelings of polytene chromosomes with JIL-1, Mof, H3S10ph, and H4K16ac antibodies. The results showed that JIL-1 and JIL-1 mediated H3S10 phosphorylation colocalize with Mof and H4K16 acetylation both on male and female chromosomes. We also performed RNAi-mediated knockdown of Mof using the Gal4-UAS system. Interestingly, we found that JIL-1 levels and localization were unaffected by Mof RNAi in females, but JIL-1 levels were substantially decreased in males. In contrast, loss of JIL-1 did not cause obvious changes to Mof or H4K16 acetylation localization or levels on polytene chromosomes. By analysis of a Mof partial loss-of-function mutant, *mof1*, we confirmed that a reduction of Mof acetyltransferase activity led to a substantial reduction of JIL-1 and H3S10 phosphorylation on polytene chromosomes in males. These levels could be restored by expression of Mof-LacI in the *mof1* mutant background indicating that the loss of JIL-1 indeed was caused by reduced Mof activity. Furthermore, applying a LacI tethering system we show that ectopic targeting of LacI-Mof induces enhanced H4K16 acetylation and recruitment of other MSL complex proteins, but not of JIL-1. Taken together, these results suggest that Mof acetyltransferase activity is necessary for stabilizing the JIL-1 kinase, but not for its chromosome localization in *Drosophila* males. Supported by NIH grant GM62916.

**Function of HP1 proteins as a component in kinetochore formation and its relation with chromosome instability.**

R. Gonzalez Barrios<sup>1</sup>, E. Soto-Reyes<sup>1</sup>, J. Mendoza Perez<sup>1</sup>, A. Lopez-Saavedra<sup>1</sup>, C. Castro H. <sup>1</sup>, L. Herrera<sup>1</sup>; <sup>1</sup>Unidad de Investigación Biomédica en Cáncer, Instituto Nacional de Cancerología (INCan)-Instituto de Investigaciones Biomédicas (IIB), Universidad Nacional Autónoma de México (UNAM), National Cancer Institute, Mexico City, Mexico

HP1 Family of proteins are involved in the formation and maintenance of chromatin higher order structure. In mammals there are known three isotypes (HP1 $\alpha$ , HP1 $\beta$  and HP1 $\gamma$ ). Recently, it has been proposed that HP1 may play an important roll in inner centromere establishment, generated by its interaction with HMis12 complex, (HMis12C) which is relevant in kinetochore formation and microtubule recognition which ensure correct chromosomal segregation. However, alterations in chromatin structure or loss in H3K9 methylation lead to a reduction of

the protein presence and changes of HP1 proteins localization to heterochromatin followed by chromosome instability. It has not been studied if this is mediated by loss of recruitment of HMis12C to the kinetochore and which is its relation with chromosomal instability generation. Thus, the aim of this study is to determine if alteration of HP1 proteins is capable of reducing HMis12C recruitment to the kinetochore. We elaborated transfections of constructions of HP1-GFP for each isotype in HCT116 cells and performed time-lapse to observe localization along cell cycle by confocal microscopy; in addition, we treated cells with TSA 1 $\mu$ M to analyze changes in HP1 localization. We used ChIP assay in satellite alpha and satellite 2 to determine presence of H3H9me3, HP1 proteins, CENPA, and HMis12 in HCT116 transfected cells with HP1-GFP and with Jmjd2b to observe the effect of the loss of H3K9me3 to HMis12C incorporation. We found that each isotype presents a different localization at interphase, but HP1 $\alpha$  and  $\beta$  are present at the centromere at this phase, also this localization is highly dynamic in mitosis where HP1 $\alpha$  is removed and HP1 $\beta$  is enriched at the chromosomes centromere. Treatment with TSA generates relocalization of HP1 proteins to pericentromeric chromatin and an increase of chromosome instability. Jmjd2b over-expression reduces HP1 presence at chromatin and also reduces HMis12 in mitosis. These results support another function of HP1 as a kinetochore partner leading to incorporation of HMis12 during cell division.

#### **A conformational switch in HP1 allows conditional activation and drives assembly of the minimal heterochromatin unit.**

*D. Canzio<sup>1</sup>, M. Liao<sup>1</sup>, N. Naber<sup>1</sup>, E. Pate<sup>2</sup>, A. Larson<sup>1</sup>, S. Wu<sup>1</sup>, R. Cooke<sup>1</sup>, P. Schuck<sup>3</sup>, G. Narlikar<sup>1</sup>; <sup>1</sup>Biochemistry & Biophysics, UCSF, San Francisco, CA, <sup>2</sup>Washington State University, Pullman, WA, <sup>3</sup>NIH, Bethesda, MD*

HP1 proteins play a central role in the assembly and spread of H3K9-methylated heterochromatin. HP1-mediated heterochromatin is critical for diverse nuclear processes ranging from gene silencing to chromosome segregation. Yet how HP1 proteins assemble on their methylated nucleosomal templates and how the resulting HP1-nucleosome complex is regulated are poorly understood. Here we show that binding of the major *S. pombe* HP1 protein, Swi6, to methylated nucleosomes drives a switch from an auto-inhibited state to a spreading competent state. In the auto-inhibited state, a histone mimic sequence in one Swi6 monomer blocks methyl mark recognition by the chromodomain of another monomer. Auto-inhibition is relieved by recognition of two template features, the H3K9 methyl mark and nucleosomal DNA. Single-particle reconstruction of the Swi6-nucleosome complex by cryo-EM reveals the architecture of the spreading-competent state in which two unbound chromodomain sticky ends are exposed. The conditional activation of Swi6 uncovered here is reminiscent of other auto-inhibition controlled molecular assemblies such as actin nucleation and opens up a new class of mechanisms to explain the diverse functions of HP1 proteins.

#### **Single-cell epigenetics reveals that cellular variations in histone acetylation predict cellular phenotypic variations.**

*A. Chambliss<sup>1,2</sup>, P-H. Wu<sup>1,2</sup>, D. Wirtz<sup>1,2</sup>; <sup>1</sup>Chemical & Biomolecular Engineering, Johns Hopkins University, Baltimore, MD, <sup>2</sup>Physical Sciences-Oncology Center and Institute for NanoBioTechnology, Johns Hopkins University, Baltimore, MD*

Even isogenic clonal cells in culture dishes, which provide cells with a biochemically and biophysically controlled environment, tend to display extremely large variations in properties such as morphology and cytoskeleton organization. Here we developed, tested, and validated a

new assay to measure global acetylation on histones H3 and H4 of individual cells and simultaneously measure, in the same cells, a wide range of cell phenotypic properties, including cell and nuclear morphology, cytoskeletal content and organization, cell-cycle phase, and chromosomal organization. These measurements show that isogenic clonal cells of similar DNA content and same cell-cycle phase still display large variations in H3 and H4 acetylation and that these epigenetic variations predict phenotypic variations, in particular nuclear size and actin cytoskeleton content and organization, but not cell size or cell shape. To demonstrate its versatility, this assay is also used to quantify the complex interplay between cell cycle, epigenetics, and phenotypic variations following pharmacological treatments at single-cell resolution.

738

**Nuclear IGF-1 receptor phosphorylates histone H3 and recruits chromatin remodeling factors.**

*D. Warsito<sup>1</sup>, S. Sjöström<sup>1</sup>, O. Larsson<sup>1</sup>, B. Sehat<sup>1</sup>; <sup>1</sup>Dept. Oncology-Pathology, Karolinska Institutet, Stockholm, Sweden*

Recent findings suggest that the insulin like growth factor 1 receptor (IGF-1R) can translocate from the plasma membrane into the cell nucleus. In the nucleus it was found to associate with regulatory genomic elements to induce transcription of oncogenes in highly malignant cells. Studies have also shown an enrichment of nuclear IGF-1R in highly aggressive tumours. The mechanism by which the nuclear translocation occurs and the mechanism of how nuclear IGF-1R mediates its function still remains elusive. In this study we aim to elucidate the role of nuclear IGF-1R regarding chromatin remodeling and its biological effect. We here show that nuclear IGF-1R associates with histone H3 and phosphorylates it in cancer cells. Phosphorylated histone H3 is recognized by histone acetyl transferases which acetylates the pre-phosphorylated histone H3. Acetylated histone H3 functions as a platform for the Brahma-related gene 1 chromatin remodeling factor where it can mediate its function. Taken together, this study show that IGF-1R can regulate histone modifications and chromatin dynamics in a more direct manner by phosphorylating histone H3. In contrast to previous studies, which focused on IGF-1R at the cell surface, we here show a new and novel function for IGF-1R in the cell nucleus. An increased knowledge about the role of nuclear IGF-1R would enable the development of novel cancer therapies.

739

**The N-terminal tail of the histone variant H3.3 is required for its early deposition into chromatin.**

*E. Delbarre<sup>1</sup>, K. Ivanauskiene<sup>1</sup>, T. Küntziger<sup>1</sup>, P. Collas<sup>1</sup>; <sup>1</sup>Stem Cell Epigenetics Laboratory, University of Oslo, Oslo, Norway*

Histone variant H3.3 is, in contrast to canonical H3.1 and H3.2, synthesized throughout the cell cycle and incorporated into nucleosomal chromatin in a replication-independent manner, notably at transcriptionally active sites. Despite recent identification of several H3.3 chaperones, the pathways of deposition of H3.3 into chromatin remain unclear. In our previous work, we have used transiently transfected primary cells to determine the behaviour of newly synthesized epitope-tagged H3.3. We show that exogenously expressed, newly synthesized H3.3 is recruited to promyelocytic leukemia protein (PML) bodies together with histone H4, in a DAXX dependent manner. PML bodies also contain other H3.3 chaperones including ATRX, ASF1A and HIRA, supporting a working model of DAXX-mediated targeting of (H3.3-H4) dimers to PML bodies, where (H3.3-H4) is available for deposition into chromatin by the distinct chaperones.

Here, we investigate the role of the N-terminal tail of H3.3 on the deposition of this histone variant into chromatin shortly after synthesis. We show that in the absence of the amino acid stretch (3-35), truncated exogenous H3.3 (referred to as H3.3[core]) is unable to incorporate into chromatin shortly after induction of expression. However, we find in fluorescence recovery after photobleaching experiments that H3.3[core] is targeted (together with H4) by DAXX to PML bodies, where it resides for several days as a highly mobile pool, whereas full-length H3.3 is fully incorporated into chromatin in a much shorter time frame. HIRA and ASF1A are also found at PML bodies enriched in H3.3[core]. Deletion of residues 3 to 26 does not affect the kinetics of H3.3 deposition into chromatin, narrowing a critical domain of the N-terminal tail of H3.3, containing post-translationally modifiable residues which may be important for chromatin deposition. Using deletion and single amino acid mutation analysis, we are scanning this region to identify the critical residue(s) necessary for deposition of H3.3 shortly after its synthesis, and the chaperones involved in this process.

740

**ATM-mediated phosphorylation of the chromatin remodeling enzyme BRG1 modulates DNA double-strand break repair.**

S. Kwon<sup>1</sup>, D. Chung<sup>1</sup>, J. Park<sup>1</sup>, E. Park<sup>1</sup>, S. Lee<sup>1</sup>, H. Lee<sup>1</sup>, S. Lee<sup>1</sup>, J. Kwon<sup>1</sup>; <sup>1</sup>Department of Life Science, Ewha Womans University, Seoul, Korea

Although ATP-dependent chromatin remodeling complexes have been implicated in DNA double-strand break (DSB) repair and damage responses, the regulatory mechanisms that control their functions are largely unknown. Here, we show that ATM mediates the phosphorylation of BRG1, the catalytic ATPase of the SWI/SNF complex, at Ser-721 rapidly after DNA damage. Phosphorylated BRG1 binds gamma-H2AX-containing nucleosomes to form the repair foci. The Ser-721 phosphorylation of BRG1 is critical for binding gamma-H2AX-containing nucleosomes and stimulating gamma-H2AX formation and DSB repair. While the bromodomain of BRG1, which recognizes acetylated histones, is essential for DSB repair and transcription, the phosphorylation of Ser-721 is dispensable for transcriptional activity. This work establishes BRG1 as a novel and functional ATM substrate and reveals that the ATM-mediated phosphorylation of this chromatin-remodeling enzyme not only modulates DNA repair but also defines the specificity for DNA repair distinct from transcription.

741

**The SCF<sup>Slimb</sup> ubiquitin-ligase regulates Cap-H2 levels to suppress condensin II-mediated nuclear reorganization.**

D. W. Buster<sup>1</sup>, S. G. Danie<sup>2</sup>, H. Q. Nguyen<sup>3</sup>, S. L. Windler<sup>4</sup>, M. Peterson<sup>3</sup>, M. Roberts<sup>2</sup>, J. H. Meserve<sup>2</sup>, T. Hart<sup>2</sup>, J. E. Klebba<sup>1</sup>, D. Bilder<sup>4</sup>, G. Bosco<sup>3</sup>, G. C. Rogers<sup>1</sup>; <sup>1</sup>Cellular and Molecular Medicine, University of Arizona, Tucson, AZ, <sup>2</sup>Molecular and Cellular Biology, University of Arizona, Tucson, AZ, <sup>3</sup>Genetics, Geisel School of Medicine at Dartmouth, Hanover, NH, <sup>4</sup>Molecular and Cellular Biology, University of California at Berkeley, Berkeley, CA

Condensin complexes play vital roles in chromosome condensation during mitosis and meiosis. Condensin II uniquely localizes to chromatin throughout the cell cycle, and in addition to its mitotic duties, modulates chromosome organization and gene expression during interphase. Mitotic condensin activity is regulated by phosphorylation, but mechanisms that regulate condensin II during interphase are unknown. Here, we report the first such mechanism: condensin II is inactivated when its subunit, Cap-H2, is targeted for degradation by the SCF<sup>Slimb</sup> ubiquitin-ligase complex, and disruption of this process dramatically changes interphase chromatin organization. Inhibition of SCF<sup>Slimb</sup> function reorganizes interphase chromosomes

into dense, compact domains and disrupts homolog pairing in both cultured *Drosophila* cells and *in vivo*, but is rescued by condensin II inactivation. Furthermore, Cap-H2 stabilization distorts nuclear envelopes and misregulates localization of Cid/CENP-A on interphase chromosomes. Therefore, SCF<sup>Slimb</sup>-mediated down-regulation of condensin II is required to maintain proper organization and morphology of the interphase nucleus.

742

### Epigenetic control of the Osterix gene promoter activity during mesenchymal cell differentiation.

H. Sepulveda<sup>1</sup>, C. Rojas<sup>1</sup>, M. Montecino<sup>1</sup>; <sup>1</sup>Center for Biomedical Research, Andres Bello University, Santiago, Chile

Osterix (Osx) is a key regulator of osteoblast differentiation as it controls transcription of a number of bone-phenotypic genes. Here, we investigate epigenetic mechanisms that govern Osx gene transcription during the engagement of pluripotent mesenchymal cells to the osteoblast lineage. Epigenetic posttranslational modifications and binding of regulatory proteins to chromatin were determined by chromatin immunoprecipitation. DNA methylation was determined by cleavage with methylation-sensitive restriction endonucleases and immunoprecipitation of methylated DNA. Changes in Osx mRNA were assessed by RT-qPCR. The effect of the histone-deacetylase (HDAC) inhibitor TSA was verified by Western blot. We find that the Osx gene promoter in osteoblastic cells exhibits histone modifications normally associated with transcriptional activity (H3Ac/H3K4me3) together with minimal DNA methylation. In contrast, non-bone cells show histone modifications associated with transcriptional repression (H3K9me3/H3K27me3) and elevated DNA methylation. Interestingly, uncommitted pluripotent mesenchymal cells show a combination of both types of histone modifications (H3K4me1/H3K27me3), accompanied by reduced, but still significant, DNA methylation. Commitment of these cells to either bone or muscle lineages is accompanied by changes in chromatin modifiers including HDACs, histone-methyltransferases (HMTs) and DNA-methyltransferases (DNMTs) at the Osx promoter in tight correlation with the transcriptional status. DNMT1, DNMT3a, HDAC2, and HDAC4 are enriched during Osx silencing in muscle cells, whereas these proteins are released from the Osx promoter during osteoblast differentiation, together with demethylation of DNA. Also, inhibition of HDAC and DNMT activities in uncommitted mesenchymal precursors induces Osx mRNA expression. Thus, Histone and DNA modifications represent key regulatory mechanisms during control of Osx gene expression in mesenchymal-derived cell lineages, thereby controlling the osteoblastic cell fate choice.

### Identification and characterisation of monoallelic expression upon differentiation of mouse embryonic stem cells to neural progenitor cells.

M. A. Eckersley-Maslin<sup>1,2</sup>, D. Thybert<sup>3</sup>, J. H. Bergmann<sup>1</sup>, J. Marioni<sup>3</sup>, P. Flicek<sup>3</sup>, D. L. Spector<sup>1,2</sup>; <sup>1</sup>Cold Spring Harbor Laboratory, Cold Spring Harbor, NY, <sup>2</sup>Cold Spring Harbor Laboratory, Watson School of Biological Sciences, Cold Spring Harbor, NY, <sup>3</sup>EMBL-EBI, Hinxton, United Kingdom

Monoallelic gene expression refers to the transcription of a gene from only one of its two homologous alleles. Well-characterised examples include X-chromosome inactivation and genomic imprinting, however a third category, random autosomal monoallelic expression, remains poorly understood. We performed an allele-specific RNA-sequencing screen in clonal

populations of hybrid mouse embryonic stem cells (ESC) and neural progenitor cells (NPC) to identify monoallelically expressed genes in both cell types.

We identified 138 genes that switched to a monoallelic gene expression pattern during ESC to NPC differentiation. The expressed allele was independent in each clone and was not coupled to the genotype or the parent of origin, consistent with a random choice of allele expressed. Candidate genes were validated by PCR amplification of exonic SNPs followed by Sanger sequencing.

The 138 monoallelic candidate genes were randomly distributed throughout the genome with no apparent clustering observed. Global analysis showed the distribution of transcript levels of monoallelic genes was not significantly different to overall gene expression levels, suggesting that allelic bias is not limited to low expression levels. Furthermore, quantitative real-time RT-PCR analysis of genes that were monoallelic in a subset of clones and biallelic in others, revealed no correlation between the number of active alleles and the total level of gene expression. This suggests that transcriptional compensation must take place, and that monoallelic gene expression is not a bona-fide mechanism to regulate the level of a particular gene product in a cell.

A key question is how this form of random autosomal monoallelic expression is maintained across cell divisions. Ongoing genomic analysis as well as molecular characterisation of the epigenetic modifications marking the active and inactive allele of monoallelic genes will be presented.

744

**DNA methylation in the miR-210 gene influences HIFa1 binding.**

K-C. Chen<sup>1</sup>, Y-S. Wang<sup>1</sup>, Y-C. Liao<sup>2</sup>, S-H. H. Juo<sup>1</sup>; <sup>1</sup>Genome Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan, <sup>2</sup>Section of Neurology, Taichung Veterans General Hospital, Taichung, Taiwan

microRNA-210 (miR-210) has been reported to involve in hypoxia-related events. Several studies suggested that miR-210 expression can be regulated by hypoxia-inducible transcription factors-1alpha (HIF-1a) during hypoxia. Furthermore, by using the bioinformatics analysis, the promoter of the miR-210 gene contains several CpG-rich regions. However, there are no reports about epigenetic regulation of miR-210 gene. We investigated the role and mechanism of miR-210 in the cardiovascular system. We first found miR-210 gene was upregulated in vascular smooth muscle cells (VSMC) and human umbilical venous endothelial cells (HUVEC) when they were exposed to oxidized low-density lipoprotein (oxLDL). By combining with 5-Aza-2'-deoxycytidine treatment or DNA methyltransferase 3b knockdown, we found that miR-210 gene expression could be epigenetically regulated by oxLDL. By using the bisulfite sequencing assay, the decreased methylation levels of miR-210 gene was identified in vitro and in vivo. This methylation change could affect the HIF-1a-regulated miR-210 gene expression. Furthermore, over-expression or knockdown of miR-210 influenced the ability of oxLDL-mediated VSMCs and HUVECs migration. According to the bioinformatic prediction, SPRED2 (an inhibition regulator in ERK activation) could be a major miR-210's target gene involved in cell migration. Our reporter assays using wild-type and mutant 3' UTR of SPRED2 gene confirmed that SPRED2 was a novel direct target of miR-210. Over-expression or knockdown of SPRED2 affected oxLDL-mediated ERK/c-Fos/MMPs pathways in cell migration. Altogether, the data suggest that epigenetic regulation of miR-210 gene and its effect on cell migration are involved in the cardiovascular diseases formation.

745

**X. laevis ISWI remodels nucleosomes through a random-walk.**

G. Al-Ani<sup>1</sup>, K. Briggs<sup>2</sup>, S. Malik<sup>2</sup>, M. Conner<sup>1</sup>, C. J. Fischer<sup>2</sup>; <sup>1</sup>Molecular Biosciences, University of Kansas, Lawrence, KS, <sup>2</sup>Physics and Astronomy, University of Kansas, Lawrence, KS

The chromatin remodeler ISWI from *Xenopus laevis* is capable of repositioning clusters of nucleosomes to create well-ordered arrays or moving single nucleosomes from the center of DNA fragments toward the ends without disrupting their integrity. Using standard electrophoresis assays we have monitored the ISWI-catalyzed repositioning of different nucleosome samples each containing a different length of DNA symmetrically flanking the initially centrally positioned histone octamer. We find that ISWI moves the histone octamer between distinct and thermodynamically stable positions on the DNA according to a random walk mechanism. By comparing the number of positions observed in experiments with different nucleosomes we have determined that the spacing between positions is ~12 bp, which is similar to the period of certain dinucleotide spacings in nucleosome positioning sequence on the DNA (~10 bp) and the spacing between histone:DNA contacts within the nucleosome core particle (~10 bp). Thus, we believe that the distinct species that we observe correspond to nucleosomes in which the histone octamer has been shifted relative to the periodicity of the positioning sequence by 1 set of histone:DNA contacts. Through the application of a novel spectrophotometric assay for nucleosome repositioning we were further able to determine the macroscopic rate of nucleosome repositioning by ISWI and an estimate of the efficiency at which ATP binding and hydrolysis are coupled to this activity.

746

**Regulation of HDAC2 by of the tyrosine kinase c-Abl, a new mechanism of regulation of the gene expression.**

M. A. Gonzalez<sup>1</sup>, P. Contreras<sup>1</sup>, L. Estrada<sup>1</sup>, C. David<sup>1</sup>, E. Seto<sup>2</sup>, A. Villagra<sup>3</sup>, A. R. Alvarez<sup>1</sup>; <sup>1</sup>Department of Cell and Molecular Biology, Pontificia Universidad Católica de Chile, Santiago, Chile, <sup>2</sup>Department of Molecular Oncology, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL, <sup>3</sup>Department of Immunology, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL

The transcriptional regulation of genes is a dynamic process that involve the coordinated action of multiple regulatory proteins. A group of them, known as HDACs induce the deacetylation of histone for promote a more compact chromatin conformation leading to gene repression. HDAC2, a member of this family, had demonstrated to participate in the repression of genes during neurodegenerative process. Although the role of HDAC2 in gene repression is clear, the molecular pathways involved in this process are not yet clearly understood. In this respect, our laboratory has previously described that the tyrosine kinase c-Abl is crucial in the cell signaling in neurodegenerative process such as exists in Alzheimer's Disease. In this context, our results show, for the first time, that HDAC2 is modulated by the c- Abl tyrosine kinase, which is a potential mechanism to explain the role of HDAC2 in neurodegeneration.

We results show that c-Abl activity increases both protein levels and deacetylase activity of HDAC2, besides c-Abl regulates histone H3 acetylation levels. In the same line, treatments with Imatinib (c-Abl inhibitor) reduces both protein levels and activity of HDAC2. Interestingly, the treatments with Imatinib decreases the HDAC2 association to the promoter of the neuronal genes and increases the H3 acetylation levels. Besides, in the experimental Alzheimer Diseases (AD), we found in both primary culture of neurons treated with A $\beta$  oligomers (oA $\beta$ ), as well as in the APP<sup>swe</sup>/PSEN1 $\Delta$ E9 mice, an increase of protein levels as well as the enzymatic

activity HDAC2 which depend on c-Abl activity. In addition, c-Abl induces the tyrosine phosphorylation of HDAC2, a postraductional modification that has not been described previously for this protein, that is important in the regulation of activity of HDAC2. Based on these results, we suggest that c-Abl might regulate the neuronal gene expression through tyrosine phosphorylation of HDAC2.

747

### **Chromatin structural changes by nuclear c-Abl-mediated tyrosine phosphorylation through histone deacetylation.**

*K. Aoyama<sup>1</sup>, S. Kubota<sup>1</sup>, R. Yuki<sup>1</sup>, K. Ishibashi<sup>1</sup>, Y. Horiike<sup>1</sup>, M. Morii<sup>1</sup>, Y. Fukumoto<sup>1</sup>, N. Yamaguchi<sup>1</sup>; <sup>1</sup>Department of Molecular Cell Biology, Graduate School of Pharmaceutical Sciences, Chiba University, Chiba, Japan*

Chromatin structure is dynamically changed by histone modifications, and chromatin dynamics is involved in transcriptional regulation. c-Abl tyrosine kinase is a proto-oncogene product and ubiquitously expressed. Cytoplasmic c-Abl plays important roles in cell proliferation, differentiation, and adhesion. c-Abl has three nuclear localization signals (NLSs) and translocates into the nucleus. However, the function of nuclear c-Abl is poorly understood. In this study, we examined the relationship between nuclear c-Abl and chromatin structural changes.

To examine whether nuclear c-Abl was involved in chromatin structural changes, cells were treated with adriamycin (ADR), which enhances nuclear translocation of c-Abl. The level of chromatin structural changes was significantly increased by ADR treatment and this increase was repressed by imatinib, an Abl inhibitor. Moreover, transfection with c-Abl induced chromatin structural changes. Intriguingly, the oncogenic Bcr-Abl also changed the chromatin structure. c-Abl- and Bcr-Abl-induced chromatin structural changes were enhanced by ADR, which promoted their nuclear translocation. Furthermore, NLS-c-Abl, which is tagged with fourth NLS to localize to the nucleus, induced drastic chromatin structural changes compared with intact c-Abl. These results suggest that nuclear c-Abl plays a role in chromatin dynamics.

Next, we examined the involvement of histone modifications in c-Abl-mediated chromatin structural changes. By immunofluorescence microscopy we detected repressive histone modifications including an increase in histone H3 trimethylated on lysine 9 (H3K9Me3) and a decrease in H3K4Me3, H3K14Ac (acetylated on lysine 14), and H4K16Ac in cells exhibiting chromatin structural changes strongly induced by NLS-c-Abl. Since the most prominent histone modification among them was a decrease in H4K16Ac, we examined the relationship of histone deacetylation with nuclear c-Abl-induced chromatin structural changes. A broad inhibitor of histone deacetylases, trichostatin A (TSA), inhibited both H4K16 hypoacetylation and chromatin structural changes induced by NLS-c-Abl. Inhibition of NLS-c-Abl by imatinib was found to block H4K16 hypoacetylation and chromatin structural changes. Furthermore, we observed repressed transcription of the RASSF1A tumor suppressor upon NLS-c-Abl expression. Repression of RASSF1A transcription is known to involve repressive histone modifications. Taken together, these results suggest that nuclear c-Abl-mediated tyrosine phosphorylation induces chromatin structural changes through histone deacetylation, which may affect gene expression.

In conclusion, we show that nuclear tyrosine phosphorylation by c-Abl regulates chromatin dynamics through histone deacetylation. The oncogenic Bcr-Abl-induced chromatin structural changes and nuclear c-Abl-repressed transcription of the tumor suppressor RASSF1A lead us to speculate that Abl-mediated chromatin structural changes are involved in tumorigenesis. Now, we are trying to identify the nuclear substrate of c-Abl and to clarify the mechanism of changing the chromatin structure.

748

**Emerin regulates chromatin architecture and gene expression during myogenic differentiation in cooperation with Histone Deacetylase 3 (HDAC3).**

J. Demmerle<sup>1</sup>, A. Koch<sup>2</sup>, J. Lee<sup>1</sup>, J. Holaska<sup>1,2,3</sup>; <sup>1</sup>Department of Medicine, Section of Cardiology, University of Chicago, Chicago, IL, <sup>2</sup>Committee on Genetics, Genomics and Systems Biology, University of Chicago, Chicago, IL, <sup>3</sup>Committee on Developmental, Regeneration, and Stem Cell Biology, University of Chicago, Chicago, IL

Spatial organization of the genome is critical for maintaining cell-specific gene expression and ensuring proper cellular function. Changes in chromatin architecture during development and tissue regeneration are important for regulating proper spatial and temporal gene expression throughout differentiation. It is well established that repressed chromatin preferentially associates with the nuclear lamina and that dynamic association of gene loci with the nuclear lamina contributes to temporal regulation of gene expression. However, the molecular mechanisms underlying the formation and maintenance of repressive chromatin at the nuclear lamina, as well as the spatial organization of developmentally regulated gene loci, remain poorly understood. Here we show that the inner nuclear membrane protein emerin associates with loci containing important myogenic differentiation factors in mouse muscle stem cells, including *Myf5*, *MyoD* and *Pax7*. These loci are transcriptionally silent when localized at the nuclear lamina. During muscle differentiation, *Myf5* and *MyoD* loci move to the nuclear interior concomitant with their transcriptional activation, while the *Pax7* locus, which promotes stem-cell identity, shifts from the nuclear interior to the nuclear lamina upon its transcriptional repression. Localization of *Myf5*, *MyoD* and *Pax7* to the nuclear lamina requires emerin and HDAC3. We also found these chromatin architecture changes are dependent on emerin's activation of HDAC3, as loss of *Myf5* localization to the nuclear lamina can be rescued by treatment with a small-molecule activator of HDAC3. Collectively these data support a model whereby emerin facilitates repressive chromatin formation at the nuclear lamina by activating the catalytic activity of HDAC3. We hypothesize the formation or maintenance of this repressive environment at the nuclear lamina by emerin contributes to the coordinated temporal expression of myogenic differentiation genes through modulating chromatin architecture, ensuring proper myogenic differentiation during muscle regeneration. This model illustrates the importance of interactions between the nuclear lamina and epigenetic modifiers in regulating developmental transitions, and provides insight into the molecular mechanisms responsible for the impaired muscle regeneration characteristic of X-linked Emery-Dreifuss Muscular Dystrophy, which is caused by mutations in emerin.

749

**Polycomb-Group proteins (PcG) Ezh1 and Ezh2 differentially regulate PSD-95 gene expression in developing hippocampal neurons.**

B. Henriquez<sup>1,2</sup>, F. J. Bustos<sup>1,2,3</sup>, F. Blanco<sup>2</sup>, A. Becerra<sup>2</sup>, C. Salas<sup>1,2</sup>, F. Simon<sup>2</sup>, M. Montecino<sup>1,2</sup>, B. van Zundert<sup>1,2</sup>; <sup>1</sup>Center for Biomedical Research, Andres Bello University, Santiago, Chile, <sup>2</sup>Faculty of Biological Sciences, Andres Bello University, Santiago, Chile, <sup>3</sup>University of Concepcion, Concepcion, Chile

Introduction: Polycomb-Group proteins (PcG) are key epigenetic regulators that can either silence or activate genes. Little is known about the role of PcG in controlling genes associated with neuronal plasticity. We analyzed the expression of PcG proteins, Ezh1 and Ezh2, during hippocampal development and their contribution in transcriptional regulation of the PSD-95 gene.

**Material and Methods:** mRNAs were analyzed by qRT-PCR and proteins by Western-blot at distinct development stages: rat hippocampal tissue (from E18 to P90) and cultures (from 2 to 20 DIV). Ezh1 and Ezh2 knock-down was realized using shRNAs lentiviral particles, electroporation by AMAXA® and Calcium Phosphate method. Chromatin Immunoprecipitation (ChIP) assays were realized in hippocampal tissue and quantified by qRT-PCR.

**Results:** We report that Ezh1 and Ezh2 are expressed in neurons and astrocytes, however, their expression levels depends on the developmental stage analyzed: Ezh2 expression is high during development and then declines, whereas Ezh1 expression persists with development. A switch in the association to PSD-95 gene promoter from Ezh2 to Ezh1 is also prominent during development, concomitant with specific changes in epigenetic marks. We also found that Ezh2 depletion in early neurons increased PSD-95 expression, whereas Ezh1 knockdown in mature neurons reduced expression of this gene.

**Discussion:** Our findings reveal differential roles for Ezh1 and Ezh2 in epigenetic regulation during neuronal development and on the PSD-95 gene promoter, suggesting an important role for PcG proteins in developmental-dependent neuronal plasticity.

### **Maternal high-methyl diet alters DNA methylation in mammary tissues of female rat offspring.**

*C. S. Park<sup>1</sup>, S. Bae<sup>1</sup>, K. Cho<sup>1</sup>, L. Mabasa<sup>1</sup>, M. Walters<sup>1</sup>; <sup>1</sup>North Dakota State University, Fargo, ND*

Prenatal and early neonatal nutrition is an important factor for growth and health in early and later life. It has been suggested that maternal diet affects metabolic processes in the mammary glands of offspring. Lipotropes (methionine, choline, folate, and vitamin B12) are methyl donors and cofactors essential for one-carbon metabolism, a process which provides methyl groups for biological methylation pathways. We hypothesized that a maternal lipotrope-additive diet (LAD) would alter global DNA methylation and methylation-related gene expression in the mammary glands of female rat offspring. Throughout gestation and lactation, dams were fed either a control diet (CD; AIN-93G) or LAD which contained 5 times more choline, folate, and vitamin B12, and 1.8 times more methionine. The female offspring were weaned onto the CD and organized into two groups based on the dams' diet. These female offspring were then mated, bred, and at weaning their mammary tissues were harvested for analysis of global DNA methylation and gene expression. The level of DNA methylation was significantly increased by 22.1% in the female offspring of LAD-fed dams ( $P < 0.05$ ). There was also a tendency toward lower mRNA expression of DNA methyltransferase 1 in the LAD group ( $P = 0.09$ ). Interestingly, protein expression of fatty acid synthase (FASN) was increased in the LAD rats. Our study demonstrates that supplementation of dietary lipotropes during pregnancy and lactation increases global DNA methylation and protein expression of FASN, suggesting that maternal high-methyl diet may modulate DNA methylation and metabolism in the mammary glands of offspring. Future studies are warranted to establish the putative mechanistic link responsible and its possible influence on the growth and health of offspring.

751

**Epigenetic silencing of key bone phenotypic genes during neuronal development.**

*R. Aguilar<sup>1</sup>, F. Bustos<sup>1,2</sup>, B. Henriquez<sup>1</sup>, A. Rojas<sup>1,3</sup>, B. van Zundert<sup>1</sup>, M. Montecino<sup>1</sup>; <sup>1</sup>Center for Biomedical Research, Andres Bello University, Santiago, Chile, <sup>2</sup>University of Concepcion, Concepcion, Chile, <sup>3</sup>University of Chile, Santiago, Chile*

Runx2 and Osterix transcription factors are essential for bone development and osteoblastic differentiation as they regulate the expression of key bone lineage-specific genes. In osteoblasts, epigenetic mechanisms that lead to transcriptional activation of these genes have been described, but their silencing in non-osteoblastic cells remains to be elucidated. In neurons, the regulatory networks that may trigger transcription of osteoblast-specific genes are active, although are unable to promote bone-related gene expression. We aim to evaluate the contribution of epigenetic mechanisms during silencing of osteoblast-specific genes in neuronal cells. Hippocampal tissue from E18, P10, P30 and P90 rats was obtained to perform Chromatin Immunoprecipitation (ChIP) studies using antibodies directed against covalent histone modifications and chromatin modifying enzymes. It was found that Runx2 and Osterix promoter sequences exhibit enrichment of the repressive H3K27me3 epigenetic mark in all the stages analyzed. Additionally, we detect the presence of Polycomb-group proteins Ezh1 and Ezh2, binding in a developmental stage-dependent manner at Runx2 and Osterix promoters, correlating their expression patterns. We also find the heterochromatin-associated H3K9me3 epigenetic mark in the adult stage, tightly correlated with decreased histone H3 acetylation and enrichment of Histone Deacetylases HDAC1 and HDAC2. Finally, we find a strong DNA methylation pattern at bone-specific genes (e.g. Osteocalcin) that are expressed at late stages during bone formation. Together, our results support a model where epigenetic post-translational modifications ensure the silencing of non-neuronal genes during neuronal differentiation.

**Epigenetic regulation of PSD95 gene expression during hippocampal development.**

*F. J. Bustos<sup>1,2,3</sup>, R. Aguilar<sup>2,3</sup>, B. Henriquez<sup>2</sup>, M. Montecino<sup>2,3</sup>, B. van Zundert<sup>2</sup>; <sup>1</sup>University of Concepcion, Concepcion, Chile, <sup>2</sup>Center for Biomedical Research, University Andres Bello, Santiago, Chile, <sup>3</sup>Fondap Center for Genome Regulation, Santiago, Chile*

**Introduction:** Data from us and others indicates that increased expression of PSD95, the major anchoring protein for excitatory receptors at the post-synaptic membrane, is a key contributor for the limited plasticity in the adult brain. Here we establish a pattern of histone tail modifications that are associated with PSD95 expression in hippocampal tissue during development. Also, we investigated if PSD95 expression is controlled by methylation of its DNA promoter sequence.

**Methods:** E18-P10-P30-P90 to obtain mRNA, protein or chromatin. Western blot and qRT-PCR were conducted to determine the expression of PSD95 at the different developmental stages. Chromatin immunoprecipitation (ChIP) was performed using antibodies for activation or repression marks and quantified by qPCR with specific primers for the PSD95 promoter sequence. Genomic DNA was extracted and treated with bisulfite to define DNA promoter sequence methylation. Bisulfite converted DNA was sequenced to analyze methylation status.

**Results:** Expression of PSD95 mRNA and protein levels increases gradually with hippocampal development. Concomitant with enhanced PSD95 expression during development, active epigenetic marks are associated to this promoter in mature neurons. Repressive marks

associated to the PSD95 promoter are never detected. Methylation of the PSD95 DNA promoter sequence was also not present at any stage.

Conclusions: Expression of the PSD95 gene during hippocampal development is regulated by histone tail modifications on histones associated to its promoter, but not by methylation of the promoter DNA sequence. We were able to identify a specific pattern of histone tail modifications that correlates with PSD95 expression during hippocampal development.

### Gastrulation in high-resolution: New insights into an important process of development.

M. L. Martik<sup>1</sup>, D. R. McClay<sup>2</sup>; <sup>1</sup>University Program in Genetics and Genomics, Duke University, Durham, NC, <sup>2</sup>Department of Biology, Duke University, Durham, NC

Gastrulation is a complex orchestration of movements by cells that are specified early in development. Until now, it was thought that lateral rearrangement of endoderm cells by convergent extension was the main contributor to sea urchin archenteron elongation. Our project characterizes, at high resolution, the repertoire of cellular movements contributing to the length of gut. We have performed cell transplantation to live image and analyze a subset of labeled endoderm cells in the optically clear sea urchin embryo. We have found that the endoderm cells that initially invaginate remain contiguous throughout extension, so that, if convergent extension is present, it is not a major contributor to elongation. We have also found, unexpectedly, that endoderm cells proliferate as they move to elongate the archenteron. Our descriptive studies of the cellular processes during gastrulation have allowed us to begin investigating their molecular control. The endomesoderm gene regulatory network (GRN) describes the cell fate specification of the future larval gut; however, the GRN does not describe specific cell biological events driving morphogenesis. We plan to dissect the transcriptional circuitry of the GRN responsible for the cell biological events, such as changes in polarity and adhesion, of gastrulation. Our ability to connect the endomesoderm GRN to the morphogenetic events of gastrulation will provide a framework for characterizing this remarkable sequence of cell movements in the simplest of deuterostome models at an unprecedented scale.

### The regulation of the organ morphology by cytoskeletal remodeling.

R. Morita<sup>1</sup>, M. Kihira<sup>2</sup>, Y. Nakatsu<sup>2</sup>, M. Ogawa<sup>3</sup>, T. Tsuji<sup>1,2,3</sup>; <sup>1</sup>Res. Inst. for Sci. & Tech., Tokyo Univ. of Sci., Noda city, Japan, <sup>2</sup>Fac. of Indus. Sci. & Tech., Tokyo Univ. of Sci., Noda city, Japan, <sup>3</sup>Organ Technologies Inc., Tokyo, Japan

All organs arise from their respective germs through reciprocal interactions between epithelium and mesenchyme in the developing embryo. Their morphologies are shaped by accumulation of spatiotemporally controlled cellular behaviors such as cell proliferation, differentiation and movement. In this study, we investigated how complex cellular behaviors were coordinated during morphogenesis by the quantitative kinetic analysis of developing tooth germ as an organ model.

We first took a long-term live imaging of developing tooth germ using the confocal laser microscopy, visualizing three-dimensional cell dynamics with the spatio-temporal pattern of

proliferation. We subsequently constructed four-dimensional analysis system of organ morphogenesis, which reproduced morphological changes and complex cell behaviors such as cell movements and divisions on the computer by cell tracking. The quantitative analysis using this system revealed that the spatial relative position of the cells hardly moved on the growth-arrested area, although the cells actively moved with cell division on high proliferative area, suggesting that cell proliferation and motility are orchestrated in developing tooth germ. We therefore investigated the molecular mechanism underlying these coordinated cell behaviors during tooth morphogenesis. Since cytoskeleton reorganization is essential for cell shape change, migration and mitosis, we focused on the regulatory mechanism via the cytoskeleton remodeling and found that a phosphorylated (inactivated) cofilin, which is a member of the actin depolymerization factor (ADF)/cofilin family, was localized in low proliferative area in tooth germ. We also found that these phosphorylated cofilins localized in low proliferative area of only tooth germ but also hair germ through development process. Fluorescence recovery after photobleaching (FRAP) analysis revealed that actin-filament assembly was inhibited at the regions where highly phosphorylated cofilins were localized. Furthermore, proliferation and migration of epithelial cells were significantly inhibited according to the elevation of phosphorylation level of cofilin.

These results suggested the possibility that the morphological changes in tooth germ development were controlled by the spatiotemporal coordinates of cell proliferation and cell movement via regulation of actin remodeling.

#### **Rab8a-regulated Wnt-Gpr177 Exocytic Trafficking and Stem Cell Niche Development in Mouse Small Intestine.**

*S. Das<sup>1</sup>, S. Yu<sup>1</sup>, R. Sakamori<sup>1</sup>, N. Gao<sup>1</sup>; <sup>1</sup>Biological Sciences, Rutgers University, Newark, NJ*

Being a crucial morphogen driving mammalian tissue development, the scheduled secretion of Wnt ligands (or the wingless-type MMTV integration site family proteins) calls for high regulation. However, in contrast to the extensive studies done on Wnt downstream signaling pathways, relatively less is known about the molecular basis regulating Wnt ligand secretion in Wnt-producing cells. We have explored the role of Rab8a, a master regulator of intracellular protein endo- and exo-cytosis, in regulating Wnt transport and intestinal stem cell niche development. We demonstrate that in absence of Rab8a, the mouse intestinal crypts exhibit a phenotype indicating perturbed Wnt signaling. The Rab8a-deficient crypts are enlarged with an increased population of stem and transit amplifying cells. In contrast, Paneth cells are drastically reduced with ultrastructurally abnormal endoplasmic reticulum and secretory vesicles. Using a Wnt signal reporter, the Axin2-LacZ mice, we revealed a reduced Wnt-receiving zone in Rab8a-deficient intestinal crypts, indicating an affected gradient formation. We propose that Rab8a regulates Wnt secretion in the intestinal stem cell niche, putatively by recruiting the Wnt transporter GPR177 into a highly regulated secretory route. These data shed light on factors contributing to stem cell niche development and maintenance, and will open up new prospects in manipulating Wnt production that has translational potentials.

#### **Towards an understanding of the role of apical mitosis in pseudostratified epithelia.**

*P. J. Strzyz<sup>1</sup>, C. Norden<sup>1</sup>; <sup>1</sup>MPI-CBG, Dresden, Germany*

Pseudostratified epithelia feature a single layer of highly elongated cells, whose nuclei occupy positions all along the apico-basal axis, creating the stratified appearance. This cellular organization is prevalent in rapidly proliferating embryonic tissues during development of a

broad range of species. A hallmark of pseudostratified epithelia is interkinetic nuclear migration (IKNM). IKNM comprises of stochastic nuclear movements, punctuated by rapid migration towards the apical surface in G2. This results in apical localization of all mitoses. Despite extensive studies on mechanisms and kinetics of IKNM, one fundamental questions remains unanswered: What is the significance of the apical division for tissue development? Why do nuclei migrate towards the apical side prior to each division? One possible reason could be the apical localization of the centrosome, which serves as a basal body of the primary cilium in the interphases. We are therefore currently investigating whether apical centrosome location is necessary and/or sufficient for apical mitosis.

We found that until shortly before mitotic entry, the centrosome is attached to the apical surface via short, dynamic astral microtubules. Interference with this pool of microtubules leads to mispositioning of the centrosome towards more basal locations. Subsequently, chromosome condensation and nuclear envelope breakdown occur at more basal positions. Nevertheless, rapid apical migration of nuclei still takes place but under these conditions nucleus and centrosome travel together.

To understand whether centriole number plays a role in apical mitosis, we have decreased the amount of centrioles by inhibiting a centriole duplication pathway. However, this manipulation also does not abolish rapid apical migration. Cells still divide at apical locations, often featuring monopolar spindles, significantly increasing the time needed for successful mitosis. Additionally, centriole overduplication leading to extranumerary, non-apical centrosome-like structures does not inhibit apically directed IKNM.

In summary, we have shown that neither centrosomal localization nor centriole number influences rapid nuclear migration during IKNM. Restricting all mitoses to the apical side might therefore be needed to facilitate rapid, vertically oriented divisions that are not possible in case divisions would happen all along the epithelium. Thus IKNM may serve to sequester nuclei of different cell cycle phases and create a distinct germinal zone to the tissue. We are currently testing this hypothesis.

**Stimulation of angiogenesis and protection of vascular permeability by C-peptide *in vitro* and *in vivo*.**

Y-C. Lim<sup>1</sup>, M. P. Bhatt<sup>1</sup>, Y-M. Kim<sup>1</sup>, K-S. Ha<sup>1</sup>; <sup>1</sup>Cellular and Molecular Biochemistry, Kangwon National University School of Medicine, Chuncheon, Kangwon-do, Korea

Human C-peptide has a beneficial effect on the prevention of diabetic neuropathy, nephropathy, and vascular complications; however, its role in angiogenesis and in protection against increased vascular permeability in diabetic retinopathy remains unclear. Increased vascular permeability and defective angiogenesis due to the hyperglycemia-induced elevation of vascular endothelial growth factor (VEGF) contributes to diabetic retinopathy, a leading cause of blindness. We investigated the potential roles of C-peptide, in parallel with VEGF, in angiogenesis and vascular permeability using human umbilical vein endothelial cells (HUVECs) and streptozotocin diabetic mice. C-peptide induced migration and capillary-like networks formation of endothelial cells in dose-dependent manners, with the maximal effect at 0.5 nM, through pathways involving extracellular signal-related kinase 1/2, Akt, and nitric oxide. Consequently, C-peptide enhanced angiogenesis *in vivo* as demonstrated by the Matrigel plug assay. We also demonstrated the preventive role of C-peptide against VEGF-induced vascular permeability by inhibiting the generation of intracellular reactive oxygen species (ROS), ROS-dependent stress fiber formation, and the disassembly of the adherens junction protein VE-cadherin. Consistently, intravitreal injection of C-peptide prevented extravasation of FITC-dextran in the retinas of diabetic mice. Thus, our results suggest that C-peptide plays a novel

angiogenic role that may have significant implications in reparative and therapeutic angiogenesis in diabetes, and it protects against VEGF-induced vascular permeability in diabetes; this suggests that C-peptide replacement is a promising therapy to prevent diabetic retinopathy.

**Wounded cells drive rapid epidermal repair in the early *Drosophila* embryo.**

R. Fernandez-Gonzalez<sup>1,2</sup>, J. Zallen<sup>3</sup>; <sup>1</sup>*Institute of Biomaterials and Biomedical Engineering and Department of Cell and Systems Biology, University of Toronto, Toronto, ON, Canada,* <sup>2</sup>*Developmental and Stem Cell Biology Program, The Hospital for Sick Children, Toronto, ON, Canada,* <sup>3</sup>*Developmental Biology Program, Sloan-Kettering Institute and Howard Hughes Medical Institute, New York, NY*

A striking feature of wound repair is that its efficiency decreases with age. In embryos, epidermal lesions heal fast and with no scars, whereas adult wounds heal slowly and with scar formation. In humans, the transition from rapid to slow wound repair occurs at the final stages of fetal development. To determine if a similar transition occurs in *Drosophila*, we quantified wound closure in the epidermis of early and late embryos (3 and 14 hours after egg laying, respectively). We developed computational image analysis tools to automate the identification and tracking of the wound margin in time-lapse movies, facilitating the analysis of a large number of samples.

Wound repair was significantly faster in the epidermis of the early embryo, where wounded structures sustained greater mechanical tension than in the late embryo. A contractile actin-myosin II ring formed around early and late wounds. In the early embryo, ring formation was followed by the assembly of dense actomyosin networks at the medial-apical surface of the wounded cells, in parallel with rapid wound contraction. Laser ablation demonstrated that medial actomyosin networks in the wounded cells were contractile and pulled on the wound margin. In the early embryo medial networks were disassembled as they contracted, whereas in the late embryo the total levels of actin and myosin remained constant during ring contraction. Taken together, our data indicate that wounded cells in the early embryo trigger a program of apical constriction that contributes to rapid wound closure. These experiments also suggest that actomyosin network architecture may determine the mechanisms of network contraction and the magnitude of the forces generated. We are currently using super-resolution microscopy, particle tracking and 3D image analysis to investigate the molecular architecture and mechanisms of assembly of the contractile networks associated with wound closure, as well as the association between mechanical changes in the epidermis and the transition from fast to slow wound repair in the *Drosophila* embryo.

**Laser scanning-based tissue autofluorescence/ fluorescence imaging (LS-TAFI), a new technique for analysis of microanatomy in whole mount tissues.**

H. Mori<sup>1</sup>, A. D. Borowsky<sup>2</sup>, R. Bhat<sup>1</sup>, C. M. Ghajar<sup>1</sup>, M. Seiki<sup>3</sup>, M. J. Bissell<sup>1</sup>; <sup>1</sup>*Lawrence Berkeley National Laboratory, Berkeley, CA,* <sup>2</sup>*University of California Davis, Davis, CA,* <sup>3</sup>*Cancer Cell Research, Institute of Medical Science, The University of Tokyo, Tokyo, Japan*

Intact organ structure is essential in maintaining tissue-specificity and cellular differentiation. Subtle physiological or genetic variations lead to changes in microanatomy that if persist, would have functional consequences and could easily be masked by the heterogeneity of tissue response. Current techniques rely on histological sections requiring sample manipulation that

are essentially two-dimensional (2D). We have developed a method for 3D imaging of whole mount, un-sectioned mammalian tissues to elucidate distinct and detailed micro- and macro-anatomies in mammalian organs and embryos. We analyzed intact or dissected organ whole mounts with laser scanning confocal microscopy-based tissue autofluorescence/fluorescence imaging (LS-TAFI). We report clear visualization of microstructures within murine mammary glands and mammary tumors and other tissues without the use of immunostaining, and without probes or fluorescent reporter genes. Combining autofluorescence with reflected light signals from chromophore-stained tissues allowed identification of individual cells within 3D structures of whole mounted organs. This technique could be also useful for rapid diagnosis of human clinical samples.

**Investigating the role of Shroom: Rock signaling module in cellular morphogenesis.**

*D. Das<sup>1</sup>, J. Hildebrand<sup>1</sup>; <sup>1</sup>University of Pittsburgh, Pittsburgh, PA*

Cellular morphogenesis is critical for diverse cellular behaviors and processes like cell adhesion, migration, shape and polarity and defects in these processes lead to malignant human conditions. This cellular remodelling is brought about by proteins that modulate the dynamics and organization of the cytoskeleton in a spatially restricted manner. Of the vast number of proteins that act on the cytoskeleton, Shroom family members have been implicated in, or are required for, several biological processes. Shroom, a class of Actin-associated proteins have been implicated in regulating cell and tissue architecture via activation of non-muscle Myosin II. This activity is restricted to its evolutionarily conserved motif, Shroom Domain 2(SD2) that binds directly to the Shroom Binding Domain(SBD) of Rho-kinase(Rock). Rock then activates MyoII contractility by regulating the phosphorylation status of Myosin light chain and brings about change in cell shape. My project uses structural, biochemical and cell biological assays to dissect the molecular nature of the Shroom:Rock interaction. The structure of Shroom SD2 domain has been shown to be an antiparallel coiled-coil dimer. The surface exposed residues in Shroom SD2 play an important role in mediating Shroom:Rock binding whereas the residues buried interiorly are required for dimerization. SD2 mutants that fail to bind Rock or dimerize also fail to cause apical constriction in MDCK cells. In order to map this Shroom-Rock interaction, we have mapped the SBD of Rock to a stretch of 79 amino acids in the coiled-coil region of Rock. This sequence is highly conserved across species, with the most conserved amino acid residues being surface exposed in the SBD crystal. We have generated mutations in these highly conserved residues in Rock SBD and tested for disruption of binding to Shroom SD2 via in vitro binding assays and co-localization with Shroom in vivo. Six different Rock SBD mutants have been identified that disrupt Shroom binding in vitro and prevent colocalization with Shroom3 in vivo. Efforts to recreate these Rock SBD mutants in full length Rock are being made to conduct cell-based apical constriction rescue assays after siRNA mediated knockdown of RockI and RockII in MDCK cells. These results will be supplemented by the crystal structure of Rock SBD which will facilitate better understanding of the molecular nature of Shroom:Rock interaction and ultimately cell shape change.

### Embryo Scale Integration of Forces and Gene Patterns Controlling Tissue Morphogenesis.

M. Rauzi<sup>1</sup>, T. Saunders<sup>2</sup>, U. Krzic<sup>2</sup>, L. Hufnagel<sup>2</sup>, M. Leptin<sup>1</sup>; <sup>1</sup>Developmental Biology, EMBL, Heidelberg, Germany, <sup>2</sup>Cell Biology and Biophysics, EMBL, Heidelberg, Germany

The shape of a developing organism is generated by the activities of its constituent cells: cell growth and proliferation, cell movements and cell shape changes. We are particularly interested in shape changes.

Much has been learned about how cell differentiation programmes determine the morphogenetic activity of the cell, and we know the subcellular protein networks that are the effectors of cell behaviour. However, cells do not act in isolation, and morphogenesis requires an integration of forces across neighbouring cell populations. In addition to the subcellular mechanisms, it is now necessary to understand the supracellular integration of forces if we want to understand morphogenesis at the whole tissue or organismal level.

We are studying a simple morphogenetic process, the formation of the ventral furrow in the *Drosophila* embryo, which is well understood in its genetics and cell biology. The cells that form the furrow are the major force generators that drive furrow formation, but the neighbouring cells must respond and may contribute. We show by quasi-simultaneous time-lapse imaging of multiple-angle views of the embryo that the neighbouring cells undergo specific shape changes.

We are now studying the interdependence of cell behaviours and their coordination. We will use genetic and mechanical manipulations to reveal the underlying control circuits.

762

### A new model for investigating the regulation of epithelial-mesenchymal transition and cell plasticity in vivo.

L. C. Skwarek<sup>1</sup>, D. Bilder<sup>1</sup>; <sup>1</sup>Molecular and Cellular Biology, University of California, Berkeley, Berkeley, CA

During development, morphogenetic rearrangements are often accomplished through a remarkable cellular transformation known as epithelial-mesenchymal transition (EMT). During EMT, epithelial cells dramatically alter polarity, change shape and often become migratory. These changes in polarity and behavior occur without cell division and are often reversible, making EMT an excellent model of cellular plasticity. EMT is essential for normal development and is also a hallmark of tumor metastasis. Despite its importance, we still lack a comprehensive knowledge of the integrated cell biology involved in coordinating EMT. To address this I am studying an EMT-like event required for the final steps of *Drosophila* wing development. When a fly emerges from its pupal case the wings are folded and contain a bilayer of epithelial cells. Over the next few hours the wing expands and the epithelial cells undergo a transformation that closely resembles early EMT. Eventually, all epithelial cells are lost from the mature wing. Though this process differs from other EMT events in that the cells do not ultimately differentiate or proliferate and are not protected from death, this system nevertheless shows many of the hallmark cellular and molecular features of EMT. To understand whether *Drosophila* wing maturation can be used as a model to identify new regulators of EMT *in vivo*, I am using a combination of live imaging and genetic manipulation to further characterize the behavior and ultimate fate of these cells. I have confirmed through confocal analysis of fixed and living maturing wings that the epithelial bilayer is disrupted, with loss of adherens junctions preceding changes in membrane integrity, apical-basal polarity, and acquisition of motile cell morphologies. In addition, knock down of EMT-relevant gene products during wing maturation results in adult wings with easily scored visible defects that can be used

for primary forward genetic screening. Furthermore, GFP fusion proteins and immunostaining demonstrate that these defects correlate with failure to complete the epithelial transition. Taken together, these studies will identify new mechanisms regulating the cell biology of epithelial transition and cellular plasticity.

764

**CFTR expression in iPSCs differentiated to airway epithelium.**

M. E. Gordon<sup>1</sup>, A. Esmaeili-Shandiz<sup>1</sup>, S. Suzuki<sup>1</sup>, A. Lee<sup>1</sup>, R. G. Sargent<sup>1</sup>, D. C. Gruener<sup>1,2,3,4</sup>,  
<sup>1</sup>Otolaryngology-Head and Neck Surgery, UCSF, San Francisco, CA, <sup>2</sup>Laboratory Medicine, UCSF, San Francisco, CA, <sup>3</sup>Eli and Edythe Broad Institute for Regenerative Medicine and Stem Cell Research, UCSF, San Francisco, CA, <sup>4</sup>Institute for Human Genetics, UCSF, San Francisco, CA

Cystic fibrosis (CF), the most common genetic disorder in the Caucasian population, has over 1,000 new cases diagnosed each year in the US alone. While >1800 mutations may lead to CF, the most prevalent mutation (found in ~70% of all CF chromosomes) is a phenylalanine deletion at codon 508 in the CF transmembrane conductance regulator (*CFTR*) gene (delF508). The *CFTR* protein is a cAMP-dependent Cl channel found in the apical membrane of epithelial cells that regulates the Cl gradient at the cell surface. While the *CFTR* gene has been well characterized, little research has been done on the regulation of *CFTR* throughout development. The studies described will evaluate *CFTR* expression in an *in vitro* developmental system using induced pluripotent stem cells (iPSCs) that are directed to differentiate along an endodermal lineage-specific pathway. An expression vector, (pcDNA3-CF1-EGFP), comprised of a pcDNA3 backbone and EGFP under the regulation of a ~1.7kb *CFTR* promoter element was constructed. To test whether this construct was specific for *CFTR* expressing cell types, it was transfected into immortalized human airway epithelial cells (16HBE14o-) that are known to express *CFTR* and primary human airway fibroblasts (FHTF-18) that are negative for *CFTR* expression. A pcDNA3-EGFP with EGFP under the regulation of a CMV promoter was used as a positive control and untransfected cells as a negative control. Expression of the pcDNA3-CF1-EGFP construct was observed in 16HBE14o-, but not FHTF-18, while expression of pcDNA3-EGFP was observed in both cell lines. No expression was detected in untransfected cells. These data indicate that the pcDNA3-CF1-EGFP construct contains the necessary elements for cell specific expression of *CFTR*. Studies are now underway to evaluate the expression of *CFTR* in the directed endodermal differentiation of iPSCs.

These studies are supported by grants from CIRM and PACFI.

765

**Regulation of lung branching morphogenesis by dynamic luminal fluid flows.**

J. P. Gleghorn<sup>1</sup>, V. D. Varner<sup>1</sup>, D. C. Radisky<sup>2</sup>, H. A. Stone<sup>3</sup>, C. M. Nelson<sup>1,4</sup>, <sup>1</sup>Chemical & Biological Engineering, Princeton University, Princeton, NJ, <sup>2</sup>Mayo Clinic Cancer Center, Jacksonville, FL, <sup>3</sup>Mechanical & Aerospace Engineering, Princeton University, Princeton, NJ, <sup>4</sup>Molecular Biology, Princeton University, Princeton, NJ

Branching morphogenesis of the lung is dynamic, highly regulated, and stereotyped, leading to an architecture that is conserved within a given species and critical for survival. Whereas the architecture of the airways is optimized for efficient conduction of air, development occurs while the lumen is filled with liquid, which is pushed throughout the airways via periodic peristaltic contraction of smooth muscle. Clinical observations and large animal models suggest a critical role for the (dynamic) regulation of transmural pressure in the lung, with dysregulation resulting

in hypo- and hyperplastic airways. However, experimental limitations have prevented precise control of the mechanical environment during development to distinguish the effects of dynamic transmural pressure from those due to peristaltic fluid flow. To address these shortcomings, we designed a microfluidic device to culture and apply dynamically-controlled transmural pressures within murine whole lung explants. Lungs explanted from E12 mouse embryos were intubated and inserted into the microdevice, which consisted of two fluidic chambers - one that surrounded the organ (pleural chamber) and one that was continuous with the airways via the intubated trachea (luminal chamber). Luminal and pleural pressures were regulated dynamically and imaged in real-time over 48 hours of culture. Transmural pressure significantly altered both the branch morphology and spatial localization, organization, and amount of airway smooth muscle. In addition to using allometric analysis to quantify pressure-induced morphological changes during branching, separate experiments mapped tissue deformations and fluid flow within the lumen using fluorescent microspheres. Whereas small-scale local peristaltic movements ( $\sim 1/\text{min}$ ) from airway smooth muscle have been documented, our timelapse-imaging studies also demonstrated significant systemic low-frequency long-duration contractions of the proximal airways ( $\sim 0.1/\text{hr}$ ). We also found significant fluid flow into the lung end-buds, producing bud dilation followed by branch extension. These fluid movements and cyclic temporal pressure changes within the bud resulted in spatially non-uniform epithelial surface strains consistent with previously reported patterns of cell proliferation during branching morphogenesis. Our studies suggest that luminal fluid forces may be critical for sculpting the airway architecture, through regulation of spatial patterns of growth, tuning branch angles, lengths, and/or diameters, ultimately leading to enhanced convection of air through the mature airway tree. Our microfluidic approach complements existing molecular and genetic tools in the mouse to elucidate how the mechanical microenvironment regulates lung development. These studies indicate a previously unappreciated role for the flow of luminal fluid in the regulation of branching morphogenesis.

766

**Apical constriction initiates budding morphogenesis in the embryonic chicken lung: insights from computational modeling.**

*V. D. Varner<sup>1</sup>, H. Kim<sup>1</sup>, C. M. Nelson<sup>1</sup>; <sup>1</sup>Princeton University, Princeton, NJ*

During early lung development, the complex system of interconnected airways is formed via branching morphogenesis. Physical forces play an indispensable role in this process, as altered mechanical loads have been shown to drive abnormal branching. Moreover, defects in branching can lead to a host of congenital respiratory defects, so determining how this tree-like structure arises in the embryo is crucial to understanding these disorders. In the early chicken embryo, airway branching is monopodial; that is, new branches form laterally off of a parent branch or stem. Here, we characterized the physical and cellular mechanisms which drive bud formation in the avian lung. Using culture of lung explants *ex vivo*, we found that apical localization of both F-actin and phosphorylated myosin light chain (pMLC) accompanies the formation of new secondary buds along the primary bronchial tube. Moreover, inhibiting actomyosin contractility prevents new buds from forming, which suggests a possible morphogenetic role for apical constriction (AC). To test if AC alone is sufficient to drive the formation of new buds, we constructed a nonlinear, 3D finite element model of the lung epithelium and used it to simulate AC in a bud-forming region of the bronchial tube. To model active shape changes in the epithelium, we employed a continuum theory for finite volumetric growth. Our results suggest that AC can drive only the initial stages of bud formation, and is insufficient to generate the more fully developed bud geometries observed experimentally. Moreover, a gradient in AC (decreasing with distance from the bud tip) is necessary to match these initial bud geometries – a result consistent with our F-actin staining. Since the developing

lung epithelium is also highly proliferative, we included growth in our model to assess whether AC and growth together are sufficient to drive bud formation. We considered cases where growth is either (i) uniform along the tube or (ii) elevated in the bud-forming region, and either (i) isotropic or (ii) longitudinal. In each case, however, we were unable to match the fully developed bud geometries observed in the embryo, which may suggest a possible mechanical role for the surrounding mesenchyme during branching. Since localized cell proliferation is generally considered to be the primary driving force behind lung bud formation, our finding that AC (not growth) initiates bud morphogenesis constitutes a novel mechanism in the lung.

767

**A moving zone of actomyosin contractility drives epidermal zippering and neural tube closure in ascidian embryos.**

*H. Hashimoto<sup>1</sup>, F. Robin<sup>1</sup>, K. Sherrard<sup>1</sup>, E. Munro<sup>1</sup>; <sup>1</sup>Molecular Genetics and Cell Biology, University of Chicago, Chicago, IL*

Neural tube closure is a key morphogenetic event in chordate development, whose failure leads to birth defects in humans, but its underlying mechanisms remain poorly understood. We are investigating the cytomechanical basis for neural tube closure in ascidians - basal chordates that share a similar body plan with vertebrates and form a simple neural tube with <100 cells. Ascidian neurulation occurs by neuroectoderm (ne) folding, followed by unidirectional "zippering" in which the neural folds and adjacent epidermis (epi) meet at the midline, then undergo junctional exchange (ne/epi → ne/ne + epi/epi) in a posterior-anterior progression to form a simple tube beneath a continuous epidermal sheet. Combining time-lapse fluorescence microscopy and immuno-staining of fixed embryos, we show that active non-muscle myosin II is highly enriched within a localized contractile zone (CZ) just ahead of the moving zipper where individual ne/epi junctions undergo rapid and pronounced shortening. Laser ablation experiments reveal that junctional tension is high along the entire ne/epi boundary and highest in the CZ. Chemical inhibitors of RhoA/Rho Kinase prevents localized myosin activation in the CZ, and inhibitors of either Rho kinase or Myosin II activity prevent the increase in junctional tension, ne/epi junction shortening, zipper progression and neural tube closure. Kinetic analysis reveals that newly met epidermal cells remain associated with the zipper during junction exchange, become highly elongated as the zipper moves anteriorly and then release from the zipper and relax towards more isodiametric shapes. Individual release events are often associated with transient increases in zipper progression, suggesting that active contraction ahead of the zipper is balanced by resistance to cell deformations behind the zipper, which is dissipated by junctional exchange and cell shape relaxation. Consistent with this, we measured elevated tensions at elongated epi/epi junctions just behind the zipper, but not following cell shape relaxation. These data suggest, and computer simulations validate, a model in which a localized zone of actomyosin contractility provides the driving force, while junctional exchange and cell shape relaxation create the essential force asymmetry to produce unidirectional zipper progression. We highlight mechanical advantages associated with this mode of tissue closure and suggest that similar mechanisms may operate during the late stages of neural tube closure in other chordates, including humans.

768

**Involvement of cell polarity and cell migration in folding phenomena of epithelial sheets**

S. Ishida<sup>1</sup>, R. Tanaka<sup>1</sup>, N. Yamaguchi<sup>2</sup>, T. Mizutani<sup>1</sup>, K. Kawabata<sup>1</sup>, H. Haga<sup>1</sup>; <sup>1</sup>*Transd. Life Sci., Grad. Sch. of Life Sci., Hokkaido Univ., Sapporo, Japan,* <sup>2</sup>*Faculty of Science, Hokkaido Univ., Sapporo, Japan*

Epithelial cells form a three dimensional (3D) structure while keeping epithelial polarity, consisting of apical and basolateral surfaces. Canine kidney epithelial cells (MDCK cells) form a cyst structure when embedded in a collagen gel. On a collagen gel (2D environment), MDCK cells form a monolayer sheet. Our group found that MDCK cells migrate to change the morphology from an epithelial sheet to a cyst structure when culture environment is shifted from 2D to 3D by collagen gel-overlay. However, the process and the mechanism of the migratory cyst formation after gel-overlay are unclear. Therefore, this study aimed at observing the cyst formation from following two points; 1: Rho and Rac activity that is known as a key regulator for cell migration, 2: cell polarity that is reported about an important role for morphogenesis in a collagen gel.

3D live cell imaging was performed to observe the process of the cyst formation. As a result, an epithelial sheet showed collective migration, folding from the very edge of the sheet. In order to observe the contribution of Rho activity, cells were treated with Y-27632 that is an inhibitor for ROCK, a downstream effector of Rho. For inhibition of Rac activity, Rac1 inhibitor II (Z62954982) was used. Each inhibitor decreased the folding speed. To clarify the contribution of the cell polarity to the folding phenomena, cells were treated with TGF- $\beta$ 1 that is a reagent to disturb apical-basal polarity and taken time-lapse images by using phase contrast microscopy. Compared with non-treated cells, TGF- $\beta$ 1 treated cells did not showed folding behavior. They just moved randomly. In order to perturb the function of basolateral protein, cells were treated with AIB2, which is an inhibitor of integrin- $\beta$ 1 known to localize at basolateral surface. The AIB2 treatment resulted in reduction of the folding speed.

Furthermore, the simulation model was built based on migratory force and cell polarity. The model showed that the weaker migratory force delayed the morphological change. In addition, the model did not display folding phenomena under the disruption of the polarity. These results indicate that the maintenance of cell migration and cell polarity is responsible for the cyst formation under the collagen gel-overlay.

**Foxg1 is necessary for thymic epithelial cell differentiation and survival.**

B. R. Jarvis<sup>1</sup>, Q. Wei<sup>1</sup>, B. G. Condie<sup>1</sup>; <sup>1</sup>*Genetics, University of Georgia, Athens, GA*

Thymic epithelial cells (TECs) are an essential component of the thymic microenvironment and are necessary for the production of normal T cells. Cortical (cTEC) and medullary TEC (mTEC) subtypes have different functions and distinct gene expression profiles. However, the transcription regulatory network controlling the specification and differentiation of TECs is poorly understood. We have identified additional transcription factors required for normal TEC differentiation and maintenance. Our gene expression analysis identified Foxg1 as a possible regulator of thymic epithelial cell differentiation. We have found that Foxg1 is expressed in TECs before the onset of TEC differentiation and continues to be expressed in them throughout fetal and postnatal development. Analysis of Foxg1 mutant mouse embryos revealed that TEC differentiation initiates normally but then becomes abnormal at E13.5-E14.5. In addition, levels of apoptosis are elevated in the fetal thymus of Foxg1 mutants. Foxn1, which is required for the initiation of TEC differentiation, is expressed throughout fetal development in Foxg1 mutant TECs suggesting that Foxg1 activity is not necessary for Foxn1 expression. Our results

suggest that Foxg1 may regulate TEC differentiation independently or in collaboration with Foxn1. Our genetic analysis supports a key role for Foxg1 in the development and survival of fetal thymic epithelial cells.

770

**A spatiotemporal blueprint for actomyosin assembly/disassembly during focal contractions in *C. elegans*.**

*F. B. Robin<sup>1</sup>, J. Michaux<sup>1</sup>, E. M. Munro<sup>1</sup>; <sup>1</sup>Molecular Genetics and Cell Biology, University of Chicago, Chicago, IL*

Actomyosin contractility plays many key roles during animal development by controlling changes in cell size and shape, migration, rearrangements and cell division. We are using the early *C. elegans* embryo as a model system to study a particularly dynamic mode of contractility known as pulsed or focal contractility, which is characterized by periodic cycles of actomyosin accumulation, contraction and disappearance. Focal contractility is used during many morphogenetic processes, including polarization in *C. elegans* embryos, ventral furrow invagination and germband elongation in *Drosophila* and convergent extension in *Xenopus*. Yet despite their apparent importance, the mechanisms that govern focal contractions remain unclear.

As an excitable event, pulsed contractility requires a combination of positive and negative feedback to start and terminate, respectively. One simple model - termed cortical instability - is that local stochastic accumulation of myosin drives local contraction of the cortex, thereby increasing local myosin concentration and favoring further contraction of the cortex. Alternatively, local accumulation of actin and myosin regulators under a pulsing master regulator might drive the local accumulation and dissipation of the actin and the myosin leading to the contraction. Distinguishing these possibilities requires measuring kinetics of F-actin and myosin turnover with very high spatial and temporal resolution. To this end, we developed methods that combine single molecule imaging and particle tracking to quantify local assembly, movement and disassembly of actin filaments and myosin motor minifilaments during focal contractions at very high spatial and temporal resolution.

Our results show that the focal contraction cycle can be separated into (1) an initiation phase that predates the contraction, and which correlates with a burst in actin assembly and myosin recruitment to the cortex, (2) a contraction phase, where actin and myosin are stabilized on the cortex and their movements undergo a transition from a rapid, uncorrelated to slow and directional, suggesting bipolar engagement of the myosin mini-filaments to the actin meshwork, and (3) a termination phase correlated with a burst in actin and myosin disassembly. These results show that focal contractions cannot be driven by a simple contractile instability – instead, they suggest that pulses are driven by phasic modulation of both actin and myosin assembly and disassembly by upstream regulators.

Knocking down cofilin, a regulator of actin disassembly, we observe an inhibition of contractility - demonstrating that actin turnover is critical to produce effective focal contractions – and while local pulses of actin concentration are retained, their dynamics is different. On the other hand, knocking down CYK-1, a formin actin nucleator, we observed larger, stronger contractions with temporal signatures similar to control.

Our work demonstrates that (1) the contraction is not required as a pacemaker but modulates the temporal dynamics of the pulses and (2) actin and myosin regulators tune the macroscopic properties – size, period, and intensity - of the focal contractions.

771

**Analysis of Caspase-dependent Signaling Mechanism on Myogenic Differentiation**

K. Shimizu<sup>1</sup>, T. Sawasaki<sup>1</sup>; <sup>1</sup>Cell-free Science and Technology Research Center, Ehime University, Matsuyama, Japan

To clarify the whole picture of caspase-dependent signaling mechanism, we developed the high-throughput protease substrate screening platform based on wheat germ cell-free protein synthesis system and molecular interaction detection technology (AlphaScreen). Using this system, we identified 30 protein kinases (PKs) as new substrates for caspase-3. Furthermore, we reported that the role of cleavage of TRB3, one of the substrate, under ER stress condition. It has been thus far shown that caspase activation accompanied by substrate cleavage is mainly involved in the execution of apoptosis, and yet at the same time is also increasingly being recognized as an important factor of regulation of cell differentiation. In this study, we investigated the effect of substrate PKs for caspase-3 on myogenic differentiation of C2C12 myoblasts as a model system. As a result, expression of myosin heavy chain, a late marker of myogenic differentiation, was increased by transient overexpression of two caspase-substrate PKs, suggesting that these PKs accelerate myogenic differentiation. Interestingly, cell death was observed in a large number of cells expressing one of the two PKs during the early phase of differentiation. Additionally, another PK induced process formation in C2C12 myoblasts and HeLa cells, and these cell mobility was increased. Now, we are investigating the crosstalk between caspase and these PKs signaling during the differentiation process.

<sup>4</sup>Centre for Microscopy, Characterisation and Analysis, University of Western Australia, Perth, Australia

The maintenance of bone homeostasis requires a tight balance between bone formation and bone resorption by osteoblasts and osteoclasts. The molecular mechanism(s) underlying the fundamental activities of these cells still remains largely unclear. In search of novel molecules that potentially play an important role in bone homeostasis we screened a number of ENU-induced mutant mouse lines. We identify choline kinase beta, a kinase that phosphorylates the first reaction in the biosynthesis of phosphatidylcholine, as a novel candidate regulator of bone homeostasis. Choline kinase beta mutant mice exhibit an osteoporotic phenotype as evidenced by microCT and histological assessment. In vivo and in vitro analysis reveals elevated osteoclast numbers in the mutant mice. Furthermore, osteoclasts from choline kinase beta mutant mice exhibit increased resorptive activity compared to those of littermate controls. Interestingly, exposure to elevated extracellular calcium results in a significant increase in intracellular calcium in osteoclasts derived from control mice however, this response is significantly attenuated in osteoclasts derived from choline kinase beta mutant mice. This may account for the increased resorptive activity in osteoclasts derived from the mutant mice. Treatment with CDP-choline in vivo and in vitro reduces osteoclast numbers, thereby rescuing the osteoclast phenotype. In vitro assays show a reduction in bone mineralisation in osteoblast cultures derived from the bone marrow of mutant mice. Taken together, our data document, for the first time, that choline kinase beta plays an important role in bone homeostasis by regulating both osteoclasts and osteoblasts.

**Tissue-specific stiffening of embryos parallels myosin and matrix expression and dynamically matches cardiomyocyte function.**

S. F. Majkut<sup>1</sup>, J. Swift<sup>2</sup>, D. Discher<sup>2</sup>; <sup>1</sup>Physics and Astronomy, University of Pennsylvania, Philadelphia, PA, <sup>2</sup>Chemical and Biomolecular Engineering, University of Pennsylvania, Philadelphia, PA

Healthy heart function and structure, from the tissue to cellular scale, depends on the establishment of mature tissue mechanics. On the cellular scale, late embryonic, neonatal and adult cardiomyocytes have demonstrated mechanosensitivity to ECM elasticity [1], namely that contractile activity, longevity in culture, and electrophysiological function is optimized when the cells are cultured on substrates of physiological stiffness of ~10-20 kPa. However, the heart begins functioning long before this mature mechanical environment is established. Here we examine the effects of microenvironment mechanics on chick cardiomyocyte function during early development, embryonic day 2-4 (E2-E4). We use micropipette aspiration to measure an effective local Young's modulus for the developing heart tube, finding an average value of ~1-2 kPa at these earliest stages. We use quantitative Mass Spectroscopy to identify abundant structural proteins that most likely contribute to tissue mechanics. Primarily actomyosin contractile protein and collagen I expression parallels the mechanical stiffening of the heart tissue. Pharmacologically interfering with either actomyosin contractility or the collagen network with blebbistatin or collagenase, respectively, softens heart tissue, in a dose dependent manner in the case of collagenase. In addition, transglutaminase can be used to stiffen the collagenous ECM. Stiffening or softening the ECM of intact heart tubes should allow for the maintenance of functional cellular contractile machinery. Both the stiffened or softened heart tube strains less during contraction than in the untreated case, suggesting an optimum mechanics for myocardial contraction even at the earliest functional stages. The contraction wave along the heart tube propagates with a velocity proportional to the stiffness of the tissue. When we culture isolated E3-4 cardiomyocytes on collagen coated polyacrylamide gel substrates of different stiffnesses and allow them to beat spontaneously in culture, we find that the cells are best able to contract on substrates of ~1.5 kPa, consistent with the physiological stiffness of the tissue from which they were derived. As in the whole heart, the cells were also less able to contract on much softer substrates of 300 Pa, or stiffer substrates of 10 kPa or more. This further points to an optimizing mechanics or cardiomyocyte strain that matches the physiological stiffness of the myocardium throughout development.

**Mechanical Stretch Promotes Elastic Fiber Formation in Rat Aortic Smooth Muscle Cells.**

T. Aida<sup>1</sup>, U. Yokoyama<sup>2</sup>, S. Minamisawa<sup>1,3</sup>; <sup>1</sup>Department of Life Science and Medical Bioscience, Waseda University, Tokyo, Japan, <sup>2</sup>Cardiovascular Research Institute, Yokohama City University, Kanagawa, Japan, <sup>3</sup>Cell Physiology Research Institute, The Jikei University School of Medicine, Tokyo, Japan

**[Background]** The elastic fiber system plays a principal role in the structural integrity and function of pulsating arteries. Vessels are exposed to various stresses by pulsatile and blood flow. These stresses are very important epigenetic factors for construction of vascular elastic fiber system through changes in extracellular matrix. Stretch is considered to change the elastic modulus, the expression levels of metalloproteinase-2 (MMP2), and phenotypes of vascular smooth muscle cells (SMCs). However, the relationship between mechanical stretch and elastic

fiber formation remains unknown. Therefore, our aim is to quantitatively evaluate the effect of stretch on elastic fiber formation. **[Methods]** The aortic SMCs of rat at embryonic days 21<sup>st</sup> were plated on a silicone chamber coated with fibronectin. The chamber was set on a pulse-motor-driven stretch machine (STREX, Japan), and stretched for 1day-14 days (60 cycles/min, extension rate: 10%). We assessed the elastic fiber formation, the expression levels of elastic fiber associated-genes and differentiation markers of SMCs in the stretched SMCs by immunostaining and qRT-PCR. **[Results]** Stretch promoted elastic fiber formation after 10days and 14days. The deposition of elastin was markedly aligned by stretch as the same alignment of SMCs. The expression levels of elastic fiber associated-genes such as elastin, lysyl oxidase, lysyl oxidase like protein 1, fibrillin1, fibulin4 and 5, latent TGF- $\beta$  binding protein 1 and 2, TGF- $\beta$  1 were increased by stretch, although the timing of increasing these genes expression was different. Especially, the expression of lysyl oxidase like protein 1 mRNAs was increased earlier from 2 days after stretch. Stretch also increased the expression of MMP2 mRNA, but decreased the expression of tissue inhibitor of MMP 1, 2 mRNAs. Collagen $\pm$ T $\alpha$ 1 and Collagen  $\pm$ V  $\alpha$ 1 were also increased after stretch. qRT-PCR analysis showed that SMCs differentiation markers such as h-caldesmon, SM1 and SM2 were increased after 14day-stretch, whereas the inflammatory mediator interleukin-6 was immediately increased after 1day-stretch and rapidly decreased afterward. **[Conclusion]** Cyclic stretch promoted elastic fiber formation through the alignment of elastin and the repeat of deposition and decomposition by changing in the gene expression and differentiation of aortic SMCs.

775

#### **Role of Telethonin in Sarcomere Assembly and Maintenance.**

*T. Sadikot<sup>1</sup>, M. Ferrar<sup>2</sup>; <sup>1</sup>Biology, Washburn University, Topeka, KS, <sup>2</sup>Molecular and Integrative Physiology, University of Michigan Ann Arbor, Ann Arbor, MI*

The N-terminus of telethonin forms a unique structure linking two titin N-termini at the Z-disc. While a specific role for the C-terminus has not been established, several studies indicate it may have a regulatory function. Using a morpholino approach in *Xenopus*, we show that telethonin knockdown leads to embryonic paralysis, myocyte defects, and sarcomeric disruption. These dystrophic defects can be rescued by expressing full-length telethonin mRNA in morpholino background, indicating that telethonin is required for myofibrillogenesis. However, a construct missing C-terminal residues (C<sup>del</sup>) is incapable of rescuing motility or sarcomere assembly in cultured myocytes. We therefore tested two additional constructs: one where four C-terminal phosphorylatable residues were mutated to alanines (C<sup>Ala</sup>) and another where terminal residues were randomly replaced (C<sup>mis</sup>). Observations with these constructs support that the telethonin C-terminus is required for assembly, but in a context-dependent manner, indicating that factors and forces present *in vivo* can compensate for C-terminal truncation or mutation. Further to determine if the phosphorylatable residues at the telethonin C-terminus are required for sarcomere organization additional constructs with individual alanine substitutions and two constructs containing phosphorylation mimics were also tested. These results corroborate our previous finding that telethonin is required for sarcomeric organization and also demonstrate that phosphorylation at telethonin C-terminus may be essential for its functions.

**Roles of CCN2 in energy metabolism in chondrocytes.**

A. Maeda<sup>1,2</sup>, S. Kubota<sup>1</sup>, Y. Miyake<sup>1</sup>, K. Kawata<sup>1</sup>, T. Nishida<sup>1</sup>, T. Hattori<sup>1</sup>, N. Moritan<sup>2</sup>, H. Kawaki<sup>1</sup>, K. M. Lyons<sup>3</sup>, S. Iida<sup>2</sup>, M. Takigawa<sup>1</sup>; <sup>1</sup>Department of Biochemistry and Molecular Dentistry, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan, <sup>2</sup>Department of Oral and Maxillofacial Reconstructive Surgery, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan, <sup>3</sup>Department of Orthopaedic Surgery, David Geffen School of Medicine at UCLA, Los Angeles, CA

*Purpose* : CCN2, also known as connective tissue growth factor (CTGF), is a classical member of the CCN family and is composed of four modules that interact with various molecules, such as growth factors, membrane receptors, and extracellular matrix components. CCN2 acts as a multifunctional molecule and regulates extracellular signaling in the microenvironment. CCN2 is known to play a critical part in the development and regeneration of mesenchymal tissues. In CCN2-null mice, skeletal dysmorphisms and deficiency in cell proliferation and extracellular matrix production in osteoblasts and chondrocytes are observed. These findings suggest that CCN2 is involved in the basic metabolism in osteoblasts and chondrocytes. Therefore, we aimed to clarify the role of CCN2 in energy metabolism therein.

*Methods*: Murine chondrocytes from CCN2-null and wild type(WT) mice, and a human chondrocytic HCS-2/8 cell line were utilized. Total RNA was extracted from those cells for subsequent microarray and real-time RT-PCR analysis. Metabolites were also extracted from the cells by methanol for the metabolome analysis with a capillary electrophoresis-tandem mass spectrometry. Cellular ATP levels were quantified by a bioluminescent assay system.

*Results*: Initially, we extracted and analyzed the RNA from chondrocytes obtained from rib cartilage of CCN2-null and WT mice. The result of DNA microarray analysis showed that the lack of CCN2 increased the expression of several ribosomal protein genes and remarkably decreased ATP synthase subunit  $\gamma$  gene expression. Since ATP synthase is a critical mitochondrial molecule motor that supplies a major part of cellular ATP. We next comparatively quantified ATP content in chondrocytes from CCN2-null and WT mice. ATP bioluminescence assay showed that ATP concentration in CCN2-null chondrocytes was significantly lower than that of WT chondrocytes. Subsequently, after knocking down the CCN2 mRNA using CCN2 siRNA, we analyzed the expression of these genes in a human chondrocytic cell line HCS-2/8 by real-time RT-PCR. Indeed, we found that even by temporarily knockdown of CCN2 gene, the expression of ATP synthase subunit  $\gamma$  gene was also suppressed. Furthermore Cto uncover the effects of CCN2/CTGF defect on energy metabolism in chondrocytes, metabolome analysis was performed with CCN2-null and WT chondrocytes. In CCN2-null mice, the intracellular levels of ATP, acetyl CoA and several amino acids including Glutamine, Serine, Tryptophan were remarkably lower than those in WT mice.

*Conclusions*: These findings indicate that CCN2 plays an important role in the maintenance of energy metabolism system in chondrocytes by supporting the production of ATP synthase.

777

### **Osteopontin Expression in Human Fetal Osteoblastic Cells Grown on a Chitosan Composite Biomaterial.**

*D. M. Peterson<sup>1</sup>, J. Stone<sup>2</sup>, A. Oyefusi<sup>3</sup>, P. Traisawatwong<sup>2</sup>, L. Carson<sup>2</sup>, A. Okri<sup>3</sup>, G. Regisford<sup>1</sup>; <sup>1</sup>Biology, Prairie View A&M University, Prairie View, TX, <sup>2</sup>CARC, Prairie View A&M University, Prairie View, TX, <sup>3</sup>Chemistry, Prairie View A&M University, Prairie View, TX*

Identification of a safe bone scaffolding material that would enhance the bone modeling process is needed. Interpretation and analysis of osteoblast cell biology in the presence of Chitosantrimethoxysilylpropyl Methacrylate (CTS) is the genesis of understanding the future potential of CTS bone scaffolding technology as an effective promoter of osteoblast function. We investigate human Fetal Osteoblast 19 (hFOB.19) cells in the presence of various concentrations of CTS. Analysis of cell viability, proliferation, as well as, identification of expression and localization of Osteopontin (OPN) was observed and recorded. MTT assay results suggest CTS directly enhances hFOB.19 proliferations in-vitro. Immunocytochemistry observations demonstrate OPN is localized in the plasma membrane. Increased concentration of CTS significantly increased hFOB.19 cell proliferation. OPN is localized throughout the plasma membrane of hFOB 1.19 cells. CTS proves to be an effective promoter of hFOB 1.19 function in-vitro.

778

### **Delayed Bone Development in a Preeclampsia Mouse Model.**

*S. L. Lababidi<sup>1</sup>, S. Nakhla<sup>2</sup>, M. Al-Ghafry<sup>3</sup>, A. Rafii<sup>3</sup>, R. L. Davisson<sup>4</sup>, F. Safadi<sup>1</sup>; <sup>1</sup>Northeast Ohio Medical University, Rootstown, OH, <sup>2</sup>Johns Hopkins University School of Medicine, Baltimore, MD, <sup>3</sup>Weill Cornell Medical College in Qatar, Doha, Qatar, <sup>4</sup>Weill Cornell Medical College, New York City, NY*

Pre-eclampsia (PE), a disease associated with high blood pressure during pregnancy, is a devastating and potentially fatal process which can negatively impact both mother and fetus. Beyond simple hypertension, the disease has negative impacts on maternal kidney function as well as fetal development. PE is highly associated with intrauterine growth retardation (IUGR) which can also impact bone and cartilage development. In this study, we investigate the effects of this disease during fetal and post-natal bone development. It is currently unclear how PE affects cartilage and bone development, though angiogenesis may be one possible connection, particularly because vasculature is crucial during endochondral ossification. Recent studies have demonstrated a down-regulation of VEGF to be a contributing factor in the development of PE. This study has focused on a BPH mouse model which imitates human PE (the mice develop hypertension and proteinuria in the final trimester, which resolve postpartum). The fetuses born to these mice show a significant delay in bone development, supporting our hypothesis of an association between angiogenesis and bone development. Specifically, it appears that BPH mice experience a significant delay in endochondral ossification. Histological analysis showed that BPH mice demonstrate significantly less von kassa staining (and therefore less matrix mineralization) when compared to the C57, wild type (WT) at E18.5 and in newborns. Expression of aggrecan protein, a key component of the cartilage ECM framework, was dramatically decreased in BPH fetuses when compared to the WT. Link protein, an anchor protein for aggrecan in cartilage, was also substantially decreased in BPH compared to WT fetuses. Further histomorphometric analysis of the BPH growth plate demonstrated considerably thicker hypertrophic zones in the cartilage growth plate, indicative of delayed endochondral ossification. These elements, coupled with the decrease in von kassa staining, confirm delays in endochondral bone ossification in BPH compared to WT fetuses. Taken together, further studies

are warranted to demonstrate the mechanism involved in delayed bone formation in PE as well as possible therapeutic strategies for the treatment of this devastating disease.

779

***Gpr177*, a novel locus for bone-mineral-density and osteoporosis, regulates osteogenesis and chondrogenesis in skeletal development.**

T. Maruyama<sup>1</sup>, M. Jiang<sup>1</sup>, W. Hsu<sup>1</sup>; <sup>1</sup>Department of Biomedical Genetics, Center for Oral Biology, James P Wilmot Cancer Center, University of Rochester Medical Center, Rochester, NY

Human genetic analysis has recently identified *Gpr177* as a susceptibility locus for bone-mineral-density and osteoporosis. Determining the unknown function of this gene is therefore extremely important to further our knowledge base of skeletal development and disease. The protein encoded by *Gpr177* exhibits an ability to modulate the trafficking of Wnt similar to the *Drosophila* Wls/Evi/Srt. Because of a critical role in Wnt regulation, *Gpr177* might be required for several key steps of skeletogenesis. To overcome the axial patterning defects with embryonic lethality associated with the inactivation of *Gpr177* in mice [1], conditional gene deletion is utilized to assess its functionality. Here we report the generation of four different mouse models with *Gpr177* deficiency in various skeletogenic cell types, including the mesenchymal cell, osteoblast and chondrocyte. The mesenchymal ablation of *Gpr177* severely impairs development of the craniofacial and body skeletons, demonstrating its requirement for intramembranous and endochondral ossification, respectively. Defects in the expansion of skeletal precursors and their differentiation into osteoblasts and chondrocytes suggest that Wnt production and signaling mediated by *Gpr177* cannot be substituted. Because the *Gpr177* ablation impairs the secretion of Wnt protein, we therefore identify their sources essential for osteogenesis and chondrogenesis. Contrary to the requirement of  $\beta$ -catenin signaling in the osteoblast precursors, our data show that the deletion of *Gpr177* in this population does not impair osteogenesis, suggesting that Wnt production from the undifferentiated mesenchymal cells is critical for Wnt signaling in the osteoblast precursors. In contrast, the deletion of *Gpr177* in either mesenchymal cells or chondrocytes causes similar skeletal deformities, implying that Wnt secretion from both cell types are required for chondrogenesis. These results indicate that the intercross of Wnt signaling between distinct cell types is carefully orchestrated and necessary for skeletogenesis. Our findings lead to a proposed mechanism by which *Gpr177* controls skeletal development through modulation of autocrine and paracrine Wnt signals in a lineage-specific fashion.

**Prenatal exposure to ethinylestradiol leads to the increase of premalignant lesions multiplicity and alters the morphologic pattern of male and female prostate of senile gerbils.**

A. P. Perez<sup>1</sup>, M. F. Biancardi<sup>1</sup>, C. S. Caires<sup>2</sup>, L. R. Falleiros Jr<sup>2</sup>, F. A. Santos<sup>3</sup>, S. R. Taboga<sup>2</sup>;  
<sup>1</sup>Biology, Unicamp, Campinas, Brazil, <sup>2</sup>Biology, Ibilce/Unesp, São José do Rio Preto, Brazil,  
<sup>3</sup>Morphology, Federal University of Goiás, Goiânia, Brazil

Endocrine disruptors (ED) are substances that have the potential to alter the structure and function of the endocrine system, including prostate. The aim of this study was to analyze the behavior of senile male and female gerbil prostatic gland exposed to ethinylestradiol (EE - component of oral contraceptive) during the prenatal period. Pregnant female received 15 µg/Kg/day EE diluted in mineral oil (EE/PRE group), whereas control group received only mineral oil. When male and female pups completed 12 months the male ventral prostate (VP) and female prostate were removed and processed for paraffin embedding. The prostates were stained with HE for multiplicity analysis of prostatic intraepithelial neoplasia (PIN) (n=5 and p≤0.05) and Gömori's reticulin for prostatic stromal analysis. In addition, the sections underwent smooth muscle alpha actin immunofluorescence and ultrastructural analysis using electron microscopy. The male and female prostate of EE/PRE group presented an increase in the number of PIN compared with the respective control. The stromal analysis revealed derangements in reticulin and collagen fibers disposition, mainly in PIN regions of EE/PRE male and female prostate. Moreover, it was verified through immunofluorescence the absence of alpha actin immunoreaction in prostatic buds areas and increased immunoreactivity in PIN regions of EE/PRE male and female prostate compared to respective control group. The ultrastructural analysis of male VP in EE/PRE group showed an apparent increase in Golgi apparatus, osmiophilic deposits such as lipofuscins, basal membrane detachment and collagen system derangements. Regarding to EE/PRE female prostate, it was noted the presence of vesicle fusion with secretion accumulation, lipofuscins deposits and displaced basal nucleus. The exposure to EE during the prenatal period contributed for appearance of PIN and disturbance in stromal compartment of senile gerbil male and female prostate. The gerbil prostate presents spontaneous lesions with aging due to hormonal imbalance that occurs in both sexes at this phase. Furthermore, the cellular ageing tends to augment in response to EE. The prostatic synthesis was also altered. Therefore, the action of this synthetic hormone can interfere in functionality of these glands. Thus, it can be concluded that exposure to EE during critical period, such as prenatal, promotes premalignant lesions and development alterations in the male and female prostate gland, and may contribute for the emergence of aging prostatic diseases.

**Behavior of the contractile myonemes of the ciliate *Stentor coeruleus* during oral regeneration and division.**

M. S. Maloney<sup>1</sup>; <sup>1</sup>Biol. Sci., Butler University, Indianapolis, IN

The contractile myonemes of *Stentor* are linear fibers that run longitudinally over the entire length of the cone-shaped cell some distance under the cell membrane that are thicker at the posterior end and gradually become thinner as they progress anteriorly. These myonemes have been shown to be composed of centrin-related proteins and an antibody to these proteins has been used to show their arrangement in normal cells (Maloney et al, J. Euk. Micro. 2005). During oral regeneration, the new oral apparatus forms as a oral primordium (OP) on the ventral surface of the cell in the area where the myonemes are thinner and more mesh-like. Initially the basal bodies of the new OP form above the myonemes and the myonemes can be seen running

through this area. As the primordium lengthens, the myonemes now curve along the ventral surface of the primordium and do not appear to be continuous with the myonemes on the dorsal surface of the OP. Furthermore, some of the myonemes just ventral to the OP often branch, forming a V shape in this area. On the dorsal surface of the OP, the myonemes begin forming the frontal field of the OP where they become much more numerous and tightly packed and precise branches form at right angles so that the myonemes here form a very tight, precise mesh seen in the mature oral apparatus. Cell division in *Stentor* involves transverse fission of the cone-shaped cell and the formation of an OP for the new posterior cell in a manner almost identical to that occurring during oral regeneration. Changes in the myonemes near the OP were the same as seen during oral regeneration with one dramatic exception. At the point where the cleavage furrow would form, the myonemes above the region of the prospective furrow began to thicken considerably whereas those below the prospective furrow remained thinner. The area above the furrow will become the posterior end of the new anterior daughter cell and the myonemes in this area should be thick. This thickening of the myonemes initially began on both sides of the OP and then proceeded in opposite directions around the cell, just as the cleavage furrow would when it becomes apparent.

### **Rac1 Activity Maintains the Human Tenocyte Phenotype.**

R. McBeath<sup>1</sup>, A. L. Osterman<sup>1</sup>, A. Fertala<sup>2</sup>; <sup>1</sup>The Philadelphia Hand Center, Thomas Jefferson University, Philadelphia, PA, <sup>2</sup>Department of Orthopaedic Surgery, Thomas Jefferson University, Philadelphia, PA

When cultured *in vitro*, human tenocytes undergo 'dedifferentiation', a process by which they change shape – lose their normal elongated phenotype – and stop producing collagen I. Previous work has demonstrated the involvement of the Rho GTPases, including RhoA and Rac1, in human connective tissue cell differentiation. We hypothesized that the process of human tenocyte dedifferentiation is caused by loss of activity of Rac1GTPase.

Human tenocytes were dedifferentiated via *in vitro* culture at low cell density. Human tenocytes were harvested from tendons of individuals undergoing finger revision amputation using IRB-approved protocols. Human tenocytes were plated at 5k cells/cm<sup>2</sup> and passaged *in vitro*. Tenocytes from passage 0, passage 2 and passage 8 were harvested after one week in culture and collected. With time in culture at low density, there is a change in tenocyte phenotype from elongated to polygonal. Furthermore, there is also decreased collagen I fibril formation, and decreased expression of collagen I and scleraxis in dedifferentiated tenocytes.

Inhibition of Rac1 activity via pharmacologic inhibition in human tenocytes resulted in dedifferentiation, cell shape changes and decreased collagen I production. Normal human tenocytes were treated with the Rac1 inhibitor NSC23766. The normal tenocyte phenotype was lost with Rac1 inhibition, as seen by changes in cell shape and decreased collagen I fibril formation. There was also decreased expression of collagen I and scleraxis with pharmacologic Rac1 inhibition.

When Rac1 activity was controlled in dedifferentiated human tenocytes using adenoviral infection of constitutively active Rac1, the tenocyte phenotype was regained, and collagen I production was increased. Human dedifferentiated tenocytes were infected with constitutively active Rac1, and harvested after one week and three weeks in culture. The human tenocyte phenotype is regained with Rac1 activation *in vitro*, as seen by resumption of elongated cell shape, increased collagen I fibril formation, and increased expression of collagen I and scleraxis

in those cells infected with constitutively active Rac1. These findings show that increased Rac1 activity underlies the maintenance of the normal human tenocyte phenotype *in vitro*.

We have observed the dedifferentiation of human tenocytes when plated at low density in culture. We have reproduced this phenotype via Rac1 inhibition, and have discovered that the normal human tenocyte phenotype can be potentiated in dedifferentiated tenocytes by increasing Rac1 activity. Knowledge of this molecular mechanism lends insight into strategies to improve connective tissue engineering, repair and regeneration.

#### **Abnormal tracheal cartilage formation in mice lacking Ca<sub>v</sub>3.2 T-type Ca<sup>2+</sup> channels.**

S-S. Lin<sup>1</sup>, K-R. Lee<sup>2</sup>, R. Smith<sup>3</sup>, K. Campbell<sup>4</sup>, C-C. Chen<sup>1</sup>; <sup>1</sup>*Institute of Biomedical Sciences, Academia Sinica, Taipei, Taiwan, Taipei, Taiwan,* <sup>2</sup>*Institute of Molecular Medicine, National Tsing Hua University, Hsinchu, Taiwan, Hsinchu, Taiwan,* <sup>3</sup>*Departments of Otolaryngology, Internal Medicine, Pediatrics and Molecular Physiology and Biophysics, University of Iowa, Iowa City, Iowa, USA, Iowa, IL,* <sup>4</sup>*Howard Hughes Medical Institute, Department of Molecular Physiology and Biophysics, Neurology and Internal Medicine, Iowa City, IA, Iowa City, IL*

Ca<sup>2+</sup> influx is crucial in initiating the differentiation of mesenchymal cells into chondrocytes, but which Ca<sup>2+</sup> channels are involved remains uncertain. Here we show that the T-type voltage-gated Ca<sup>2+</sup> channel Ca<sub>v</sub>3.2 is essential for tracheal chondrogenesis. Mice lacking this channel (Ca<sub>v</sub>3.2<sup>-/-</sup>) develop congenital tracheal stenosis, as a consequence of incomplete formation of cartilaginous tracheal support. Conversely, forced Ca<sub>v</sub>3.2 overexpression in ATDC5 cells leads to enhanced chondrogenesis, an effect that can be blunted by both a blocker of T-type Ca<sup>2+</sup> channels and an inhibitor of calcineurin, suggesting that Ca<sub>v</sub>3.2 is responsible for Ca<sup>2+</sup> influx during chondrogenesis. Finally, tracheas from Ca<sub>v</sub>3.2<sup>-/-</sup> mice exhibit a reduction in Sox9 expression. Ca<sub>v</sub>3.2-dependent Sox9 upregulation requires a putative NFAT binding site that we identified within the mouse Sox9 promoter. Our findings show that the signaling pathway underlying Ca<sup>2+</sup>-induced chondrogenesis involves the Ca<sub>v</sub>3.2 T-type channel and is dependent on calcineurin and NFAT

784

#### **Salt-Inducible Kinase 3 is critical for chondrocyte hypertrophy during bone development.**

S. Sasagawa<sup>1,2</sup>, K. Itoh<sup>1</sup>; <sup>1</sup>*Biology, Osaka Medical Center for Cancer and Cardiovascular Diseases, Osaka, Japan,* <sup>2</sup>*Graduate School of Medicine, Osaka University, Osaka, Japan*

Salt-inducible kinase 3 (SIK3) belongs to AMPK family, but its physiological and functional role was so far poorly understood. To elucidate its biological function, we generated SIK3 deficient mice and found that SIK3 deficient adult mice presented systemic bone abnormality. The feature of skeletal malformation in SIK3 deficient mice was close to characteristic of that in rickets, but the concentration of phosphate and calcium in serum were almost normal compared with wild-type mice. Thus, we suspected that the cause of this bone malformation was bone in itself. Anatomical and histological analyses revealed that the bone inside was occupied by massive chondrocytes at adulthood and pointed out that the bone defect occurred since E14.5 stage, in which chondrocyte hypertrophy was almost blocked. Consistent with this phenotype, SIK3 expression was detected in cytoplasm of prehypertrophic and hypertrophic chondrocytes in wild-type embryos. By immunofluorescence imaging, we found that HDAC4, a crucial repressor of chondrocyte hypertrophy, remained in the nuclei in SIK3-deficient chondrocytes, but was localized in the cytoplasm in wild-type hypertrophic chondrocytes, suggesting that SIK3 was required for translocation of HDAC4 to quit its transcriptional repressive activity. In order to

confirm this hypothesis, we demonstrated that SIK3 directly formed complex with HDAC4 and SIK3 was required for anchoring HDAC4 in the cytoplasm, thereby releasing MEF2C, a crucial facilitator of chondrocyte hypertrophy, from suppression by HDAC4 in nuclei. As a gain-of-function approach, we also generated chondrocyte-specific SIK3 transgenic mouse. Although we could not see any phenotype in developmental and juvenile stage, we finally found the abnormal closure of growth plate and flatten face since 4.5 month-old age, suggesting that overexpression of SIK3 induced excessive consumption of chondrocytes. The SIK3-deficient phenotype in bone was rescued by this transgenic SIK3 expression. In conclusion, we here report an essential role for SIK3 in facilitating chondrocyte hypertrophy during skeletogenesis and growth plate maintenance.

## Cell Fate Determination

785

### The Role of *Rx* in cell fate decisions during retinogenesis.

*H. M. Rodgers*<sup>1</sup>, *P. H. Mathers*<sup>1</sup>; <sup>1</sup>West Virginia University, Morgantown, WV

During retinogenesis, retinal neuron cell birth occurs in two distinct temporal phases: early (during embryonic ages) and late (in the first ten postnatal days). Retinal neurons generated during the late phase are dependent on continued retinal progenitor proliferation. The transcription factor *Rx* is crucial for eye development, playing roles in both optic vesicle initiation and progenitor proliferation and is therefore necessary for late-born cells. Cone photoreceptors are early-born cells and therefore are not as dependent on continued progenitor proliferation. In mice with a conditional *Rx* deletion, we observed an absence of cone opsin expression in postnatal day 21 retinas, in addition to the loss of the late-born cell markers for Muller glia, bipolar cells and rod photoreceptors. In this study, we sought to explore the necessity of *Rx* on retinal cell fate early in retinogenesis. We hypothesized that *Rx* is essential for cone photoreceptor development in addition to being necessary for the formation of the late-born cells via its role in progenitor proliferation. Using embryonic retinas to explore the effects of *Rx*-deletion on early development, we used a panel of antibodies to assess cell fate changes in the embryonic retina. The results showed similar cell fate changes to those seen in adult tissue and activated caspase-3 labeling suggest that the changes were not due to cell death. This evidence suggests that *Rx* is necessary for cone cell fate decisions in the vertebrate eye.

786

### Functional rescue of PR null mammary epithelium by redirected testicular cells in vivo.

*G. H. Smith*<sup>1</sup>, *C. A. Boulanger*<sup>1</sup>, *L. H. Anderson*<sup>1</sup>, *R. D. Bruno*<sup>1</sup>, *J. P. Lydon*<sup>2</sup>; <sup>1</sup>National Cancer Institute, Bethesda, MD, <sup>2</sup>Baylor College of Medicine, Houston, TX

Stem and progenitor cells in most adult tissues reside in specialized, highly regulated microenvironments called stem cell niches. We have previously shown that testicular, neural, bone marrow and cancer cells respond to the signals provided by the mammary niche (stroma, epithelial cells, local and extrinsic factors) and alter their cell fate to that of mammary epithelial progenitor cells. In an effort to determine if hormonal signals from progesterone receptor (PR) expressing mammary epithelial cells are required for this redirection, we mixed PR null epithelial cells with Wap-Cre/Rosa26reporter testicular cells from adult male mouse seminiferous tubules. The testicular cells were redirected to mammary epithelial cell fate and in the process rescued the functionally deficient PR null cells, allowing them to produce alveolar secretory structures in the chimeric outgrowths at parturition.. We identified redirected testicular cells by staining with

anti-Progesterone Receptor (anti-PR) antibodies. Positive cells were found both in ducts and in secretory structures. PR null outgrowths were uniformly negative for anti-PR staining. This demonstrates that PR null mammary tissue can redirect testicular cells to undertake mammary epithelial cell fates and in addition PR null testicular cells are redirected as well to mammary epithelial secretory cell fate by signals emanating from the PR-positive redirected wild type testicular cells.

787

**Regulated phosphorylation of the stem cell fate determinant Musashi controls cell cycle progression during development and differentiation.**

*M. C. MacNicol<sup>1</sup>, C. E. Cragle<sup>1</sup>, A. M. MacNicol<sup>1</sup>; <sup>1</sup>Neurobiology & Developmental Sciences, University of Arkansas for Medical Sciences, Little Rock, AR*

Musashi is an evolutionarily conserved, sequence-specific RNA binding protein that has been shown to play a critical role in promoting physiological stem and progenitor cell self-renewal. Musashi has also been implicated pathologically in the development and progression of neural, colon, breast and hematopoietic cancers. During self-renewal of mammalian stem cells, Musashi represses translation of mRNAs encoding inhibitors of cell cycle progression. However, during stem cell differentiation Musashi target mRNAs are translated. The underlying molecular mechanism controlling this functional switch in Musashi activity has not been established. In this study, we demonstrate that differentiation of rat embryonic neural stem cells and human SH-SY5Y neuroblastoma cells results in the rapid phosphorylation of Musashi on two evolutionarily conserved serine residues. Musashi phosphorylation is associated with de-repression and translation of Musashi target mRNAs. Expression of a Musashi phosphorylation mutant protein blocked differentiation and promoted inappropriate growth of SH-SY5Y cells under nutrient deprivation. Using a novel biological assay to directly assess Musashi function we have found that phosphorylation of Musashi is mediated by both cyclin-dependent kinase and MAP kinase signaling pathways. Taken together, our data indicate that regulated phosphorylation directs a functional switch in Musashi action by converting it from a repressor to an activator of mRNA translation to promote cell cycle arrest in response to environmental cues. The identified phosphorylation-dependent switch in Musashi function may present a novel regulatory node for therapeutic control of pathological stem cell proliferation.

788

**maternal KLF2 regulates the expression of early pan-ectodermal activator, Foxi1e, in *Xenopus* development.**

*S-W. Cha<sup>1</sup>, A. Shoemaker<sup>1</sup>, C. Wylie<sup>1</sup>, M. Kofron<sup>1</sup>; <sup>1</sup>Cincinnati Children's Research Foundation, Cincinnati, OH*

One of the first, and major, patterning events that takes place in all triploblastic embryos is the formation of the three primary germ layers. In the early *Xenopus* embryo, maternally encoded T-box transcription factor, VegT, is localized to the vegetal cytoplasm in the oocyte, and can initiate mesoderm and endoderm formation. But, much less is known about the formation of the ectoderm, which arises from the most animally located cells of the blastula. Previously we shown that Foxi1e is the first known early zygotic pan-ectoderm activating gene and another Forkhead box protein, Foxi2, is key activator for its expression and other epidermal genes' expressions. Despite having maternal activator, Foxi2, in entire ectodermal tissue, Foxi1e is only expressed in deep layer of presumptive ectodermal tissue, it suggests that the existence of potential repressor in superficial layer. Here, we report that a member of Kruppel-like factor

family, KLF2, as the maternal repressor for Foxi1e expression. This set of maternal activator/repressor (Foxi2/KLF2) will provide the mechanism of differential expression of Foxi1e.

789

**Testing a role for dHb9 expressing neurons in eclosion behavior in *Drosophila* by targeting the cell death gene, reaper.**

*J. J. Fernandes<sup>1</sup>, S. Banerjee<sup>1</sup>, M. Toral<sup>1</sup>, D. Conway<sup>1</sup>; <sup>1</sup>Zoology, Miami University, Oxford, OH*

**Introduction:** The *Drosophila* nervous system undergoes structural changes during metamorphosis to accommodate new behaviors that are manifested by the adult. Among these changes is a drastic reduction of the abdominal ganglion. Our lab is interested in understanding motor remodeling, specifically how larval motor neurons are restructured to innervate adult specific muscles and how they contribute to adult-specific neural circuits. Since there are 34 motor neurons in each hemisegment, we use subset specific motor neuron markers to follow the fate of larval motor neurons through metamorphosis. dHb9 is an identity gene that labels motor neurons that project to mostly ventral muscles and some dorsal targets in the larva. Initial work has shown that dHb9 is expressed by several neurons in the anterior abdominal hemisegments and that these innervate segment specific muscles. Among the muscles innervated by the neurons are two that are known to affect the early adult behavior of eclosion (Kimura et al 1990), the act of emerging from the pupal casing. The objective of this study is to test the role of dHb9 expressing neurons in eclosion by expressing the cell death gene reaper. **Methods:** Using a dHb9-Gal4 driver, a UAS-reaper transgene will be targeted to dHb9 expressing cells during the entire period of metamorphosis to bring about elimination of the ventrally projecting neurons. Temporal control of reaper expression will be achieved by expressing a temperature sensitive Gal80 gene which blocks Gal4 function at permissive temperatures. The restrictive temperature will be deployed during the period of metamorphosis. The average time for normal fly to eclose at 25°C is 101 hours after puparium formation (APF). Therefore, flies that eclose between 98 and 103 hours APF will be classified as normal. Flies that eclose after this time range will be classified as late eclosers. The flies that develop in the puparium but do not eclose will be classified as non-eclosers. 100 animals of both the control and experimental types will be examined. At least 10 animals from each category will be dissected to determine (1) the number/pattern of dHb9 expressing cells, (2) presence/absence of neuromuscular junctions made on muscles in A1 and A2, with an emphasis on MFs 12 and 13. **Results:** Preliminary studies have shown that when the cell death gene, reaper was targeted to dHb9 expressing cells during the pupal phase, 36% failed to eclose (n= 38), a 3 fold deviation from control animals (12%, n=26). These data allow us to conclude that dHb9expressing neurons do contribute to the function of eclosion. **Future Directions:** (1) We anticipate that lack of eclosion/delay in eclosion will involve absence of/defects in dHb9 innervation of the eclosion muscles in A1 and A2. These attributes will be assessed using immunohistochemistry to detect dHb9 expression (anti-GFP), Innervation (anti-HRP) and Muscles (phalloidin). (2) The motor neurons and their terminals will also be followed during metamorphosis to analyze any developmental deviations in neuromuscular patterns (3) A more severe transgene, Diptheria toxin, which blocks protein synthesis will also be targeted to dHb9 expressing neurons. All these experiments are ongoing and the emerging data will be presented.

790

**Vexin (Vxn) is a novel neural-specific gene that regulates cell cycle exit downstream of proneural factors in Xenopus.**

*K. B. Moore<sup>1</sup>, M. Logan<sup>2</sup>, I. Al Diri<sup>1</sup>, M. Vetter<sup>1</sup>; <sup>1</sup>Dept of Neurobiology & Anatomy, University of Utah, Salt Lake City, UT, <sup>2</sup>Department of Neurology, Oregon Health & Science University, Portland, OR*

We identified vexin (vxn; previously called sbt1) as a target gene for proneural basic helix-loop helix transcription factors during *Xenopus* development. Vxn is conserved across vertebrate species and encodes a novel protein with no known functional motifs. Vxn is transiently expressed as cells initiate differentiation in the *Xenopus* nervous system. In mouse, vxn is expressed in differentiating neurons and is maintained in subsets of postmitotic neurons, with high expression levels in the adult cerebral cortex.

To assess the function of vxn, we performed gain and loss of function experiments in *Xenopus*. Inhibition of Vxn translation by injection of antisense morpholino (MO) into cleavage-stage blastomeres blocked neuronal differentiation. Similarly, targeting vxn MO to retinal progenitors inhibited retinal neuron differentiation, resulting in an increase in Müller glia.

Conversely, overexpression of vxn causes enhanced neural differentiation, with expansion of the domains of N-tubulin positive neurons within the neural plate. Similarly, overexpression of *Xenopus* or mouse vxn in retinal progenitors promoted differentiation of early born retinal neurons, and also strongly cooperated with the proneural bHLH factor Atoh7 to promote neurogenesis.

Overexpression of vxn caused a reduction in mitotic cells in neurula stage embryos, as measured by phospho-histone H3 staining, and also caused an increase in expression of the cyclin-dependent kinase inhibitor p27Xic1. Morpholino knockdown of both vxn and p27Xic1 enhanced the block on neural differentiation in the *Xenopus* neural plate. The function of vxn during *Xenopus* neurogenesis is strikingly similar to that of Pak3, and we showed that vxn and Pak3 synergize to promote expansion of N-tubulin positive domains during primary neurogenesis, and that knockdown of both vxn and Pak3 enhanced the block on neural differentiation.

Both exogenously expressed epitope-tagged Vxn protein (mouse and *Xenopus*), as well as endogenous Vxn protein, localize to the cell membrane and the nucleus in *Xenopus*. By generating forms of Vxn tagged with either nuclear localization or nuclear export sequences we showed that Vxn must localize to the nucleus to promote cell cycle exit and neural differentiation.

We propose that vxn is expressed in progenitors as they initiate neuronal differentiation, and appears to regulate cell cycle exit downstream of proneural bHLH factors during *Xenopus* development.

**The role of fad104, a regulator of adipogenesis, in calvarial bone formation through BMP/Smad signaling.**

*K. Kishimoto<sup>1</sup>, M. Nishizuka<sup>1</sup>, D. Katoh<sup>1</sup>, S. Osada<sup>1</sup>, M. Imagawa<sup>1</sup>; <sup>1</sup>Nagoya City University, Nagoya, Japan*

To elucidate the molecular mechanism of adipogenesis, we isolated numerous genes whose expression was increased at the beginning of adipogenesis. Among them, factor for adipocyte differentiation 104 (fad104) is a novel gene, which positively regulates adipogenesis. FAD104 is a transmembrane protein containing proline-rich region and nine fibronectin type III domains. In previous study, we reported that disruption of fad104 causes neonatal lethality due to lung hypoplasia including immaturity of alveolar type II cells. In addition, we found that fad104 negatively regulates the differentiation of MEFs into osteocytes. This result implied that fad104 was involved in bone formation, but the physiological role of fad104 in bone formation was not known. Therefore, we prompted to characterize the role of fad104 in bone formation.

Alizarin red S/Alcian blue skeletal staining revealed skeletal alteration in fad104-deficient mice. In calvarial bones, anterior fontanel closure was accelerated in fad104-deficient mice at E18.5. Furthermore, the femur was widened in fad104-deficient mice at E18.5. Next, we examined the role of fad104 for the differentiation of primary cultured mouse calvarial cells. In calvarial cells, the expression of fad104 was decreased in the early stage of differentiation. Deletion of fad104 enhanced calvarial cell differentiation. Moreover, adenoviral infection of adfad104 into fad104-deficient calvarial cells suppressed the enhanced ossification by disruption of fad104. These results indicate that fad104 inhibits calvarial osteoblast differentiation. Bone morphogenetic protein (BMP) plays essential roles in osteoblast differentiation. It is largely known that activation of BMP/Smad signaling pathway strongly promotes osteoblast differentiation. Therefore, we examined whether fad104 participated in BMP/Smad signaling pathway. In calvarial cells, disruption of fad104 enhanced the level of BMP2-induced Smad1/5/8 phosphorylation and the mRNA expression of Inhibitor of DNA binding 1 (Id1), a BMP target gene. Additionally, FAD104 overexpression attenuated the level of Smad1/5/8 phosphorylation and Id1 expression. In conclusion, our results demonstrate that fad104 inhibits BMP/Smad signaling pathway, and negatively regulates calvarial bone formation.

792

**Alkaline phosphatase expression in 3T3F44-2A adipocytes is related to gene regulation of lipid metabolism.**

*C. P. Hernández-Mosqueira<sup>1</sup>, C. A. Velez-delValle<sup>1</sup>, W. Kuri-Harcuch<sup>1</sup>; <sup>1</sup>Cell Biology, Centro de Investigación y de Estudios Avanzados del IPN, México D.F., Mexico*

The increasing worldwide prevalence of obesity and its related disorders, make of relevance the understanding of the molecular interconnections related to increased adiposity. Differentiation of adipocytes is a complex process in which preadipocytes undergo changes in gene expression that produce biochemical, morphological and metabolic transformations that culminate with the cell ability to store energy in form of triglycerides in organelles known as lipid droplets. Regulation of synthesis, storage and release of triglycerides is mediated by different mechanisms involving the expression of molecules with specific functions for fatty acids synthesis and degradation.

There are three types of alkaline phosphatase: tissue nonspecific (TNAP) or liver/bone/kidney, intestinal, and placental, which are encoded by different genes *akp2*, *akp3* and *akp5* respectively that have different physiological tissue specific functions. The activity of alkaline

phosphatase in 3T3L1 cell line and in murine and human adipose tissue has been described, but it is not clear if this activity is addressed only to *akp2* gene. By RTPCR we measured the mRNA levels of these enzymes in 3T3F44-2A cells and in mice adipose tissue; we found only the expression of *akp2*. Enzymatic activity assays showed that the activity of the enzyme alkaline phosphatase increases during differentiation into adipocytes of the 3T3F44-2A cells as has been shown for the sister cell line 3T3L1, reinforcing the idea of a possible role for this enzyme in the metabolism of adipocytes. In order to gain some insight we used the specific inhibitors of TNAP, levamisole and L-histidine. We found that inhibition of TNAP alters the expression and activity of the enzyme glycerol phosphate dehydrogenase, but has no impact in malic enzyme. Also, inhibition of TNAP modifies mRNA levels of the main lipogenic regulator PPAR $\gamma$ 2 and other specific genes of lipid and carbohydrate metabolism. Our data demonstrate that the activity of alkaline phosphatase is involved in the regulation of the activity and gene expression of relevant metabolic molecules in adipose cells.

**Probing mammalian neural stem cell differentiation in vivo.**

*C. Esk<sup>1</sup>, J. Zuber<sup>2</sup>, J. Knoblich<sup>1</sup>; <sup>1</sup>IMBA - Institute of Molecular Biotechnology Austria, Vienna, Austria, <sup>2</sup>IMP – Institute of Molecular Pathology, Vienna, Austria*

Mammalian neurogenesis in the cerebral cortex requires the generation of millions of neurons originating from neural stem cells while maintaining an active population of undifferentiated progenitors. This necessitates a tightly controlled balance of symmetric and asymmetric neural stem cell divisions as well as subsequent manifestation of stem cell versus neuronal fates. Many cellular processes influence these crucial balances but systematic analysis of factors involved has been missing. Here we describe an approach to probe multiple genes in a parallel screening setting in vivo allowing for systematic analysis of mammalian neurogenesis. To this end we developed an effective viral delivery method to the developing murine neocortex targeting cycling neural stem cells lining the lateral ventricle. Comparison of viral constructs and promoters yielded a retroviral construct that is highly efficient in transducing stem cells and exhibits sustained expression in differentiated progeny. Retroviral preparations carrying short hairpin RNA (shRNA) targeting specific mRNAs as well as a fluorescent marker were used to follow the fate of neural stem cells and their progeny at embryonic day E13.5. Analysis followed 4-5 days post transduction by immunofluorescence, as well as separation of shRNA carrying neurons and stem cells using FACS. The goal of this setup is to quantify individual shRNAs in both populations in parallel using next generation sequencing. This will allow for characterization of both total stem cell and neuron pool size as well as their respective balance depending on individual shRNAs. Initial candidate shRNAs will target transcriptional and epigenetic factors as these are key to establishing differential cell fates. This systematic approach to characterize mammalian neurogenesis will deepen our understanding of this vital process.

**Molecular and biochemical responses of *Volvox carteri* to oxidative stress.**

E. K. Rankin-Gee<sup>1,2,3</sup>, M. Lera<sup>2,4</sup>, U. Lingappa<sup>2,3</sup>, B. Bebout<sup>2</sup>, O. Marcu<sup>2,3</sup>; <sup>1</sup>UCLA, Los Angeles, CA, <sup>2</sup>NASA Ames Research Center, Moffett Field, CA, <sup>3</sup>Carl Sagan Center, SETI Institute, Mountain View, CA, <sup>4</sup>Lockheed Martin, Moffett Field, CA

Reactive oxygen species (ROS) can act as signaling molecules to cause physiological changes to gene expression and metabolism. ROS, including superoxide (O<sub>2</sub><sup>-</sup>) and peroxides, are also highly reactive molecules that cause oxidative damage to proteins, lipids and DNA. It has previously been shown that exposure of the multicellular, eukaryotic green alga *Volvox carteri* to heat shock conditions (42.5°C), which induces the onset of the sexual reproductive cycle, results in the production of ROS. Here we show that the ROS response to heat stress is paralleled by changes in photosynthetic metabolism, antioxidant enzyme activity and gene expression, and fluctuations in the elemental composition of cells. Metabolism, as measured by pulse amplitude modulated (PAM) fluorometry over two hours of heat stress, showed a linear decrease in the photosynthetic efficiency of *Volvox*. ROS quantification uncovered an increase in ROS in the culture medium accompanied by a decrease in ROS produced inside the *Volvox* colonies, suggesting an export mechanism is utilized to mitigate stress. Enzyme kinetics indicated an increase in SOD activity over time when cultures were heat shocked. Using X-ray fluorescence at the Stanford Synchrotron Radiation Lightsource, we show that these changes coincide with cell-specific import/export and intracellular redistribution of transition elements and halides. This suggests that the cellular metallome is also engaged in mediating oxidative stress in *Volvox* by modulating ROS signaling and developmental pathway decisions.

795

**Actin stress fiber disruption triggers adipocyte differentiation.**

H. Nobusue<sup>1</sup>, N. Onishi<sup>2</sup>, T. Shimizu<sup>2</sup>, E. Sugihara<sup>2</sup>, Y. Oki<sup>1</sup>, Y. Sumikawa<sup>1</sup>, T. Chiyoda<sup>2</sup>, H. Saya<sup>2</sup>, K. Kano<sup>1</sup>; <sup>1</sup>Nihon University, Fujisawa, Japan, <sup>2</sup>Keio University School of Medicine, Shinjyuku, Japan

Adipocyte differentiation at an early stage is directly regulated by gene expression of a master regulator such as peroxisome proliferator-activated receptor-γ (PPARγ). On the other hand, the hallmark of adipogenesis process is the dramatic alteration in actin cytoskeleton as the structure of filamentous actin is converted from stress fibers to cortical actin. However, the correlation between actin cytoskeleton remodeling and PPARγ-mediated adipocyte differentiation program still remains to be clarified. Here, we report that actin cytoskeleton remodeling itself acts as a trigger of adipocyte differentiation. Actin stress fibers were immediately disrupted prior to PPARγ expression after adipogenic induction. The inhibition of actin stress fiber disruption by treatment with an cytoskeletal fixation agent phalloidin and transfection of an actin depolymerizing factor cofilin siRNAs resulted in suppressed PPARγ expression and lipid droplet accumulation after adipogenic induction. In addition, the activation of RhoA protein, which is a prominent regulator of cytoskeletal dynamics, was rapidly reduced after adipogenic induction. We further found that ectopic expression of activated RhoA inhibited actin stress fiber disruption and adipogenesis, and these effects were recovered by treatment with the RhoA kinase inhibitor Y-27632. Moreover, addition of an actin polymerization inhibitor cytochalasin D (CytD) in active RhoA-expressing cells led to the disruption of actin stress fibers and, thereby rescued adipocyte differentiation. Amazingly, we found that treatment of Y-27632 alone or CytD alone is sufficient for causing adipocyte differentiation even without an adipogenic cocktail by mimicking actin cytoskeleton remodeling. Our findings strongly suggest that actin stress fiber disruption triggers adipocyte differentiation, which provide a new insight to the regulatory mechanisms of adipogenesis.

796

**Lgr5+ Supporting Cells Proliferation and Hair Cell Transdifferentiation in Response to Wnt/ $\beta$ -Catenin and Atoh1 Expression in the Postnatal Mouse Cochlea *in vivo*.**

B. R. Kuo<sup>1</sup>, E. Baldwin<sup>1,2</sup>, R. Chai<sup>3</sup>, Z. Liu<sup>1</sup>, M. Taketo<sup>4</sup>, R. Nusse<sup>5</sup>, A. Cheng<sup>3</sup>, J. Zuo<sup>1</sup>;  
<sup>1</sup>Developmental Neurobiology, St. Jude Children's Research Hospital, Memphis, TN, <sup>2</sup>Bath University, Bath, United Kingdom, <sup>3</sup>Department of Otolaryngology-Head and Neck Surgery, Stanford University School of Medicine, Stanford, CA, <sup>4</sup>Department of Pharmacology, Graduate School of Medicine, Kyoto University, Kyoto, Japan, <sup>5</sup>Department of Developmental Biology, Stanford University, School of Medicine, Stanford, CA

During the development of the inner ear, Wnt signaling plays a role in the formation of the otic placode, and Wnt-responsive cells are present in the postnatal quiescent cochlea and vestibular sensory organs. Lgr5 is a Wnt target gene that is expressed in actively cycling cells of the intestinal crypt and hair follicles of the skin, and lineage tracing shows that Lgr5+ cells can self-renew and give rise to the major cell types and derivatives of the aforementioned organs. Thus, Lgr5 has been proposed to be a stem cell marker. Lgr5 has been shown to be expressed in the inner ear during the first week of postnatal development. We hypothesize that these Lgr5+ supporting cells might represent the progenitor/stem cells of the postnatal mouse inner ear with potential for hair cell regeneration, and that Wnt/ $\beta$ -catenin overexpression in these cells would result in cell fate switch to hair cells. To test this hypothesis we characterized the Lgr5-EGFP-IRES-CreER;Rosa-floxed-stop- $\beta$ -catenin overexpressor mouse that can be induced to ectopically express  $\beta$ -catenin specifically in Lgr5+ cells. Following the induction at P0-P1, Lgr5+ cells medial to the inner hair cells divided and formed many isolated replication foci throughout the cochlea that persisted up until P21. The Wnt-responsive cells did not transdifferentiate into hair cells, as they do not express putative hair cell markers (Myosin7a or Calbindin), but retain the expression of putative supporting cell marker (Sox2), and Lgr5. We conclude that the Wnt/ $\beta$ -catenin overexpression alone in Lgr5+ supporting cells leads to their division, but is not sufficient to promote their differentiation into hair cells. We are investigating whether the co-expression of Atoh-1, a hair cell differentiation factor, will promote the transdifferentiation of the proliferating Lgr5+ supporting cells into hair cells. **Inflammatory cytokines alter cell fate decisions during airway epithelial morphogenesis.**

H. Danahay<sup>1,2</sup>, B. E. Montgomery<sup>2</sup>, A. B. Jaffe<sup>2</sup>; <sup>1</sup>Respiratory Diseases Area, Novartis Institutes for BioMedical Research, Horsham, United Kingdom, <sup>2</sup>Developmental & Molecular Pathways, Novartis Institutes for BioMedical Research, Cambridge, MA

The precise balance and distribution of different epithelial cell types is required to maintain tissue homeostasis. In the lung, perturbations of this balance are hallmarks of human respiratory diseases, leading to goblet cell metaplasia and enhanced mucus secretion in asthma and chronic obstructive pulmonary disease (COPD). In the conducting airway, the basal cell acts as the progenitor for both secretory and ciliated cells. To examine the mechanisms regulating cell fate decisions in the airway, primary human basal cells were grown in a three-dimensional matrix to generate 'bronchospheres' containing a single, central lumen surrounded by a pseudostratified layer of epithelial cells. During development of the bronchospheres, the basal cells differentiated into mucus-producing goblet cells and ciliated cells. We found that inflammatory cytokine treatment resulted in a skewing of basal cell differentiation towards a

goblet cell fate, culminating in enhanced mucus production. We conclude that inflammatory cytokines, such as IL17A, direct the fate of the airway basal cell towards a mucus-secreting goblet cell, thereby altering the composition of the airway epithelium to produce the goblet cell metaplasia described in many respiratory diseases.

798

**Clonal analysis of hematopoietic stem and progenitor cells marked by five fluorescent proteins using confocal and multiphoton microscopy.**

*D. Malide<sup>1</sup>, J-Y. Metais<sup>2</sup>, C. E. Dunbar<sup>2</sup>; <sup>1</sup>Light Microscopy Core Facility, NIH-NHLBI, Bethesda, MD, <sup>2</sup>Hematology Branch, NIH-NHLBI, Bethesda, MD*

We demonstrate a methodology for tracing the clonal history of hematopoietic stem and progenitor cells (HSPCs) behavior in live tissues in four dimensions (4D). This integrates genetic combinatorial marking using lentiviral vectors encoding various fluorescent proteins (FPs) with advanced imaging methods. Five FPs: Cerulean, EGFP, Venus, tdTomato, and mCherry were concurrently used to create a diverse palette of color-marked cells. Imaging using a confocal/two-photon hybrid microscopy approach enables simultaneous assessment with high resolution of uniquely marked cells in conjunction with structural components of the tissues. Generation of a diverse palette of clone colors via co-transduction of HSPCs with five LeGO vectors, combined with new imaging and analysis technologies, allowed tracing of HSPC engraftment and hematopoietic contributions at a clonal level, in the bone marrow and in a wide variety of other tissues in transplanted mice. The unprecedented high resolution images from optical sections were used to computationally reconstruct 3D-patterns of great complexity to depths of 150-300  $\mu\text{m}$ , elucidating biologically-interesting clonal reconstitution patterns. We demonstrate that confocal imaging can be combined with multiphoton microscopy, revealing complementary information from autofluorescent and second-harmonic-generating (SHG) structures. Furthermore dynamic 4D high-resolution imaging is achievable by using video-rate scanning, red-shifted FPs and longer wavelengths lasers. Live studies combining video-rate multiphoton and confocal time-lapse imaging in 4D demonstrate the possibility of dynamic cellular and clonal tracking in a quantitative manner. Our approach allows clear tracking of color-marked hematopoietic clones readily identifiable in tissues of recipient for extended periods of time, bringing a new tool for assessing the plasticity that HSCPs possess. Understanding different aspects of development of hematopoietic clones in an irradiated reconstituted animal is of clinical relevance for chemotherapy, transplantation and gene therapy.

**Cell Cycle Arrest is Required For Cell Invasion Through Basement Membranes.**

*D. Q. Matus<sup>1</sup>, L. C. Kelley<sup>1</sup>, A. J. Schindler<sup>1</sup>, Q. Chi<sup>1</sup>, D. R. Sherwood<sup>1</sup>; <sup>1</sup>Biology, Duke University, Durham, NC*

There is an intimate and well-established link between cell cycle arrest and the transcriptional control of the differentiation of discrete cell types. Emerging data suggests that the complex cell biological behaviors that occur during morphogenesis (e.g., EMT and convergent extension) also require a prolonged G1 gap phase. Cell invasion through the basement membrane is a poorly understood morphogenetic cellular behavior, which occurs during development, immune surveillance and cancer metastasis. To functionally dissect cell invasive behavior at single-cell resolution, we are using the simple *in vivo* model of anchor cell (AC) invasion that occurs during *C. elegans* larval development. The AC, a specialized somatic gonadal cell, undergoes a basement membrane transmigration event to connect the developing uterine and vulval tissues. In order to identify transcriptional regulators of AC invasion, we performed a tissue-specific

RNAi screen targeting 697 *C. elegans* transcription factors, identifying the TLX ortholog, NHR-67, as a new regulator of invasion. Strikingly, loss of NHR-67 results in multiple ACs that fail to invade. Prevention of cell cycle progression in NHR-67-depleted animals rescues the invasion defect, demonstrating that cell cycle arrest is required for invasion. Time-lapse microscopy shows that mitotic ACs lack invadopodia, subcellular structures within the AC that function to breach the BM. Additionally, dividing ACs show reduced expression of downstream markers of invasive differentiated ACs, including matrix metalloproteinases (MMPs). Our data indicates the requirement for the precise transcriptional control of a genetic program that links cell cycle arrest to the differentiation of the invasive phenotype.

### **Complement C1q production by osteoclasts and its regulation of osteoclast development.**

*B. Teo<sup>1,2</sup>, Y. Bobryshev<sup>3</sup>, B. Teh<sup>1,2</sup>, S. Wong<sup>1,2</sup>, J. Lu<sup>1,2</sup>; <sup>1</sup>Department of Microbiology, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore, <sup>2</sup>Immunology Programme, National University of Singapore, Singapore, Singapore, <sup>3</sup>Faculty of Medicine, University of New South Wales, Kensington, Australia*

C1q deficiency is the strongest known risk factor for systemic lupus erythematosus (SLE) but its endogenous cellular origin remains limitedly understood. Here we investigate its production by both cultured and endogenous bone osteoclasts. Blood monocytes were cultured with RANKL and M-CSF to generate osteoclasts and these cells expressed C1q mRNA and also secreted C1q protein. Intracellular C1q was detectable in developing osteoclasts at day 3 by Western blotting and was also detectable by flow cytometry. By immunofluorescence microscopy, C1q was preferentially detected in immature osteoclasts. By multiple detection methods, C1q expression was markedly increased after IFN $\gamma$  treatment. By immunohistochemistry, C1q was also detected in endogenous bone osteoclasts. When osteoclasts were cultured on immobilized C1q, these cells exhibited 2-7 folds increases in the expression of signature osteoclast genes (TRAP, cathepsin K, calcitonin receptor, carbonic anhydrase II and NFATc1), suggesting an osteoclastogenic capability. This is the first report of C1q production by osteoclasts. Its ability to enhance osteoclast development implies reduced osteoclastogenesis in SLE patients as they often experience decreased C1q levels. This is consistent with the non-erosive nature of lupus arthritis.

### **Bioelectric Control of Regenerative Patterning.**

*V. P. Pai<sup>1</sup>, S. Aw<sup>2</sup>, D. Blackiston<sup>1</sup>, M. Levin<sup>1</sup>; <sup>1</sup>Center for Regenerative and Developmental Biology, Tufts University, Medford, MA, <sup>2</sup>Institute of Molecular and Cell Biology, Singapore, Singapore*

Regenerative biology holds the potential for developing transformative biomedical approaches addressing birth defects, injuries and degenerative diseases. Biophysical signals are crucial but still poorly-understood regulators of cell shape, differentiation, migration, and proliferation in vivo. Thus, patterns of resting potential in non-neural cells in vivo comprise an important system of instructive information that guides the structure and function of organ systems during embryogenesis and regenerative repair. During normal *Xenopus* development, a striking hyperpolarization demarcates specific clusters of cells in the anterior neural field. Specifically altering these Vmem patterns results in malformed eyes. Moreover, manipulating Vmem pattern in non-eye cells induces formation of well-formed ectopic eyes, even well outside the anterior neural field, suggesting that bioelectric signals reveal novel aspects of tissue lineage

competence. These ectopic eyes are morphologically and physiologically similar to endogenous eyes, and we characterized a feedback loop by which the transcriptional controls of eye induction interact with the biophysics of ion flows in early embryonic cells. Likewise we report that patterned control of resting potential in the anterior neural field is critically important in *Xenopus* brain tissue patterning. By developing strategies for specific, molecular-level control of bioelectric signals *in vivo*, we also identified cryptic asymmetries in the development of eye and neural crest (linked to the main left-right asymmetry determining pathway). Our data reveal that gradients of  $V_{mem}$  in patterning tissues are a new, instructive signal in during development, and demonstrate techniques by which these biophysical regulators of growth and form can be characterized and functionally manipulated at molecular resolution. Learning to control bioelectric initiators of organogenesis offers significant potential for regenerative biomedical treatment of diseases and for the basic understanding of patterning in evolutionary developmental biology.

## Chaperones, Protein Folding, and Quality Control I

802

### Unusual post-translational modification of GFP derivatives.

*H. Kawashima<sup>1</sup>, Y. Goto<sup>1</sup>, D. Saitoh<sup>1</sup>, W. Nemoto<sup>1</sup>, M. Tanaka<sup>1</sup>; <sup>1</sup>Dept.of Biotech., Tokyo Denki Univ., Hiki-Gun, Hatoyama-machi, Japan*

We have already reported a novel post-translational modification on the BraC protein in mammalian cells including human cells. The modification consists of two types of modifier, a peptide modifier and its N-glycosylation. The modification did not occur when the C-terminal lysine of BraC protein was replaced to Alanine or Arginine. In addition to the C-terminal requirement, a C-terminal sequence of 4 amino acids, TXXK is required for the modification. Recently, we found another target of the modifier, a CFP derivative expressed in mammalian cells by pCMV-secCFPmcs3. The plasmid encodes CFP fused with a mouse secretion signal of MHC Class I H-2K<sup>d</sup> on the N-terminus and a peptide coded by multi-cloning-site (mcs3) on C-terminus. To study the sequence requirements of modification, we mutated C-terminal glutamic acid to the other 19 amino acid and then all the CFP derivatives were expressed in COS-7 cells. The cells were cultured in the presence or absence of epoxomicin, and the cell-lysates were immune-precipitated with anti GFP antibody. The immune-precipitates were analyzed with western blotting using anti GFP antibody. The modification occurred when the CFP were the C-terminal derivatives of R, K, E, H, M, G and D. Whereas the modification efficiencies were different with each amino acids of C-terminus, the other CFP derivatives of C-terminus were never modified. These results indicated that the C-terminal amino acid of secCFPmcs3 affects the modification in a different manner from that of BraC protein. Then, we examined whether the secCFP derivative fused with TEVK of C-terminal sequence of BraC is modified or not. The CFP derivative was modified. The C-terminal 4 amino acids sequence might be essential for the modification. We report here the GFP derivative as a novel target of the modification.

803

**Systematic genetic interaction mapping of protein folding and stress response pathways in the human ER.**

*M. Kampmann<sup>1</sup>, J. Weissman<sup>1</sup>; <sup>1</sup>Cellular and Molecular Pharmacology, HHMI / UCSF, San Francisco, CA*

Systematic mapping of genetic interactions is a powerful approach to gaining a comprehensive mechanistic understanding of complex biological processes, and has successfully been applied to the yeast endoplasmic reticulum (ER) and other areas of biology in microorganisms. However, systematic genetic interaction mapping has thus far not been applied to mammalian cells. A genetic interaction map of the human ER would likely yield important insights into mammalian-specific ER functions.

We have now developed an RNA interference-based platform that allows us to conduct highly quantitative genetic screens and genetic interaction mapping in mammalian cells. To probe human ER function, we used the bacterial subtilase cytotoxin (SubAB), which kills cells by specifically cleaving BiP/GRP78, the Hsp70 chaperone of the ER, and thereby inducing the unfolded protein response (UPR) and apoptosis. We have identified a large number of genes that modulate the response of human cells to SubAB: Host factors required for SubAB trafficking to the ER, many of which we also identified for other ER-trafficking toxins; factors contributing to protein load in the ER; a variety of chaperones and other protein folding factors; signaling components of the UPR; and previously uncharacterized factors. Surprisingly, factors implicated in other types of cellular stress responses also modulated sensitivity to subAB, hinting at possible cross-talk between different homeostatic and stress response pathways. We are now systematically mapping genetic interactions between these factors to understand how they interact in pathways, and in order to pinpoint putative functions for previously uncharacterized proteins.

804

**Alteration of Hsp70 co-chaperone levels suppresses amyloid-like protein proteotoxicity by increasing the cells capacity to sequester polyQ into benign aggregates.**

*K. J. Wolfe<sup>1</sup>, H. Ren<sup>1</sup>, D. Cyr<sup>1</sup>; <sup>1</sup>Cell biology and physiology, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Protein quality control (PQC), led by molecular chaperones, is crucial for partitioning misfolded proteins towards refolding or degradation via the ubiquitin proteasome (Meacham GC, et al. Nat Cell Biol 2001; Nillegoda NB, et al. Mol Biol Cell 2010). Improper PQC can result in misfolded protein aggregation. Numerous human diseases, particularly neurodegenerative disorders, are characterized by the accumulation of amyloid-like protein aggregates containing the disease protein (Wolfe KJ, Cyr DM. Semin Cell Dev Biol 2011). While the Hsp70 system is the first line of defense against protein aggregation by facilitating refolding, more recent work suggests a protective role of chaperone dependent promotion of aggregation (Douglas PM, et al. PNAS 2008). Rather than being causative, the inclusions seen in protein aggregation diseases may actually be a cellular coping mechanism. However, what determines the fate of a misfolded protein remains unclear. To address the debate of harmful versus helpful aggregation, we studied proteotoxicity associated with expression of polyglutamine expanded Huntingtin (Htt103Q) in a yeast model. We carried out a high copy toxicity suppressor screen in order to find a link between suppressors of toxicity and an increase in Htt103Q aggregation. Excitingly, we discovered that elevation of Hsp70 co-chaperone levels promotes formation of protective higher order species of amyloid-like aggregates. Suppression of proteotoxicity by the Hsp70 co-chaperone correlated with the packaging of Htt103Q in the JUNQ and IPOD quality control compartments (Kaganovich D, et al. Nature 2008). Thus, sequestration of Htt103Q into

intracellular protein deposits decreases cytotoxicity, and the Hsp70 system plays an active role in aggregate formation. [Work funded by Grant Number F31NS074777 from the NINDS]

**Determination of the Intracellular, Surface, and Extracellular Localization of Hsp70s under Different Stress Conditions.**

*R. Medina<sup>1</sup>, M. Rashedan<sup>1</sup>, N. Nikolaidis<sup>1</sup>; <sup>1</sup>Biological Science, California State University, Fullerton, Fullerton, CA*

The 70-kD Heat shock proteins (Hsp70s) are a family of molecular chaperones that play essential roles in stress response by promoting protein homeostasis. Members of the Hsp70 family are primarily localized in different subcellular compartments, including the cytosol, endoplasmic reticulum, and mitochondria. Apart from their primary intracellular locations, several Hsp70s have also been found in different locations within the cell, as well as at the plasma membrane and extracellular milieu. Although few stresses and pathophysiological conditions, like cancer, have been related with the re-localization of Hsp70s within the cell, their translocation to the membrane, and secretion from viable cells, the majority of these conditions remain largely unknown. To this end we studied the localization of four members of the Hsp70 family under different stresses using sub-cellular fractionation. These experiments revealed that under normal growth conditions all four Hsp70s were present in multiple fractions, as well as in the extracellular medium in varying amounts. In stressed cells, Hsp70s' amounts in each fraction were significantly different from the untreated cells. These results suggest that heat and ethanol stresses cause re-localization and differential membrane-anchorage and secretion of the four Hsp70s. Additional experiments using pharmacological manipulation of intracellular trafficking pathways are currently being performed to identify the molecular mechanism used by Hsp70s to achieve their translocation, membrane anchorage, and subsequent secretion. This study is the first step towards elucidating the biological importance of the re-localization and membrane occurrence of these chaperones under stress conditions.

806

**The Co-chaperone Hch1 regulates Hsp90 function differently than its homologue Aha1 and confers sensitivity to yeast to the Hsp90 inhibitor NVP-AUY922.**

*H. Armstrong<sup>1</sup>, A. Wolmarans<sup>1</sup>, K. Horvat<sup>1</sup>, R. Mercier<sup>1</sup>, P. G. LaPointe<sup>1</sup>; <sup>1</sup>Cell Biology, University of Alberta, Edmonton, AB, Canada*

The 90 kiloDalton heat shock protein (Hsp90) plays a critical role in supporting the aberrant proliferative and anti-apoptotic signaling observed in cancer cells. Together with its numerous co-chaperones, Hsp90 stabilizes the active but labile forms of many oncoproteins. Like other molecular chaperones, Hsp90 is an ATPase but it possesses a unique ATP binding fold that is specifically targeted by certain small molecules. These Hsp90 inhibitors are being aggressively developed as anti cancer agents as Hsp90 in cancer cells is more sensitive to them than Hsp90 in normal cells. The basis for this selectivity is not known but thought to be related to the multiprotein complexes that Hsp90 forms with its co-chaperones and substrates in cancer cells. Using yeast as a model system, we have discovered that the co-chaperone Hch1p is a key determinant of Hsp90 inhibitor drug sensitivity. We show that the deletion of *HCH1* confers resistance to Hsp90 inhibitor drugs in yeast. Hch1p is a close relative of another co-chaperone protein called Aha1p which is a potent stimulator of the very low ATPase activity of Hsp90. Aha1p is comprised of an N terminal and C terminal domain that interact with the Hsp90 dimer at two discrete sites. Hch1p has a high degree of sequence identity to the N terminus of Aha1p but lacks the C terminal domain necessary for full ATPase stimulation. Interestingly, a chimeric protein comprised of Hch1p fused to the C terminal domain of Aha1p (which should behave like

Aha1p as an ATPase stimulator) does not stimulate the Hsp90 ATPase activity suggesting that there are important differences between Hch1p and the Aha1p N terminus. Our analysis of the interaction of these two co-chaperones with Hsp90 revealed that they cause very different conformational changes in the Hsp90 structure that influence nucleotide binding. Domain swaps show that this difference can be traced to a small region of these co-chaperones and reveal the importance of nucleotide exchange in drug sensitivity. Despite the similarity in the sequence and structure of these two co-chaperone proteins, they define Hsp90 complexes with very different sensitivity to Hsp90 drugs.

807

**Structural and Mechanistic Investigation of the Hsp90 ATPase Stimulator Aha1.**

*N. K. Horvat<sup>1</sup>, P. LaPointe<sup>1</sup>; <sup>1</sup>Cell Biology, University of Alberta, Edmonton, AB, Canada*

The 90kDa heat shock protein (Hsp90) is an essential ATP-dependent eukaryotic chaperone that is upregulated during times of stress and helps to fold substrate proteins, called client proteins. Many of Hsp90's clients are key components for the development and maintenance of malignant cells. Because of this, the selectivity of Hsp90 inhibitors makes ideal candidates for cancer therapy and some Hsp90 inhibitors, such as 17-AAG, have entered the first phase of clinical trials. Hsp90 acts within a highly regulated and structurally dynamic cycle that includes the hydrolysis of ATP, cochaperone proteins and clients. Cochaperones interact with Hsp90 help to regulate client activation and ATPase rate. The cochaperones Hch1p and Aha1p are highly conserved and interact with Hsp90 in similar ways yet Aha1p is a robust stimulator of Hsp90's ATPase rate but Hch1p is not. To investigate the difference between these cochaperones, I created 8 chimeric proteins where either domains or small loops located at the Hsp90-cochaperone interface are interchanged between Hch1p and the N terminal domain of Aha1p. I used ATPase assays to test these Aha1p-Hch1p chimeric cochaperones' ability to stimulate WT Hsp90's ATPase rate. These results provide insight into the mechanistic basis for Aha1p-mediated ATPase stimulation of Hsp90. Moreover, this work shows the importance of conformational changes in the Hsp90 middle domain and how they allosterically regulate ATPase activation in the N terminal domain.

Lotz, G.P., Lin, H., Harst, A., and Obermann W. 2003 Aha1 Binds to the Middle Domain of Hsp90, Contributes to Client Protein Activation, and Stimulates the ATPase activity of the Molecular Chaperone. *Journal of Cell Biology*, 19: 17228-17235.

808

**EMC2 Encodes a Putative Novel Hsp90 Co-chaperone in *Saccharomyces cerevisiae*.**

*T. Kudze<sup>1</sup>, A. J. McClellan<sup>1</sup>; <sup>1</sup>Division of Natural Sciences and Mathematics, Bennington College, Bennington, VT*

The open reading frame *YJR088C* encodes a protein named Emc2p (for ER membrane protein complex 2); *EMC2* deletion results in a constitutively upregulated unfolded protein response (UPR). Yeast deleted for *EMC2* also exhibit synthetic genetic effects with Hsp90 in two different published high-throughput approaches. Of interest, *EMC2* encodes a ~35 amino acid TPR motif, suggesting the possibility that it may act as an Hsp90 co-chaperone.

In order to assess whether Emc2p is an Hsp90 co-chaperone, we first tested whether yeast deleted for *emc2* exhibit Hsp90 substrate folding defects using the well-established substrate glucocorticoid receptor (GR), the folding and function of which is dependent upon Hsp90. We find that yeast lacking Emc2p fail to robustly fold GR, similar to what is observed in yeast lacking the known Hsp90 co-chaperone Sti1p.

If Emc2p is indeed an Hsp90 co-chaperone, we would expect to find a physical interaction between the two proteins. Affinity pulldown experiments demonstrate a specific interaction between Emc2p and Hsp90. Of note, this interaction does not require the TPR domain of Emc2p.

Altogether, our data demonstrate both a functional and physical interaction of Emc2p with the Hsp90 chaperone machinery, supporting its role as a putative novel Hsp90 co-chaperone.

809

**The co-chaperone Hch1p regulates sensitivity to heat shock protein 90 inhibiting drugs in yeast.**

*H. Armstrong<sup>1</sup>, P. LaPointe<sup>1</sup>; <sup>1</sup>Cell Biology, University of Alberta, Edmonton, AB, Canada*

The 90kDa heat shock protein (Hsp90) is a highly conserved molecular chaperone that plays a vital role in regulation of a specific subset of target proteins termed 'clients'. Hsp90 regulates its clients, many of which are oncoproteins, through a conformationally dynamic cycle involving ATP and co-chaperone proteins. Cancer cells depend on Hsp90 making them sensitive to Hsp90 inhibitors, such as geldanamycin and NVP-AUY922, which are known to target multiple signaling pathways involved in cancer progression. Within eukaryotic cells Hsp90 is found in two highly conserved isoforms, and thus components of the yeast and human Hsp90 systems are functionally interchangeable. Human Hsp90 $\alpha$  and the *Saccharomyces cerevisiae* Hsp90 gene, *HSP82*, share 60% amino acid identity, making yeast an excellent model organism. Using yeast genetics I have determined that deletion of the co-chaperone *HCH1*, but not its homologue *AHA1*, rescues two temperature sensitive Hsp90 mutants, A587T and G313S. Importantly, strains that express either of these two mutant forms of Hsp90 are hypersensitive to Hsp90 inhibitors. This sensitivity is reversed when *HCH1* is deleted. Overexpression of *HCH1* confers hypersensitivity to Hsp90 inhibitors in wild type yeast and *HCH1* deletion confers high resistance to these drugs. We conclude that the co-chaperone Hch1p plays an important role in regulating sensitivity to Hsp90 inhibitor drugs and regulates Hsp90 in a manner distinct from its homologue Aha1p.

810

**Analysis of dynamic complex formations in heat shock protein 90 mutants utilizing ATPase assays and immunoprecipitation.**

*A. Wolmarans<sup>1</sup>, H. Armstrong<sup>1</sup>, R. Mercier<sup>1</sup>, P. LaPointe<sup>1</sup>; <sup>1</sup>Cell Biology, University of Alberta, Edmonton, AB, Canada*

The 90kDa heat shock protein (Hsp90) is a highly abundant, ATP-dependent molecular chaperone essential for regulation of a specific set of substrate proteins called 'clients', many of which are oncoproteins. Dozens of co-chaperone proteins regulate Hsp90 by assisting in client-protein recruitment or release, as well as activating or inhibiting Hsp90's ATPase activity. The relationship between Hsp90 and its co-chaperones is of great clinical importance as drugs targeting these co-chaperones alter Hsp90 action and arrest anti-apoptotic and pro-proliferative signaling in cancers. Hsp90 acts in the context of a conformationally dynamic ATPase cycle. Mutants of Hsp90 can confer growth defects to yeast owing to impairments in specific conformational transitions. Importantly, these defects can be overcome by co-chaperone proteins. These Hsp90 mutants are useful tools to determine the precise roles that specific co-chaperone proteins play in the Hsp90 cycle. We have shown that yeast that express either of the two different mutants (A587T or G313S) are rescued via deletion of the co-chaperone *HCH1*. I have investigated the co-chaperone dynamics of these two Hsp90 mutants

enzymatically through ATPase assays and assessed complex formation by immunoprecipitation to elucidate why *HCH1* deletion mitigates their disrupted growth phenotype. Hch1p and its homologue Aha1p are ATPase stimulators that can be inhibited by the action of another co-chaperone, Sba1p. The G313S and A587T mutants have very different intrinsic ATPase activities and are not affected by co-chaperones in the same way. Analysis of complexes formed in vitro between these mutants and co-chaperone proteins shows that the in vivo phenotypes in yeast involve other regulatory factors. Despite being considered homologues, Hch1p and Aha1p play very different roles in the Hsp90 cycle.

811

### Defining the Hsp104 folding reservoir: novel prions and toxic, intrinsically aggregation-prone proteins.

M. Y. Soo<sup>1,2</sup>, A. D. Gitler<sup>3</sup>, J. Shorter<sup>2</sup>; <sup>1</sup>Graduate Group in Biochemistry and Molecular Biophysics, Perelman School of Medicine at University of Pennsylvania, Philadelphia, PA, <sup>2</sup>Department of Biochemistry and Biophysics, Perelman School of Medicine at The University of Pennsylvania, Philadelphia, PA, <sup>3</sup>Department of Genetics, Stanford University, Stanford, CA

Hsp104 is a yeast protein that performs two distinct and biologically important functions. First, Hsp104 fragments yeast prions to ensure their inheritance through successive generations. Prions are infectious amyloid conformers that convert soluble copies of the same protein to the amyloid form. Second, Hsp104 rescues proteins that have aggregated due to age or environmental stress and returns them to the native form and function. However, few natural Hsp104 substrates are known other than a handful of prions. To define Hsp104 clients with prion or aggregation-prone characteristics we exploited an Hsp104-deficient yeast strain ( $\Delta hsp104$ ). Hsp104 is not essential for survival under regular growth conditions, but confers massive selective advantages in environments that elicit protein-folding stress.  $\Delta hsp104$  yeast have reduced longevity, decreased stress tolerance and cannot maintain prion states. Extended overexpression of some prion proteins is toxic in wild type (WT) yeast due to loss of wild-type protein function or sequestration of other essential proteins, but  $\Delta hsp104$  cells cannot propagate prions and are thus resistant to prion toxicity. Hence, we hypothesize that if proteins are overexpressed to induce toxic prion formation they will only do so in WT yeast and not in the  $\Delta hsp104$  yeast. In this way, we can identify prion candidates in an unbiased manner. In addition, we hypothesize that if Hsp104 buffers against the toxicity of intrinsically aggregation-prone proteins, then overexpression of these proteins will be toxic only in  $\Delta hsp104$  yeast but not in WT yeast. To determine the clients of Hsp104, a genome-wide dosage lethality screen in WT and  $\Delta hsp104$  yeast was used. In this screen, WT and  $\Delta hsp104$  yeast were transfected with a library of plasmids, in which overexpression of each yeast gene is controlled by a galactose-inducible promoter. Genes that are 'hits' in our screen fall into three broad classes: (A) toxic in WT and  $\Delta hsp104$ , (B) toxic in WT but not  $\Delta hsp104$  and (C) toxic in  $\Delta hsp104$  but not WT. We hypothesize class B is enriched in Hsp104-dependent prions and class C is enriched in toxic, intrinsically aggregation-prone proteins. Further assays such as fluorescence microscopy, SDS-resistance, and domain mapping will be used to determine whether proteins are forming prions or amorphous aggregates.

812

**Conformational changes of Hsp104 revealed through Small Angle X-ray Scattering (SAXS).**

E. A. Sweeny<sup>1</sup>, K. Gupta<sup>1</sup>, J. Shorter<sup>1</sup>; <sup>1</sup>Biochemistry and biophysics, University of Pennsylvania, Philadelphia, PA

Hsp104 is a hexameric AAA+ disaggregase found in yeast. Hsp104 has two key roles *in vivo*; thermotolerance and the regulation of prions. After thermal or chemical stress Hsp104 has the ability, in collaboration with co-chaperones Hsp40 and Hsp70, to remodel cytosolic aggregates and return proteins to their soluble, native form. Its role in prion regulation is two-fold. In yeast, prions function as non-genetic heritable traits. Hsp104 is required for prion propagation from mother to daughter through nucleation and fiber fragmentation, but cures some prion phenotypes when overexpressed.

Hsp104 is a large, multidomain protein. Each monomer contains two AAA+ domains resulting in an oligomeric species containing 12 sites of ATP hydrolysis. To date, there are no high resolution structures of either monomeric or hexameric Hsp104, and little is known about how the protein changes in shape during the ATPase cycle and how it uses these changes to exert remodeling forces on a variety of substrates.

Here I present ongoing work that uses an in solution technique, SAXS, to study the conformational changes of the Hsp104 hexamer during the ATPase cycle. SAXS studies are well suited to the Hsp104 system due to the large size of the particle, the large available yield after purification, the monodispersity of the hexamer and the large changes that take place in the presence of different nucleotides.

813

**Potentiated Hsp104 variants antagonize diverse proteotoxic misfolding events.**

M. E. Jackrel<sup>1</sup>, M. E. DeSantis<sup>1</sup>, L. M. Castellano<sup>1</sup>, J. Shorter<sup>1</sup>; <sup>1</sup>University of Pennsylvania, Philadelphia, PA

Aberrant protein folding is implicated in several devastating neurodegenerative diseases. Inclusions containing the proteins TDP-43 and FUS are implicated in some cases of amyotrophic lateral sclerosis (ALS), while amyloid fibers comprised of  $\alpha$ -synuclein are implicated in Parkinson's disease. Hsp104, an AAA+ protein from yeast, functions in regulating the disassembly of amorphous aggregates as well as prions. There are no other proteins known that are capable of specifically disassembling and solubilizing amyloid. Though Hsp104 is highly conserved, it has no human homologue. Therefore, we have developed potentiated Hsp104 variants and applied them to disease models of TDP-43, FUS, and  $\alpha$ -synuclein pathology. These potentiated Hsp104 variants dissolve the aggregates, return the proteins to their proper cellular location, and strongly suppress toxicity in each of these disease models at levels far greater than wild-type. Surprisingly, we have also found that at certain positions in Hsp104, generic mutations to nearly any class of amino acid yield a hyperactive protein capable of eliminating aggregates. Using pure protein biochemistry experiments, we have probed the biochemical basis for these variants' potentiated activity and found that they have an enhanced ATPase and translocation rate, and are capable of dissolving aggregates without requiring co-chaperone collaboration. These results reveal important new insights into the mechanism by which Hsp104 dissolves amyloid, and demonstrate that proteins that misfold in neurodegenerative disease can be reactivated to their native state.

814

**Heat shock protein expression induced by elevated seawater temperature in the larvae of the reef-building coral *Porites astreoides*.**

K. Olsen<sup>1</sup>, J. D. Ochrietor<sup>1</sup>, R. Ritson-Williams<sup>2</sup>, C. Ross<sup>1</sup>, V. Paul<sup>2</sup>; <sup>1</sup>Biological Sciences, University of North Florida, Jacksonville, FL, <sup>2</sup>Smithsonian Marine Station, Fort Pierce, FL

Many scleractinian (hard) corals are living at or near their upper temperature limits, and are negatively impacted by global increases in sea surface temperatures. While elevated seawater temperatures have been shown to affect the survival of corals, few have investigated the physiological response of corals exposed to thermal stress. One mechanism of this response is the production of heat shock proteins (hsps), which have been shown to elevate thermotolerance in many organisms. To evaluate the expression of hsps, larvae of the reef-building coral *Porites astreoides* were incubated in either ambient (27°C) or elevated (31°C) seawater baths. Larvae were removed from the baths following either 4, 24 or 48 hours of incubation and analyzed for the differential expression of hsps with the molecular weights of 16 and 60 kDa. Larvae exposed to elevated seawater temperatures had greater expression of HSP16 and HSP60 following 24 and 48 hours of incubation compared to their ambient counterparts. The results indicate that hsp production is induced by elevated seawater temperature and may increase the thermotolerance of those reef-building corals with the genetic capacity to synthesize them. This may have implications about the effects of rising seawater temperatures on the future generations of hard corals and the ecosystems they construct.

**The SIRT1 modulators AROS and DBC1 regulate HSF1 activity and the heat shock response.**

R. Raynes<sup>1</sup>, K. Pombier<sup>1</sup>, K. Nguyen<sup>1</sup>, J. Mendez<sup>1</sup>, S. D. Westerheide<sup>1</sup>; <sup>1</sup>Cell Biology, Microbiology, and Molecular Biology, USF, Tampa, FL

The heat shock response (HSR) is the cellular response to protein damaging stress and is critical in the management of denatured proteins. The HSR plays a role in a number of diseases including heart disease, diabetes, cancer, and neurodegenerative diseases. We note that SIRT1 has been indicated as an important regulator of the HSR in an HSF1-dependent manner. In addition, protein modulators AROS and DBC1 have been indicated as important regulators of SIRT1. We are interested in gaining a better understanding of the mechanism of SIRT1 regulation of the HSR. We have found that the transcriptional and translational levels of SIRT1 are not effected upon the initiation of the HSR and that changes in the activity of SIRT1 are responsible for HSR regulation in an HSF1-dependent manner. We found that heat shock (HS) results in a decrease in NADH levels, an increase in the NAD<sup>+</sup>/NADH ratio, and an increase in recruitment of SIRT1 to the *hsp70* promoter. We also found that protein modulators AROS and DBC1 have an impact on *hsp70* transcription, HSF1 acetylation status, and HSF1 recruitment to and activation of *hsp* promoters. Our results indicate that SIRT1 regulation of the HSR impacts the deacetylation of HSF1 through a direct interaction that is influenced by an increase in the NAD<sup>+</sup>/NADH ratio. Furthermore, AROS and DBC1 regulate the acetylation status and thus the activity of HSF1. AROS and DBC1 are now two new targets available for therapeutic regulation of the HSR.

### Cellular nucleic acid binding protein ZNF9 is required for stimulating translation of terminal oligo pyrimidine tract containing mRNAs in HeLa cells during recovery from heat shock.

A-K. Datu<sup>1</sup>, J. Bag<sup>1</sup>; <sup>1</sup>Molecular and Cellular Biology, University of Guelph, Guelph, ON, Canada

The mRNAs encoding poly (A) binding protein (PABP1), eukaryotic elongation factor 1A (eEF1A) and ribosomal protein S6 (RPS6) are members of the terminal oligo pyrimidine tract (TOP) containing family of mRNAs. Translation of these mRNAs is regulated by growth signals and usually encodes proteins involved in mRNA translation. Previous studies from our laboratory showed that translation of PABP1 mRNA is stimulated during recovery of HeLa cells from heat shock. It was shown that the presence of the 5' TOP *cis* element was required for the preferred increase of PABP1 mRNA translation during recovery from heat shock. In the studies reported here we showed that translation of eEF1A and RPS6 was similarly enhanced during recovery. Analyses of samples of *in vivo* cross linked RNA– protein complexes, immunoprecipitated by ZNF9 antibody, for the presence of specific mRNAs revealed that the cellular nucleic acid binding protein ZNF9 binds to TOP mRNAs. However, mRNA lacking the TOP element, such as, the  $\beta$ -actin mRNA was also bound to ZNF9. To further elucidate the role of ZNF9 in stimulation of TOP mRNA translation during recovery from heat shock, siRNA was used to prevent expression of cellular ZNF9. Our results show that depletion of ZNF9 prevented the preferred stimulation of PABP1, eEF1A and RPS6 expression during recovery from heat shock. However, the constitutive expression of either  $\beta$ -actin or PABP1, eEF1A and RPS6 in HeLa cells was not affected by the absence of ZNF9. Our results suggest that binding of ZNF9 per se to mRNA does not inhibit translation. It is rather likely that ZNF9 act as a general facilitator of mRNA translation. Perhaps modification of the interaction between ZNF9 with other protein partners is responsible for its preferred effect on all three TOP mRNAs studied here. Furthermore, our results suggest that different TOP sequence responds similarly to ZNF9.

## Regulation of Aging

817

### Mitofusin 2 is necessary for maintaining axonal targeting in midbrain dopamine neurons.

S. Lee<sup>1</sup>, F. H. Sterky<sup>1</sup>, A. Mourier<sup>2</sup>, M. Terzioglu<sup>2</sup>, S. Cullheim<sup>3</sup>, L. Olson<sup>3</sup>, N-G. Larsson<sup>1,2</sup>;

<sup>1</sup>Laboratory Medicine, Karolinska Institutet, Stockholm, Sweden, <sup>2</sup>Max Planck Institute for Biology of Ageing, Cologne, Germany, <sup>3</sup>Neuroscience, Karolinska Institutet, Stockholm, Sweden

Defects in precise control of mitochondrial dynamics can contribute to increase of dysfunctional mitochondria in mammalian cells. This is believed to play a role in aging and neurodegenerative diseases, such as Parkinson's disease (PD). However the link to the pathophysiological relevance is not well established. Here we generated conditional knockout mice with disruption of *Mfn1* or *Mfn2*, two homologous large GTPases that mediate mitochondrial fusion, in midbrain dopamine (DA) neurons to study the importance of *Mfn1* and *Mfn2* in DA neurons *in vivo*. Loss of *Mfn1* in DA neurons is clinically unaffected. We find no differences in life span or spontaneous motor activity of *Mfn1* DA neuron-specific knockouts. In contrast, disruption of *Mfn2* in DA neurons cause a lethal phenotype accompanied with reduced body weight and defects in rearing activity at 5 weeks of age. In addition, *Mfn2* DA neuron-specific knockouts died before 7 weeks of age. By using a reporter mouse with tissue-specific expression of YFP targeted to the mitochondrial matrix (mito-YFP), we find that loss of *Mfn2* in DA neurons leads to fragmentation of mitochondrial network and enlarged mitochondria. These spherical

mitochondria have abnormal cristae structure and impaired respiratory chain function. Parkin is involved in clearance of dysfunctional mitochondria *in vitro*, we therefore performed stereotaxic injections of adeno-associated virus (AAV) encoding mCherry-Parkin into the midbrain of *Mfn2* DA neuron-specific knockouts. However, mitochondria in *Mfn2*-deficient DA neurons with defective respiratory chain function do not recruit virally expressed Parkin *in vivo*. Surprisingly, we find no loss of midbrain DA neurons in *Mfn2* DA neuron-specific knockout mice, whereas there is a severe loss of DA nerve terminals in striatum accompanied by altered DA homeostasis. Our results show that *Mfn2*, but not *Mfn1*, is indispensable for maintaining mitochondrial morphology and axon integrity of DA neurons *in vivo*. Future elucidation of the underlying molecular mechanism may provide a role of mitochondrial dynamics in PD with degeneration of striatal DA nerve terminals.

818

### Retention of aging factors in yeast mother cells is SAGA-dependent.

A. Denoth<sup>1</sup>, Y. Barral<sup>1</sup>; <sup>1</sup>Institute of Biochemistry, ETH Zürich, Zürich, Switzerland

Almost all organisms undergo aging, even uni-cellular organisms such as *S. cerevisiae*: each mother cell produces a limited number of daughter cells before it eventually dies. However, the daughter cells are born young, indicating that the aging factors are retained in the aging mother cell. One such aging factor are extrachromosomal rDNA circles (ERCs). ERCs, like all non-centromeric plasmids replicate in S-phase but preferentially stay in the mother cell, where they accumulate and cause aging.

The retention of ERCs in yeast mother cells is crucial to produce rejuvenated progeny, but still the mechanism ensuring asymmetric segregation of ERCs is poorly understood. Previous work from our lab proposed that ERCs are attached to nuclear pore complexes (NPCs) and thereby are subjected to a diffusion barrier in the outer nuclear membrane at the bud neck (Shcheprova *et al.* Nature 2008). To investigate how ERCs are retained in the mother cell, we screened for proteins involved in this process.

The SAGA complex is a histone acetyl transferase complex involved in transcriptional activation, transcription elongation and mRNA export by linking actively transcribed genes to NPCs via the TREX-2 complex. Remarkably, we found that retention of non-centromeric DNA circles and ERCs in the mother cell require both SAGA and TREX-2 activity. Non-centromeric circles were less frequently found at the nuclear rim in SAGA-deficient cells, no longer co-localized with NPCs and moved faster. This suggests that the SAGA complex anchors plasmids to NPCs. Consistent with this conclusion, the defect in circle retention observed in SAGA mutants was reverted by either expression of SAGA-NPC fusion proteins or by artificial anchoring of the circle to NPCs. Furthermore, SAGA deficient cells show extended lifespan or age in an ERC independent manner, supporting the hypothesis that they fail to accumulate ERCs.

Taken together our work proposes a new role of the SAGA complex in the retention of aging factors in yeast mother cells.

819

### Trehalose defines yeast longevity by modulating cellular proteostasis.

V. R. Richard<sup>1</sup>, A. Beach<sup>1</sup>, M. T. Burstein<sup>1</sup>, A. Leonov<sup>1</sup>, S. Levy<sup>1</sup>, V. Titorenko<sup>1</sup>; <sup>1</sup>Biology Department, Concordia University, Montreal, QC, Canada

The nonreducing disaccharide trehalose has been long considered only as a reserve carbohydrate. However, our recent study of how a lifespan-extending caloric restriction (CR) diet alters the metabolic history of chronologically aging yeast suggested that their longevity is

programmed by the level of metabolic capacity - including trehalose biosynthesis and degradation - that yeast cells developed prior to entry into quiescence. To investigate whether trehalose homeostasis in chronologically aging yeast may play a role in longevity extension by CR, we examined how mutations affecting trehalose biosynthesis and degradation impact 1) the age-related dynamics of changes in trehalose concentration; 2) yeast chronological lifespan under CR conditions; 3) the chronology of oxidative protein damage, intracellular reactive oxygen species level and protein aggregation; and 4) the timeline of thermal inactivation of a protein in heat-shocked yeast cells and its subsequent reactivation in yeast returned to low temperature. Our data imply that CR extends yeast longevity in part by altering a pattern of age-related changes in trehalose concentration. We established molecular mechanisms underlying the essential role of trehalose in defining yeast longevity by modulating cellular protein homeostasis throughout lifespan. Our findings suggest the existence of two lifespan checkpoints at which the intracellular level of trehalose defines longevity by modulating cellular proteostasis. At one of these lifespan checkpoints in post-diauxic phase, trehalose operates as an anti-aging compound that 1) stabilizes the native state of proteins; 2) reduces the formation of insoluble protein aggregates by shielding the contiguous exposed hydrophobic side chains of amino acids that are abundant in aberrantly folded proteins and promote their aggregation; and 3) protects cellular proteins from oxidative carbonylation by interacting with their carbonylation-prone misfolded and unfolded species. At another lifespan checkpoint in stationary phase, trehalose functions as a pro-aging compound that shields the contiguous exposed hydrophobic side chains of amino acids in aberrantly folded proteins. By competing with molecular chaperones for binding with these patches of hydrophobic amino acid residues, trehalose interferes with the essential longevity-extending process of chaperone-assisted refolding of aberrantly folded proteins.

**Avian Eggshell Membrane: Cell Biology-Based Innovation of Human Health (2) Type III Collagen, Small Heat Shock Protein Alpha B-crystallin and Mild Exercise.**

*M. Shimizu<sup>1</sup>, K. Taniwaki<sup>2</sup>, E. Ohto-Fujita<sup>1</sup>, K. Yoshimura<sup>3</sup>, T. Atomi<sup>4</sup>, N. Hirose<sup>4</sup>, Y. Hasebe<sup>2</sup>, Y. Atomi<sup>5</sup>; <sup>1</sup>Dept. of Mechano-Informatics, Univ. of Tokyo, Tokyo, Japan, <sup>2</sup>Almado Co., Tokyo, Japan, <sup>3</sup>Department of Plastic Surgery, Graduate School of Medicine, Univ. of Tokyo, Tokyo, Japan, <sup>4</sup>Depart. of Physical Therapy, Faculty of Sci. Tech, Teikyo Univ. of Science, Uenohara, Japan, <sup>5</sup>Radioisotope Center, Univ. of Tokyo, Tokyo, Japan*

AlphaB-Crystallin ( $\alpha$ B), a small heat shock protein, has chaperone activities for various substrates, including proteins constituting the cytoskeleton, such as actin; intermediate filament; and tubulin.  $\alpha$ B is now used as an anti-inflammatory and neuroprotectant molecule for post-stroke (Arac et al, 2011). We have already identified  $\alpha$ B as a protective molecule for slow muscle atrophy (Atomi et al, 1991; Sakurai et al, 2005).  $\alpha$ B expresses in lens, heart, brain, muscle, and also in skin. Skin is the largest organ of the human body, interfaces to the environment and protect us from various life-threatening stimuli such as UV, heat, infection, and dry. Sirtuins are key molecules for metabolism, ageing, and diseases and induced expression of sirtuins expects to have health benefits but few studies in skin have been done. For more than 400 years, avian eggshell membrane (ESM) has been utilized for skin problems with burned skin as well as wound. ESM has a fibrous network mainly comprised of type I, V, and X collagens. We have found that water-soluble alkaline-digested form of ESM can stimulate type III collagen, decorin, and MMP2 expression in human dermal fibroblast cells (Ohto-Fujita et al, 2011). In this study, we are aim to evaluate in vivo function of the ESM and benefit of mild exercise that both contribute to skin health. Gene expression profiling of early wound healing stages were examined using  $\phi$ 6 mm full-thickness skin grafted db/db mouse and found that eggshell membrane may contribute to scar-less healing through time-limited type III collagen

expression. Hairless mouse (Hos HR-1) were exposed either single administration of ESM containing supplement and/or single 30-min mild treadmill exercise. Preliminary results showed that both ESM and mild exercise contribute to induction of type III collagen,  $\alpha$ B, and Sirtuins. Upstream gene cascade and possible cross-talks between ESM administration and exercise will be further investigated.

**Avian Eggshell Membrane: Cell Biology-Based Innovation of Human Health (1)  
Stimulation of Extra Cellular Matrix Genes and Sirtuins in Skin.**

Y. Atomi<sup>1</sup>, M. Shimizu<sup>2</sup>, K. Taniwaki<sup>3</sup>, E. Ohto-Fujita<sup>2</sup>, K. Yoshimura<sup>4</sup>, T. Atomi<sup>5</sup>, N. Hirose<sup>5</sup>, Y. Hasebe<sup>3</sup>; <sup>1</sup>Univ of Tokyo, Tokyo, Japan, <sup>2</sup>Dept. of Mechano-Informatics, Univ of Tokyo, Tokyo, Japan, <sup>3</sup>Almado Co., Tokyo, Japan, <sup>4</sup>Department of Plastic Surgery, Graduate School of Medicine, Univ of Tokyo, Tokyo, Japan, <sup>5</sup>Depart. of Physical Therapy, Faculty of Sci. Tech, Teikyo Univ. of Sci., Uenohara, Japan

In Asian countries, avian eggshell membrane (ESM) has long been utilized as a Chinese medicine for recoveries from burns, injuries, and wound. Even nowadays, Japanese Sumo wrestlers use it for wound healing. Powdered ESM is on market and used as a supplement and it is popular among Japanese women because they feel improvements for various health problems. We previously reported that type III collagen, decorin, and MMP2 gene expressions of human dermal fibroblast cells cultured on the alkaline-solubilized eggshell membrane (ASESM) conjugated with 2-methacryloyloxyethyl phosphorylcholine polymer (PMBN) biointerface were significantly higher than those on type I collagen dishes or tissue culture dishes, where similar microenvironment to dermal tissue such as spared cell distribution (Ohto-Fujita et al, 2011). We also performed an evaluation study of topical ASESM application on both human and mouse and reported at 2011 annual meeting. Aged 20-65 years of women human subjects were tested. The elasticity of both arms was measured after 12 weeks. Topical 1% ASESM solution's significantly increases of elasticity shown as Cutometer parameters at forearms and upper arms. It is postulated that some factors in ASESM may stimulate dermis regeneration/rejuvenation. Effects were also evaluated in mouse skin. Extracellular matrix (ECM) gene expressions of dorsal skin of hairless mice (Hos HR-1, male 6 weeks) after 10 days application of 10% ASESM solution were examined. Significant increase in both major fibrous ECMs of type III collagens and elastin and MMP2 mRNAs were observed. Recently Sirtuins (SIRTs) are reported to be responding to the photodamage in human skin (Benavente et al, 2012). In this study we tested the expression of SIRTs 1-7 in mouse skin after ASESM application and found that SIRT3 mRNA were significantly higher. Possible signaling cross talks between ECM effects and sirtuin stimulation by ESM will be discussed.

822

**The role of KLOTHO protein in regulation of melanin synthesis and protection against oxidative stress in Retinal Pigment Epithelia.**

M. Kokkinaki<sup>1</sup>, J. Young<sup>2</sup>, M. Javidnia<sup>3</sup>, G. Ahern<sup>3</sup>, N. Golestaneh<sup>1,4,5</sup>; <sup>1</sup>Ophthalmology, Georgetown University Medical Center, Washington, DC, <sup>2</sup>Anatomy, Howard University College of Medicine, Washington, DC, <sup>3</sup>Pharmacology, Georgetown University Medical Center, Washington, DC, <sup>4</sup>Neurology, Georgetown University Medical Center, Washington, DC, <sup>5</sup>Biochemistry and Molecular & Cellular Biology, Georgetown University Medical Center, Washington, DC

**Purpose:** Increased susceptibility of the Retinal Pigment Epithelium (RPE) to chronic oxidative stress has been implicated in the pathogenesis of age-related macular degeneration (AMD), the

leading cause of vision loss and blindness among the elderly. Melanin, the pigment synthesized in the RPE, is important for light absorption and for protection against oxidative damages. Therefore, sustaining normal levels of melanin synthesis is crucial for RPE functions. In this study, we are investigating the role of KLOTHO (KL) protein in the pigment synthesis and oxidative stress response of RPE.

**Methods:** Histology, Real-time PCR, siRNA, cAMP assay, Ca<sup>2+</sup> imaging, Immunostaining, ELISA.

**Results:** We have observed significant loss of pigmentation in the RPE of *Kl*<sup>-/-</sup> knockout mice by histological examination of their paraffin embedded eyes, suggesting that KL might play a role in promoting pigment synthesis. To further test this hypothesis, we treated the human RPE with KL protein at the physiological levels (100-200pM) and showed that KL significantly increases the expression levels of the key melalogenesis genes, Microphthalmia-associated Transcription Factor (*MITF*) and tyrosinase (*TYR*), the rate-limiting enzyme for controlling the production of melanin. Since *MITF* gene expression is regulated by its upstream cAMP response elements and *MITF* is a known transcriptional regulator of *TYR* gene, we measured the levels of cAMP in the presence of KL and have shown a 50% increase in cAMP concentration after 10 minutes incubation with KL. In addition, knocking down the expression of the endogenous *KL* gene of RPE by *KL*-specific siRNA, decreased the expression levels of both *MITF* and *TYR* genes by 80%. To explore the role of KL in the stress response of RPE, we generated an *in vitro* system by exposing RPE to the oxidative stress inducing agent tertiary-butyl hydroperoxide (tBH) for 2 hours, and measuring the expression of stress response genes. We have observed a significant increase in gene expression for crystallin alpha A (*CRYAA*), crystallin gamma S (*CRYGS*) and vascular endothelial growth factor (*VEGF*). We demonstrated that pretreatment with KL protects the RPE from tBH-induced stress, by reducing the expression of the above stress response genes to control levels.

**Conclusion:** Our current results, together with our previous findings that KL decreases VEGF secretion in RPE, strongly suggest that KL has an important role in the regulation of the melanin synthesis by increasing the endogenous cAMP levels and in protection against oxidative stress in RPE.

823

### Cell Biological Approaches to Test the Efficacy of Botanical Ingredients for Aging Skin - Method development.

A. Rajgopal<sup>1</sup>, M. Subramanian<sup>1</sup>, D. Fast<sup>1</sup>, C. Burns<sup>1</sup>, K. Glynn<sup>1</sup>, J. Scholten<sup>1</sup>; <sup>1</sup>Analytical Sciences & Amway R&D, Amway, Ada, MI

Skin is the largest organ in the human body as it provides a protective barrier against the environment which also defends us from external pathogens. It is an indicator of overall well being and health. In the recent times there is a high demand of using a non invasive technology in restoring "youthfulness" of the skin. Therefore, there is a need for a method that will help in testing efficacy of 'antiaging' ingredients. Outlined below, we identified novel approaches to better characterize 'antiaging' ingredients.

It is known that oxidative stress is a primary culprit in causing cutaneous aging. The first method we developed was to screen ingredients which resist oxidative stress. We coined this method as the 'anti-stress' assay. In this assay we induced aging of the human dermal fibroblast (HDF) cells with hydrogen peroxide, which simulates oxidative stress conditions. The 'aged' cells were

then treated with one of our botanical ingredients and the cell viability was measured by a fluorescent-based assay. We concluded that our ingredient protected HDF cells from oxidative stress and hence from known 'aging' processes.

Further, from the above experiment we investigated deeper into the molecular mechanism of this novel ingredient. We know Sirtuins, especially SIRT 1 is a longevity gene. This gene is also known as the 'youth protein'. Stimulation of this protein extends the lifespan in yeast and delays the onset of age-related diseases in mammals. We observed that our ingredient upregulated SIRT1 protein expression.

A good anti-aging ingredient must not only activate anti-aging parameters but also inhibit the "aging gene programming". An aging program in cells can be initiated by activation of NF $\kappa$ B. Therefore, we hypothesized that an ideal antiaging ingredient should inhibit this pathway. Our ingredient inhibited NF $\kappa$ B activity in a cell-based reporter assay.

Furthermore, we tested to see if the stimulation or inhibition of the 'aging' pathways modulates any response of the target genes which makes the skin youthful. We saw an increase in the gene expression of HAS and Ki67 by qPCR assay.

Another key cause of aging is the glycation of collagen, known to increase with age. The glycation process disrupts the collagen assembly and its networking capability making the skin appear stiff and aged. We showed that our ingredient also inhibited glycation.

824

#### **Mediation of metal-catalyzed oxidative damage by a Nutraceutical Formulation.**

*M. A. Taddeo<sup>1</sup>, S. Lee<sup>1</sup>, T. B. Shea<sup>1</sup>; <sup>1</sup>Center of Cellular Neurobiology and Neurodegeneration Research, Biochemistry and Biological Sciences, University of Massachusetts - Lowell, Lowell, MA*

As advances in medicine and nutrition have led to increased human longevity, diseases of aging have thus become more prevalent and have stimulated increased research interest. These diseases of aging include neurodegenerative disorders such as Alzheimer's Disease (AD) and Parkinson's Disease. A better understanding of the pathophysiology underlying these disease states and factors mediating their progression is critical. One such factor is the aggregation of amyloid beta, a normal protein which misfolds in AD and forms plaque deposits in the brain. A second factor is oxidative damage caused by excessive levels of free transition metals, which exist normally in human physiology but are toxic to neurons at high levels.

Recently, we developed a Nutraceutical Formulation (NF) which has been shown to improve cognitive function in people with AD, Mild Cognitive Impairment or even in normal aged individuals. The aim of this study was to determine the impact of exogenous iron and copper on the effectiveness of NF in neuronal cell culture at 2 hours to 7 days post-treatment, as well as the interplay between these metals and amyloid beta. Evaluation of cell cultures was accomplished using fluorescence microscopy, with dichlorofluorescein (DCF) used to detect oxidative damage and diamidino phenylindole (DAPI) used to determine cell death.

We determined that excessive exogenous metals, particularly iron, can increase oxidative damage to at least the same extent as amyloid beta in neuronal cell culture. NF counteracts this damage. Also, simultaneous exposure of cultured neurons to metals and amyloid beta produced a synergistic deleterious impact; ongoing research is examining if NF can counteract this

synergy. Future treatment of neurodegenerative diseases such as AD may include strategies to eliminate excess amounts of these metals while at the same time employing nutrients such as those found in NF to counteract neuronal damage.

825

### **Sestrin2 modulates ROS-dependent cellular senescence through the NADPH oxidase 4 activation.**

*C. Hwang<sup>1</sup>, Y-H. Han<sup>2</sup>, D-Y. Yu<sup>2</sup>, K-S. Kwon<sup>1</sup>; <sup>1</sup>Laboratory of Cell Signaling, Aging Research Center, Korea Research Institute of Bioscience and Biotechnology, Daejeon, Korea, <sup>2</sup>Disease Model Research Laboratory, Aging Research Center, Korea Research Institute of Bioscience and Biotechnology, Daejeon, Korea*

Sestrin2 (Sesn2) is known to be involved in the maintenance of metabolic homeostasis and in aging through modulation of the AMPK-mTOR pathway. We show here that Sesn2 also plays a role in the cellular senescence in mouse embryonic fibroblasts (MEFs). Sesn2 knockout MEFs showed senescent-like morphology, including flattened, irregular shape and enlarged size, as well as senescence associated (SA)- $\beta$ -galactosidase activity. Reactive oxygen species (ROS) were significantly increased in the Sesn2 knockout MEFs. While the levels of many antioxidant proteins including thioredoxin and 6-members of peroxiredoxins were not changed in the Sesn2 knockout MEFs, the level of NADPH oxidases 4 (NOX4), one of ROS generating enzymes, increased dramatically. Additionally, AMP-activated protein kinase (AMPK), a sensor of cellular energy, was activated in Sesn2 knockout MEFs. Pretreatment of Sesn2 knockout MEFs with an antioxidant N-acetyl-cysteine (NAC) reduced SA- $\beta$ -galactosidase activity and inhibited AMPK activation. Therefore we suggest that the induction of NOX4, which causes ROS generation and subsequent AMPK activation, is a likely mechanism of cellular senescence resulted from the loss of Sesn2.

## **Cell Death**

826

### **Simultaneous analysis of DNA damage, cell cycle, and apoptosis using multiparameter flow cytometry.**

*E. A. O'Donnell<sup>1</sup>, G-J. Gao<sup>1</sup>, J. Elia<sup>1</sup>, C. M. Lane<sup>1</sup>, C. Carson<sup>1</sup>; <sup>1</sup>BD Biosciences, San Diego, CA*

DNA double-strand breaks can be induced by a number of cellular events, including exposure to genotoxic agents, apoptotic DNA fragmentation, and normal cellular processes such as immunoglobulin gene recombination. Histone H2AX is phosphorylated on serine 139 in response to DNA double-strand breaks. Antibody-mediated detection of H2AX (pS139), also known as gamma-H2AX, has been shown to be a useful indicator of DNA damage, enabling the detection of double-strand breaks induced by genotoxic agents or by apoptosis. The topoisomerase inhibitors camptothecin and etoposide induce DNA double-strand breaks in cycling cells by two mechanisms. Both inhibitors have direct DNA-damaging effects, while also triggering apoptosis and the associated DNA fragmentation. To distinguish between direct versus apoptosis-initiated DNA damage, H2AX (pS139) was analyzed simultaneously with other indicators of cell status, including markers of cell cycle position and apoptosis. Conditions for cellular fixation and permeabilization were optimized to achieve the highest resolution of all markers of interest. The kinetics of H2AX phosphorylation, caspase-3 activation, and PARP cleavage were assessed following cellular treatment with camptothecin, etoposide, or TNF in the presence or absence of caspase inhibitors. Caspase-independent, early phosphorylation of

H2AX was induced by both camptothecin and etoposide but not by TNF. In contrast, all three cellular treatments induced late phosphorylation of H2AX in a caspase-dependent manner. The kinetics of the late H2AX phosphorylation corresponded closely with caspase-3 and PARP cleavage kinetics. Multiparameter flow cytometric analysis of H2AX (pS139), cleaved caspase-3, cleaved PARP, and DNA content provides a powerful tool for studies of normal cellular processes and responses to cytotoxic agents.

827

### **Induction of Cellular Apoptosis and Necrosis following Manganese Oxide Nanoparticle Exposure in Neuronal Cell Cultures.**

*J. A. Jordan<sup>1</sup>, Y. Wang<sup>2</sup>, K. Pennell<sup>2</sup>, G. Miller<sup>3</sup>; <sup>1</sup>Natural Sciences, Clayton State University, Morrow, GA, <sup>2</sup>Civil and Environmental Engineering, Tufts University, Medford, MA, <sup>3</sup>Department of Environmental Health, Emory University, Atlanta, GA*

Exposure to high levels of manganese (Mn) has been linked to a Parkinson-like disorder called manganism, also called Welder's disease. These exposure levels may result in irreversible neuronal damage to critical areas of the brain. The exact mechanism of neurotoxicity associated with high manganese exposure is unknown. In previous studies, we have shown that manganese oxide nanoparticles (Mn<sub>2</sub>O<sub>3</sub>) and ionic manganese containing compounds, manganese chloride (MnCl<sub>2</sub>) and manganese acetate (MnAc), result in a dose-dependent increase in cytotoxicity and oxidative stress using human embryonic kidney cells (HEK 293). At the same comparative dose, Mn<sub>2</sub>O<sub>3</sub> was more cytotoxic and induced a greater level of oxidative stress. In this study, we first addressed the role of dispersion and dissolution in the neurotoxicity of Mn<sub>2</sub>O<sub>3</sub> nanoparticles. There was a significant reduction in the agglomeration of particles with the addition of fetal bovine serum, FBS (media alone 4194nm vs. media/serum 261nm). The dissolution rate of free Mn following the incubation of Mn<sub>2</sub>O<sub>3</sub> nanoparticles in cell culture media for 48h at 37°C was minimal (<1%). Increasing concentrations of all Mn-containing compounds resulted in time- and dose- dependent increases in the number of apoptotic cells. At higher concentrations of Mn<sub>2</sub>O<sub>3</sub>, in comparison to MnCl or MnAc, we observed the accumulation of particles inside cells, alterations in cellular nuclei, and increased cellular necrosis. These studies suggest the toxicity of manganese containing compounds may not only be related to the release of free Mn but the physical properties of manufactured nanoparticles.

828

### **Rapid Mitochondrial Depolarization Induced by Gambogic Acid in Cytotoxicity Studies**

*J. Clor<sup>1</sup>, K. Tran<sup>1</sup>, K. Gillis<sup>1</sup>, A. Khan<sup>1</sup>, K. Tyagarajan<sup>1</sup>; <sup>1</sup>Bioscience, EMD Millipore, Hayward, CA*

Understanding and evaluation of drug induced cyto-toxicity requires evaluation of how treatments impact multiple cell health parameters. Gambogic acid, a xanthone from *Garcinia hanburyi*, is a compound with potent anti-cancer activity. It stimulates apoptosis and cell death in a number of cell lines however its mechanism of action is not well understood. In this study, we present results from the treatment of gambogic acid on Jurkat and HB Cells evaluated using multiple assays that helped assess mitochondrial potential changes, caspase 3,7 and MultiCaspase activity and phosphatidylserine expression using Annexin V binding, all being performed with inclusion of a cell death marker. Data from both dose response and time course studies were obtained and samples analyzed on the Muse Cell Analyzer. Our results demonstrate that gambogic acid induces rapid cell death in Jurkat, HB and HL-60 cell lines by induction of cellular apoptosis. Further, time course studies with Jurkat cells with gambogic acid demonstrate that a high proportion of cells exhibited rapid mitochondrial membrane

depolarization in less than 1 hr of treatment while apoptotic impacts such as Annexin V response, and cell death showed a slower rate of appearance for the same concentration of treatment. Apoptosis is soon followed by cell death in these treatments. Overnight treatment of Jurkat cells with low doses of gambogic acid demonstrated significant apoptotic impacts on Jurkat cells with negligible impact on cell cycle observed under the same conditions indicating apoptosis being the primary and initial impact on these cells. Treatment of HB cells with gambogic acid also resulted in significant apoptosis with pan-caspase and Caspase-3,7 and cell death activity being observed. Our studies suggest that gambogic acid induced apoptosis proceeds through significant and rapid impacts of the drug on the mitochondria which subsequently trigger other apoptotic and cytotoxic effects. Comprehensive concentration and time course studies with multiple apoptotic markers can thus provide valuable insights into mechanism of compound action.

829

### **Structural and Functional Determinants of Toxicity in Spinal and Bulbar Muscular Atrophy.**

*T. Berger<sup>1</sup>, E. Heine<sup>2</sup>, Y. Liu<sup>2</sup>, H. Montie<sup>2</sup>, D. Merry<sup>2</sup>; <sup>1</sup>Department of Neuroscience, Thomas Jefferson University, Philadelphia, PA, <sup>2</sup>Department of Biochemistry, Thomas Jefferson University, Philadelphia, PA*

Polyglutamine-repeat disorders are part of a larger family of neurodegenerative diseases characterized by protein misfolding and aggregation. In spinal and bulbar muscular atrophy (SBMA), polyglutamine expansion within the androgen receptor (AR) causes progressive debilitating muscular atrophy and lower motor neuron loss in males. Histologically, the polyglutamine-expanded AR aggregates to form nuclear inclusions upon hormone binding. Soluble (pre-inclusion) aggregates of the AR are considered to be a toxic intermediate in the aggregation process. Determining the molecular criteria guiding the formation of soluble aggregates is fundamental to understanding SBMA pathogenesis.

Gender-specificity is unique to SBMA and is caused by the requirement of hormone (testosterone or dihydrotestosterone) for disease. Several events downstream of the hormone-bound AR, including an interdomain interaction between the amino- and carboxyl- terminus of the AR, nuclear localization, and acetylation are also necessary for toxicity. In order to gain further insight on nuclear events that may contribute to the formation of a toxic conformation of the polyglutamine-expanded AR, we sought to determine the role of AR DNA binding in SBMA pathogenesis. Based on differences in aggregate morphology - but not toxicity - between DNA binding-competent and DNA binding-deficient cells, we carried out extensive biochemical analyses to identify similarities between aggregated species that may be indicative of a toxic conformation. Utilizing SDS agarose gel electrophoresis (SDS-AGE), ultracentrifugation, and filter trap by cellulose acetate, we identified a heterogeneous distribution of AR oligomers that precede the formation of frank nuclear inclusions. Using tet-on AR112Q PC12 cells, we show that oligomers that form early in the course of hormone treatment are comprised of full-length AR and retain reactivity to the conformation-specific antibody 3B5H10. With time, we see a predominant shift towards faster migrating oligomers that are not reactive for 3B5H10. We further show that these 'late oligomers' are comprised of full-length, insoluble AR species; this conformational change directly correlates with an increase in nuclear inclusions, as detected by fluorescent microscopy. In an attempt to hone in on a particular conformation of AR species that may be correlative with toxicity, ongoing studies are focused on characterizing commonalities between DNA binding-competent and DNA binding-deficient cells. Identifying a common signature of soluble AR species will advance the development of targeted therapies applicable to a wide range of neurodegenerative diseases caused by protein misfolding.

**Effect of vitamin A on recovery of noise-induced hearing loss.**

M. Gi<sup>1</sup>, J. Kim<sup>1</sup>, J. Choi<sup>1</sup>; <sup>1</sup>Brain Korea 21 project, Yonsei University College of Medicine, Seoul, Korea

To determine the relation between vitamin A deficiency and noise-induced tissue repair, groups of normal diet or vitamin A-deficient diet C57BL/B6 mice were exposed to a white-band noise for 3 hours at levels of 95 dB SPL. Auditory brainstem response thresholds were measured pre-exposure and several times post-exposure (1-30 days) to determine magnitude of threshold shift. Degree of hearing loss immediately after exposure to noise at all 4 frequencies (4, 8, 16, and 32 kHz) was similar in two groups. However, hearing recovery after noise exposure was different. Vitamin A-deficient diet mice were not recovered at 4 kHz frequency while normal diet mice were recovered at 4, 8, and 16 kHz frequencies. At 32 kHz frequency, two groups were recovered with similar level but not fully rescued.

**Mgrn1 regulates neuronal endosomal trafficking and functions in cellular defense against apoptosis.**

D. V. Fallaize<sup>1</sup>, L-S. Chin<sup>1</sup>, L. Li<sup>1</sup>; <sup>1</sup>Pharmacology, Emory University, Atlanta, GA

Mahogunin RING finger 1 (Mgrn1) is a ubiquitously expressed protein whose null mutation causes age-dependent prion disease-like spongiform neurodegeneration in mice. Moreover, depletion of Mgrn1 by pathogenic prion protein isoforms has been implicated in the pathogenesis of human prion disease. These findings highlight the importance of understanding the cellular function of this poorly characterized protein. We have shown that Mgrn1 is an E3 ubiquitin-protein ligase that regulates endosome-to-lysosome trafficking by ubiquitinating ESCRT-I component TSG101 in HeLa cells. Immunofluorescence confocal microscopic analysis reveals that endogenous Mgrn1 protein is associated with early endosomes in axons, dendrites, and synapses of mouse cortical neurons. We find that Mgrn1 null mutation causes accumulation of enlarged and clustered endosomes and lysosomes in adult brain tissue and cortical neurons from Mgrn1 deficient mice. Furthermore, our analyses reveal that loss of Mgrn1 leads to increased susceptibility of cortical neurons to oxidative stress induced apoptosis. Our findings support a role for Mgrn1 in the regulation of neuronal endosome-to-lysosome trafficking and cellular defense against apoptosis, and they suggest a pathogenic mechanism by which Mgrn1 null mutation causes spongiform neurodegeneration by impairing neuronal endosomal trafficking.

832

**Genetic Interactions Between BX11 and IRE1 in the Regulation of the Unfolded Protein Response and Cell Death in Yeast.**

C. Selinski<sup>1</sup>, B. Swan<sup>1</sup>, J. O'Brien<sup>1</sup>, R. Frazier<sup>1</sup>, K. Murphy<sup>1</sup>, N. Austriaco<sup>1</sup>; <sup>1</sup>Biology, Providence College, Providence, RI

Bax inhibitor-1 (BI-1) is an anti-apoptotic gene whose expression is upregulated in a wide range of human cancers. Studies in both mammalian and plant cells suggest that the BI-1 protein resides in the endoplasmic reticulum and is involved in the unfolded protein response (UPR) that is triggered by ER stress. We have been investigating the function of the yeast gene, BX11, which appears to be a homolog for mammalian BI-1. In previous studies, we showed that yeast cells from two different strain backgrounds lacking BX11 are more sensitive to heat-shock

induced cell death and ER-stress induced cell death. They also have lower viabilities in ethanol and 2% glucose, two known triggers of yeast programmed cell death. Finally, we noted that  $\Delta bxi1$  cells have a decreased unfolded protein response as measured with a UPRE-lacZ reporter. More recently, we have created  $\Delta bxi1 \Delta ire1$ ,  $oeBXI1 \Delta ire1$ , and  $oeIRE1 \Delta bxi1$  double mutants that have allowed us to characterize the genetic interactions between these two genes in the regulation of the UPR and cell death in yeast. Our data suggests that both genes may work in different pathways to influence the physiology of yeast cells undergoing programmed cell death. [Our laboratory is supported by the following grants: NIGMS R15 GM094712, NSF MRI-R2 0959354, and a subcontract from NIH Grant 2 P20 RR016457 awarded to the Rhode Island INBRE Program, for undergraduate student training.]

**Non-canonical apoptotic caspase cleavage after glutamic acid is biologically relevant.**

*J. Seaman<sup>1</sup>, J. A. Wells<sup>1</sup>; <sup>1</sup>UCSF, San Francisco, CA*

The caspase proteases play a major role in initiating and executing apoptosis. Caspases were discovered in the mid 1990's and were quickly shown to have a unique and required preference to cleave after aspartic acid. Recent proteomics studies have identified close to 2000 apoptotic caspase substrates in human cells. However, caspase cleavages after aspartic acid represent only 30% of identified apoptotic cleavage events. Analysis of non-aspartic acid apoptotic cleavage events reveals a smaller set of ~250 cleavages after glutamic acid that are as significantly enriched as aspartic acid cleavages over untreated levels. The sequence logo for the glutamic acid cleavages shows enrichment for DEVE|[G/S/A], identical to the preferred executioner caspase substrate sequence. Kinetic, structural, and further substrate analysis confirm that caspase -3 and -7 do cleave after glutamic acid in cells.

834

**Depletion of either nuclear poly (A) binding protein (PABP) or the cytoplasmic PABP1 results in nuclear translocation of PABP4 and apoptotic cell death triggered by p53 phosphorylation.**

*R. B. Bhattacharjee<sup>1</sup>, T. Zannat<sup>1</sup>, J. Bag<sup>1</sup>; <sup>1</sup>Molecular & Cellular Biology, University of Guelph, Guelph, ON, Canada*

In vertebrates, poly(A) binding protein (PABP) is known to exist in five different isoform. PABPs are primarily cytosolic with the exception of the nuclear PABP (PABPN1), which is located in the nucleus. PABP1 binds to the 3' poly(A) tail of the mature mRNA and facilitates the recruitment of the ribosome to the mRNAs 5' end. PABPN1 binds to poly(A) of the nascent mRNA and regulates the polyadenylation process. The cellular function of other PABPs (PABP3, 4, 5) remains relatively uncharacterized. In this study we have investigated the effect of PABP1 and PABPN1 ablation on human cells. For this, we depleted PABP1 or PABPN1 using RNAi from both HeLa and HEK293 cells. In all cases the survival rate of transfected cells was severely affected. After 72 hours of transfection, 40-60% cells were found to undergo apoptosis by p53 phosphorylation at ser46. PABP1 depletion led to almost 50% reduction in cellular protein synthesis, whereas PABPN1 depletion did not have any effect on poly(A) tail length, transcription, or translation of mRNA. However, in both situations a unique mechanism of PABP homeostasis was observed. Notably two non targeted cytoplasmic PABPs, PABP4 and 5, expressions were altered in PABPN1 or PABP1 depleted cells. There was approximately 3 fold increase ( $p \leq 0.05$ ) in the cellular abundance of PABP4 and PABP5 in PABP1 depleted cells. In PABP1 depleted cells PABP4 but not PABP5 was associated with the polyribosomes and co-immunoprecipitated with eIF4G. However, this homeostasis was not sufficient to prevent cell

death as the number of apoptotic cells further increased to 85% in 96 hour culture. In PABPN1 depleted cells, the level of PABP5 increased by 4-5 fold ( $p \leq 0.05$ ); PABP4 level remained unaffected, however significant amount of the protein translocated to the nucleus (4-5 fold increase in nuclear PABP4). Furthermore, PABP4 was detected in the nuclear  $\alpha$ -actin pre-mRNA of PABPN1 depleted cells by RNA immunoprecipitation studies. Nevertheless, like PABP1 depletion, PABPN1 cells also showed significant apoptosis in 96 hours culture suggesting PABP4 and PABP5 homeostasis were not sufficient to rescue the PABPN1 depleted cells. Our results suggest that PABPN1 may have a novel anti apoptotic role in mammalian cells.

835

**Protective role of C-peptide against hyperglycemia-induced endothelial apoptosis by regulating ROS-mediated TG2 activation in diabetes.**

*M. P. Bhatt<sup>1</sup>, Y-C. Lim<sup>1</sup>, M-H. Kwon<sup>1</sup>, Y-M. Kim<sup>1</sup>, K-S. Ha<sup>1</sup>; <sup>1</sup>Cellular and Molecular Biochemistry, Kangwon National University School of Medicine, Chuncheon, Kangwon-do, Korea*

C-peptide is a bioactive peptide with a potentially protective role in diabetic complications; however, its molecular mechanism of protection against cardiovascular damage due to hyperglycemia-induced apoptosis remains unclear. We investigated the protective mechanism of C-peptide against hyperglycemia-induced apoptosis using human umbilical vein endothelial cells and streptozotocin diabetic mice. High glucose (33 mM) induced apoptotic cell death in endothelial cells via sequential elevation of intracellular  $Ca^{2+}$  and ROS as well as subsequent activation of transglutaminase 2 (TG2). C-peptide (1 nM) prevented endothelial cell death by inhibiting protein kinase C- and NADPH oxidase-dependent intracellular ROS generation and by abolishing high glucose-induced TG2 activation, without affecting intracellular  $Ca^{2+}$  levels. Consistently, in the aorta of streptozotocin diabetic mice, hyperglycemia stimulated transamidating activity and endothelial cell apoptosis that was inhibited by C-peptide replacement therapy (35 pmol/min/kg) using osmotic pumps. In addition, C-peptide prevented hyperglycemia-induced activation of transamidating activity and apoptosis in the heart and renal cortex of streptozotocin diabetic mice. Thus, C-peptide protects endothelial cells from hyperglycemia-induced apoptotic cell death by inhibiting intracellular ROS-mediated activation of TG2. Furthermore, TG2 may be a promising avenue of therapeutic investigation to treat diabetic vasculopathies.

**Xenoestrogens, Bisphenol A (BPA) and 4-nonilphenol (NP), induce activity of ADAM17.**

*P. A. Urriola-Muñoz<sup>1</sup>, R. Lagos-Cabré<sup>2</sup>, C. P. Blobel<sup>3</sup>, R. D. Moreno<sup>2</sup>; <sup>1</sup>Physiology Department, Pontificia Universidad Católica de Chile, Santiago, Chile, <sup>2</sup>Physiology, Pontificia Universidad Católica de Chile, Santiago, Chile, <sup>3</sup>Arthritis and Tissue Degeneration Program, Hospital for Special Surgery, New York, NY*

**Introduction:** Plasticizers with estrogenic activity such as BPA and NP disrupt spermatogenesis by a still unknown mechanism. In our lab, we have shown that ADAM17, an extracellular metalloprotease capable of shedding the ectodomain of several membrane-anchored proteins like neuregulin [1], participates in physiological and genotoxic induced-germ cells apoptosis [2]. The aim of our work was to determine if apoptosis induced by xenoestrogens is dependent of ADAM17 activity.

**Materials and Methods:** Prostate cancer cell line LnCap were stably transfected with a vector encoding a fusion protein encompassing alkaline phosphatase (AP) and neuregulin $\beta$ 1, (AP)-NRG $\beta$ 1. ADAM17 sheddase activity was measure as the release of AP into the culture medium after incubation with BPA and NP, in the presence or absence of different metalloprotease

inhibitors. Active ADAM17 protein levels were evaluated by western blot in the different conditions. Cell death was evaluated by trypan blue incorporation, cleavage of Poly ADP ribose polymerase (PARP) by Western blot and active caspase-3-positive cells by immunohistochemistry.

Results: LnCap cells express ADAM17, but not NRG $\beta$ 1, as evaluated by RT-PCR, Western blot and immunofluorescence. AP activity showed a robust increase after 3 h of treatment with 100  $\mu$ M BPA or 50  $\mu$ M NP compared with the vehicle, which was reduced by GW280264X (10  $\mu$ M), an ADAM17 inhibitor. In addition we observed a statistically significant increase of the processed active ADAM17 in the total protein extract.

Active caspase-3-positive cells were robustly increased after incubation with 50 or 100  $\mu$ M NP, and an increase in cleaved PARP protein levels (which is a substrate of caspase-3) was detected starting from 1 h after treatment. In addition, trypan blue positive cells were observed with 100  $\mu$ M NP. In order to study the pathway involved in ADAM17 activation we found that the p38 MAPK inhibitor PD169316 (5  $\mu$ M) and the calcium chelator BAPTA-AM (10  $\mu$ M) did not have any effect upon AP shedding after NP treatment.

Discussion: Our results show that xenoestrogens (BPA and NP) induce ADAM17 sheddase activity in LnCap cells, and suggest that this may be related to its role in apoptosis.

#### **Characterization of anti apoptotic protein family (Bax inhibitor and Lifeguard) in *Hydra vulgaris*.**

M. Motamedi<sup>1</sup>, A. Wagner<sup>1</sup>, A. Böttger<sup>1</sup>; <sup>1</sup>*Cell and developmental biology, LMU, Munich, Germany*

*Hydra vulgaris* belongs to the phylum Cnidaria with a very well conserved programmed cell death signalling pathway. Components of the apoptotic molecular pathway such as Bcl2-family members, caspases, caspase inhibitors (IAPs), APAF-1, TNF-receptor and FADD have been identified in hydra. However, two cytoprotective protein families, which consider playing important role in regulation of apoptosis pathways, remain to be investigated.

Our results revealed that two cytoprotective protein families with cell death suppressing function exist in hydra i.e., the Bax inhibitor protein family and the Lifeguard-family (LFG). These proteins are hydrophobic with 6-7 helix transmembrane domain structures and have been shown to be localized in membranes (Golgi, endoplasmic reticulum and nuclear membrane).

Moreover, Bax inhibitor1 is an integral endoplasmic reticulum -membrane protein and is shown to inhibit apoptosis induced by camptothecin when expressed in HEK293 cells. In situ hybridisation experiments show that it is expressed during both, oogenesis and spermatogenesis, where apoptosis pathways also play roles.

In addition, we have found three sequences encoding LFG proteins in Hydra i.e., LFG4 and two homologous of LFG1i. We cloned TMBIM4/LFG4 (Golgi anti apoptotic protein) and found it to be localized in Golgi and endoplasmic reticulum compartments. In situ hybridisation experiments indicate expression of LFG4 in endodermal epithelial cells. We are currently analyzing, whether it protects hydra cells from both intrinsic and extrinsic apoptotic stimulating factors.

Further studies on these proteins will provide more evidence about their role in regulating cell death pathways.

**The apoptosis inhibitor ARC alleviates the ER stress response to promote  $\beta$ -cell survival in diabetes.**

*W. McKimpson<sup>1</sup>, J. Weinberger<sup>1</sup>, L. Czerski<sup>1</sup>, M. Zheng<sup>1</sup>, M. Crow<sup>2</sup>, J. Pessin<sup>1</sup>, S. Chua<sup>1</sup>, R. Kitsis<sup>1</sup>; <sup>1</sup>Albert Einstein College of Medicine, Bronx, NY, <sup>2</sup>Johns Hopkins University, Baltimore, MD*

Type 2 diabetes involves both insulin resistance and “failure” of  $\beta$ -cells, the cells responsible for insulin secretion. An important component of  $\beta$ -cell failure is cell loss by apoptosis. ARC (Apoptosis Repressor with Caspase Recruitment Domain) is an inhibitor of apoptosis that is highly expressed in cardiac and skeletal myocytes and neurons. ARC possesses the unusual property of antagonizing both the extrinsic (death receptor) and intrinsic (mitochondria/endoplasmic reticulum (ER)) cell death pathways. We discovered that ARC protein is abundant in cells of the pancreatic islets, including >99.5% of mouse and 73% of human  $\beta$ -cells. Moreover, we found that deletion of *nol3*, encoding ARC, markedly exacerbates hyperglycemia and further impairs glucose tolerance in diabetic (*ob/ob*) mice, and this is accompanied by pancreatic islet disorganization and increases in  $\beta$ -cell apoptosis. ER stress is a major component of type 2 diabetes and an important trigger of  $\beta$ -cell death. Genetic gain- and loss-of-function studies in cultured cells demonstrated that ARC inhibits  $\beta$ -cell apoptosis elicited by the ER stressors tunicamycin, thapsigargin, and the free fatty acid palmitate. Unexpectedly, inhibition of cell death by ARC is mediated by suppression of the ER stress response, a novel function of ARC. Further analysis showed that ARC acts distal to ER stress sensors PERK and IRE1 $\alpha$  to suppress induction of CHOP, a transcription factor that activates both genes involved in resolving ER stress and genes involved in cell death. In pancreatic islet tissue stimulated with palmitate, depletion of ARC augments CHOP abundance and apoptosis, which is dramatically rescued by deletion of CHOP. Taken together, these data demonstrate that ARC is a previously unrecognized inhibitor of  $\beta$ -cell apoptosis in type 2 diabetes, and its protective effects are mediated through a novel mechanism involving suppression of the ER stress response pathway.

839

**Moderate ER stress induces p44/p42 kinase activation and an ITPR-dependent apoptosis.**

*A. Scholl<sup>1</sup>, A. Osborne<sup>1</sup>, A. Vargas<sup>1</sup>, E. Lumley<sup>1</sup>, J. Scott<sup>1</sup>, J. L. Brewster<sup>1</sup>; <sup>1</sup>Natural Science Division, Pepperdine University, Malibu, CA*

When unfolded proteins accumulate in the endoplasmic reticulum (ER), stress signaling pathways called the Unfolded Protein Response (UPR) are induced. Modeling of ER stress in cultured cells is often performed with high doses of poisons that arrest essential functions within the ER. In examining the potential implications of chronic ER stress signaling in organismal models, a modest ER stress would be anticipated as clinically appropriate. In this study, the ER was challenged with a 50-fold range of tunicamycin, an inhibitor of N-linked glycosylation.

Tunicamycin induced cellular apoptosis and stress signaling over a range of concentration from 20 nM to 1000 nM. Activation of the ER transmembrane protein IRE1 was measured by quantification of IRE1-mediated splicing of the XBP1 pre-mRNA. IRE1 activity increased with dose of tunicamycin, but was detectably activated at doses as low as 20 nM. GRP78 expression, another marker of ER stress signaling, was increasingly induced with dosage of tunicamycin exposure. Interestingly, apoptosis induced by moderate levels of ER stress was susceptible to inhibitors of the inositol trisphosphate receptor (ITPR), a key release point for ER Ca<sup>2+</sup> stores. This susceptibility was not observed with doses of tunicamycin above 40 nM, suggesting apoptosis induced by moderate doses is controlled by ITPR signaling. Assessment of cytosolic protein kinase pathways revealed the p44/p42 kinases to be specifically induced at tunicamycin concentrations from 20-40 nM while the p38 kinase was increasingly stimulated with increasing tunicamycin dose. This work collectively reveals moderate ER stress to generate a distinct stress signal relative to more severe ER stress exposure.

#### **Nanoparticle accumulation in human alveolar cells induce reactive oxygen species and ER stress signaling.**

*B. Manes<sup>1</sup>, S. Alvarado<sup>1</sup>, J. L. Brewster<sup>1</sup>; <sup>1</sup>Natural Science Division, Pepperdine University, Malibu, CA*

The signaling of cell stress in response to organelle dysfunction, toxin exposure, and mutation is complex; generating responses that can include adaptation, or in severe cases cellular apoptosis. Nanoparticles (20-100 nm diameter) have been shown to induced cell stress in lung cells, potentially identifying a cause of lung disease in areas with high levels of air pollution. This study examines the effect of carbon black (CB) and titanium dioxide (TiO<sub>2</sub>) nanoparticles on stress signaling and apoptosis in cultured A549 human alveolar epithelial cells. Nanoparticles were prepared via sonication and physical disruption. Cellular accumulation in A549 was confirmed by microscopy and shown to result in a primarily perinuclear cellular localization. Cells exposed to CB and TiO<sub>2</sub> nanoparticles over a 25-100 ug/ml range of concentration displayed significant increases in cellular apoptosis, determined by nuclear morphology, over a period of 72 hours. We hypothesize that accumulated nanoparticles may generate stress signaling similar to that exhibited by cytosolic aggregates of misfolded proteins which generate endoplasmic reticulum (ER) stress. Mobilation of cellular reactive oxygen species (ROS) was rapidly induced by CB exposure, or by exposure to an ER stress-inducing toxin (tunicamycin, 400 nM). TiO<sub>2</sub> did not generate elevated ROS levels. An evaluation of stress signaling pathways induced by ER stressors showed TiO<sub>2</sub> to induce phosphorylation of eIF2 $\alpha$ , consistent with activation of the PERK pathway. Neither GRP78 expression, nor IRE1 $\alpha$  activity were induced by nanoparticle exposure. This work reveals that nanoparticle composition strongly influences the signaling pathways induced during exposure, and that select components of ER stress signaling pathways are induced by nanoparticle exposure.

841

#### **AGE-LDL affects the risk of foam cell apoptosis associated with hydrolysis of CE, corresponding to PC-FC Complex formation.**

*M. Mori<sup>1</sup>, R. Motohashi<sup>1</sup>, M. Imamura<sup>1</sup>, R. Takahashi<sup>1</sup>, S. Kikuchi<sup>1</sup>, M. Takahashi<sup>1</sup>; <sup>1</sup>Cell Biological Pathology, Chiba Institute of Science, Choshi, Japan*

**[Objective] Phosphatidylcholine (PC)-cholesterol (FC) complex** structures, a unique atheroma related antigen expressed on the surface of FC rich lipid droplets, associating with foam cell death. To elucidate the role of antigen in the development of atherosclerosis, the

relationship among **AGE(Advanced Glycation Endproduct)-LDL**, PC-FC complex, cellular FC transport and role of HDL in cultured foam cell were investigated.

**[Method]** Foam cells were prepared by incubation with various modified LDL for 24hr, then cultured up to 3 \6 days in the presence of LPDS +/- HDL and various inhibitors against ABC transporter, nCEase. PC-FC complex and Apoptotic cells were detected by immunofluorescent microscopy using specific monoclonal antibodies or FITC-AnnexinV. FC rich lipid droplet can be detected by Filipin staining.

**[Results & Discussion]**

Acetylated LDL(AcLDL) strongly induces PC-FC Complex in foam cells via FC-rich lipid droplet formation, however, HDL treatment can induce CE hydrolyse and FC export associated with foam cell survival. FC-rich particles once appeared in the AcLDL induced foam cells, HDL treatment leads to decrease these particles associating with foam cell apoptosis, whereas, the phenotype of the cell is significantly different in AGE-LDL induced foam cells. FC-rich lipid droplets were not reduced by HDL treatment in these cells. Probucol, a potent ABC transporter inhibitor leading reduce FC export, no significant difference can be detected on AGE-LDL induced foam cells after probucol treatment. Among two potent foam cell inducer, AcLDL and AGE-LDL, distinctive difference can be investigated. Once accumulated AGE-LDL can be hydrolysed in Late Endosome, however, the rate of accumulation and re-esterified to CE is proceeding slowly, comparing with Ac-LDL induced foam cells. HDL treatment might be affected cellular nCEase activity leading to cellular FC increase, in resulting foam cells expreed FC-rich lipid droplets, no significant difference PC-FC complex formation and foam cell death, whereas, amount of FC in the cells increased markedly.

These phenomena would be related to PC-cholesterol complex formation and foam cell death via cellular FC export. HDL played an important role in FC-rich lipid droplets and PC-FC complex formation.

These significantly relationship in AGE-induced foam cells, among the PC-FC complex formation, cellular FC export and foam cell apoptosis can reflect to development of atherosclerosis in thickened intima.

**Neurotoxicity of lovastatin is not associated with cholesterol reduction in human neuroblastoma cells.**

A. Mendoza-Oliva<sup>1</sup>, P. Ferrera<sup>1</sup>, C. Arias<sup>1</sup>; <sup>1</sup>Medicina Genómica y Toxicología Ambiental, Instituto de Investigaciones Biomédicas, Universidad Nacional Autónoma de México, México D.F., Mexico

The brain is the organ with the highest cholesterol content which essentially comes from *de novo* synthesis. Epidemiological and experimental studies indicate that high cholesterol increases the susceptibility to neurodegenerative disorders such as Alzheimer Disease (AD). Several studies have analyzed the relationship between the use of statins, a class of drugs that lower serum cholesterol, and the onset of AD yielded conflicting result. Statins are inhibitors of the enzyme hydroxy-methylglutaryl-coenzyme A reductase (HMGCR), which catalyzes the rate limiting step in cholesterol synthesis. **Aims:** We have analyzed the effects of lovastatin a statin able to cross the brain blood barrier, in cholesterol levels and cell viability in human neuroblastoma cells. **Methods and Results:** To examine the effects of lovastatin on cholesterol content, we fist studied its effects on neuronal viability in the absence of added serum to the culture media or with low (2%) or normal content of serum (10%). Different doses of lovastatin (10, 5 and 2  $\mu$ M) induced 50-80% of cell death that was more prominent when serum was absent and cholesterol completely removed from the media. Addition of cholesterol 50  $\cdot$  M did not protect from lovastatin toxicity. Moreover, added cholesterol showed to be more toxic under conditions of

normal serum content than in the absence of serum. Incubation of cells with lovastatin did not induce a reduction of endogenous cholesterol even if there was an important induction of the HMGCR. **Conclusions:** Lovastatin induced-neurotoxicity was not associated with inhibition of cellular cholesterol synthesis but increased when cholesterol was removed from de culture media.

### Selective & Inducible Proteolysis of the Apoptotic Substrate ICAD.

C. W. Morgan<sup>1</sup>, J. A. Wells<sup>1</sup>; <sup>1</sup>UCSF, San Francisco, CA

Programmed cell death or apoptosis is essential for maintaining tissue homeostasis and plays a crucial role in a variety of disease pathologies including cancer, viral infection, and neurodegeneration. Apoptosis results in the elimination of cells coordinated by a family of cysteine-aspartyl specific proteases called caspases. A subset of caspases, termed executioners, selectively cleaves death substrates that result in the profound morphological transformations characteristic of apoptotic cells. The list of known death substrates continues to grow, however the functional consequences ensuing from proteolysis of individual substrates remains an unanswered challenge. We propose a novel protein engineering and genetic strategy to investigate loss of protein function as a result of proteolytic processing. Our approach incorporates a novel lenti-viral vector to simultaneously knockdown the endogenous substrate and replace it with a Nla Tobacco Etch Virus (TEV) susceptible allele. Site-specific proteolysis is controlled temporally through the utilization of a small molecule activated split-TEV protease. We are validating the functionality of our system with a classic example of caspase-mediated loss of function, inhibitor of caspase activated DNase (ICAD). ICAD is a mandatory folding chaperone and inhibitor of caspase activated DNase (CAD). Upon liberation from ICAD, CAD dimerizes leading to CAD mediated DNA cleavage. We demonstrate our approach utilizing ICAD as a model substrate by presenting functional ICAD knockdown, single isoform replacement, and inducible site-specific proteolysis. We discuss results from on-going experiments that suggest new molecular requirements for CAD mediated DNA cleavage during apoptosis.

### CtIP is Required to Initiate Replication Dependent Interstrand Crosslink Repair.

M. L. Duquette<sup>1,2</sup>, Q. Zhu<sup>1</sup>, E. Taylor<sup>2</sup>, A. Tsay<sup>1</sup>, L. Shi<sup>1</sup>, C. McGowan<sup>2</sup>, M. Berns<sup>1</sup>; <sup>1</sup>University of California, San Diego, La Jolla, CA, <sup>2</sup>The Scripps Research Institute, La Jolla, CA

DNA interstrand crosslinks (ICLs) are toxic lesions that block the progression of replication and transcription. CtIP is a conserved DNA repair protein that facilitates DNA end resection in the Double Strand Break (DSB) repair pathway. Here we show that CtIP plays a critical role during initiation of ICL processing in replicating human cells that is distinct from its role in DSB repair. CtIP depletion sensitizes human cells to ICL inducing agents and significantly impairs the accumulation of DNA damage response proteins RPA, ATR, FANCD2,  $\gamma$ H2AX, and phosphorylated ATM at sites of laser generated ICLs. In contrast, the appearance of  $\gamma$ H2AX, and phosphorylated ATM at sites of laser generated double strand breaks (DSBs) are CtIP independent. We present a model in which CtIP functions early in ICL repair in a BRCA1 and FANCM dependent manner prior to generation of DSB repair intermediates.

**Interferon regulatory factor-1 (IRF-1) and regulated in development and DNA damage response 2 (REDD2): interaction, localization and effect on cell cycle and apoptosis.***M. Gupta<sup>1</sup>, P. C. Rath<sup>1</sup>; <sup>1</sup>School of Life Sciences, Jawaharlal Nehru University, New Delhi, India*

IRF-1 is the first member of the IRF-family of transcription factors, involved in type I and type II interferon (IFN)-mediated signaling, regulation of cell growth, development of immune cells, immune response, tumor suppression, apoptosis and autophagy in mammalian cells. IRF-1 is a modular protein with an intrinsic disordered domain and it interacts with many other proteins. We show that GST-IRF-1 pull-down assay from mouse bone marrow cells (BMCs) and MALDI-TOF/MS analysis identified regulated in development and DNA damage response 2/DNA-damage-inducible transcript 4-like (REDD2/DDIT4L) protein, a negative regulator of mTOR, as a novel IRF-1-interacting protein. Moreover, coimmunoprecipitation and confocal microscopy showed association of cellular IRF-1 and REDD2 in the cytoplasm of mouse bone marrow cells as speckles in a punctate distribution pattern indicating large protein complexes. In vitro interaction of the two recombinant proteins showed that IRF-1 physically interacts with REDD2. IRF-1 and REDD2 were overexpressed in the human embryonic kidney (HEK-293) cells up to 3.5x ( $p=0.023$ ) and 8.2x ( $p=0.005$ ) folds higher respectively. REDD2-overexpression induced endogenous IRF-1 up to 2.5x fold but IRF-1-overexpression reduced endogenous REDD2 up to 0.75x fold. Hence, IRF-1 and REDD2 influenced each-other's gene expression. Cell cycle analysis showed that overexpression of IRF-1 decreased 22% of the cells in G0/G1 phase and increased 23% of the cells in S phase whereas overexpression of REDD2 showed no apparent effect. Overexpression of IRF-1 and REDD2 showed a 2.2x and 1.5x fold increase in the endogenous NF- $\kappa$ B activity, which was reduced up to 1.2-1.7x fold when IRF-1 and REDD2 were coexpressed. In response to Lipopolysaccharides (LPS), IRF-1-overexpressed cells showed 8-13% reduction of cells in S phase and an increase of cells in G0/G1 phase by 10% whereas REDD2-overexpressed cells showed a 7% increase in cell death selectively only at low dose of LPS. However, LPS-treatment of IRF-1+REDD2 coexpressed cells increased the cells in G0/G1 phase by 8% and decreased the cells in S phase by 6-13% whereas at high dose of LPS, cell death was increased by 10%. In conclusion, IRF-1 interacts with REDD2 in BMCs, IRF-1 and REDD2 participate in cross-talk between the cytokine (interferon) pathway and the DNA damage response pathway for cellular regulations related to cell growth, proliferation and apoptosis.

**Differential regulation of poly(ADP-ribose) polymerases in cancer cells.***K. A. Krukenberg<sup>1</sup>, C. H. Benes<sup>2</sup>, J. Steen<sup>3</sup>, T. J. Mitchison<sup>1</sup>; <sup>1</sup>Harvard Medical School, Boston, MA, <sup>2</sup>Massachusetts General Hospital, Boston, MA, <sup>3</sup>Boston Children's Hospital, Boston, MA*

Poly(ADP-ribose) (PAR) is an important but poorly understood post-translational modification. Poly(ADP-ribose) polymerases (PARPs) catalyze the addition of ADP-ribose onto acceptor proteins using NAD<sup>+</sup> as a substrate. The function of PAR has been best studied in the context of the DNA damage response where PARPs are activated by DNA damage. Emerging evidence reveals broader roles for PAR in other essential cellular pathways including transcriptional control, apoptosis and inflammation. The role of PARPs in DNA damage has led to much interest in PARP inhibitors as chemotherapeutics, and multiple inhibitors are currently in clinical trials. The focus so far has been on using PARP inhibitors in combination with DNA damaging agents or in cancers deficient in DNA damage repair pathways (e.g. BRCA1/2 deficient cancers). Recent studies suggest that PARP inhibitors may also have utility in treating some cancers independent of DNA damage, e.g. Ewing's sarcoma. A weakness of previous work on PAR in cancer cells has been a lack of quantitative assays. PAR levels are typically inferred

from smears on western blots. We have developed an assay for quantifying PAR levels in cell lysates that has a large dynamic range and high selectivity. We have found that PAR levels vary widely between cancer cell lines, apparently independently of DNA damage responses. The differences in PAR levels appear to be largely attributable to differences in PARP1 activity. We are currently investigating mechanisms of PARP1 activation and the consequences for cell physiology and chemotherapeutic drug responses. Using proteomics we have identified several candidate regulators of downstream pathways, some of which are known oncogenes, that are selectively PARsylated in a cell line with high PARP1 activity. In a complementary approach we are investigating the relationship between PARP1 activity and drug sensitivity in several cell lines. Not only will this provide insight into the biological function of PAR, but PAR levels may also be useful as an indicator of which cancer cells respond best to PARP inhibitors or other treatments.

### **DNA Damage Sensitivity of Developing Oocytes Is Regulated by a p63 Autofeedback Regulatory Loop.**

*D-A. Kim<sup>1</sup>, E-K. Suh<sup>1</sup>; <sup>1</sup>Ewha womans univirsity, Seoul, Korea*

TAp63 $\alpha$  is an isoform of the p53 tumor suppressor gene and is highly expressed in the primordial follicle oocytes. Pre-dictyate stage oocytes generate hundreds of meiotic DNA double strand breaks for meiotic recombination. TAp63 $\alpha$  phosphorylation is essential for oocyte death after DNA damage. Ironically, however, many oocyte continue to live during meiosis I. The mechanistic details underlying the role of TAp63 $\alpha$  in DNA damage-induced cell death remain unclear. So, we focused on how TAp63 $\alpha$  regulates cell death in response to DNA damage.

p63 is low expressed in post-natal 0.5 (P0.5) oocytes which fail to undergo phosphorylation and cell death unlike P5.5 oocytes. ATM inhibitors block TAp63 $\alpha$  phosphorylation and abolishes cell death induced by DNA damage. Due to weak phosphorylation of TAp63 $\alpha$  in P0.5 oocyte we investigated whether protein phosphatase activity might downregulate TAp63 $\alpha$  phosphorylation. Calyculin A, which is a Ser/Thr phosphatase inhibitor, facilitated ATM-mediated TAp63 $\alpha$  phosphorylation in predictyate oocytes. We propose the balance between kinase and phosphatase activity determine oocyte sensitivity to DNA damage. DNA binding TAp63 $\alpha$  mutant fail to undergo phosphorylation. Furthermore, phosphorylation is linked to transcription involving an autofeedback regulatory loop. Also, we find that ATM plays a very important role in TAp63 $\alpha$  phosphorylation but is not the TAp63 $\alpha$  transcriptional target gene. Our results also suggest high expression of TAp63 $\alpha$  activates the autofeedback loop to augment TAp63 $\alpha$  phosphorylation and overcome phosphatase-mediated TAp63 $\alpha$  phosphorylation suppression.

Taken together, control of p63 level-dependent phosphorylation has the potential to be useful in cancer therapy as well as in radiation-induced infertility prevention in female cancer patients.

### **p53 regulates the Ets transcription factor MEF/Elf4 via MDM2.**

*M. Suico<sup>1</sup>, R. Miyakita<sup>1</sup>, K. Koyama<sup>1</sup>, M. Taura<sup>1</sup>, T. Shuto<sup>1</sup>, H. Kai<sup>1</sup>; <sup>1</sup>Department of Molecular Medicine, Kumamoto University, Kumamoto City, Japan*

Myeloid elf-1-like factor (MEF) or Elf4 is an ETS-related transcription factor that influences cell cycle progression. MEF is transcriptionally activated by E2F1, but is inhibited by p53 through E2F1-p53 protein interaction. While the transcriptional activation of MEF has been investigated in depth, its post-translational regulation is not well explored. By overexpressing MEF plasmid in human cell lines, here we show that MEF protein is suppressed by p53. MEF protein level was invariably higher in HCT116 p53 knockout (KO) cells and in p53 siRNA-transfected cells than in control cells. Consistently, p53 dose-dependently suppressed the transcription of MEF target

genes, lysozyme, perforin and interleukin-8. The stability of MEF was lower in HCT116 p53 WT than in KO cells, but MEF stability was enhanced by proteasome inhibitor MG132. By screening a number of E3 ligases regulated by p53, we found that MDM2 is involved in the effect of p53 on MEF. MDM2 interacts with MEF to influence its degradation. Together, these results indicate that p53 affects MEF protein level through MDM2. Our findings reveal another mechanism by which a cell proliferative factor, such as MEF, is modulated by p53.

849

**Bod1L regulates the dissociation of MDC1 from the site of double-strand DNA breaks.**

A. M. Davies<sup>1</sup>, I. M. Porter<sup>1</sup>, J. R. Swedlow<sup>1</sup>; <sup>1</sup>Wellcome Trust Centre for Gene Regulation and Expression, University of Dundee, Dundee, United Kingdom

Double-strand breaks (DSBs) are often considered to be the most detrimental and destructive type of DNA damage in cells. Unrepaired DSBs can lead to gene deletions or mutations often linked with cancer. Here we show that the novel protein Bod1L, from the same family as the PP2A-B56 inhibitor Bod1, acts to modulate the localisation of MDC1 at DSB repair foci. In HeLa cells depleted of Bod1L by siRNA, we observed progression through mitosis with fragmented and acentric chromatin, likely to have arisen from unrepaired DSBs. Induction of DSBs in Bod1L depleted cells with the topoisomerase inhibitor Etoposide, led to normal  $\gamma$ H2AX localisation at the DSB foci, yet caused a significant increase in the levels of MDC1 at these sites. Treatment of HeLa cells for 18 hours with Etoposide followed by removal, produced DSB sites that slowly lost MDC1 over an 8 hour period. In cells depleted of Bod1L however, MDC1 was never lost but continued to increase at these sites over this period. In contrast to this increasing MDC1, no observable change could be seen in the accumulation of  $\gamma$ H2AX when compared with control. As Bod1L is related to the PP2A-B56 inhibitor Bod1, we next determined if Bod1L works through a PP2A-dependent pathway. Co-depletion of both Bod1L and the B56 regulatory subunit of PP2A rescued MDC1 accumulation at DSB foci and allowed MDC1 to recover following withdrawal of Etoposide. These results suggest that Bod1L is acting as a novel PP2A-B56 modulator, the function of which is critical in controlling the dissociation of MDC1 from the DSB repair foci to ensure proper resolution of DNA damage.

**Regulation of Dvl and PP2A by the Retinoblastoma protein in the MC3T3 cell line.**

V. Vázquez-Rivera<sup>1</sup>, R. J. Noel<sup>1</sup>, P. G. Santiago-Cardona<sup>1</sup>; <sup>1</sup>Biochemistry, Ponce School of Medicine & Health Sciences, Ponce, Puerto Rico

Disruption of the retinoblastoma (Rb) pathway is observed in most human cancers. In addition to acting as a cell cycle repressor, Rb is a co-activator of differentiation-specific transcription factors such as Runx2, which is needed for osteoblast differentiation. As with the Rb pathway, the Wnt pathway also plays an important role in osteoblast differentiation. Given the observed inactivation of both pathways in some human cancers, we hypothesize that they are functionally linked. We propose that Rb inactivation results in de-regulation of the Wnt pathway. Using MC3T3 pRb+/+ and pRb-/- osteoblasts, we determined the expression levels of the Wnt pathway components PP2A and Dvl and performed a phosphatase assay to test PP2A activity to determine if these are affected by Rb. Experiments were performed in the presence and absence of the Wnt3a ligand. Also, histology analyses of normal bone and osteosarcomas were performed to determine if Rb regulates  $\beta$ -catenin's localization. qRT-PCR show a 0.4 fold-decrease in the Dvl and a 1.6 fold-increase in the PP2A mRNA expression levels in Rb+/+ relative to the Rb-/- cells ( $p \leq 0.05$ ). Addition of Wnt3a abolished the changes in the Dvl levels but

produced a 0.4 fold-decrease in PP2A expression in the Rb+/+ relative to Rb-/- cells ( $p \leq 0.05$ ). Immunoblots show no significant change in the protein levels of PP2A and Dvl when comparing Rb+/+ and Rb-/- cells, however, they revealed a significant increase in the phosphorylated-to-total Dvl ratio in the Rb+/+ cells. The phosphatase assay show a higher PP2A activity in Rb+/+ compared to Rb-/-cells ( $p \leq 0.05$ ), but this change was abrogated by Wnt3a addition. Our preliminary histology results show that the absence of a functional Rb does not affect  $\beta$ -catenin's localization. In summary, our results show that Rb can regulate the expression and activity of several Wnt related proteins, and the addition of the Wnt3a ligand can modify this regulation. PP2A inhibits Wnt pathway by promoting  $\beta$ -catenin degradation. Therefore, the increase of the PP2A phosphatase activity in the presence of Rb suggests that Rb may be promoting  $\beta$ -catenin degradation, which subsequently inhibits Wnt pathway. This research was supported by grants from the National Center for Research Resources (G12 RR003050), National Institute on Minority Health and Health Disparities (8G12MD007579-27), National Cancer Institute (U56CA118809) from the National Institutes of Health, and ACS Grant 93-032-13.

**E-cadherin is a molecular switch for Caveolin-1 function in melanoma cells that synergizes in tumor suppression and blocks Caveolin-1-enhanced metastasis.**

*L. Lobos-González<sup>1</sup>, L. Aguilar<sup>1</sup>, J. Diaz<sup>1</sup>, N. Diaz<sup>1</sup>, H. Urra<sup>1</sup>, A. Lladser<sup>2</sup>, K. Hoek<sup>3</sup>, L. Leyton<sup>1</sup>, A. Quest<sup>1</sup>; <sup>1</sup>Laboratorio de Comunicaciones Celulares, Centro de Estudios Moleculares de la Célula (CEMC), Santiago, Chile, <sup>2</sup>Laboratory of Gene Immunotherapy, Fundación Ciencia para la Vida, Santiago, Chile, <sup>3</sup>Department of Dermatology, University Hospital of Zuerich, Zuerich, Switzerland*

The role of caveolin-1 (CAV1) in cancer development and progression is highly controversial. For example, results from this laboratory have shown that CAV1 dependent suppression of genes favoring tumor development requires E-cadherin. Moreover, CAV1 promotes focal adhesion turnover and migration of metastatic cells. How these contrasting observations relate to CAV1 function in vivo is unclear. Here, murine melanoma B16F10 cells, with low endogenous CAV1 and E-cadherin levels, were employed to evaluate how introducing CAV1 affects tumor growth and metastasis in syngeneic C57BL/6 mice and how co expressing E cadherin modulates CAV1 function in vivo. Augmented CAV1 expression in B16F10(cav 1) cells reduced subcutaneous tumor formation, but, when injected intravenously, enhanced metastasis compared with plasmid transfected B16F10(mock) or wild type cells. E-cadherin expression in B16F10(E cad) cells reduced both subcutaneous tumor formation and metastasis to the lung. Importantly, for B16F10(cav 1/E cad) cells, expressing CAV1 together with E-cadherin, tumor formation and lung metastasis of B16F10 cells were completely abolished. Thus, CAV1 is shown for the first time in a pre-clinical model to function both as a tumor suppressor and promoter of metastasis. Moreover, E-cadherin synergizes with CAV1 in suppressing tumor formation and, importantly, blocks the ability of CAV1 to promote metastasis. These observations identify E-cadherin as a molecular "switch" that determines whether or not CAV1 can promote B16F10 metastasis. Consistent with these findings, expression profiling analysis of data available for a large number of melanoma lines suggests that elevated CAV1 and reduced E cadherin are associated with melanoma transition from a proliferative phenotype to an invasive one.

**B-type cyclins exert concurrent oncogenic properties through distinct aneuploidization mechanisms.**

*H-J. Nam<sup>1</sup>, J. Van Deursen<sup>1,2</sup>; <sup>1</sup>Department of Pediatrics and Adolescent Medicine, Mayo Clinic College of Medicine, Rochester, MN, <sup>2</sup>Department of Molecular Biology and Biochemistry, Mayo Clinic College of Medicine, Rochester, MN*

Cyclin B1 and B2 are part of a signature of overexpressed genes that predicts chromosomal instability and poor clinical outcome in multiple human cancers. However, whether and how these mitotic cyclins might drive aneuploidization and malignant cell transformation when overexpressed is unknown. To address these questions, we generated transgenic mice that overexpress cyclin B1 or B2. Here, we show that both of these transgenic strains exhibit high rates of aberrant chromosome segregation, with cyclin B1 overexpression inducing chromatin bridges and cyclin B2 overexpression inducing lagging chromosomes. At the molecular level, cyclin B1 overexpression precludes full activation of separase upon chromosome bi-orientation, resulting in anaphase onset prior to complete cleavage of cohesin molecules that hold sister chromatids together. In contrast, cyclin B2 overexpression perturbs spindle geometry rather than timely activation of separase. The observed spindle geometry defect is caused by precocious splitting of centrosomes in early mitosis, which we find is due to hyperactivation of Plk1 by Aurora A. Importantly, both cyclin B1 and B2 transgenic mice develop a broad spectrum of spontaneous tumors and form increased numbers of colon tumors on a APC<sup>Min</sup> genetic background. Consistent with the observation that lung tumors are highly prevalent in both transgenic strains, we find that cyclin B1 and B2 transcript levels are frequently elevated in human lung tumors. Together, these data reveal that cyclin B1 and B2 overexpression causes aneuploidization through entirely distinct mechanisms of chromosome missegregation and suggest that overexpression of B-type cyclins is causally implicated in the pathogenesis of human cancer.

853

**The involvement of MCT-1 oncoprotein in inducing mitotic catastrophe and nuclear abnormalities.**

*H-J. Shih<sup>1</sup>, H-L. Hsu<sup>1</sup>; <sup>1</sup>Institutes of Molecular and Genomic Medicine, National Health Research Institutes, Miaoli, Taiwan*

Centrosome amplification and chromosome abnormality are frequently identified in neoplasia and tumorigenesis. However, the mechanisms underlying these defects remain unclear. We here identify that MCT-1 is a centrosomal oncoprotein involved in mitosis. Knockdown of MCT-1 protein results in intercellular bridging, chromosome mis-congregation, cytokinesis delay, and mitotic death. Introduction of MCT-1 oncogene into the p53 deficient cells (MCT-1-p53), the mitotic checkpoint kinases and proteins are deregulated synergistically. These biochemical alterations are accompanied with increased frequencies of cytokinesis failure, multi-nucleation, and centrosome amplification in subsequent cell cycle. As a result, the incidences of polyploidy and aneuploidy are progressively induced by prolonged cell cultivation or further promoted by sustained spindle damage on MCT-1-p53 background. These data show that the oncoprotein perturbs centrosome structure and mitotic progression, which provide the molecular aspect of chromosomal abnormality in vitro and the information for understanding the stepwise progression of tumors under oncogenic stress.

854

**Association of Lin28 Expression and Tumorigenesis in Human Wilms' Tumor Cell Lines.**

S. Nguyen<sup>1,2</sup>, A. Urbach<sup>2</sup>, G. Q. Daley<sup>2</sup>; <sup>1</sup>Biochemistry, University of California, Riverside, Riverside, CA, <sup>2</sup>Howard Hughes Medical Institute, Children's Hospital of Boston, and Harvard Stem Cell Institute, Boston, MA

LIN28 is an evolutionarily conserved RNA binding protein that plays an essential role in regulating developmental timing in *Caenorhabditis elegans*. Recently, many reports have shown the effect of LIN28 in stem cell function, cell differentiation, cell proliferation and tumorigenesis. In mammals, LIN28 is highly expressed in embryonic stem cells and in early embryogenesis. One of the major targets of LIN28 is the Let7 microRNA family. By binding to the pri/pre Let-7 microRNA genes, LIN28 prevents the maturation of this miRNA family and thus enables the translation of genes that are suppressed by Let-7 miRNAs. Therefore, LIN28 is capable of regulating translation and stability of oncogenes including K-Ras, C-Mys and many others. In cancer cells, LIN28 is up-regulated as an oncogene, which promotes transformation and tumor progression. It has been shown by our lab that ~15% of human cancers are linked to the expression of LIN28A or its paralog LIN28B. In addition, some reports show that knocking-down LIN28A reduces cancer cell viability and cell growth *in vitro*. We have shown that LIN28B is expressed in samples of Wilms' tumor cells. In Wilms' tumor cell lines, *in vitro* LIN28B-knockdown significantly decreased cell proliferation compared with control cells. Taken together, LIN28B might function in controlling cell survival and differentiation in Wilms' tumor. To further study the role of LIN28 in Wilms' tumor formation, we will transplant "normal" and knockdown human Wilms' tumor cell lines under the kidney capsule of immunodeficient mice to compare each other. We will also over-express LIN28A/B during normal mouse kidney development.

855

**Investigating the contribution of centrosome amplification in tumorigenesis.**

B. D. Vitre<sup>1,2</sup>, A. J. Holland<sup>1,2</sup>, Y. Wang<sup>1,2</sup>, D. W. Cleveland<sup>1,2</sup>; <sup>1</sup>Ludwig Institute For Cancer Research, La Jolla, CA, <sup>2</sup>Department of Cellular and Molecular Medicine, University of California, San Diego, La Jolla, CA

As the major microtubule organizing centers, centrosomes play a central role in facilitating the formation of a bipolar mitotic spindle. Defects in centrosome duplication can induce an abnormal centrosome number and may lead to chromosome missegregation and subsequent aneuploidy. Although aneuploidy is an extremely common feature of tumor cells, its status as a cause or a consequence of cancer is highly controversial. In vertebrates and invertebrates, the conserved protein kinase Polo-like kinase 4 (Plk4) plays a key role in initiating centriole duplication and overexpression of Plk4 promotes the formation of extra centrosomes. Here we will describe the construction of two mouse models in which centrosome amplification can be induced through conditional overexpression of Plk4. We have made use of both a doxycycline-inducible promoter and the Cre-LoxP system to allow reversible and non-reversible expression of Plk4 in a tissue specific manner. These mice are used to study the contribution of centrosome amplification in tumorigenesis. Preliminary results suggest that centrosome amplification cannot be the sole driver mechanism leading to tumor development.

856

**Discovery of cancer drug targets using RNAi screening with pooled lentiviral shRNA libraries.**

*D. Tedesco<sup>1</sup>, K. Bonneau<sup>1</sup>, M. Makhanov<sup>1</sup>, G. Frangou<sup>2</sup>, A. Chenchik<sup>1</sup>; <sup>1</sup>Cellecta, Inc., Mountain View, CA, <sup>2</sup>Roswell Park Cancer Institute, Buffalo, NY*

This presentation will provide an overview of the recent innovations in the development of a lentiviral pooled format RNAi screening platform, in bioinformatics target prioritization, and in validation of potential drug targets in xenograft mouse models. We will present results of large-scale viability screens for cell-specific lethal and synthetic-lethal genes in a panel of blood, prostate, and breast cancer cell lines. Subsequent validation using single shRNA-expressing constructs showed that about 80% of the shRNAs identified in each complex library screen did in fact lead to cell death when transduced in cells. Analysis of the identified essential genes for known biological interactions revealed non-random clusters of interacting proteins that provide a useful strategy for prioritization of potential targets. Analysis of the lethal combinations indicates redundant, complementary, and compensatory responses in cancer cells. Genes modulating proliferation and survival in oncogenic cells have been further validated using *ex vivo* genetic screens with sub-pooled lentiviral shRNA libraries in xenograft mouse models. Also, we have recently developed combinatorial RNAi screening technology with bi-specific pooled shRNA libraries for the unbiased discovery and annotation of additive and synergistic synthetically lethal interactions. We will present results of combinatorial RNAi screening of DNA damage and repair genes in a breast cancer cell model.

**Tumor Invasion and Metastasis I**

857

**Macrophages induce invadopodium formation in tumor cells during intravasation.**

*M. Roh-Johnson<sup>1,2</sup>, J. Condeelis<sup>1,2</sup>; <sup>1</sup>Anatomy and Structural Biology, Albert Einstein College of Medicine, Bronx, NY, <sup>2</sup>Gruss Lipper Biophotonics Center, Bronx, NY*

Most cancer patients die as a result of metastasis. Spread of metastatic cancer cells by blood circulation is responsible for most distant metastases, thus it is important to understand the molecular mechanisms of transendothelial migration. The discovery that a tripartite structure composed of an invasive carcinoma cell, a macrophage and an endothelial cell, termed Tumor MicroEnvironment of Metastasis (TMEM), can be used as a predictor of distant metastasis in patients (Robinson et al., 2009) highlights the importance of the interaction of these three cell types during transendothelial migration. The mechanistic role of each cell type in transendothelial migration, however, is not well understood. Additionally, while much is known about the process of extravasation, far less is known about intravasation. Thus, we studied intravasation using a combination of fixed and live imaging, and found that human breast cancer cells undergo intercellular transendothelial migration *in vitro* and *in vivo*. As tumor cells penetrate through the endothelium, they form invadopodia, actin-rich structures that degrade basement membrane. Using pharmacological inhibitors, we found that tumor cell intravasation is dependent on signaling from macrophages. We further found that macrophages induce the formation of invadopodia in tumor cells. Taken together, our results suggest that signals from macrophages induce the formation of invadopodia in tumor cells to break through endothelial barriers during intravasation, and thereby demonstrates the significance of TMEM.

858

**Extracellular matrix guides tumor cell invadopodia formation by modulating  $\beta$ 1-integrin signaling.**

V. V. Artym<sup>1,2</sup>, R. J. Petrie<sup>1</sup>, K. M. Yamada<sup>1</sup>; <sup>1</sup>NIDCR/LCDB, NIH, Bethesda, MD, <sup>2</sup>Lombardi Cancer Center, Georgetown University, Washington, DC

Cancer cell invasion and metastasis to distant sites are hallmarks of cancer malignancy and the leading cause of cancer deaths. Invadopodia are specialized microscopic membrane protrusions of invading tumor cells that extend into the extracellular matrix (ECM) to mediate proteolytic digestion of, and invasion through, the ECM. We recently reported that structural cores of invadopodia rich in actin and cortactin are formed first, then the metalloprotease MT1-MMP accumulates and triggers ECM degradation; membranes at these invadopodia are highly dynamic compared to podosomes and focal adhesions. Our current research is focused on: (1) understanding the role of the ECM in induction of invadopodia, and (2) identifying the regulatory roles of integrins and downstream signaling pathways leading to invadopodia formation and function in proteolytic degradation of ECM.

We have developed novel, physiologically relevant fibrillar collagen matrices that are superior for inducing large numbers of invadopodia in several different types of invading tumor cells. We have discovered that integrin  $\alpha$ 2 $\beta$ 1 regulates invadopodia initiation by fibrillar collagen, and that  $\alpha$ 2 $\beta$ 1 signaling does not require co-stimulation from the epidermal growth factor receptor (EGFR) for assembly of numerous mature invadopodia. In contrast, conventional gelatin matrices mimic fibronectin matrices and induce only modest numbers of invadopodia in metastatic cancer cells. We have found that fibronectin matrices engage  $\alpha$ 5 $\beta$ 1 integrin to induce only preinvadopodia, and maturation of invadopodia on these substrates requires co-signaling from EGFR. Analyses of the localization of small GTPases to invadopodia and FRET studies using Rac1 biosensors allowed us to determine that activated Rac1 preferentially localizes to invadopodia induced by collagen matrix. Over-expression of a dominant-negative Rac1 mutant or siRNA-targeted depletion of Rac1 inhibited invadopodia formation in cells invading collagen. Thus, collagen- and fibronectin-rich ECMs regulate invadopodia formation via activation of different  $\beta$ 1-integrin heterodimers that elicit unique regulatory effects on activation of small GTPases and on the efficiency of invadopodia formation. Our findings also identify an important role for matrix itself in regulating tumor cell invadopodia.

859

**Comparison of cellular invasion through cross-linked and non-cross-linked fibrillar collagen.**

H. Liu<sup>1</sup>, R. Shea<sup>1</sup>, J. Ma<sup>1</sup>, L. C. Armstrong<sup>1</sup>; <sup>1</sup>Bioscience R&D, EMD Millipore, Temecula, CA

The process of cellular invasion through extracellular matrices is increasingly recognized to be heterogeneous with respect to variations in both the phenotypes of the invading cells and the properties of the extracellular matrix. One aspect of the extracellular matrix that influences invasion is the degree of cross-linking of collagenous matrices. We have compared invasion characteristics of tumor cells through gels composed of acid-extracted (cross-linked) and pepsin-extracted (non-cross-linked) type I collagens in a modified Boyden chamber assay. We find that, in general, tumor cells invade through gels consisting of non-cross-linked collagen at a higher rate than through gels composed of cross-linked collagen. A highly invasive cell type, MDA-MB-231, and a moderately invasive cell type, Hs578T, are capable of invading both forms of collagen, but the rate and magnitude of invasion is higher through non-cross-linked than cross-linked collagen. In addition, the use of non-cross-linked collagen allows lower quantities of invasive cells to be used than are required with cross-linked collagen. Finally, B16F1

melanoma cells were able to invade non-cross-linked collagen but were not observed to invade cross-linked collagen. Although non-cross-linked collagen has been reported to support amoeboid, protease-independent invasion and cross-linked collagen reported to require protease-dependent, mesenchymal invasion, we find that invasion through both cross-linked and non-cross-linked collagen is completely inhibited by a cocktail of protease inhibitors in the modified Boyden chamber assay format. We conclude that use of comparison of tumor cell invasion through cross-linked and non-cross-linked collagen provides extra insight into the invasive potential of the cells, and that the increased sensitivity of non-cross-linked collagen may be useful for characterizing less aggressively invasive cell types.

860

**Oncogenic K-Ras Promotes Basal Extrusion of Epithelial Cells.**

*G. Slattum<sup>1</sup>, Y. Gu<sup>1</sup>, J. Rosenblatt<sup>1</sup>; <sup>1</sup>Oncological Science, Huntsman Cancer Institute, Salt Lake City, UT*

Epithelia provide a protective barrier for the organs they encase, yet the cells compromising the epithelia are constantly turning over via cell death and cell division. To maintain a functional barrier, cells destined to die are squeezed out of the epithelium by a mechanism that we have termed "cell extrusion". In order to extrude, a cell produces sphingosine 1-phosphate (S1P), which binds to a G-protein coupled receptor (S1P2) in the neighboring cells to trigger contraction of an intercellular actomyosin band. This contraction squeezes the cell out of the epithelial sheet while closing any gaps that may have resulted from the cell's exit. Typically, live cells are extruded and later die by anoikis, a type of cell death caused by the loss of survival signals from cell matrix detachment. Since oncogenic K-Ras cells upregulate survival signals and override anoikis, we tested if extruded oncogenic K-Ras cells survive following extrusion. Surprisingly, we found that oncogenic K-Ras cells not only survive and proliferate after extrusion, but also extrude basally into the tissue the epithelium encases, rather than apically out of the tissue (the normal direction). Moreover, K-Ras cell basal extrusion is cell-autonomous. We found that high levels of autophagy in extruding oncogenic K-Ras cells disrupt the normal S1P production and signaling required for apical extrusion. S1P normally forms puncta at the interface between an apically extruding cell and its neighboring cells and is also required only for apical but not basal extrusion. In extruding oncogenic K-Ras cells, however, S1P is greatly decreased despite the fact that its precursor, sphingosine kinase, is upregulated. We found that markers of autophagy, typically upregulated in oncogenic K-Ras cells, are even more pronounced in extruding K-Ras cells. Blocking autophagy rescues S1P localization and apical extrusion. Thus, we propose that elevated autophagy in oncogenic extruding K-Ras cells induces increased survival and basal extrusion. K-Ras transformation, therefore, could promote basal extrusion and enable cells with higher survival and proliferation potential to exit the epithelia and initiate invasion.

**Versican V2 enhances angiogenesis by regulating endothelial cell activities and fibronectin expression.**

*W. Yang<sup>1</sup>, A. Yee<sup>1</sup>; <sup>1</sup>Sunnybrook Research Institute, Toronto, ON, Canada*

Versican is a proteoglycan expressed in the extracellular matrix, where it regulates a variety of cell activities and affects tumor development. With alternative splicing, there are four versican isoforms, denoted V0, V1, V2 and V3. The V2 isoform is highly expressed in the mature brain but its function in the mature brain has not yet been elucidated. Since brain tumors are among the most angiogenic of human tumors, we investigated whether or not the V2 isoform plays a

role in angiogenesis and found that astrocytoma cell line U87 stably transfected with V2 formed tumors containing extensive vasculature. Although the V2-expressing cells grew slowly, they survived well in serum-free medium. They also displayed high adhesive ability to endothelial cells and facilitated tube-like structure formation. Importantly, fibronectin was up-regulated by V2 and mediated V2 function. To understand the role of endogenous versican function, we expressed the versican 3'UTR fragment in the cancer cells. We hypothesized that expression of versican 3'UTR could promote the function of existing mRNAs by regulating endogenous miRNA activity. Human breast cancer cells, which express high levels of versican V2 mRNA, when stably transfected with the 3'UTR expression construct, were found to increase expression of versican V2 protein. The cell also displayed decreased proliferation but increased survival and tube-like structure formation. Tumors formed by these cells showed decreased rate of growth but increased rate of angiogenesis. We investigated whether or not expression of versican 3'UTR could regulate endogenous microRNA function and found that versican 3'UTR could bind miRNAs miR-133a, miR-199a\*, and miR-431, which also interacted with fibronectin. As a consequence, expression of versican and fibronectin was up-regulated by ectopic transfection of versican 3'UTR. Transfection with siRNAs against versican 3'UTR abolished the 3'UTR's effects on regulation of the expression of versican and fibronectin and tumor growth and angiogenesis. Taken together, our results demonstrated that versican can regulate fibronectin expression by the V2 isoform and by expression of the 3'UTR. Our studies suggest that versican V2 and fibronectin could be potential targets for intervention of brain tumor angiogenesis.

**Caveolin-1 expression alters MT1-MMP and cell behavior in human melanoma lines.**

*M. S. McGrew<sup>1</sup>, R. W. Baer<sup>1</sup>; <sup>1</sup>Physiology, A. T. Still University, Kirksville, MO*

Caveolin-1 is known for its role in cell signaling and trafficking. A recent study suggests that upregulation of caveolin-1 greatly attenuates melanoma metastasis and could be a potential therapeutic target. The mechanism by which caveolin-1 might attenuate metastasis remains unclear and may involve multiple signaling pathways. The metalloproteinase MT1-MMP associates with caveolin-1 in lipid rafts of endothelial cells, and this association could also occur in melanoma and be involved in the anti-metastatic effect of caveolin-1 expression in melanoma. The aim of our study was to examine the consequences of caveolin-1 upregulation in human melanoma cell lines, 1205Lu and BLM, and its possible interaction with MT1-MMP. 1205 and BLM wild-type cells were transfected with a GFP tagged caveolin-1 plasmid allowing examination of caveolin-1 location within the cell. Colocalization of MT1-MMP and caveolin-1 along the plasma membrane was observed in the caveolin-1 expressing cells through the use of immunofluorescent staining. An increase in pro-MMP2 activity, an inactive precursor form of MT1-MMP, was observed in caveolin-1 expressers versus wild-type cells when performing gelatin zymography. An increase in net proliferation of caveolin-1 expresser lines versus wild-type lines was demonstrated by MTT assay. A decrease in migration rate measured by wound healing assay was observed in both caveolin-1 expresser lines as compared to wild type lines, and as compared to wild type lines treated with the metalloproteinase stimulant concanavalin-A. Our collective data suggests that induced caveolin-1 expression in 1205Lu and BLM lines attenuates MT1-MMP activation versus the corresponding wild-type lines while simultaneously slowing migration. The attenuation of these metastatic behaviors may come at the expense of greater melanoma proliferation rates. Given that rates of metastasis are directly related to mortality in melanoma patients, caveolin-1 upregulation remains a reasonable target for further studies directed at increasing patient survival rates in melanoma victims and may exert its action in part by attenuating MT1-MMP activation.

863

**Cav1 suppresses tumor growth and metastasis in a murine model of cutaneous SCC.**

*C. Trimmer<sup>1</sup>, F. Capozza<sup>1</sup>; <sup>1</sup>Stem Cell Biology & Regenerative Medicine, Thomas Jefferson University, Philadelphia, PA*

Caveolin-1 (Cav1) is the main structural protein of specialized lipid rafts called caveolae, and it functions as a scaffolding protein that is able to bind and negatively regulate a multitude of signaling molecules. Because many of those molecules are involved in cellular proliferation and survival, the loss or misregulation of Cav1 has been linked to transformation and tumorigenesis in several cancer types, including breast cancer and melanoma. However, Cav1's role in the development of cutaneous squamous cell carcinoma (cSCC) remains largely unknown. The objective of this study was to clarify the function of Cav1 in cSCC development.

To this end, we stably transduced a murine keratinocyte cell line, PAM212, to over-express or down-regulate Cav1, and assessed the function of this protein in skin tumor biology. We first show that Cav1 over-expression decreases cell proliferation and tumor incidence and growth. In contrast, Cav1 knock-down dramatically increases primary tumor growth. Additionally, Cav1 knock-down increases both invasive ability and the incidence of spontaneous lymph node metastasis. We attribute this phenotype to increased Erk1/2 MAPK/AP-1 pathway activation, as inhibition of MAPK pathways rescues the invasive advantage conferred by Cav1 knock-down. We note that the expression of the AP-1 transcriptional targets K18 and cyclin D1 are inversely correlated to the expression of Cav1 in PAM212. In conclusion, we demonstrate that Cav1 may be an important modulator of both primary tumor development and metastatic dissemination in cSCC. These studies provide further evidence that Cav1 acts as a putative tumor suppressor in the skin

**Regulation of breast tumor dormancy by the perivascular niche.**

*C. M. Ghajar<sup>1</sup>, H. Peinado<sup>2</sup>, H. Mori<sup>1</sup>, I. R. Matei<sup>2</sup>, H. Brazier<sup>2</sup>, E. I. Chen<sup>3</sup>, D. C. Lyden<sup>2</sup>, M. J. Bissell<sup>1</sup>; <sup>1</sup>Lawrence Berkeley National Laboratory, Berkeley, CA, <sup>2</sup>Weill Cornell Medical College, New York, NY, <sup>3</sup>Stony Brook University, Stony Brook, NY*

It is now well-established that breast cancer cells (BCCs) disseminate early during metastatic progression. However, distant metastases may not emerge until years or decades after treatment. Whether growth of disseminated tumor cells (DTCs) is regulated by the microenvironment of distant organs, and how, are fundamental questions of tumor biology. To address these problems, we adopted a multi-disciplinary approach incorporating murine models of human breast cancer dissemination and novel engineered tumor microenvironments. Two different in vivo assays revealed that dormant (i.e., Ki67-negative) breast DTCs reside upon the microvasculature of lung, bone marrow, and brain. To show whether this association was coincidental or if it reflected functional interactions, we created organotypic models of lung and bone marrow microvascular niches in which sparsely seeded BCCs could be tracked long-term. Using 3 different BCC lines, we confirmed that lung and BoMa stroma each promote rampant outgrowth of sparsely seeded BCCs. As suggested also by our in vivo data, endothelial cells (ECs) restrained this outgrowth (~5-fold) and induced quiescence of up to 90% of resultant tumor clusters. Importantly, these tumor cells remained quiescent long-term-- i.e., they were dormant. Conditioned media experiments suggested that the putative endothelial-derived ('angiocrine') mediators of tumor dormancy were not soluble; therefore, we performed comparative tandem mass spectrometry on decellularized extracellular matrix from microvascular niche cultures and their stromal counterparts. This approach revealed a number of potential angiocrine regulators of DTC dormancy. Gain- and loss-of-function studies were

conducted to validate one such mediator. Importantly our experiments also revealed that suppressive cues were downregulated at the neovascular tips of microvasculature. Time-lapse analysis revealed that neovascular sub-niches actually accelerate BCC growth. We confirmed this surprising result using different approaches to enrich and deplete these sub-niches, and performed further LC-MS/MS analysis to identify neovascular mediators of this tumor-promoting behavior. The localization of a subset of these factors to the neovascular sub-niche was confirmed via immunofluorescence, and gain-of-function studies demonstrated that these factors permit BCCs to overcome the suppressive effects of the stable microvasculature. This study defines distinct endothelial sub-niches that regulate dormancy or expansion of disseminated breast tumor cells depending on the nature of the local microenvironments. The identification of inhibitory- and growth-promoting- factors derived from each of these sub-niches may yield supplementation therapies that enforce dormancy of DTCs and provide novel molecules to target in order to prevent disruption of tumor dormancy.

**Laminin-derived peptide C16 induces invasion and invadopodia activity in oral squamous cell carcinoma and fibrosarcoma cells.**

A. S. Siqueira<sup>1</sup>, M. P. Pinto<sup>1</sup>, M. C. Cruz<sup>1,2</sup>, V. M. Freitas<sup>1</sup>, R. G. Jaeger<sup>1</sup>; <sup>1</sup>Cell and Developmental Biology, Institute of Biomedical Sciences, Sao Paulo, Brazil, <sup>2</sup>ICB Core Facility for Research Support - Institute of Biomedical Sciences, Sao Paulo, Brazil

Our Laboratory has been studying the effects of laminin-derived peptides in tumor biology. Here we addressed whether the peptide C16 (Kafdiyvrkfk, gamma 1 chain) would stimulate invasion activity in cell lines derived from oral squamous cell carcinoma (CAL27) and fibrosarcoma (HT1080), two malignant tumors with different origins and poor prognosis. C16 increased invasion rate in both cell lines compared to scrambled control peptide (C16SX), as shown by invasion assays in Boyden chambers coated by Matrigel. Tumor cells that actively invade surrounding tissues depend on invadopodia to degrade extracellular matrix barriers. Invadopodia are actin-rich membrane protrusions associated with pericellular proteolysis. Therefore, we analyzed the role of C16 on invadopodia activity of CAL27 and HT1080 cells, through a fluorescent substrate degradation assay. Measurements of digestion spots (black areas in fluorescent background) showed that C16 significantly increased invadopodia activity of both neoplastic cell lines. This peptide also increased expression of phospho-cortactin and MT1-MMP in CAL27 and HT1080 cells. These proteins are regarded as important invadopodia markers. Using time-lapse 4D fluorescence microscopy, we explored invadopodia dynamics in C16-treated cells. CAL27 and HT1080 cells were transfected with GFP-cortactin, followed by growth on fluorescent gelatin. Time-lapse videos showed that C16 increased invadopodia activity of both cell lines over time. Furthermore, we analyzed signaling pathways related to C16 effects in CAL27 and HT1080 cells. Immunoblots showed that C16 increased activation of ERK 1/2 and Rac1 pathways in CAL27 and HT1080 cells. Moreover, inhibition of ERK 1/2 signaling pathway by MEK inhibitor U0126 decreased invasion rate and invadopodia activity in both cell lines. We propose that C16 stimulates invasion and invadopodia activity in cells derived from oral squamous cell carcinoma and fibrosarcoma, probably through ERK1/2 and Rac1 signaling pathways. Support: FAPESP (2008/57103-8; 2009/17336-6) and CNPq (304986/2009-7).

**Characterization of Two Subtypes of the SW-13 Human Adenocarcinoma Cell Line.**

*J. J. Daggett<sup>1</sup>, A. S. Pascual<sup>1</sup>, K. E. Cooper<sup>1</sup>, K. J. Leyva<sup>2</sup>, E. E. Hull<sup>1</sup>; <sup>1</sup>Biomedical Sciences Program, Midwestern University, Glendale, AZ, <sup>2</sup>Microbiology & Immunology, Arizona College of Osteopathic Medicine, Glendale, AZ*

The human adenocarcinoma cell line SW13 has been reported to switch between two subtypes, one expressing vimentin (SW13+) and the other not (SW13-) and that this switch is at the post-transcriptional level. Given the importance of epithelial to mesenchymal transition (EMT) in metastasis and the fact that vimentin expression induced during as cells adopt the mesenchymal or metastatic form, we have investigated the properties of the two SW13 subtypes further. We have found that the vimentin expressing SW13+ appear to divide more slowly but have the more spindly morphology characteristic of mesenchymal cells while the vimentin negative SW13- cells appear to divide more quickly and are more rounded. More interesting is that mixed cultures appear to maintain different characteristics than homogeneous cultures of either subtype, suggestive of communication during culture between the two subtypes. As increased cell motility is a characteristic of mesenchymal cells, we tested the ability of each subtype to chemotax in response to serum in a transwell migration assay after serum starvation. Preliminary results suggest that vimentin positive SW13+ subtype may have greater motility than SW13- in our transwell chemotaxis assay. We are also very interested in investigating the unknown factors that might trigger the switch between SW13+ and SW13- subtypes. As Rho and Rac GTPases are associated with regulating the mechanisms of migration involved in metastasis, we investigated the ability of inhibitors and activators of both Rho and Rac to facilitate the switch between SW13+ and SW13- subtypes. Preliminary results suggest that alterations in the activity of these GTPases changes in the percentage of SW13+ cells in co-cultures. These results suggest that the subtype switch may be related to the ability of these cancer cells to metastasize and that the ability of SW13 cells to switch between subtypes may be controlled by altering GTPase activity.

**Role of the endocytic adaptor Epsin in cancer cell migration.**

*K. Madhivanan<sup>1</sup>, R. Aguilar<sup>1</sup>; <sup>1</sup>Biological Sciences, Purdue University, West Lafayette, IN*

One of the most common links between cancer and endocytosis is defective internalization of Receptor Tyrosine Kinases, for example, linked to a deficit in endocytic proteins. This scenario leads to hypersignaling and in turn to malignant transformation. Nevertheless, there are also cases in which endocytic proteins, such as the epsin adaptors, are found upregulated in invasive cancers. Indeed, we demonstrated that overexpression of the epsins enhances cancer cell migration and invasion. Furthermore, depletion of epsins (by siRNA) led to impairment of cancer cell invasion. However, the different epsin paralogs varied in their capacity to enhance migration/invasion in the following order: epsin 3 > epsin2 >> epsin1. The epsin paralogs have a highly conserved Epsin N-terminal Homology or the ENTH domain (N-terminus) and a C-terminus where the most divergent regions are housed. While our data shows that both the ENTH domain and the C-terminus are required for enhancing migration, we speculate that the differential ability of the paralogs to migrate/invade lies in their less conserved C-terminus region.

This study aims to uncover the mechanism by which epsin overexpression leads to enhanced migration/invasion and to identify the regions of the epsin C-terminus which gives the paralogs their differential ability to enhance migration/invasion. Here we describe a systematic combinatorial approach for mapping the epsin determinants involved in localizing epsin at

endocytic sites and required for its effect on cancer cell migration/invasion. Our data clearly shows that Clathrin binding motifs (out of the 4 types of endocytic determinants) are the strongest localization determinants of epsin2, however are not sufficient. In fact, 2 types of endocytic determinants are required for proper epsin2 localization suggesting co-operativity and redundancy. We also found that mutation of any 2 types of endocytic determinants can also reduce the ability of epsin2 to enhance migration as compared to the wild-type protein. Expanding the results obtained from epsin2 to epsin3 will reveal the similarities and differences between the paralogs. Taking together our findings and the requirement of these proteins for cancer cell invasion, we envision epsin2 and epsin3 as targets for novel anti-cancer and anti-metastatic approaches.

### **Galectin-3 Plays a Role in Murine NK cell-mediated INF- $\gamma$ Production.**

*E-H. Kim<sup>1</sup>, B-R. Choi<sup>1</sup>, J. Lee<sup>1</sup>, H-J. Woo<sup>1</sup>; <sup>1</sup>Seoul National University, Seoul, Korea*

Natural killer (NK) cells serve as a crucial first line of defense against tumors and a diverse range of pathogens in the innate immunity. Highly related to receptors recognizing tumor cells, the activation receptors trigger cytotoxicity and cytokine production. IFN- $\gamma$ , secreted by NK cells, plays a critical role in suppressing pathogen challenge, both to contain the initial infection, and to promote an appropriate adaptive response. Galectin-3, a member of  $\beta$ -galactoside-binding animal lectin, acts as immune modulators implicated in a variety of biological functions such as inflammation, tumor metastasis, and cell apoptosis. However, the role of immune regulation of galectin-3 on NK cells is not known. In our study, galectin-3 induced IFN- $\gamma$  production in murine NK cells in a dose-dependent manner. IFN- $\gamma$  production of NK cells by galectin-3 was inhibited by either anti-galectin-3 antibody or NF- $\kappa$ B inhibitor, but not lactose. These indicated that active site of galectin-3 in IFN- $\gamma$  generation was in N-terminal but not in lectin domain that has many other physiological function of the molecule. IFN- $\gamma$  production by galectin-3 was dependent on the activation, translocation and the transcriptional control of NF- $\kappa$ B. Galectin-3 induced IFN- $\gamma$  production was enhanced through signaling pathway of phosphorylated Erk1/2. Erk1/2 phosphorylation was synergistically increased in galectin-3 treated NK cells and MEK1/2 inhibitor abrogated the phosphorylation of Erk1/2 by galectin-3. Our results provided new insights into mechanism of NK cell activation and, also, a novel function of galectin-3 in immune reaction.

### **Docetaxel and Metformin act synergistically to inhibit growth of prostate cancer cell lines.**

*B. K. Carney<sup>1</sup>, L. Cassimeris<sup>1</sup>; <sup>1</sup>Biological Sciences, Lehigh University, Bethlehem, PA*

Treatments for prostate cancer, one of the most prevalent cancers among men, are an area of ongoing investigation. While docetaxel, a microtubule-stabilizing drug, is effective against many forms of prostate cancer this drug, while the best available treatment to date, shows little improvement in the duration of patient survival (only a few months) in castration resistant prostate cancers. It has been previously shown that increasing microtubule stability (by multiple mechanisms, including paclitaxel treatment, a natural analog of docetaxel) can lead to a cell cycle delay/mitotic arrest and an increase in cell death. Inhibiting intracellular metabolism has also been proposed as a treatment for multiple cancer types because many cancers favor

glycolysis for most of their ATP production (Warburg effect). It has been shown previously that most glycolytic enzymes are localized to the microtubule cytoskeleton; therefore we hypothesize that disturbing the microtubule network should further interfere with ATP production via glycolysis and limit growth of cancer cells. Normal cells, however, should be resistant to these treatments due to their reliance on oxidative phosphorylation. Here we test the hypothesis that there is a synergy between the microtubule stabilizing drug, docetaxel, and drugs that can block intracellular metabolism, such as metformin (a drug that inhibits metabolism at multiple points). Cell proliferation was measured for each drug alone and in combination using a colorimetric assay (MTT). While both drugs individually significantly inhibited cell proliferation, initial results show a super-additive (synergistic) effect between docetaxel and metformin in multiple prostate cancer cell lines including LNCaP (androgen dependent) and PC-3 (androgen independent) cell lines. This synergy both decreases the concentration of each drug needed to inhibit cell proliferation (therefore decreasing possible toxicity) while also increasing the potency of the combination. Based on our results the data suggests a potential new drug combination to treat castration resistant prostate cancers.

### **Sensitivity of Human Acute Myeloid Leukemia Cells to a Recombinant Human Arginase I (Co)-PEG5000 [HuArgI (Co)-PEG5000].**

*R. Tanios<sup>1</sup>, A. Bekdash<sup>1</sup>, E. Kassab<sup>1</sup>, G. Georgiou<sup>2</sup>, A. E. Franke<sup>3</sup>, R. J. Abi-Habib<sup>1</sup>;*

*<sup>1</sup>Department of Biology, Lebanese American University, Beirut, Lebanon, <sup>2</sup>Department of Chemical Engineering, University of Texas, Austin, TX, <sup>3</sup>Cancer Research Institute, Scott&White Hospital, Temple, TX*

Though combination induction and consolidation chemotherapy induce complete remission in a high proportion of patients with Acute Myeloid Leukemia (AML), most eventually relapse. Hence, alternative approaches with potent, more selective mechanisms for targeting AML are needed. In this study, we attempt to target the potential Arginine auxotrophy of AML cells using a pegylated recombinant human Arginase I cobalt [HuArgI (Co)-PEG5000].

Potency and selectivity of HuArgI (Co)-PEG5000 were tested on a panel of 10 human AML cell lines and on normal human monocytes using a proliferation inhibition assay. Cell cycle analysis was carried out by propidium iodide (PI)-staining and type of cell death was determined by AnnexinV/PI staining and caspase staining using flow cytometry.

Nine AML cell lines were sensitive to HuArgI (Co)-PEG5000 at 48-hour incubation ( $IC_{50}$  = 14-550 pM, Percent cell death > 80%) with only one cell line deemed not sensitive to arginine depletion ( $IC_{50}$  > 10,000 pM). Human monocytes were not sensitive to HuArgI (Co)-PEG5000 ( $IC_{50}$  > 10,000 pM). Incubation times of 48 and 72 hours had similar potency but were 7-fold more potent than 24-hour incubation. Addition of L-citrulline (40 mM) did not salvage AML cells from arginine depletion-induced cytotoxicity, thus demonstrating the complete arginine auxotrophy of these cells. There was no impact of treatment on cell cycle with both the G0/G1 and G2/M peaks decreasing significantly with increased concentrations of HuArgI (Co)-PEG5000, along with a significant increase in the pre-G0/G1 peak (up to 90% of total events). AnnexinV/PI staining showed a dose-dependent increase in cells stained with both annexinV and PI (4.5% and 55% in non-treated vs treated cells) with no increase in cells staining with annexinV alone. In addition, caspase staining revealed the lack of caspase activation following incubation with HuArgI (Co)-PEG5000 demonstrating that arginine depletion, through HuArgI (Co)-PEG5000, induces caspase-independent, non-apoptotic cell death in AML cells.

These findings indicate that AML cell lines are auxotrophic for arginine and demonstrate the selective cytotoxicity of HuArgI (Co)-PEG5000-induced arginine depletion to these cells. Hence,

HuArgI (Co)-PEG5000 is a potent and selective molecule which constitutes a potential targeted therapeutic for AML.

871

**Cayaponia tayuya and Dihydrocucurbitacin B are Potent Inducers of Apoptosis in Immune Cells.**

*K. McCormick<sup>1</sup>, T. Laakko Train<sup>1</sup>; <sup>1</sup>Biology, Elon University, Elon, NC*

A malfunctioning immune system contributes to a number of autoimmune disorders and dysregulated immune cell growth can result in leukemia. Treatments for autoimmune disorders and leukemia often include agents which suppress the immune system by reducing populations of immune cells. Current immunosuppressive treatments can, sometimes, have limited effectiveness or serious side-effects, thus causing the need for new options. *Cayaponia tayuya* (tayuya) is a plant found in South America and has been shown to possess anti-inflammatory properties. Understanding the underlying mechanism of this effect could result in additional therapies for immune disorders. These anti-inflammatory properties may be a result of chemical compounds known as cucurbitacins found in the tayuya plant. This study aims to investigate the reported anti-inflammatory activity of tayuya by determining the effects of tayuya and cucurbitacin on immune cell function and survival. To determine whether tayuya modulated T cell growth and/or survival, Jurkat T cells, a human leukemic cell line, were incubated with or without various concentrations of tayuya extract over time. Culturing cells with 25  $\mu$ l/ml of a 40 mg/ml tayuya extract for 24 hours resulted in a 43% decrease in viable cell numbers as compared to controls. In addition, culturing cells with 2.5  $\mu$ M dihydrocucurbitacin B resulted in an 83% reduction. Western blot analysis for proteins involved in eliciting apoptosis confirmed that both tayuya and dihydrocucurbitacin B reduce Jurkat cell concentrations by inducing apoptotic cell death. Treated cells showed a dramatic increase in cleaved caspases 7, 9 and PARP. Similar results were observed with the THP-1 monocytic leukemia cell line. These studies show that tayuya significantly reduced immune cell viability and survival by inducing apoptosis. Additionally, dihydrocucurbitacin B demonstrated similar effects when added alone, supporting the suggestion that it is the main active immunosuppressive component in tayuya. These results indicate that tayuya and dihydrocucurbitacin B warrant further investigation as possible therapies in immune cell disorders.

872

**A Plant Lectin can Target Podoplanin to Inhibit Melanoma Cell Growth and Migration.**
