Skin cancer is extremely common, with melanoma accounting for about 80% of skin cancer deaths in many countries. Melanoma cell motility contributes to metastatic invasion that is responsible for the vast majority of skin cancer deaths. Extracellular receptors modified by  $\alpha$ 2,3-sialic acids that promote this motility can serve as ideal chemotherapeutic targets. For example, the extracellular domain of the mucin receptor podoplanin (PDPN) is highly O-glycosylated with  $\alpha$ 2,3-sialic acid linked to galactose. PDPN is activated by endogenous ligands to induce tumor cell motility and metastasis. Some lectins that target proteins containing  $\alpha$ 2,3-sialic acid can inhibit tumor cell growth. However, anti-cancer lectins that have been examined thus far target

receptors that have not been identified. We report here that *Maackia amurensis* seed lectin (MASL), which binds O-linked carbohydrate chains containing sialic acid, targets PDPN to inhibit transformed cell growth and motility at nanomolar concentrations. Interestingly, the biological activity of this lectin survives gastrointestinal proteolysis and enters the cardiovascular system to inhibit melanoma cell growth, migration, and tumorigenesis. These studies demonstrate how lectins may be used to help develop oral drugs that target specific receptors to combat malignant cell growth.

**Inhibition of Phosphatidic Acid Phosphohydrolase activity induces EGFR, EGFvIII and ErbB2 endocytosis and decreases their mitogenic potential.**

C. Metz<sup>1</sup>, R. Shaughnessy<sup>1</sup>, M. Apud<sup>1</sup>, J. Jung<sup>1</sup>, C. Otero<sup>1</sup>, A. Soza<sup>1</sup>, A. González<sup>1</sup>;

<sup>1</sup>*Inmunología Clínica y Reumatología, Facultad de Medicina, Centro de Envejecimiento y Regeneración, Facultad de Ciencias Biológicas, Pontificia Universidad Católica de Chile, Santiago, Chile*

A signaling pathway involving phospholipase D (PLD)-generated phosphatidic acid (PA), activation of type 4 phosphodiesterases (PDE4) and subsequent decrease of protein kinase A (PKA) activity (PA/PKA pathway), leads to removal of empty/inactive EGFR from the cell surface by endocytosis and accumulation in recycling endosomes, in a reversible manner (Norambuena et. al Mol Biol Cell-2010). This pathway might provide several potential targets for counteracting the oncogenic action of EGFR and other ErbB receptors in tumoral cells. Signaling PA levels mainly depend on rates of generation by PLD and hydrolysis by phosphatidic acid phosphohydrolase (PAP) activity. The relative contribution of plasma membrane-residing lipid phosphatidate phosphatases (LPPs) or cytosolic lipins to PA degradation, the PKA downstream elements and the consequence of the PA/PKA signaling to oncogenesis remain undefined. The PA/PKA pathway can be easily activated by PAP inhibitors, such as propranolol, resulting in transient elevations of PA levels. Here we show that cells transfected to overexpress LPP-1 or LPP-3 display increased levels of EGFR at the cell surface without changes in total receptor expression levels. LPPs seem to be crucial regulators of the PA/PKA signaling pathway that modulate the relative distribution of EGFR between the cell surface and intracellular compartments. Inhibition of the three MAPKs (ERK, p38, JNK) completely abrogates the internalization of EGFR induced by propranolol. These MAPKs seem to act downstream of PKA. EGFRvIII variant and ErbB2 are also internalized by the effect of propranolol. Strikingly, cell proliferation that depends on overexpression of EGFR, EGFRvIII or ErbB2 is highly sensitive to PAP inhibitors. Therefore, decreased accessibility of EGFR to ligand stimuli, as well as exaggerated tyrosine kinase signaling from intracellular compartments, might be particularly deleterious for cells "addicted" to ErbB mitogenic signals emerging from the plasma membrane. PAP inhibition might be a potential target to counteract malignancy of oncogenic ErbB tyrosine kinase receptors.

**High-Content Screening of Crude Extracts Identifies Inhibitors of Triple-Negative Breast Cancer Subtypes.**

A. J. Robles<sup>1</sup>, J. King<sup>2</sup>, R. H. Cichewicz<sup>2</sup>, S. L. Mooberry<sup>1,3,4</sup>; <sup>1</sup>*Department of Pharmacology, University of Texas Health Science Center at San Antonio, San Antonio, TX,* <sup>2</sup>*Natural Products Discovery Group, Department of Chemistry and Biochemistry, University of Oklahoma, Norman, OK,* <sup>3</sup>*Department of Medicine, University of Texas Health Science Center at San Antonio, San*

Antonio, TX, <sup>4</sup>Cancer Therapy and Research Center, University of Texas Health Science Center at San Antonio, San Antonio, TX

Triple-negative breast cancers (TNBC) remain difficult to treat with current chemotherapy regimens, with no currently approved targeted therapies for metastatic disease. The lack of development of targeted therapies for TNBC is partly due to the lack of clearly identified pharmacological targets. Recent subtyping of TNBC patients and identification of driver pathways has made it possible to begin searching for targeted therapies with efficacy for treating particular TNBC subtypes. New therapeutic strategies targeting these various molecular phenotypes of breast cancer are needed to more effectively treat this heterogeneous disease. Libraries of crude extracts from understudied Texas plants and fungal cultures were screened for cytotoxic and antiproliferative activity against a panel of cell lines representative several breast cancer subtypes; including estrogen receptor positive, HER2-positive and 5 triple-negative subtypes with a fluorescence-based assay using the Operetta High-Content Imaging system and Columbus Image Data Storage and Analysis software. These extracts provide novel sources for drug discovery and a majority of their biological sources have never been studied for potential anticancer effects. In total, 920 different fungal extracts and 764 extracts from 367 different species of Texas plants were screened against 9 breast cancer cell lines. We identified 21 extracts with selective activity against one TNBC cell line. 4 extracts were selective for the MDA-MB-468 cell line, 4 extracts were selective for the MDA-MB-231 cell line, and 13 extracts were selective for the MDA-MB-453 cell line. Additionally, 6 extracts showed selectivity for the HER2+ cell line, SK-BR-3. Many of these extracts demonstrated a dose-dependent ability to selectively inhibit cells possessing each of these phenotypes. Future bioassay-guided fractionation will identify the biologically active compounds from these crude extracts. Our results demonstrate the potential to identify specific inhibitors of molecularly distinct breast cancer subtypes from nature.

Wang<sup>1</sup>, J. Canales<sup>1</sup>, S. Lagor<sup>1</sup>, E. Seto<sup>2</sup>, J. Weber<sup>3</sup>, E. Sotomayor<sup>4</sup>, A. Villagra<sup>1</sup>; <sup>1</sup>Immunology, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL, <sup>2</sup>Molecular Oncology, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL, <sup>3</sup>Cutaneous Oncology, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL, <sup>4</sup>Immunology and Malignant Hematology, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL

An understanding of the cellular and molecular processes involved in the progression of melanoma is crucial for the development of more efficacious treatments and improved diagnostics. Acetylation and deacetylation of proteins plays a crucial role in the control of important cellular pathways, such as transcriptional control, proliferation, apoptosis, immunogenicity, etc. Specifically, histone deacetylases (HDACs) have garnered significant interest due to the availability of drugs that selectively inhibits these protein modifications and therefore, control these cellular functions.

In our studies we investigated the effect of HDAC6 selective inhibitor(s) (HDAC6i) in human melanoma cell lines (WM164, WM983A and SKMEL21) over the proliferation and cell cycle profile. In all melanomas analyzed pharmacological inhibition of HDAC6 resulted in a delayed growth characterized by a G1 cell cycle arrest. In addition to the pharmacological inhibition of HDAC6, we explored the effect of knocking-down HDAC6 (HDAC6KD) by the generation of monoclonal melanoma cell lines lacking HDAC6 using specific shRNA. As expected, the proliferation of HDAC6KD melanoma cells was diminished when compared to wild-type and

non-target shRNA control cells. Likewise, we observed a similar G1 arrest in the cell cycle that was observed with the use of HDAC6 specific inhibitors.

Our data has also implicated HDAC6 in the regulation of the STAT1 and STAT3 pathways in melanoma cells. These findings were demonstrated by the stimulation of HDAC6KD melanoma cells with cytokines, such as IL-6, IFN[gamma] or TNF[alpha], we found significant changes in the expression of genes involved in cell cycle control and immune regulation, specifically target genes of STAT3 and STAT1 measure by qRT-PCR. We also observed changes in the phosphorylation of STAT3 and STAT1 proteins in cells lacking HDAC6 and/or treated with HDAC6i by immunoblot. To further validate our findings, we evaluated, by ELISA the effect of HDAC6KD over the production of selected cytokines in melanoma cells. These studies provide critical insights into the molecular pathways and/or partners that are involved in the regulatory role of HDAC6 in cell proliferation survival and immunogenicity of human melanoma cells. Collectively, our data has identified HDAC6 as an attractive therapeutic target in melanoma due to its ability to delay tumor growth and target the STAT1/STAT3 pathways, known to be altered in several melanoma malignancies, providing rationale for the development and use of selective HDAC6i.

The role of histone deacetylases (HDACs) in cell biology, initially limited to their effects upon histones, now encompasses more complex regulatory functions that are dependent on their tissue expression, cellular compartment distribution, pathophysiological conditions and stage of cellular differentiation. Although major advances have been made in understanding the role of specific HDACs in cell proliferation and the survival of cancer cells, their individual participation in specific intracellular pathways is not completely understood. Here we present evidence for the participation of HDAC6 in the control of the proliferation of leukemic cells through the regulation of the Jak/STAT3 pathway.

We initially evaluated the pharmacological effects of both pan-HDAC inhibitors (LBH589) and selective HDAC6 inhibitors (i.e. Tubastatin A), on several leukemic cell lines of myeloid lineage (MO7e, THP-1, K562, HEL, UKE-1, SET2 and TF-1). On this first approach we observed a pronounced inhibition in proliferation of all cell lines when treated with pan-HDACi. However, when these cells were treated with selective HDAC6 inhibitors, only the cell lines MO7e, THP-1, K562 and TF-1 had decreased proliferation, whereas the leukemic cell lines that have an activating mutation in the pseudokinase domain of Jak2 (Jak2V617F), including HEL, UKE-1 and SET2, did not. MO7e, a cytokine dependent cell line, displayed the highest degree of sensitivity to HDAC6 inhibition. These results were mirrored in the HDAC6 shRNA knockdown (HDAC6KD) cell lines. Additionally, cell lines that demonstrated a slower rate of proliferation had a diminished expression of STAT3 target genes by qRT-PCR and a decrease in the amount of phosphorylated STAT3 in both the wild type cell lines treated with HDACi and in the HDAC6KD cell lines where the Jak2 mutations were absent.

In summary, these results demonstrate a decrease in the proliferation of leukemic cells using selective HDAC6i that is comparable to the results obtained from pan-HDACi. However, when the leukemic cell lines contain a Jak2 mutation, both the pharmacological intervention and

the shRNA knockdown of HDAC6 had little to no effect on the proliferation of the cells. Furthermore, cell lines that are particularly dependent on the activation of the Jak/STAT pathway had increased sensitivity to both the inhibition of HDAC6 pharmacologically and by knocking down HDAC6, as was the case in particular with the cell line MO7e. Our findings have demonstrated that HDAC6 may play a role in the regulation of the Jak/STAT pathway.

#### **Direct inhibition of the Glut1 hexose transporter by resveratrol.**

M. R. Salas<sup>1</sup>, L. Ojeda<sup>1</sup>, P. Obando<sup>1</sup>, P. Ojeda<sup>1</sup>, A. Perez<sup>1</sup>, D. Parada<sup>1</sup>, E. Vega<sup>1</sup>, B. Castillo<sup>1</sup>, A. Zambrano<sup>1</sup>, C. I. Rivas<sup>2</sup>, J. Vera<sup>3</sup>, A. M. Reyes<sup>1</sup>; <sup>1</sup>Institute of Biochemistry and Microbiology, Universidad Austral de Chile, Valdivia, Chile, <sup>2</sup>Pathophysiology, Universidad de Concepcion, Concepcion, Chile, <sup>3</sup>Pathophysiology, Universidad de Concepcion, concepcion, Chile

Interest in the biological actions of resveratrol (3,5,4'-trihydroxystilbene) arises from its identification as a chemo preventive agent for cancer, its cardio protective effects, and as a potential anti-obesity and anti-diabetic compound, since it seems to mimic the effects of energy restriction, thus leading to reduced body fat and improved glucose homeostasis. The exact mechanisms involved in improving hyperglycemic state are not known, but most of glucose uptake into mammalian cells is facilitated by the GLUT hexose transporters. Resveratrol is structurally similar to isoflavones such as genistein, which has been reported to inhibit the glucose uptake facilitated by the GLUT1 hexose transporter.

In the present study we examined the direct effects of resveratrol on glucose uptake in human red cells and in HL-60 and U937 leukemic cell lines, which express mainly GLUT1, and investigated the mechanism involved. We show here that resveratrol inhibits glucose exit in human red cells, and the displacement of previously bound cytochalasin B revealed the direct interaction of resveratrol with GLUT1. Resveratrol behaves as a competitive blocker of glucose uptake under zero-trans exit and exchange kinetic assays, but it becomes a mixed noncompetitive blocker when zero-trans entry transport was assayed, suggesting that the binding site for resveratrol lies on the endofacial face of the transporter. The effect of resveratrol over hexose transport was also tested in human HL-60 and U937 cells under conditions that discriminate transport from the intracellular substrate phosphorylation/ accumulation. Resveratrol also blocks GLUT1-mediated hexose uptake and independently affects cellular substrate accumulation on these cells.

We propose that resveratrol interacts directly with the human GLUT1 hexose transporter by binding to an endofacial site and that this interaction overrides the transport of hexoses across the plasma membrane.

#### **Analysis of drug resistance in HER-2 positive breast cancer.**

N. Lerma<sup>1</sup>, P. Valenzuela<sup>1</sup>, K. Parra<sup>1</sup>, C. L. Becerril<sup>1</sup>, I. Miramontes<sup>1</sup>, E. Ramirez<sup>1</sup>, C. Rodriguez<sup>1</sup>, G. Francia<sup>1</sup>; <sup>1</sup>Biological Sciences, University of Texas at El Paso, El Paso, TX

Breast cancer is a deadly disease, and approximately one in four women with breast cancer show overexpression of the HER-2 protein in their tumors. There are a number of effective treatments for women with HER-2 positive breast cancer, including the combination of chemotherapy with HER-2 targeting drugs such as lapatinib, trastuzumab or the recently approved pertuzumab. However, in a number of cases, tumors that initially respond to therapy eventually develop drug resistance, leading to the relapse of the disease. By studying the genes of different drug resistant variants, we have observed two mechanisms by which drug resistance

may develop. Thus, some HER-2 human breast cancer cells (e.g., 231-H2N) treated with the clinically used trastuzumab agent, can escape therapy by shedding, or losing, the target HER-2 gene. We can better understand the biology of drug resistant cancers and devise new therapies to treat cancers that no longer respond to currently available treatments by analyzing the RNA in drug sensitive and drug resistant cell lines. This way, we can identify genes whose copy number or expression level correlates with drug resistance. Previous data shows that tumors relapsing to anti-HER-2 regimens overexpressed a gene termed VEGF. Anti-VEGF treatment was then shown to delay the growth of such drug resistant tumors.

**USP7 and Daxx regulate mitosis progression and taxane sensitivity by affecting stability of Aurora A kinase.**

*S. Giovanazzi<sup>1</sup>, V. M. Morozov<sup>1</sup>, M. K. Summers<sup>2</sup>, W. C. Reinhold<sup>3</sup>, A. M. Ishov<sup>1</sup>; <sup>1</sup>Department of Anatomy and Cell Biology, University of Florida, Gainesville, FL, <sup>2</sup>Department of Cancer Biology, Lerner Research Institute, Cleveland, OH, <sup>3</sup>Genomics and Bioinformatics Group, Laboratory of Molecular Pharmacology, National Cancer Institute, NIH, Bethesda, MD*

A large number of patients are resistant to taxane-based chemotherapy. Functional mitotic checkpoints are essential for taxane sensitivity. Thus, mitotic regulators are potential markers for therapy response and could be targeted for anticancer therapy. In this study we identified a novel function of Ubiquitin Specific processing Protease-7 (USP7) that interacts and cooperates with protein Daxx in regulation of mitosis and taxane resistance. Depletion of USP7 impairs mitotic progression, stabilizes cyclin B and reduces stability of the mitotic E3 ubiquitin ligase, Checkpoint with Forkhead and RING finger (CHFR). Consequently, cells with depleted of USP7 accumulate Aurora A kinase, a CHFR substrate, thus elevating multipolar mitoses. We further show that these effects are independent from the USP7 substrate p53. Thus, USP7 and Daxx are necessary to regulate proper execution of mitosis, partially via regulation of CHFR and Aurora A kinase stability.

Results from colony formation assay, in silico analysis across the NCI60 platform and in breast cancer patients suggest that USP7 levels inversely correlate with response to taxanes, pointing at the USP7 protein as a potential predictive factor for taxane response in cancer patients. In addition, we demonstrated that inhibition of Aurora A attenuates USP7-mediated taxane resistance, suggesting that combinatorial drug regimens of Taxol and Aurora A inhibitors may improve the outcome of chemotherapy response in cancer patients resistant to taxane treatment. Finally our study offers novel insights on USP7 inhibition as cancer therapy.

880

**Sub-lethal High Intensity Focused Ultrasound Exposure Results in Altered Mechanosensitive Gene Expression in Mammary Epithelial Cells.**

*L. H. Malkhassian<sup>1</sup>, M. Al Qurain<sup>2</sup>, H. Zahr<sup>1</sup>, G. Oweis<sup>2</sup>, D. E. Jaalouk<sup>1</sup>; <sup>1</sup>Biology, American University of Beirut, Beirut, Lebanon, <sup>2</sup>Mechanical Engineering, American University of Beirut, Beirut, Lebanon*

High Intensity Focused Ultrasound (HIFU) is a non-invasive therapeutic modality that allows the ablation of unwanted tissues inside the body. In recent years, HIFU gained much attention for its potential applications in the treatment of multiple disorders including breast cancer. At the focal spot, intensified energy results in immediate cell death due to instantaneous temperature rise and/or cavitation effects in the target tissue. The surrounding tissue, though routinely receives residual energy, is believed to be left undamaged. Considering that HIFU exposure results in pressure/tension waves which can potentially cause cellular deformations in exposed tissue due

to altered mechanotransduction, and that a number of mechanosensitive genes have been shown to be implicated in tumorigenesis, we hypothesize that sub-lethal HIFU treatment would result in mechanotransduction alterations that may induce tumorigenesis of mammary epithelial cells. The objective of this study is to investigate the *in vitro* effects of residual HIFU exposure on cellular viability, proliferation, and mechanosensitive gene expression in mammary epithelial cells. An experimental setup was custom-designed and manufactured to permit utilization of a 2.158 MHz HIFU transducer for *in vitro* exposure of MCF-10A immortalized human mammary epithelial cells and MDA-MB-231 invasive human breast cancer cells. Cellular viability and proliferation were assessed days 1-to-4 post HIFU treatment using: i) trypan blue vital stain exclusion assay, ii) WST-1 assay, and iii) standard phase-contrast microscopy. Our results show significant decrease in cellular viability and proliferation of MCF-10A and MDA-MB-231 cells exposed at the focal spot in comparison to mock controls ( $P < 0.01$  for both). Post exposure to 2.5% and 22% residual ultrasound intensity, we find no significant difference in cellular viability and proliferation in comparison to the mock controls in both cell lines. Real-Time PCR quantification of *CAV-1 $\alpha$*  (encodes for caveolin-1  $\alpha$ ) and *PXN* (encodes for paxillin) gene expression in MCF-10A cells shows 1.65- and 2.39- fold increase in *CAV-1  $\alpha$* ; 1.54- and 2.40- fold increase in *PXN*, when assessed at 1 hour following 2.5% and 22% HIFU application respectively (mean fold change,  $P < 0.01$ ). Our findings indicate that while a single exposure to residual HIFU has no significant effect on cellular viability and proliferation in MCF-10A and MDA-MB-231 cells, it does result in a significant immediate-early increase in the transcriptional levels of two mechanosensitive genes known to be implicated in mammary tumorigenesis. Future directions will address the bio-functional relevance of these modulations by evaluating their effects on cell motility, migration, invasiveness, and cytotoxic response to anti-neoplastic agents, hence providing insights into the potential role of sub-lethal HIFU exposure in breast cancer pathogenesis.

#### **Cytotoxic Effects of Novel Compounds on Human Breast Cancer Cells.**

*E. Robles-Escajeda*<sup>1</sup>, *Y. Santiago-Vazquez*<sup>1</sup>, *N. Ortega*<sup>1</sup>, *C. Lema*<sup>1</sup>, *A. Varela-Ramirez*<sup>1</sup>, *J. R. Dimmock*<sup>2</sup>, *R. J. Aguilera*<sup>1</sup>; <sup>1</sup>Department of Biological Sciences, The University of Texas at El Paso, El Paso, TX, <sup>2</sup>College of Pharmacy and Nutrition, The University of Saskatchewan, Saskatoon, SK, Canada

A deeper understanding of the biochemistry of cancer has resulted in the generation of a large number of novel compounds that could be used as anticancer agents that may improve anticancer therapy. The main goal of this project was to determine if a novel set of compounds had selective cytotoxicity on a panel of human breast cancer cell lines, but with lower toxicity on non-cancer cells. Novel compounds were characterized for their cytotoxicity on a panel of cancer and non-cancer cells, measured by the Differential Nuclear Staining (DNS) assay validated for screening by our group. This assay was used to determine the percentage of cytotoxicity after compound treatment. The DNS assay utilizes hoechst to label all the cell nuclei and propidium iodide to stain dead cell nuclei. Selected compounds were tested in secondary assays for the mechanism of cell death (apoptosis/necrosis). Our results confirmed that novel compounds have significant anticancer activity and they induce cell death via apoptosis. One of the most significant findings of our drug screens was the finding that one breast cancer cell line derived from an African American (AA) woman was more sensitive to the treatments than controls and other breast cancer cell lines. Further studies are underway to determine if other AA-derived breast cancer lines are also sensitive to the same compounds. In addition, the specific pathway(s) that induce cell death will be characterized. The present results could provide valuable information for future research applicable in the anti-cancer chemotherapy

arena. Research supported by NIGMS-RISE Grant 2R25GM069621-09 and NIH-RCMI-NIMHD-BBRC Grant G12MD007592.

### **Hormonal Regulation of HB-EGF and SMAD4 in an Endometrial Cancer Cell Line, RL95-2 Cells.**

D. Macaulay<sup>1</sup>, E. Williams<sup>1</sup>, C. Woodard<sup>1</sup>, D. Peterson<sup>1</sup>, C. Johnson<sup>1</sup>, D. Johnson<sup>1</sup>, S. Walls<sup>1</sup>;  
<sup>1</sup>Biology, Prairie View A&M University, Prairie View, TX

Endometrial cancer has been linked to deregulation of cell signaling pathways, especially apoptotic pathways. Identifying molecular biomarkers and their role in affecting the proliferation of endometrial cancer cells will be paramount in ensuring early prognosis and overall survival of patients. Unregulated secretion of HB-EGF exerts acute effects on endometrial cells resulting in proliferation and progression of endometrial cancer. SMAD4 on the other hand is one of the molecules involved in TGF signaling pathway and it has been implicated in playing a role in the development of several carcinomas. Ovarian steroid hormones, Progesterone (P4) and estrogen (E2), affect normal endometrial functions as well as their associated abnormalities. The aim of this project is to evaluate the role of P4 and E2 on the expression and secretion of HB-EGF and SMAD4 in an endometrial cancer cell line, RL95-2 cells. We hypothesized that P4 and E2, would down-regulate the expression of HB-EGF and SMAD4 in RL95-2 cells, in vitro. To test this hypothesis, RL95-2 cells were cultured and treated for four days as follows: (a)  $10^{-8}$ M E2, (b)  $10^{-6}$ M P4, (c)  $10^{-8}$ M E2 +  $10^{-6}$ M P4 (d)  $10^{-8}$ M E2 in two days followed by  $10^{-6}$ M P4 for another two days. Immunocytochemistry (ICC) and western blot analysis revealed E2 treated cells followed by P4 treatment resulted in reduced expression and secretion levels of HB-EGF whereas SMAD4 expression levels increased in E2-treated cells, but decreased in P4-treated cells. Our results indicate that ovarian steroid hormones may modulate the expression of HB-EGF and SMAD4, and may impede the progression of endometrial cancer.

883

### **Chitosan and Docosahexanoic Acid Exert Synergistic Effects on NF- $\kappa$ B Expression in an Ovarian Cancer Cell Line, SKOV-3**

E. L. Williams<sup>1</sup>, C. Woodard<sup>1</sup>, P. Otenyo<sup>1</sup>, D. MaCaulay<sup>1</sup>, D. Peterson<sup>1</sup>, J. Stone<sup>2</sup>, L. Carson<sup>2</sup>, G. Regisford<sup>1</sup>; <sup>1</sup>Biology, Prairie View A&M University, Prairie View, TX, <sup>2</sup>Cooperative Agricultural Research Center, Prairie View A&M University, Prairie View, TX

The current treatments for the deadliest gynecological disease, ovarian cancer, have a significantly high level of reoccurrence. Hence, it is imperative that alternative treatments, and more specifically a natural therapeutic product be adopted. Recent studies have shown that natural products, such as chitosan and docosahexanoic acid (DHA), an omega-3 fatty acid, inhibit the proliferation of cancer cells. Nuclear factor kappa B (NF- $\kappa$ B) is a latent gene regulatory protein transcription factor that lies at the heart of most inflammatory responses. It has been shown to be upregulated in ovarian cancer patients. Therefore, the objective of this study was to determine the effect of chitosan and DHA on NF- $\kappa$ B expression levels in an ovarian cancer cell line, SKOV-3 cells. We hypothesized that chitosan and DHA will decrease NF- $\kappa$ B expression in a dose-dependent manner. To test our hypothesis, SKOV-3 cells were treated with (a) 0 ng/mL, (b) 1% Acetic acid; (c) 250 ng/mL of chitosan, (d) 100  $\mu$ M of DHA, (e) 250 ng/mL of chitosan + 100  $\mu$ M of DHA for 48 hours. Western Blot analysis and immunocytochemistry were performed to observe the expression and localization of NF- $\kappa$ B, while an ELISA was used to determine NF- $\kappa$ B DNA binding activity. Quantitative RT-PCR was also performed to determine NF- $\kappa$ B mRNA expression in the treated cells. Nuclear factor kappa

B protein was localized within the nucleus of SKOV-3 cells and its DNA binding activity decreased when treated with chitosan and DHA individually. Furthermore in cells treated with both chitosan and DHA, there was an even greater decrease in NF- $\kappa$ B expression. The synergistic effects of chitosan and DHA suggest that these natural products may serve as potential natural treatment for ovarian cancer.

884

#### **Expression of Kallikrein 6 in a Chitosan-Treated Ovarian Cancer Cell Line, SKOV-3**

*C. Woodard<sup>1</sup>, E. Williams<sup>1</sup>, P. Otenyo<sup>1</sup>, D. Peterson<sup>1</sup>, G. Regisford<sup>1</sup>; <sup>1</sup>Biology, Prairie View A&M University, Prairie view, TX*

Epithelial ovarian cancer is the deadliest gynecological malignancy and despite current treatments, such as chemotherapy and radiotherapy, reoccurrence of this deadly malignancy is high. Early detection of ovarian cancer is imperative, and furthermore, novel treatments with fewer adverse effects than current treatments of chemotherapy and radiation, are currently being investigated. Kallikreins (KLK) are serine proteases that may play a role in ovarian carcinogenesis. The expression of one member of this family, KLK 6, has been reported to significantly increase in ovarian carcinogenesis. Chitosan, a natural polysaccharide that is biodegradable and biocompatible, may serve as a potential alternative treatment for ovarian cancer, and may function by regulating the expression of KLK 6. Therefore, the objective of this study was to determine the effects of chitosan on the expression and localization of KLK 6 in SKOV-3 cells. It was hypothesized that the expression of KLK 6 protein will be down-regulated in a dose-dependent manner. To test this hypothesis, SKOV-3 cells were treated with 0, 1% Acetic Acid, 50, 100, 250, 500, and 1000ng/mL of chitosan for 48 hours. Cells were also harvested, total protein extracted and the expression of KLK 6 was determined by Western blot analysis. Protein localization and expression of KLK 6 were also determined by immunocytochemistry. Western blotting and immunochemical studies revealed that chitosan treatment resulted in a decreased expression of KLK 6 protein in the cytoplasm of SKOV-3 cells, in a dose-dependent manner. These data indicate that chitosan may inhibit SKOV-3 cell proliferation by decreasing KLK 6 expression.

Human hepatocellular carcinoma (HCC) is the fifth most prevalent solid tumor in the world and the fourth main inducer of cancer-related death. In 2007, sorafenib (NexavarR), a multiple kinase inhibitor, has shown survival benefits in patients with advanced HCC and become the first clinically approved drug for HCC. Unfortunately, the response rate of sorafenib is not satisfied in clinical. Recently, we have reported that sorafenib sensitized hepatocellular carcinoma (HCC) cells to TRAIL via Src homology-2 containing protein tyrosine phosphatase-1 (SHP-1) dependent inhibition of signaling transducer and activator of transcription 3 (STAT3) (Clinical Cancer Res, 2010). In addition, we identified the effect of sorafenib on STAT3 was

independent to kinases and discovered a series of sorafenib derivatives as SHP-1 enhancers (J Hepatol, 2011; Euro J Med Chem, 2011). Here, we report the role of SHP-1 in sorafenib's determinant for anti-HCC effect. We found that sorafenib increases SHP-1 activity in vitro and in vivo, indicating that sorafenib affects phosphatase activity directly. Based on a series of deletion mutants of SHP-1, we observed that N-terminal SH2 domains (N1) strongly involved in sorafenib-induced STAT3 inhibition and apoptotic effect. Moreover, D61, a critical residue in N1 responsible to form inhibitory salt bridge with catalytic domain, also abrogates the biological effect of sorafenib. In co-IP experiments, sorafenib impairs the interaction between N1 and PTP directly. Furthermore, the role of elevated SHP-1 served as tumor suppressor of HCC was confirmed in cells expressed constitutively activate mutant (dN1 and D61A). Together, we propose a conformational change model for sorafenib-induced SHP-1 activity. Sorafenib potentially opened the inhibited structure of SHP-1 through impairing the linkage between N-SH2 and PTP domains to increase phosphatase activity and further inhibit p-STAT3-related proliferative pathway.

**a5e induces apoptosis via activation of both extrinsic and intrinsic pathways and inhibition of pi3k/akt survival signaling pathways in lung cancer cells.**

Y. Bak<sup>1</sup>, S. Ham<sup>1</sup>, O. Baatarsog<sup>2</sup>, K. Cho<sup>2</sup>, S. Jung<sup>3</sup>, T. Han<sup>4</sup>, I-Y. Han<sup>5</sup>, D. Yoon<sup>1</sup>; <sup>1</sup>Department of Bioscience and Biotechnology, Konkuk University, Seoul, Korea, <sup>2</sup>Graduate School of Bio&Information Technology, Hankyong National University, Ansong, Korea, <sup>3</sup>School of Oriental Medicine, Dongguk University, Gyeongju, Korea, <sup>4</sup>BanryongInsu Herb Clinic, Seoul, Korea, <sup>5</sup>Sunwun Biophysic, Ansong, Korea

it has been reported about the preventive and therapeutic effects of asian traditional medical plants extracts on the cancers, metabolic diseases, inflammatory diseases, and any other intractable diseases. in these studies, it has been assessed the molecular mechanism of the anticancer effect of korean medicinal plants extracts a5e. we examined the cytotoxic and apoptotic pathway for the cancer chemopreventive activity of a5e in non-small-cell lung cancer (nscic) cell lines nci-h460 and nci-h1299. a5e inhibited more efficiently proliferation of nci-h460 than nci-h1299 (p53 -/-) cells. a5e induced apoptosis via sub-g1 cell-cycle arrest in nci-h460 and cells. apoptosis was detected by nuclear condensation, annexin v-fitc/pi staining, cell cycle analysis, western blot, rt-pcr and mitochondria membrane potential analysis. a5e induced cell morphological changes and nuclear condensation at 24h in dose dependent manner. a5e also perturbed cell cycle progression at sub-g1 and altered cell cycle regulatory factors. furthermore, a5e activated apoptotic intrinsic and extrinsic pathways. each expression levels of the extrinsic death receptor complex fasl, fas, and fadd were increased by a5e. also, a5e treatment cleaved caspase-8, caspase-9, caspase-3, parp and downregulated bcl-2 and bcl-xl expression. a5e induced mitochondrial membrane potential collapse and cytochrome c release. otherwise, a5e diminished levels of cell survival factors, pi3k, akt and p-akt dose dependently. taken all these results, our results suggest that the a5e induces apoptosis via activation of both extrinsic and intrinsic pathways and inhibition of pi3k/akt survival signaling pathways in nci-h460. in conclusion, these data demonstrate that a5e can be used as a novel chemotherapeutic agent in nscic.

**Regulation of CoCl<sub>2</sub>-induced HIF1 $\alpha$  expression by a natural compound**

Y. Asami<sup>1</sup>, K. Lee<sup>2</sup>, J. Jang<sup>1</sup>, N. Soung<sup>1</sup>, I. Ryu<sup>1</sup>, H. Lee<sup>3</sup>, D. Yoon<sup>4</sup>, J. Ahn<sup>1</sup>, B. Kim<sup>1</sup>; <sup>1</sup>KRIBB, Ochang, Korea, <sup>2</sup>Dong-Guk University, Seoul, Korea, <sup>3</sup>KRIBB, Daejeon, Korea, <sup>4</sup>Kon Kook University, Seoul, Korea

Hypoxia induces HIF1 $\alpha$  expression, leading to the malignant cell transformation. In screening of inhibitors against HIF1 $\alpha$  expression using a reporter gene assay system, MO was found to strongly reduce the level of HIF1 in HeLa cells treated with a hypoxia-mimetic, CoCl<sub>2</sub>. Identification of binding proteins using agarose-bead conjugated MO (AC-685) combined with subsequent MS data revealed several proteins affected by MO. AC-685 colocalized with a nuclear protein (Np-K) in the nucleus of CoCl<sub>2</sub> treated HeLa cells. Amongst several cytoplasmic or nuclear proteins, Np-K was only found to be responsible for CoCl<sub>2</sub>-induced Hif-1 $\alpha$  expression as supported by Np-K siRNA. In this study, detailed regulatory mechanism of HIF1 $\alpha$  expression by MO in association with some nuclear and cytoplasmic proteins will be presented, which might be a clue to treat cancer. This is the first report showing the interaction of Np-K and Hif-1 $\alpha$ .

**Inhibition of Ovarian Cancer Cell Proliferation by Oleoyl Ethanolamide and Its Metabolically Stable Analog AM3102.**

E. Kisgeropoulos<sup>1</sup>, P. Michel<sup>2</sup>, C. Kramer<sup>2</sup>, P. Bagavandoss<sup>2</sup>; <sup>1</sup>Program in Biotechnology, Kent State University @ Stark, North Canton, OH, <sup>2</sup>Biological Sciences, Kent State University @ Stark, North Canton, OH

The acylethanolamide oleoylethanolamide (OEA), a well-known appetite suppressant (Nature 414:209, 2001; 425:90, 2003) also induces apoptosis of human neuroepithelioma (BBRC 255:456,1999), glioma (Cell Death Differ 11:853, 2004), and prostate (Int J Urol 13:148, 2006) cancer cells. Although OEA has also been found in the human ovary (Chem Phys Lipids 121:211, 2002), its effect on ovarian cells has not been studied. In the present study, we have investigated the role of OEA and its metabolically stable analog AM3102 (N-[(1R)-2-hydroxy-1-methylethyl-9Z-octadecenamide) on human ovarian cancer cell line OV2008. In serum-free medium, both OEA and AM3102 inhibited the proliferation of subconfluent OV2008 cells. Numerous apoptotic cells were observed floating in the culture medium in the presence of these acylethanolamides. In the presence of charcoal stripped serum, the inhibitory effect of OEA and AM3102 on the cells was markedly reduced. However, inclusion of 20  $\mu$ M of palmitoyl trifluoromethyl ketone (PTK), an inhibitor of phospholipase A<sub>2</sub>, to the culture medium enhanced the toxicity of the cells to both OEA and AM3102. No toxicity was observed in the presence of an inactive analog of PTK (PACOCH<sub>3</sub>). Moreover, PTK by itself did not inhibit the proliferation of the cells. The inhibitory effect of OEA and AM3102 in serum-free medium or in the presence of PTK in serum-containing medium was significantly reversed if the cells were incubated with 100-200  $\mu$ M of the antioxidant  $\alpha$ -tocopherol but not by its water-soluble analog Trolox. Our results suggest that both OEA and AM3102 may generate reactive oxygen species, which leads to the inhibition of proliferation in OV2008 cells. Further, phospholipase A<sub>2</sub> inhibition may play a role in the generation of reactive oxygen species in response to OEA and AM3102 (This undergraduate student research was supported by funds from the University Research Council).

### **Green barley extract possesses selective antiproliferative and cytotoxic activity on human cancer cells.**

A. Varela-Ramirez<sup>1</sup>, E. Robles-Escajeda<sup>1</sup>, D. Lerma<sup>2</sup>, A. Nyakeriga<sup>3</sup>, R. J. Aguilera<sup>1</sup>; <sup>1</sup>Biological Sciences and Border Biomedical Research Center, University of Texas at El Paso, El Paso, TX, <sup>2</sup>School of Science, Engineering and Technology, St. Mary's University, San Antonio, TX, <sup>3</sup>Paul L Foster School of Medicine, Biomedical Sciences, Texas Tech University Health Sciences Center, El Paso, TX

The use of plants for medical purposes is an ancient practice and this knowledge has been transferred by oral communication and/or by imitation among various cultures for generations. Green barley (GB) has been proposed to contain an anticancer curative activity and has been actively promoted by producers of natural herbal supplements with little, if any, evidence for the validity of these proclamations. In this study, we have attempted to confirm some of the proposed activities ascribed to GB and have investigated if such extracts possesses antiproliferative and cytotoxic effect. Treatment of three human lymphoma cell lines with GB extracts resulted in decreased cell numbers after 96h of incubation as compared to untreated cells. However, treatment of non-cancer cells (Hs27 human fibroblasts) did not result in a significant negative effect. Cell cycle analysis of treated lymphoma cells (BJAB) revealed that GB induced slight, but statistically significant, apoptosis after 96h, as evidenced by an increase in the sub G0/G1 population. This result was confirmed by using annexin V-FITC and propidium iodide assay, which detected a subpopulation of treated cells undergoing apoptosis. In addition, GB altered the cell cycle by arresting BJAB cells at the G2/M phase. On the other hand, GB inflicted strong cytotoxicity on another lymphoma cell line (NALM-6) after 48h of exposure and this was mediated by caspase-3 activation. In conclusion, GB exhibited selective antiproliferative and cytotoxicity activity on lymphoma cells. This study suggests that GB extract could possibly be used in a combinatorial therapy with well-known anti-cancer drugs.

890

### **The anti-tumor effects of ethanolic extract of *Antrodia cinnamomea* in human lung cancer-derived A549 cell.**

C-H. Wu<sup>1</sup>, F-C. Liu<sup>1</sup>; <sup>1</sup>Pharmacy, China Medical University, Taichung, Taiwan

**Aim of the study:** *Antrodia cinnamomea* (AC) is a popular Taiwanese folk medicine with numerous beneficial biological effects. The purpose of the present studies is to explore the potential activities of ethanolic extract of *Antrodia cinnamomea* (EEAC) in inhibiting cell growth and migration of human lung adenocarcinoma epithelial cell line (A549).

**Materials and Methods:** A549 cells were treated with various concentration of EEAC. Anti-proliferative effects of EEAC were analyzed by 3-[4,5-dimethylthiazol- 2-yl]-2,5-diphenyl tetrazolium bromide (MTT) assay and flow cytometry; wound healing assay was used to examine anti-migration property; antioxidation activity was measured by 1-diphenyl-2-picrylhydrazyl (DPPH) and malondialdehyde (MDA) assay; Western blot was employed for examining the molecular mechanisms of EEAC in anti-tumor. HPLC separation was applied to verify the potential bioactive compounds within EEAC.

**Results:** EEAC has been found to decrease cell viability of A549 cells in a dose- and time-dependent manner, which might be caused through cell cycle arrest at G0/G1 and G2/M phase. In the regulation of the proliferation-associated proteins, EEAC could increase and activate AMPK protein but downregulate the proteins expression of p-Akt, Akt, p-ERK1/2 and ERK1/2. EEAC also suppressed cells migration of A549 cells, and the expressions of migration-related proteins (MMP2 and MMP9) and its upstream regulator, p-ERK1/2, have been evidenced to be

downregulated in A549 cells after EEAC treatment. Additionally, EEAC has more potential activity in scavenging free radicals and significantly reduce free radicals-induced MDA production during lipid peroxidation. The result of HPLC showed that both adenosine and cordycepin have been detected within EEAC.

Conclusions: These results suggested that EEAC could be developed as potential clinical chemotherapy drug for lung cancer or nutraceutical supplements for preventing free radical-associated diseased conditions.

### **Zingiber Officinale Extracts Prevent Proliferation and Promote Apoptosis of Human Glioblastoma Cells.**

K. Vernon<sup>1</sup>, J. Meadows<sup>1</sup>, P. Cagle<sup>1</sup>, S. Sang<sup>2</sup>, P. Martin<sup>1</sup>; <sup>1</sup>Biology, North Carolina Agricultural and Technical State University, Greensboro, NC, <sup>2</sup>Center of Excellence for Post Harvest-Technologies, Kannapolis, NC

Glioblastoma multiforme (GBM) are aggressive malignant tumors that develop in the brain. GBMs demonstrate increased rates of cell proliferation and reduced rates of apoptosis. The clinical management of glioblastoma consists of surgical resection followed by radiotherapy and chemotherapy. This treatment regimen is not very effective and more effective therapies need to be developed. Ginger and ginger-based extracts have been widely used as natural remedies. *Zingiber officinale* plant extracts have been shown to prevent chemical induced skin tumors in a mouse model as well as prevent general inflammation. We hypothesize that bioactive ginger compounds will inhibit cell proliferation and promote apoptosis. Specifically, we tested the anti-proliferative effects of [6]-gingerol and [6]-shogaol, two chemically-defined extracts from the *Zingiber officinale* plant, on human GBM cell lines (A-172, U-251 MG and U-1242 MG). Treatment of all the cell lines with the [6]-gingerol or [6]-shogaol (100µg/µl – 10µg/µl) decreased the amount of serum-induced cell proliferation. Additionally, an increased amount of apoptosis was associated with the tested cell lines following exposure to the ginger extracts. More importantly, apoptosis was confirmed using PARP cleavage as a mechanistic measure. These data suggest that [6]-gingerol and [6]-shogaol, are capable of preventing GBM cell proliferation and promoting apoptosis in the GBM cell lines tested. More importantly, *Zingiber officinale* plant extracts may serve as an alternative or supplement to current therapeutic regimens for GBMs.

### **The role of Bst-2/Tetherin in HIV transmission from primary human macrophages.**

S. Giese<sup>1</sup>, M. Marsh<sup>1</sup>; <sup>1</sup>MRC Laboratory for Molecular Cell Biology, University College London, London, United Kingdom

Bst-2/Tetherin is a cellular protein that restricts HIV release and is antagonized by the viral protein U (Vpu). The restriction factor is thought to physically link budded virions to the host cell surface, preventing their release and cell-free transmission. Although Tetherin has been extensively studied in T cells and cell lines, little is known about its localization and functions in macrophages, and its role in the direct cell-cell transmission of HIV remains controversial.

Here we show that upon interferon treatment of primary monocyte-derived macrophages (MDM), Tetherin is highly up-regulated on both the mRNA and protein levels. Immunostaining shows that in IFN-treated MDM, Tetherin localizes to the cell surface as well as to an intracellular compartment positive for a marker of the trans-Golgi network. MDM infected with

Vpu-deficient HIV show increased overall and cell surface levels of Tetherin, higher levels of cell-associated virus and decreased HIV release into the culture supernatant, suggesting that Tetherin restricts the release and cell-free transmission of HIV in these cells.

Direct cell-cell transmission of HIV is thought to be more efficient than cell-free propagation. One of the key structures mediating cell-cell transmission is the so-called virological synapse, which is characterised by the accumulation of viral proteins and cellular receptors at the interface of the infected and the target cell. To investigate the role of Tetherin in cell-cell transmission of HIV from macrophages to T cells, we co-cultured infected MDM with autologous CD4<sup>+</sup> T cells. We find that T cells associate with MDM within minutes, while the formation of virological synapses takes at least half an hour. qPCR experiments show that in our system cell-cell transmission of HIV from MDM to T cells is about ten fold more efficient than cell-free infection of the T cells. Using Western Blot analysis to detect HIV protein in the T cells early (24 h) after the co-culture with infected MDM, we find that T cell infection is greatly diminished in the absence of the Tetherin antagonist Vpu. Depleting MDM of Tetherin by RNAi rescues the infection of the T cells.

In conclusion we find that Tetherin efficiently inhibits the release of cell-free HIV from primary macrophages and also inhibits cell-cell transmission of HIV from macrophages to autologous CD4<sup>+</sup> T cells. These results support the notion of high evolutionary pressure on HIV and related viruses to antagonize Tetherin.

893

**Annexin A1 is involved in virus-induced cell-cell fusion and syncytiogenesis.**

*M. Ciechonska<sup>1</sup>, J. Boutilier<sup>1</sup>, R. Duncan<sup>1</sup>; <sup>1</sup>Microbiology and Immunology, Dalhousie University, Halifax, NS, Canada*

Cell-to-cell fusion and syncytium formation is involved in numerous biological processes including cell differentiation, development, and organogenesis. Syncytium formation is also associated with pathological conditions such as inflammation, virus cytopathic effects and possibly cancer. Despite the ubiquitous nature of this reaction, little is known about the cellular protein machinery participating in syncytiogenesis. The fusion-associated small transmembrane (FAST) proteins encoded by the non-enveloped, fusogenic reoviruses are the smallest known membrane fusion proteins and the only viral fusogens dedicated to inducing cell-to-cell fusion and syncytium formation. The measles F protein is a canonical class I enveloped virus fusogen whose primary function is to promote virus-cell fusion but also induces cell-cell fusion in virus-infected or transfected cells. We have used these two different classes of viral fusogens to explore the role of cellular proteins and pathways in the process of syncytium formation. A yeast two-hybrid screen identified annexin A1 as a genetic interaction partner of the cytosolic domain of the p14 FAST protein. Annexin A1 is a calcium- and phospholipid-binding protein involved in multiple cellular events including anti-inflammatory signalling, differentiation, cytoskeleton rearrangement, and apoptosis. Co-immunoprecipitation results using HT-1080 cells co-transfected with p14 and FLAG-tagged annexin A1 indicated a calcium-dependent interaction between p14 and annexin A1. Furthermore, siRNA knockdown of annexin A1 dramatically impaired cell-cell fusion and syncytiogenesis mediated by both p14 and measles virus F protein. Since the p14 FAST protein and measles F protein differ in their predicted mechanisms of membrane fusion, our findings suggest that annexin A1 may participate in a ubiquitous cellular response to a membrane fusion event that promotes syncytiogenesis.

894

**Cell-type specific requirements for ER exit during BK Polyomavirus entry.***S. M. Bennett<sup>1</sup>, M. Jiang<sup>1</sup>, M. J. Imperiale<sup>1</sup>; <sup>1</sup>University of Michigan, Ann Arbor, MI*

BK Polyomavirus (BKPyV) is a non-enveloped DNA virus that establishes a lifelong subclinical infection in the majority of the population and can cause severe disease in immunocompromised individuals. In particular, BKPyV reactivation in kidney transplant patients can lead to polyomavirus-associated nephropathy (PVAN) and subsequent loss of the graft. In PVAN biopsies, evidence of BKPyV lytic infection can be detected in proximal tubule epithelial cells; therefore, to study BKPyV in a natural host cell, our laboratory has established a cell culture model of lytic infection using primary renal proximal tubule epithelial (RPTE) cells.

The productive entry pathway of BKPyV includes a microtubule-dependent endocytic trafficking route to the endoplasmic reticulum (ER), followed by entry into the nucleus. The trafficking of polyomaviruses from the ER to the nucleus is not well understood, and whether the virus enters the nucleus directly by crossing the inner nuclear membrane or first enters the cytosol and subsequently is imported into the nucleus, remains controversial. Previous studies have suggested that polyomaviruses hijack host ER quality control mechanisms including ER-associated degradation (ERAD) for capsid disassembly and crossing of the ER membrane.

Our study is the first to address BKPyV trafficking in a natural host cell, and our data indicate involvement of both the proteasome and ERAD during entry of BKPyV. Viral capsid proteins co-localize with the ERAD substrate CD3 $\delta$ , and inhibition of the proteasome with epoximycin leads to an accumulation of BKPyV in an ER subcompartment, as visualized by fluorescence in situ hybridization of the viral genome and immunofluorescence staining for viral capsid proteins. Employing a retro-translocation assay, we have evidence that BKPyV enters the cytosol during infection, beginning at a timepoint soon after ER trafficking. However, epoximycin treatment does not inhibit ER exit of BKPyV. Interestingly, under epoximycin treatment, the related polyomavirus SV40 was able to enter the cytosol as well in RPTE cells, and furthermore we saw an increase in cytosolic virus for both BKPyV and SV40. This finding differs from what has been shown for SV40 in CV-1 cells. Together these data suggest that the ERAD machinery plays a role during BKPyV entry and cytosolic ERAD factors such as the proteasome play a role after the virion crosses the ER membrane, before nuclear entry.

895

**Nuclear receptor interaction protein enhances HPV gene expression via interaction with either glucocorticoid receptor or E2.***S-L. Chen<sup>1</sup>, S-W. Chang<sup>1</sup>; <sup>1</sup>Microbiology, National Taiwan University, College of Medicine, Taipei, Taiwan*

We previously identified a gene, nuclear receptor-interaction protein (NRIP), which functions as a transcription cofactor in glucocorticoid receptor (GR) and human papillomavirus E2 (HPV E2)-driven gene expression (JBC, 2005; JV 2011). Here, we comprehensively evaluated the role of NRIP in HPV-16 gene expression. NRIP acts as a transcription cofactor to enhance GR-regulated HPV-16 gene expression in the presence of hormone. NRIP also can form complex with E2 that caused NRIP-induced HPV gene expression via E2-binding sites in a hormone-independent manner. Furthermore, NRIP can associate with GR and E2 to form tri-protein complex to activate HPV gene expression via GRE, not the E2-binding site, in a hormone-dependent manner. These results indicate that NRIP and GR are viral E2-binding proteins and that NRIP regulates HPV gene expression via GRE and/or E2 binding site in the HPV promoter in a hormone-dependent or independent manner, respectively. Due to NRIP has a function to dephosphorylate E2, therefore the complex formation with the status of E2 phosphorylation are currently investigating.

**Fighting HIV Infection by Defining Mechanisms to Disaggregate SEVI Fibrils.**

L. M. Castellano<sup>1,2</sup>, V. Holmes<sup>3</sup>, F. Klärner<sup>4</sup>, T. Schrader<sup>4</sup>, G. Bitan<sup>5,6,7</sup>, D. Weissman<sup>3</sup>, J. Shorter<sup>2</sup>; <sup>1</sup>Pharmacology Graduate Group, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, <sup>2</sup>Department of Biochemistry and Biophysics, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, <sup>3</sup>Division of Infectious Diseases, Department of Medicine, University of Pennsylvania, Philadelphia, PA, <sup>4</sup>Institute of Organic Chemistry, University of Duisburg-Essen, Essen, Germany, <sup>5</sup>Department of Neurology, David Geffen School of Medicine, University of California at Los Angeles, Los Angeles, CA, <sup>6</sup>Brain Research Institute, University of California at Los Angeles, Los Angeles, CA, <sup>7</sup>Molecular Biology Institute, University of California at Los Angeles, Los Angeles, CA

Human immunodeficiency virus (HIV) is a major public health threat worldwide, with 80% of infections acquired through sexual transmission. Naturally occurring fragments of prostatic acid phosphatase (PAP), a protein abundant in human seminal fluid, form amyloid fibrils that promote HIV infection. These amyloid fibrils, termed SEVI (semen derived enhancer of viral infection), augment HIV infectivity by up to  $\sim 10^5$ -fold by facilitating virion attachment and fusion to target cells. Despite the extremely stable structure of amyloid fibrils, certain agents can disrupt and reverse amyloid formation. Hsp104, a AAA+ ATPase found in yeast, uses energy from ATP hydrolysis to disaggregate amyloids by disrupting their generic cross- $\beta$  structure. In addition, an Hsp104 variant termed HAP has been generated that interacts with the chambered bacterial protease ClpP to degrade disaggregated substrates. Both Hsp104 and the HAP/ClpP proteolytic system were found to remodel SEVI amyloid fibrils resulting in a significant reduction in SEVI-mediated enhancement of HIV infection. In addition, a small molecule “molecular tweezer” is able to disassemble SEVI fibrils through interactions with lysine residues and completely abolishes SEVI-mediated enhancement of HIV transmission. In the future, it will be important to determine whether these agents can eradicate the enhancing effects of SEVI in the more complex milieu of seminal fluid.

897

**ZASC1 Knockout Mice Exhibit an Early Bone Marrow-specific Defect in Murine Leukemia Virus Replication.**

S. Seidel<sup>1</sup>, J. Bruce<sup>2</sup>, M. LeBlanc<sup>3</sup>, K-F. Lee<sup>3</sup>, H. Fan<sup>4</sup>, P. Ahlquist<sup>2</sup>, J. Young<sup>1</sup>; <sup>1</sup>IMPL-Y, Salk Institute and UCSD, La Jolla, CA, <sup>2</sup>University of Wisconsin, Madison, WI, <sup>3</sup>Salk Institute and UCSD, La Jolla, CA, <sup>4</sup>UC Irvine, Irvine, CA

ZASC1 is a zinc finger-containing transcription factor that was previously shown to bind to specific DNA binding sites in the Moloney murine leukemia virus (Mo-MuLV) promoter and is required for efficient viral mRNA transcription (1). To determine whether this cellular factor influences Mo-MuLV replication and virus disease pathogenesis in vivo, we generated a ZASC1 knockout mouse model. Mice lacking ZASC1 were born at the expected Mendelian ratio and showed no obvious physical or behavioral defects. Analysis of bone marrow samples revealed a specific increase in a common myeloid progenitor cell population in ZASC1-deficient mice, a result that is of considerable interest because osteoclasts derived from the myeloid lineage are amongst the first bone marrow cells infected by Mo-MuLV (2). Indeed, Mo-MuLV infection of neonatal mice revealed that ZASC1 is required for efficient early virus replication in the bone marrow, but not in the thymus or spleen. The absence of ZASC1 however did not influence the timing of subsequent tumor progression or the types of tumors resulting from virus infection. These studies have revealed that ZASC1 is important for myeloid cell differentiation in the bone

marrow compartment and that this cellular factor is required for efficient Mo-MuLV replication in this tissue at an early time point post-infection.

#### **Visualization of Murine Norovirus proteins and its genome RNA.**

*T. Shimoike<sup>1</sup>, H. Takagi<sup>1</sup>, T. Oka<sup>1</sup>, K. Murakami<sup>1</sup>, R. Todaka<sup>1</sup>, Y. Park<sup>1</sup>, Y. Fujii<sup>1</sup>, T. Wakita<sup>1</sup>, K. Katayama<sup>1</sup>; <sup>1</sup>National Institute of Infectious Diseases, Musashi-Murayama, Japan*

The study on Human Norwalk virus (HuNoV), a member of the family Caliciviridae, is hampered because there is no cell culture system or small animal model. However murine norovirus (MNV) that belongs to the same genus as HuNoV is replicated in RAW264.7 cells.

To understand MNV life cycle in cells, we used immunofluorescence microscopy to visualize MNV proteins (VPg, RNA dependent RNA polymerase: RdRp, NTPase, and structural proteins VP1), double stranded viral RNA (dsRNA), and newly synthesized viral RNA (nsRNA) during replication in RAW264.7 cells. We also detected the host proteins as markers of organelle (Calnexin as ER, GM130 as Golgi, EEA1 as endosome, and LAMP1 as lysosome markers) to address the localization of the viral proteins, and of the viral dsRNA and nsRNA in the cells.

At 13 hours post infection, the dsRNA was observed at the perinuclear region. The small amount of nsRNA was also localized at the perinuclear region, however most of the nsRNA were spread diffusely throughout the cytoplasm. The RdRp, NTPase and VPg were co-localized at the perinuclear region with viral dsRNA, indicating that MNV replicates at perinuclear region, and that the replication complex is at least composed of dsRNA, RdRp, NTPase, VPg and a small amount of nsRNA. The RdRp is partially co-localized with Calnexin, indicating that the virus replicates on ER. The structural protein, VP1 was detected in the cytoplasm and appeared to co-localize with nsRNA, suggesting that virion assembly, which involved at least nsRNA and VP1. VP1 was co-localized with EEA1 used as endosome markers indicating that endosome is involved in the virion assembly, which is the different site from the replication on ER.

#### **HCV infects and impairs CNS function.**

*B. L. Aguila<sup>1</sup>, E. Eugenin<sup>1</sup>; <sup>1</sup>UMDNJ-PHRI, Newark, NJ*

Hepatitis C virus (HCV) is the major agent that causes chronic liver disease and according to the OMS approximately 170 million are infected with this virus. In addition, to being a dangerous infection, HCV also is associated with co infections in HIV, drug abuse and other infectious diseases. HCV infects hepatic cells, however, recent evidence indicates that HCV also results in CNS compromise, but the mechanism of this brain dysfunction is unknown. Our proposal is that HCV can directly infect the brain resulting in CNS dysfunction and damage. Thus, we examined whether human brain primary cells express the receptors required for HCV entry, such as claudin-1, occludin and ephrin B2. Our results indicated that neurons, astrocytes, pericytes, macrophages and brain microvascular endothelial cells may be susceptible to HCV infection, resulting in CNS dysfunction and compromise. Our studies indicate that HCV directly attack the

brain causing CNS dysfunction and cognitive impairment in millions of people infected with this virus.

900

**Baculoviruses use actin-based motility for nuclear egress and transit to the cell surface.**

*T. Ohkawa<sup>1</sup>, M. D. Welch<sup>1</sup>; <sup>1</sup>Molecular and Cell Biology, University of California, Berkeley, CA*

Many viruses utilize the microtubule cytoskeleton for intracellular transport. In contrast, the baculovirus *Autographa californica M nucleopolyhedrovirus* (AcMNPV) utilizes the actin cytoskeleton at several points in its replication cycle. Early in infection, following viral uptake by endocytosis, AcMNPV undergoes actin-based motility, a process that accelerates transit to the cell nucleus where replication takes place. Following nuclear translocation, one of the most striking features of AcMNPV late stage infection is the polymerization of actin within the nucleus, concomitant with viral replication. However, beyond an essential role in progeny virus production, a specific function of this nuclear filamentous actin was previously unknown. We have found, using live cell imaging of virus, actin and the nuclear envelope marker lamin B2, labeled with fluorescent protein tags, that AcMNPV nucleocapsids undergo actin-based motility within the nucleus. Moving nucleocapsids collide with and form protrusions in the nuclear membrane, apparently in the process of exiting the nucleus. Using electron microscopy we observed that these protrusions are absent and nucleocapsids fail to exit the nucleus in the presence of drugs that interfere with actin polymerization, indicating that actin is essential for nuclear egress. Following nuclear exit, nucleocapsids again use actin-based motility in the cytoplasm, suggesting that actin is also important for viral translocation to the plasma membrane prior to budding out of the cell. These results indicate that manipulation of the actin cytoskeleton is essential for numerous stages of the process of baculovirus egress, and reveal new roles for actin in pathogen transport within host cells.

**Evidence of Co-purification of the Human T-cell Leukemia Virus Type 1 and Heat Shock Protein-90 (HSP90).**

*C. Nwankwo<sup>1</sup>, T. Gibson<sup>1</sup>; <sup>1</sup>Biology, University of Texas of the Permian Basin, Odessa, TX*

Retroviruses cause many human diseases, such as, immunodeficiency syndromes, autoimmune, neurological disorders, and cancer. Human T-cell leukemia virus 1 (HTLV-1) is a retrovirus that causes adult T-cell Leukemia (ATL). How HTLV-1 infection progresses to ATL is not well understood. However, identification of cellular proteins that interact with the virus will provide much needed insight into HTLV-1 pathogenesis. Evidence suggests that cellular proteins contained within the virus particle are important for the infection process. We have hypothesized that heat shock protein 90 (HSP90) is a cellular factor packaged within HTLV-1 virion. We have conducted tripartite transfection to produce HTLV-1 virus-like particles (VLPs). This procedure involved using three plasmids, which contain all the necessary viral genes. Western blots analyses demonstrated that the HTLV-1 VLPs were produced and are structurally correct. Next, we purified the HTLV-1 VLPs by spinning the virus through a 20% and 30% sucrose cushion. To further purify the HTLV-1 VLPs, samples were placed onto a 10% - 50% sucrose gradient. Western blot analyses revealed that HTLV-1 and HSP-90 are localized in the same sucrose gradient fractions. Collectively, our data supports the notion that HSP90 is packaged in the HTLV-1 virion. Currently, we are planning to use immunogold-labeling technique to investigate if HSP90 is contained within the HTLV-1 virion.

902

**Elucidating the Molecular Mechanism of Bacteriophage P22 Genome Packaging.**

R. McNulty<sup>1</sup>, A. Roy<sup>2</sup>, C-Y. Fu<sup>1</sup>, D. Veessler<sup>1</sup>, P. E. Prevelige<sup>3</sup>, G. Cingolan<sup>2</sup>, J. E. Johnson<sup>1</sup>;  
<sup>1</sup>The Scripps Research Institute, La Jolla, CA, <sup>2</sup>Biochemistry & Molecular Biology, Thomas Jefferson University, Philadelphia, PA, <sup>3</sup>Microbiology, University of Alabama at Birmingham, Birmingham, AL

The Salmonella-infecting bacteriophage P22 packages its genome from concatemers of dsDNA. This packaging machinery consists of a large (L-) and small (S-) terminase complex. The small terminase functions to properly position the large terminase for packaging initiation via the pac site. The large terminase uses ATP hydrolysis to translocate a single copy of the genome into the bacteriophage procapsid. The motor activity of L-terminase results in dsDNA packaging at a rate of up to 2000 bp/sec. Although poorly understood, termination and cleavage are induced upon reaching a filled procapsid. Upon cleavage, the L-/S-terminase complex disassociates from the capsid enabling tail and associated proteins to bind, sealing the genome inside the procapsid. There are structures of procapsids and mature phage, but no high-resolution structures with terminase proteins bound to the particle. Swift packaging, followed by rapid disassociation, has complicated procapsid-terminase complex isolation and structure elucidation.

We report here preliminary results of L-terminase mixed with procapsids visualized with negatively stained EM images that display density corresponding to the procapsid-terminase complex. Data collection of images of the complex are underway with the goal of producing a 3D reconstruction of the complex. The structure will provide insights for other viruses with related packaging mechanisms, such as Herpes virus.

903

**Purification of Human T-cell Leukemia Virus Type 1 for Mass Spectrometry Analysis.**

T. M. Gibson<sup>1</sup>, D. Kakhniashvili<sup>2</sup>, S. R. Goodman<sup>2</sup>; <sup>1</sup>Department of Biology, University of Texas at the Permian Basin, Odessa, TX, <sup>2</sup>State University of New York Upstate Medical University, Syracuse, NY

Human T-cell leukemia virus 1 (HTLV-1) is an enveloped retrovirus that causes adult T-cell leukemia. How HTLV-1 infection progresses to T-cell malignancy is not well understood. However, identification of cellular proteins that interact with the virus will provide much needed insight into HTLV-1 pathogenesis. It has been reported that enveloped viruses contain proteins derived from the host cell. **Our hypothesis is that HTLV-1 contains host cell proteins essential for the virus to infect naïve cells.** To identify cellular proteins, we will perform proteomic analysis. Initially, we transfected HEK 293T cells with three different plasmids (pCMVRU5-GFP<sub>Luc</sub>, pCMVHT1 delta X-M, and pCMV-VSV-G) to produce HTLV-1 virus-like particles (VLPs). Western blot analyses of HTLV-1 VLPs revealed that the viral protein, called capsid, is produced and structurally correct. Next, HTLV-1 VLPs were purified by sucrose gradient centrifugation. Immunoblot studies of sucrose gradient fractions revealed that HTLV-1 VLPs are purified and sediment at the 30% – 40% sucrose region. Silver stained polyacrylamide gels of the purified HTLV-1 VLPs revealed the presence of half the known viral proteins. Currently, we are further purifying the HTLV-1 VLPs to obtain samples enriched with all known viral proteins. Samples containing all known HTLV-1 viral proteins will be prepared for mass spectrometry analysis by digestion with trypsin. These studies will advance our understanding of host-pathogen interactions and should facilitate the development of novel therapeutic targets for HTLV-1 infections.

## Protists and Parasites

### Epigallocatechin-3-gallate (EGCG) blocks development of *Dictyostelium discoideum*

K. J. McQuade<sup>1</sup>, A. Nakajima<sup>2</sup>, A. N. Ilacqua<sup>1</sup>, N. Shimada<sup>2</sup>, S. Sawai<sup>2,3,4</sup>,

<sup>1</sup>Biological Sciences, Colorado Mesa University, Grand Junction, CO, <sup>2</sup>Graduate School of Arts and Sciences, University of Tokyo, Tokyo, Japan, <sup>3</sup>Research Center for Complex Systems Biology, University of Tokyo, Tokyo, Japan, <sup>4</sup>Precursory Research for Embryonic Science and Technology, Japan Science and Technology Agency, Tokyo, Japan

Green tea catechins have received significant attention due to their potential health benefits, but the precise mechanisms by which these compounds act are not known. Here, we assess whether the model organism *Dictyostelium discoideum* is a useful tool with which to characterize the effects of these natural products. Epigallocatechin-3-gallate (EGCG), the most abundant and potent catechin in green tea, affects *Dictyostelium* aggregation and morphogenesis; aggregating amoebae do not stream and development is stalled at the loose aggregate stage. These developmental effects are accompanied by defects in cell-cell signaling and delayed expression of developmentally-regulated genes. These data suggest that catechins and their derivatives may be useful tools with which to better understand cell movement and morphogenesis in *Dictyostelium*. Furthermore, because the methods used here are relatively simple, quick, and easily adaptable for high-throughput screening, *Dictyostelium* is likely to be a useful model with which to identify and characterize other bioactive natural products.

905

### New insights into Golgi complex of *Trichomonas foetus*: production of a specific marker and identification of the adenosine triphosphatase and beta-tubulin.

I. de Andrade Rosa<sup>1,2</sup>, M. B. Caruso<sup>3</sup>, S. P. Rodrigues<sup>3</sup>, R. B. Geraldo<sup>3</sup>, L. W. Kist<sup>4</sup>, M. R. Bogo<sup>4</sup>, L. Gonzaga<sup>5</sup>, A. Vasconcelos<sup>5</sup>, J. A. Morgado-Díaz<sup>6</sup>, R. B. Zingali<sup>3</sup>, M. Benchimol<sup>3</sup>; <sup>1</sup>Biofísica, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil, <sup>2</sup>Laboratório de Ultraestrutura Celular, Universidade Santa Ursula, Rio de Janeiro, Brazil, <sup>3</sup>Instituto de Bioquímica Médica (Unidade de Espectrometria de Massa e Proteômica), Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil, <sup>4</sup>Laboratório de Biologia Genômica e Molecular, Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre, Brazil, <sup>5</sup>Laboratório Nacional de Computação Científica (LNCC/MCT), Petrópolis, Brazil, <sup>6</sup>Grupo de Biologia Estrutural, Divisão de Biologia Celular, Instituto Nacional de Câncer, Rio de Janeiro, Brazil

*Trichomonas foetus* is the causative agent of bovine trichomoniasis, and is among the earliest diverging eukaryotes. This protist presents a well-developed Golgi complex and, although current information shows that the Golgi complex plays an important role in protein glycosylation, sorting and lysosome biogenesis, there are very few studies in the Golgi of trichomonads. The absence of reactivity of commercial antibodies to the Golgi complex of trichomonads contributes to the lack of new data. In this work, several approaches such as cell fractionation, Golgi isolation and monoclonal antibodies were raised as tools on Golgi studies of *T. foetus*. In addition, complementary techniques, such as immunolabelling, immunoblotting, mass spectrometry analysis and database searches were performed to identify which proteins were recognised by this antibody. The Golgi complex of *T. foetus* was purified and among the antibodies, one was named mAb anti-Golgi 20.3, which exhibited intense reactivity by light and electron microscopy. This antibody recognised proteins of 60 kDa and 66 kDa. Using proteomic approaches, these proteins were identified as putative beta-tubulin and adenosine triphosphatase, respectively. However, antigenic peptides analysis indicated a cross-reactivity

with beta-tubulin which could carry this protein during immunoprecipitation. The mAb anti-Golgi 20.3 also recognised the Golgi of *Trichomonas vaginalis* which presents an adenosine triphosphatase with an identity rate higher than 80%. The nucleotides sequences that codify these proteins were identified and included on *T. foetus* database, and the 3D structure of the proteins was also obtained. This study is the first to demonstrate the presence of ATPase and beta-tubulin in the Golgi complex from *T. foetus* using mass spectrometry and genomic data. These data indicated (1) the presence of adenosine triphosphatase in the Golgi, (2) it is conserved in *T. foetus* and *T. vaginalis*, (3) new information concerning nucleic acid sequences and proteins structures of adenosine triphosphatase and beta-tubulin from *T. foetus* and (4) the mAb anti-Golgi 20.3 is a good marker for this organelle that can be used in future studies. This work was supported by AUSU, CNPq, FAPERJ, INMETRO and Pronex.

#### **Experimental Verification of microRNAs in *Leishmania braziliensis*.**

J. M. Porter-Kelley<sup>1</sup>, D. G. Mayer<sup>2</sup>, M. J. Woodard<sup>1</sup>, K. S. Abernathy<sup>1</sup>, B. A. Hannible<sup>1</sup>; <sup>1</sup>Life Sciences, Winston Salem State University, Winston Salem, NC, <sup>2</sup>Biology, Manhattan College, Riverdale, NY

miRNAs have been described in most organisms from worms to human and more recently in protozoans. miRNAs are a group of small RNAs that regulate gene expression post-transcriptionally in a complex process of binding to mRNA in a perfect complement or almost perfect complement that cleave mRNAs or inhibit their translation. Gene expression in *Leishmania* is not well understood, however, it is known to be post-transcriptionally regulated. Argonaute-like and Dicer-like protein, the machinery needed for the processing of miRNAs have been shown to exist computationally in *Leishmania braziliensis*. Our hypothesis is that miRNAs regulate gene expression in *L. braziliensis*. We have shown by computational data analysis that there are miRNAs in *L. braziliensis*. Here we show the continuation of our study and plans for experimental verification of miRNAs in *L. braziliensis*.

907

#### **Identification of differentially expressed genes among pathogenic and nonpathogenic *Leishmania* species.**

A. Shakarian<sup>1</sup>; <sup>1</sup>Biology and Biomedical Sciences, Salve Regina University, Newport, RI

There are 31 species of *Leishmania* that are known to infect humans. The disease spectrum of leishmaniasis ranges from mild self-limiting cutaneous ulcers to a potentially fatal visceral infection, each dependant on the species of parasite with which one is infected. It is poorly understood which genes and how many proteins are involved in the survival and virulence of the pathogenesis of *Leishmania*. We hypothesize that differences in the expression of genes among pathogenic species and between pathogenic and nonpathogenic species should identify some of the proteins that are critical to the survival and important to the virulence of these parasites. Thus, in the current study we identified differentially expressed genes between pathogenic and nonpathogenic species of *Leishmania* (*L. donovani*, *L. mexicana*, *L. major* and *L. tarentolae*) by cDNA-AFLP (Amplified Fragment Length Polymorphism) and subsequently characterized these genes by DNA sequence analyses. AFLP analysis with 32 different primer sets resulted in 8 AFLP primer sets that gave data in the 50-400 bp range and therefore were considered for further analysis. We have identified 296 polymorphic fragments and 148 unique fragments to date. Interestingly, the calculated polymorphism is 25-35% across the species; this corresponds to the high degree of similarity that is seen at the genome sequence level. Analysis of some of these fragments has evolved 3 general categories of proteins. 1) hypothetical proteins in the

*Leishmania* genome database with no known function or cellular location 2) 18s and 24s rRNA and most likely result from using total RNA in the AFLP reactions and 3) protein coding sequences including calreticulin in *L. donovani*, superoxide dismutase, peptidase and ascorbate peroxidase in *L. mexicana*. Characterization of the remaining unique AFLP fragments is underway. Once characterized these cDNA-AFLP fragments may be used as probes to obtain their corresponding full length genes from genomic DNA and used to blast search against known *Leishmania* genome sequences. As toxic antimony compounds are often used unsuccessfully for its treatment, the characterization of genes differentially expressed between pathogenic and nonpathogenic species is a first step in identifying potential novel targets for the development of nontoxic drugs to be used in the treatment of leishmaniasis, a devastating and potentially fatal collection of human diseases.

908

#### **Hepatic metalloproteases activity in mice infected with malaria parasite *P. chabaudi*.**

M. M. Gomes<sup>1</sup>, P. Bagnaresi<sup>2</sup>, M. A. Juliano<sup>2</sup>, M. R. Nagaoka<sup>1</sup>, A. K. Carmona<sup>2</sup>, M. L. Gazarini<sup>1</sup>; <sup>1</sup>Biosciences, Federal University of São Paulo, Santos, Brazil, <sup>2</sup>Biophysics, Federal University of São Paulo, São Paulo, Brazil

Malaria, the disease caused by *Plasmodium* infection, remains one of the most prevalent and deadly maladies. Matrix metalloproteinases (MMPs) are a family of secreted and membrane-bound zinc-dependent endopeptidases that have the combined capacity to degrade all the components of the extracellular matrix, and to shed, activate, or inactivate cytokines, chemokines, and other MMPs through cleavage from their precursors. Among them are ACE and ACE2, critical regulators of the renin-angiotensin system. The liver is affected in two stages during the life cycle of the malarial parasite: initially in the pre-erythrocytic cycle and then in the erythrocytic phase. The latter is responsible for the clinical manifestations of malaria. The involvement of the metalloproteinases activity in the liver injury mediated by malaria remains unknown. Herein we report the evaluation of metalloproteases catalytic activity in liver homogenates (40µg / assay) infected by *Plasmodium chabaudi* with blood parasitemia of 80%. For this purpose, selective fluorogenic substrates were used as follows: MCA-PLGL-Dpa-AR-NH<sub>2</sub> (collagenase and gelatinase enzymes), Abz- GPQGLAGQ-EDDnp (MMP-9), Abz-FRK(Dnp)P-OH (ACE) and Abz-APK(Dnp)-OH (ACE2). Our data show a significant decrease (38,1 UAF/min ±3 to 11,8 UAF/min ±0,5 n=5) of hydrolysis of MCA-PLGL-Dpa-AR-NH<sub>2</sub> (general substrate for metalloproteases) in the infected liver compared to non-infected. MMP-9 activity presented a slight increase (33,2 UAF/min ± 1 to 35,8 UAF/min ±2 n=5), which is reflection of the liver inflammation by the infection. However, ACE hydrolytic activity of liver tissue upon the selective substrate Abz-FRK(Dnp)P-OH did not changed after *Plasmodium* infection and was 50% inhibited by captopril (1mM) (0,97 UAF/min ±2 to 0,45 UAF/min ± 0,7 n=5). Interestingly, we distinguished the ACE2 activity with selective substrate Abz-APK(Dnp)-OH in infected liver homogenates (70 UAF/min ± 7 n=3) and noninfected (97 UAF/min ± 12 n=3). In both situations we observed a specific inhibition of the ACE2 with addition of inhibitor DX600 (20 µM): infected liver (inhibition of 70%±3) and noninfected liver (inhibition of 80%±2). This data provide new insights for renin-angiotensin modulation in infected liver by *Plasmodium*. Our data suggest that the metalloproteases analyzed are directly involved in inflammation process and liver hemodynamics, which are important for malaria physiopathology. Supported by FAPESP.

### The unique insert in the ribosomal stalk protein, phosphoprotein P0, shared by members of the Ciliophora.

G. Pagano<sup>1</sup>, R. King<sup>2</sup>, L. M. Martin<sup>1</sup>, J. Schumacher<sup>1,2</sup>, L. A. Hufnagel<sup>1</sup>; <sup>1</sup>Cell and Molecular Biology, University of Rhode Island, Kingston, RI, <sup>2</sup>Biomedical and Pharmaceutical Sciences, University of Rhode Island, Kingston, RI

Phosphoprotein P0 is a eukaryotic 60S ribosomal protein which is a member of the L10 protein family. It functions as a scaffold for the P protein stalk complex, located at the GTPase-associated center required for protein elongation. P0 has been implicated in systemic lupus erythematosus. Recent evidence suggests that P0 may locate to the cell surface of apicomplexan parasites such as *Plasmodium* and *Toxoplasma*, and that it may play an important role in host invasion. The apicomplexans and ciliophorans are sister clades, within the protistan alveolates. Therefore, we are investigating the potential of the ciliophoran *Tetrahymena thermophila* as a model organism for vaccine research and drug development applicable to apicomplexan diseases. Our comparison of P0 orthologs from *Tetrahymena* with those of prokaryotes and other eukaryotes has revealed a 15-17 amino acid-long insert exclusive to members of the protist phylum, Ciliophora. Using several bioinformatics methods, including sequence alignments, homology modeling and motif prediction tools, we have begun to characterize the insert in *T. thermophila* and other ciliates. With the exception of *Paramecium tetraurelia*, the nine ciliophoran species examined shared a region within the insert, with the consensus sequence (D/E)XX(Y/F)(D/E). Within this region, there is a predicted casein kinase II phosphorylation site in *T. thermophila* and some species of *Euplotes* and *Eufolliculina*, with the consensus sequence (S/T)XX(D/E). Homology modeling of the *T. thermophila* P0 (TtP0) shows that the insert is located within the N terminal region, and is situated near the surface of the ribosome, near the base of the stalk. The predicted conformation of the insert is highly variable, suggesting that it could interact with the ribosomal RNA, another part of P0 or with one of the P protein dimers that bind to P0. We have also found that this insert is absent in several apicomplexan species, so the insert may have arisen after the divergence of the ciliate and apicomplexan lineages. Based on our evidence, we are continuing to investigate the hypothesis that the insert may regulate ribosomal function, via its phosphorylation site and putative interactions with stalk proteins or rRNA, and extra-ribosomal factors.

911

### Architecture and assembly of TbBILBO1, a protein that is essential for the survival of *Trypanosoma brucei*

K. Vidilaseris<sup>1</sup>, B. Morriswood<sup>2</sup>, G. Warren<sup>2</sup>, G. Dong<sup>1</sup>;

<sup>1</sup>Biochemistry & Biophysics, Structural & Computational Biology Department, Max F. Perutz Laboratory, Vienna, Austria, <sup>2</sup>Biochemistry & Biophysics, Molecular Cell Biology Department, Max F. Perutz Laboratory, Vienna, Austria

Protozoan Trypanosomatidae including *Trypanosoma brucei*, *T. cruzi* and *Leishmania spp.* are parasites to human and animals and cause significant mortality each year. The flagellar pocket (FP) is a unique compartment that resides at the base of the flagellum of these protists. It is the sole site for endo- and exocytosis and plays crucial roles in the cell's defense against the host immune system. TbBilbo1 is the first characterized FP cytoskeletal protein and is an integral component of the flagellar pocket collar (FPC). This protein is essential for both FP biogenesis and the viability of the parasites. TbBilbo1 consists of a globular N-terminal domain (NTD), two predicted central EF-hand motifs and a long coiled-coil domain followed by a C-terminal leucine zipper motif. In order to illuminate the molecular basis for TbBilbo1 in FP biogenesis and cell survival, we aim to determine the structure of the protein and to understand the structure-

function relationship by means of x-ray crystallography, NMR spectroscopy, electron microscopy, and in vivo immunofluorescence studies.

Our localization analysis of various truncated constructs of TbBilbo1 in the procyclic form of *T. brucei* 427 showed that the C-terminal leucine zipper is responsible for the protein's localization to the FPC. Overexpression of TbBilbo1-ΔNTD, but not of TbBilbo1-FL, with 20 ng/ml tetracycline was lethal to the cells after 4 days of induction. Our determined NMR structure of the TbBilbo1-NTD reveals that it adopts a ubiquitin-like fold with a surface patch consisting of eight absolutely conserved residues (5 aromatic and 3 positively charged). We have further generated two sets of mutations in the NTD for in vivo functional analysis. The first set, namely TbBilbo1-M3M0, contains F12A, K15A, K60A and K62A, and the second set, namely TbBilbo1-M1b2b, contains W71A, Y87A and F89A. Overexpression of both mutated TbBilbo1 had similar effect to that of the TbBilbo1-ΔNTD, indicating that these residues play an important role for cell viability. Based on our rotary shadowing EM studies, we conclude that TbBilbo1 dimerizes in an anti-parallel manner via its coiled-coil domain. This dimer further assembles into a long filament-like oligomer via its C-terminal leucine zipper. We are currently investigating how the EF-hand motifs might control the gating function of the FPC.

**Evaluation of recombinant filarial Troponin and Paramyosin as Diagnostic tools in lymphatic filariasis.**

A. Samyikutty<sup>1</sup>, G. Dakshinamoorthy<sup>2</sup>, R. Kalyanasundaram<sup>2</sup>, G. Munirathinam<sup>2</sup>, M. Reddy<sup>3</sup>;  
<sup>1</sup>Natural Sciences, Albany State University, Albany, GA, <sup>2</sup>Biomedical Sciences, University of Illinois, Rockford, IL, <sup>3</sup>Biochemistry, Mahatma Gandhi Institute of Medical Sciences, Sevagram, India

Lymphatic filariasis is a mosquito vector borne disease caused by the filarial nematodes *Wuchereria bancrofti* and *Brugia malayi*. This extremely painful, debilitating and disfiguring disease is a cause for major public health problem in the tropical and subtropical world. World Health Organisation estimates that at least 120 million people are affected in more than 80 countries and another 1.5 billion people are at risk. The development in molecular biology research and the sequence mapping data provided by the Filarial Genome Project is being utilised by the nematode research community to develop a better understanding of the biology of filarial parasites and to identify new diagnostic candidates for the detection of human filariasis. The production of diagnostically important recombinant antigens can now be produced in variety of expression vectors which represents the key success to the preparation of commercial diagnostic kits. Hence our focus on to detect antigens by immunoscreening from cDNA libraries and to evaluate its diagnostic efficacy. The DNA inserts from the purified plaques were amplified by PCR using T3 and T7 universal primers and sequenced.

Epitope mapping of rWbPmy and rWbTN by Kolaskar and Tongaonkar antigenicity method were able to predict the presence of potential antigenic determinant sites based on the antigenic propensity values. This analysis has shown several antigenic sites in both rWbPmy and rWbTN antigens. The filarial IgG4 antibody detection assays with individual recombinant antigens rWbL2, rWbPMY and rWbTN showed 45%, 28.88% and 22.22 % sensitivity respectively for the detection of the microfilaremics and clinical filariasis samples and the specificity was 98-100% for all the three antigens. The Filarial IgG4 antibody detection assays with different

combinations of the individual recombinant antigens (rWbL2 & rWbMY/rWbL2 & rWbTN and rWbL2,rWbPMY & rWbTN showed sensitivity of 81.81%,74.54% and 85.45% respectively. Based on the IgG4 ELISA assay results we have selected cocktail of three recombinant antigens to develop sensitive, specific, rapid and user-friendly Dot-blot assay for the detection of filarial IgG4 antibodies in different clinical groups of filariasis. The Dot-Blot assay using the cocktail of three recombinant antigens yielded a sensitivity and specificity of 100% to detect microfilaremic and clinical filariasis cases

### **Ultrastructural alterations induced by SQS-inhibitor and metronidazole on *Trichomonas vaginalis*.**

D. R. Silva<sup>1,2</sup>, I. De Andrade Rosa<sup>1,2</sup>, W. de Souza<sup>1</sup>, M. Benchimol<sup>2</sup>; <sup>1</sup>Instituto de Biofísica Carlos Chagas Filho, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil, <sup>2</sup>Laboratório de Ultraestrutura Celular, Universidade Santa Ursula, Rio de Janeiro, Brazil

*Trichomonas vaginalis* is a human parasite that causes trichomoniasis, a cosmopolitan sexually transmitted disease. In women, this disease causes adverse pregnancy outcomes, as pre-terms rupture of membranes, pre-term delivery, cervical cancer and also increases the transmission of HIV. Currently, the treatment of choice for trichomoniasis is the drug metronidazole. However, this compound presents undesirable side effects and has been observed an increase in metronidazole-resistant strains. In addition, during pregnancy, the use of metronidazole is not advised. Therefore, there is a search for alternative chemotherapy, a top priority for the management of this disease. 3-(biphenyl-4-yl)-3-hydroxyquinuclidine (BPQ-OH) is an inhibitor of the squalene synthase, an enzyme that catalyses sterol biosynthesis. The effects of BPQ-OH have already been described in *Trypanosoma cruzi*, *Leishmania mexicana* and *Candida tropicalis*. Thus, the aim of this study is to analyze the effect of this compound on *T. vaginalis* in comparison to metronidazole effects. Parasites were grown in TYM medium and different concentrations of compounds were added after 24h. The ultrastructural changes of treated cells were observed by scanning and transmission electron microscopy. The cytotoxicity of BPQ-OH on mammalian cells (HeLa, MDCK and Caco-2) was analyzed by MTT procedure. Several antiproliferative experiments demonstrated a dose-dependent effect of BPQ-OH and metronidazole on the growth of *T. vaginalis* with an IC<sub>50</sub> of 46µM and 1,8µM (0,3 µg/ml) after 24h treatment, respectively. Morphological analyses showed that both compounds induced changes in the ultrastructure of the parasite. The most significant alterations observed were (1) membrane blebbing, (2) cell wrinkling, (3) cell clusters and (4) pseudocyst formation. Cytotoxicity assays using mammalian cells showed no effect of the BPQ-OH on the viability of these cells at higher concentrations than IC<sub>50</sub>. The opposite was observed when metronidazole was used at lower concentrations. Ultrastructural analyses demonstrated that both compounds provoked alterations, such as intense vacuolization. In conclusion, the results suggest that BPQ-OH could be, after more tests, an important compound in the development of a novel chemotherapeutic agent against *T. vaginalis*.

This research was supported by AUSU, CNPq, FAPERJ and PRONEX.

**Live cell measurement of cysteine protease activity in malaria parasites – evaluation of calcium dependent proteolysis (calpain) and modulation by cell signaling messengers.**

M. M. Gomes<sup>1</sup>, P. Bagnares<sup>2</sup>, R. L. Cunha<sup>3</sup>, L. Juliano<sup>2</sup>, A. K. Carmona<sup>2</sup>, M. L. Gazarini<sup>1</sup>;

<sup>1</sup>Biosciences, Federal University of São Paulo, Santos, Brazil, <sup>2</sup>Biophysics, Federal University of São Paulo, São Paulo, Brazil, <sup>3</sup>Center of Human and Natural Sciences, UFABC, Santo Andre, Brazil

Malaria is caused by *Plasmodium* parasites and remains one of the most prevalent and persistent diseases. Due to increased resistance to the available antimalarial drugs, a better understanding of the cellular and biochemical pathways of the parasite are fundamental to achieve better strategies to control the disease. Proteolytic activity is an essential process in parasite metabolism during intraerythrocytic cycle. The regulation of *Plasmodium* proteases through cellular signaling mechanisms, such as calcium and phosphorylation, are poorly understood. Using a fluorogenic peptide as substrate, we performed a confocal microscopy analysis to investigate the intracellular proteolysis of *P. falciparum* and *P. chabaudi* (human and rodent malaria). We investigated either the role of calcium and phosphorylation in the modulation of parasites cysteine protease activity. Our data shows a rapid increase in intracellular proteolysis by calcium in the cytosol after release from the ER (89,5% ± 16 n=6) with THG (10µM) addition, which was greatly inhibited (82% ± 1 n=5) by the cysteine protease inhibitor E-64 (10µM) and by the specific calpain I inhibitor (ALLN, 0.5µM) (80,5% ± 4 n=6). *Plasmodium falciparum* calpain is believed to be one of the central mediators of parasite cell cycle and previous work shows a disruption of *Plasmodium* culture by ALLN. Interestingly, inhibition of calmodulin with calmidazolium (10µM), which is a key factor in CaMK activation and calcium homeostasis, resulted a rise in cytosolic calcium followed by a significant increase (107% ± 15 n=5) in the *P. falciparum* intracellular hydrolysis of the Z-Phe-Arg-AMC substrate. However, phosphorylation modulators for PKA (cAMP analogs: 8Br-cAMP, N6-cAMP and PKA inhibitor: H89) and PKC (PKC activator phorbol 12,13-dibutyrate and PKC inhibitor Gö6976) did not promote directly inhibition of cysteine proteases activity however could modulate the Ca<sup>2+</sup> signaling crosstalk like observed with 8Br-cAMP (20µM) and N6-cAMP (20µM) treatments with interruption of Ca<sup>2+</sup>-calmodulin proteolysis modulation. Our results establish a selective protocol for measurement of calcium dependent proteases activity (i.e. calpain) in *Plasmodium* and also verified if phosphorylation pathways (PKA and PKC) have an important modulatory effect in proteolysis. Supported by FAPESP.

**The formation of the cyst wall in *Giardia lamblia*: a missing piece of the puzzle.**

V. Midlej<sup>1,2</sup>, W. de Souza<sup>3,4</sup>, M. Benchimol<sup>2,3</sup>; <sup>1</sup>Programa de Pós-graduação em Ciências

Morfológicas, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil, <sup>2</sup>Laboratório de Ultraestrutura Celular, Universidade Santa Úrsula, Rio de Janeiro, Brazil, <sup>3</sup>Instituto de Biofísica Carlos Chagas Filho- Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil, <sup>4</sup>Instituto Nacional de Metrologia e Qualidade Industrial – Inmetro, Rio de Janeiro, Brazil

*Giardia lamblia* is a parasite protist considered a living fossil because it is placed in the earliest divergence and deepest branch in eukaryote evolution. *Giardia* is a cosmopolitan parasite and the causative agent of giardiasis, which can leads an enormous burden of human diarrheal diseases. Nonetheless, the basic biology of this protist is incompletely understood. The parasite cycle includes two developmental and morphological forms, the trophozoite and the cyst. Trophozoites colonize in the upper small intestine by attaching to the epithelial cells in which they can cause disease. While the trophozoites pass through the small intestine, they produce a rigid extracellular matrix or cyst wall (CW) that protects them from the external environment. The

CW is composed by proteins and carbohydrates. The formation of the resistant extracellular CW begins with intestinal signals, where the cyst wall proteins (CWP) 1, 2 and 3 are synthesized. All of the CWPs are transported via encystation-specific secretory vesicles (ESVs) and are released at the site of CW assembly. Although the presence of carbohydrates in cyst wall has been reported, the detection and origin of the cyst wall carbohydrate-rich moieties is the missing piece of the puzzle. The lack of specialized vesicles that contain large amounts of this carbohydrate raises the question concerning how this material is exported to the CW. In this study, the distribution of the different sugar residues and the origin of the carbohydrate components of the cyst wall were studied using transmission electron microscopy, cytochemistry for carbohydrates and immunocytochemistry. Immunofluorescence microscopy using anti-cyst wall protein 1 (CWP1) and gold- and fluorescent-conjugated lectins, such as WGA and DBA, were also used. Interestingly, encystation carbohydrate-containing vesicles (ECVs), positive for N-acetyl-galactosamine, were found in the encysting cells. The ECVs are distinct from the encystation specific vesicles (ESVs) because: (1) they are electron lucent whereas ESVs are electron dense; (2) they do not react with antibodies against cyst wall proteins; (3) their contents are positive for carbohydrates, whereas ESVs display a negative reaction; and (4) this cell compartment exhibits a positive labeling for DBA lectin indicating the presence of N-acetyl-galactosamine, whereas ESVs are negative. To evaluate if ECVs could be vesicles involved in the endocytic pathway, endocytic markers, such as Lucifer Yellow and Acridine Orange, were used. No co-localization of these markers with ECVs was observed. We suggest that the ECVs may represent a new structure involved in the cyst wall formation. This research was supported by AUSU, CNPq, FAPERJ and PRONEX.

### Acetyl-CoA Carboxylase Links Lipid Metabolism and Immune Evasion in African Trypanosomes.

S. S. Ray<sup>1</sup>, C. A. Mcknight<sup>2</sup>, K. Paul<sup>1</sup>; <sup>1</sup>Department of Genetics and Biochemistry, Clemson University, Clemson, SC, <sup>2</sup>Department of Biological Sciences, Clemson University, Clemson, SC

*Trypanosoma brucei*, a lethal unicellular parasite transmitted by the tsetse fly, infects the bloodstream and cerebrospinal fluid of humans, causing African sleeping sickness. In addition to antigenic variation of its surface glycoprotein coat, *T. brucei* employs a secondary immune evasion tactic: the upregulation of endocytosis to clear lytic cell surface immune complexes, a strategy that likely involves membrane turnover and fatty acid synthesis (FAS). Acetyl-CoA carboxylase (ACC) catalyzes the first committed step of FAS and is a control point for regulating FAS. Previous work showed that a *T. brucei* bloodstream form (BF) ACC RNA interference (RNAi) strain exhibited reduced virulence in mice, but normal growth in culture. We hypothesized that ACC is required for immune evasion via endocytosis upregulation. To test our hypothesis, we examined endocytosis in BF ACC RNAi parasites using fluorescent dextran and transferrin as markers for fluid-phase and receptor-mediated endocytosis, respectively. After 9 days of ACC RNAi, we observed a significant reduction in fluid phase (88%) and receptor-mediated endocytosis (87%). Next, we tested the clearance of surface bound antibodies and found that ACC RNAi caused a significant 26% delay in surface antibody clearance. Lastly, we tested avoidance of complement-mediated lysis. ACC RNAi resulted in a significant 42% increase in complement-mediated lysis. Because upregulation of endocytosis might increase demand for FAS, we examined if ACC is regulated in response to changes in lipid demand, which we modulated by growing the parasites in normal, low, or high lipid media. In BFs, we found no change in ACC phosphorylation, expression, or activity upon growth in low or high lipid media. Also, under these growth conditions, ACC RNAi had similar effects on endocytosis, antibody clearance, and complement-mediated lysis. In contrast, insect form parasites exhibited

a 2-fold increase in ACC protein and enzymatic activity in low lipid media. ACC phosphorylation in insect forms increased 3-fold in high lipid media and decreased by 80% in low lipid media. Based on these data we propose a model whereby ACC is up-regulated in *T. brucei* within the mammalian host to support increased endocytosis and immune evasion, while within the insect host, ACC is regulated in *T. brucei* in response to the environmental lipid supply.

## New Technologies for Cell Biology I

917

### Encapsulation of cytoplasmic extracts in lipid bilayer vesicles for spatially and temporally controlled cellular reconstitutions.

*M. D. Vahey<sup>1</sup>, E. M. Schmid<sup>1</sup>, H. Ann<sup>1</sup>, D. A. Fletcher<sup>1</sup>; <sup>1</sup>Department of Bioengineering, University of California Berkeley, Berkeley, CA*

Cytoplasmic extracts and purified proteins offer a powerful tool for understanding a broad range of cellular behaviors at the molecular level. However, dissecting how these behaviors are coordinated over space and time requires an environment that closely mimics that of the cell, including interactions with and confinement within lipid bilayer membranes. The ability to encapsulate proteins and cytoplasmic extracts within lipid membranes has traditionally presented a significant barrier for cellular reconstitution. Although giant unilamellar vesicles (GUVs) offer a promising platform for addressing this challenge, traditional techniques for forming vesicles by hydration, sonication and electroformation provide limited flexibility for encapsulating protein solutions and may produce highly polydisperse or multilamellar vesicles. To circumvent these challenges, we developed microfluidic jetting, a technique capable of loading functional cytoplasmic extracts and purified protein solutions into GUVs of controlled size, similar to the inverse emulsion technique. Unlike inverse emulsions, however, microfluidic jetting uses liquid impulses expelled from a small (~10 μm) nozzle to deform a planar lipid bilayer into spherical vesicles. Because the solution expelled from the nozzle mixes with the surrounding liquid immediately before being encapsulated inside the GUV, jetting offers excellent control over both the internal composition of vesicles as well as the timing of biochemical reactions. Previously, we demonstrated encapsulation of whole-cell extracts with viscosities up to fourfold higher than water. Here, we extend this technique to encapsulate *E. coli* extracts that are competent for the transcription and translation of plasmid DNA, and show that proteins can be expressed and targeted to the membrane or vesicle lumen depending on the presence or absence of a hydrophobic helix. Because we are able to control the size of the vesicles and the timing of transcription initiation, this technique offers a step towards the reconstitution of dynamic cellular processes and an understanding of how the self-organization of the cell is influenced by spatial constraints.

### A Novel Pulse-Chase Paradigm to Visualize the Trafficking of Transport Vesicles in Neurons.

*S. Al-Bassam<sup>1</sup>, M. Xu<sup>1</sup>, T. J. Wandless<sup>2</sup>, D. B. Arnold<sup>1</sup>; <sup>1</sup>Department of Biology, Program in Molecular and Computational Biology, University of Southern California, Los Angeles, CA, <sup>2</sup>Department of Chemical and Systems Biology, Stanford University, Stanford, CA*

The polarized structure and function of neurons is established and maintained by the differential trafficking of axonal and dendritic proteins. Transmembrane proteins are targeted to dendrites in vesicles that traffic solely within the somatodendritic compartment. How these vesicles are

retained within the somatodendritic domain is unknown. Here, we use a novel pulse-chase system, which allows synchronous release of exogenous transmembrane proteins from the endoplasmic reticulum to follow movements of post-Golgi transport vesicles. Surprisingly, we found that post-Golgi vesicles carrying dendritic proteins were equally likely to enter axons and dendrites. However, once such vesicles entered the axon, they very rarely moved beyond the axon initial segment but instead either halted or reversed direction in an actin and Myosin Va-dependent manner. In contrast, vesicles carrying either an axonal or a nonspecifically localized protein only rarely halted or reversed and instead generally proceeded to the distal axon. Thus, our results are consistent with the axon initial segment behaving as a vesicle filter that mediates the differential trafficking of transport vesicles.

#### **Spontaneous membrane translocating peptides for drug delivery.**

*J. He<sup>1</sup>, K. Hristova<sup>2</sup>, W. Wimley<sup>1</sup>; <sup>1</sup>Biochemistry, Tulane University, New Orleans, LA, <sup>2</sup>Materials Science and Engineering, Johns Hopkins University, Baltimore, MD*

Using orthogonal high-throughput screening and rational combinatorial peptide libraries, we have identified a family of peptides that can spontaneously translocate across membranes without toxicity or membrane permeabilization. The conserved 9-residue translocation motif is mostly hydrophobic, composed of leucine, isoleucine and proline, but also has several conserved arginine or lysine residues and an open terminal amino group. Using confocal fluorescence microscopy, we tested the ability of the selected peptides to transport large polar cargoes across the plasma membranes of living cells. They translocate rapidly, filling the cytoplasm with a uniform fluorescence. Translocation occurs without endocytosis and does not require a cellular energy source. These peptides could be used as delivery vehicles for a variety of polar drugs.

920

#### **Magnosphere™-based Rapid Exosome Isolation for Biomarker Detection.**

*M. George<sup>1</sup>, B. Williams<sup>1</sup>, L. Harjono<sup>1</sup>, M. Miyaji<sup>1,2</sup>, S. Katayose<sup>2</sup>, D. Azorsa<sup>3</sup>, M. Facciotti<sup>4</sup>, K. Henry<sup>1</sup>; <sup>1</sup>Life Sciences, JSR Micro Inc., Sunnyvale, CA, <sup>2</sup>Tsukuba Research Laboratories, JSR Life Sciences Corporation, Tsukuba, Japan, <sup>3</sup>Translational Genomics Research Institute, Scottsdale, AZ, <sup>4</sup>Genome Center, UC Davis, Davis, CA*

Exosomes play an increasingly important role in autoimmune diseases, cancer, stress response, and metabolic disorders. Exosomal cargo may include several biomarkers, such as membrane and soluble proteins, mRNAs, long non-coding RNAs and miRNAs. Current exosomal isolation methods are tedious and laborious. Additionally, some of these methods can indiscriminately precipitate exosomes along with other biological moieties including free circulating proteins or nucleic acids. To address the challenges of exosomal isolation, we developed a magnetic bead based isolation method. Magnosphere™ magnetic beads, exclusively manufactured by JSR Corporation, are functionalized for immunoaffinity isolation of exosomes using a proprietary combination of antibodies. Confirmation of exosomal isolation from cell culture is visualized by western blot of the soluble exosomal biomarker, HSC70 along with other exosomal proteins. Additionally, a selected few miRNAs (hsa-Let 7a, hsa-miR-21, hsa-miR-222 and hsa-miR-223) are analyzed for further verification. To evaluate non-specific binding, we introduced either a random synthetic small RNA or non-exosomal peptides into the samples. Our studies reveal successful exosomal isolation by immunoaffinity with functionalized Magnosphere beads. Furthermore, functionalized Magnosphere beads facilitate

rapid exosomal isolation from cell culture or biological fluids with high affinity and low non-specificity.

921

**Endophilin B is associated with caveolin containing vesicles in living cells.**

*J. Li<sup>1</sup>, B. Barylko<sup>2</sup>, J. D. Mueller<sup>1</sup>, J. P. Albanes<sup>2</sup>, Y. Chen<sup>1</sup>; <sup>1</sup>University of Minnesota, Minneapolis, MN, <sup>2</sup>UT Southwestern Medical Center, Dallas, TX*

Endophilins A and B comprise a family of proteins that are involved in membrane vesiculation. Both forms of endophilin contain two well-characterized domains, an amino-terminal N-BAR (Bin-Amphiphysin-Rvs) domain and a carboxy-terminal SH3 (Src-homology 3) domain. The N-BAR domain is required for binding to the lipid bilayer and the subsequent induction and stabilization of membrane curvature, while the SH3 domain interacts with proteins that contain proline-rich (PXXP) motifs. Oligomerization of endophilin A has been characterized in cells and shown to be a very tight dimer by fluorescence fluctuation spectroscopy. Here, we examine the oligomerization/multimerization of endophilin B. To our surprise, endophilin B displays much higher multimerization than endophilin A. We demonstrate that the multimerization of endophilin B is primarily controlled by its BAR domain and by its association with vesicular membranes. The endophilin BAR domain alone constitutively associates with vesicles, whereas vesicle binding of full-length endophilin B is very sensitive to dynamin 2 activity, as it is strongly inhibited by expression of a dominant negative form of the enzyme, dynamin 2-K44A. Furthermore, we directly detect that endophilin B associates with caveolin1- but not clathrin-containing vesicles using dual-color heterospecies partition analysis. This analysis allows us to unequivocally demonstrate that endophilin B engages in caveolin-dependent but clathrin-independent endocytic pathways. This work is supported by the National Institutes of Health (R01 GM64589), and the National Science Foundation (PHY-0346782).

**Characterization of Foodborne Escherichia coli Profiles.**

*E. M. Arrey-Mbi<sup>1</sup>; <sup>1</sup>Natural Sciences, Clayton State University, Morrow, GA*

The cellular fatty acid profiles of eight strains of Bacillus, Staphylococcus, and Enterobacteriaceae (Escherichia coli, and Salmonella) were analyzed by comprehensive two-dimensional gas chromatography/time-of-flight mass spectrometry (GCxGC/TOF MS). A novel template method was developed to standardize the raw GCxGC retention data through the use of a chemical indexing mixture. Analyte retention coordinates were normalized in the primary dimension with respect to a series of n-alkanes (Kovats index) and in the secondary dimension with respect to a series of aromatic hydrocarbons (Lee index). Fatty acid profiles extracted from the templates were compared by multidimensional scaling (MDS) and principal component analysis (PCA). Differences in the profiles of Gram positive and Gram negative bacteria were observed, and a series of heterogeneous mixtures comprised of different fractions (containing one Gram positive and one Gram negative bacteria strains) were also distinguished from their homogeneous constituents.

**In situ direct live single-cell exhaustive molecular analysis by video-mass spectrometry.**

*H. Mizuno<sup>1</sup>, S. Date<sup>2</sup>, N. Tsuyama<sup>1</sup>, T. Masujima<sup>1,2</sup>; <sup>1</sup>Grad. Sch. Biomedical Sciences, Hiroshima University, Hiroshima, Japan, <sup>2</sup>Quantitative Biology Center, RIKEN, Osaka, Japan*

Direct and quick exhaustive molecular detection and its site or stage specific molecular picking have been succeeded for a live single cell which is under observation of a video-microscope.

Method: We called this method as "Live single-cell video mass spectrometry" in which a live cell was directly sucked its contents by a nano-spray tip under the scope and the content was introduced into mass spec. directly after adding a ionization solven to the tip. It takes less than 10 minutes. Mammalian cell lines of RBL-2H3 and Hep G2 were used for single organelle level molecular tracing and for single cell drug metabolism, respectively. For plant cells, radish sprouts was used for detecting light responding molecular extraction.

Results: We have succeeded to detect hundreds to thousand molecular peaks from a single cell and site specific or stage specific molecular peaks have been extracted by t-test or principal component analysis. In a granule of an RBL-2H3, not only Histamine but also many granule specific molecules were found. Using stable isotope labeled Histidine, the kinetic aspect of this biosynthesis or metabolism in a granule and cytosol in a single cell were monitored directly to check the dynamic metabolic pathways. Drug metabolism can be monitored only using a single Hep G2 cells and found the drug metabolites can only found in cytosol. Incorporations of the drug molecules into a vesicle or nucleus were also monitored directly within 10 minutes.

Conclusion: Since this method is so direct, speedy and versatile, it seems to open new era of bioanalysis for cell biology.

924

**Making cell arrays out of suspended cells by open channel nanoprinting.**

*A. V. Didenko<sup>1</sup>, B. Zhang<sup>1</sup>; <sup>1</sup>Vivid Technologies, Inc., Houston, TX*

When working with cell suspensions it is frequently required that individual cells are observed under a microscope in standard conditions. This permits making meaningful comparisons of cellular morphology and intensity of labeling. For that, the cells are often centrifuged onto the slides from suspensions. However this tends to produce poor images, can damage the cells, and affects their morphology. These drawbacks are more pronounced in cell suspensions composed of several cell types, such as those obtained in blood tests.

To overcome these limitations, we have developed a new approach which permits making orderly and uniform cell arrays out of suspended cells in a matter of seconds. The approach is an application of nanotechnology to cell biology. It does not require centrifugation. Instead, it uses microscope slides patterned by the open channel Nano eNabler system, so that they can trap cells directly from cell suspensions. The approach creates arrays of cells firmly positioned on a microscope slide. The cells are undamaged and are presented in a uniform, orderly fashion required for their quantitative evaluations.

The approach is useful in comparing effects of various interventions and has general applicability in cell biology and in cell imaging.

925

### Applications of the microfluidic cell culture system with on-chip CO<sub>2</sub> incubation for cell biology.

A. Takano<sup>1</sup>, S. Inomata<sup>1</sup>, T. Ogawa<sup>1</sup>, N. Matsunaga<sup>1</sup>, N. Futai<sup>1</sup>, M. Tanaka<sup>1</sup>; <sup>1</sup>Tokyo Denki University, Saitama, Japan

We have developed a microfluidic cell culture system in which we can cultivate and monitor several mammalian cells continuously for a long-term period. Our culture system does not require conventional huge cell culture equipment such as CO<sub>2</sub> incubator, carbon dioxide bottle and gas-regulators. The system is a microscope-slide-sized chip which is capable to diffuse CO<sub>2</sub> through a gas-permeable poly (dimethylsiloxane) (PDMS) wall of nested medium reservoir which is surrounded a tiny water-jacket reservoir containing sodium bicarbonate and sodium carbonate buffer. This developed CO<sub>2</sub> incubation system, consequently, could maintain physiological conditions of cell culture medium without any external gas chamber or gas supply. The entire microfluidic cell culture system has been set up to pocket sized equipment with a temperature and pumping control device [1]. The proposed chip consists of a PDMS-microfluidic chip and flip-mounted on a microscope slide that contains a nested pair of cell culture medium reservoir and water-jacket insulated by a gas-permeable PDMS wall. By using 0.8 M sodium bicarbonate with 65mM sodium carbonate as the water-jacket and placing on a 37°C surface, the chip maintained osmolality shift and the partial CO<sub>2</sub> pressure (pCO<sub>2</sub>) in the medium reservoir stabilized at least few weeks. Since microfluidics is effective approach to manipulate small amount of fluid, it could minimize the consumption of required cells, reagents, amount of cell culture medium. Therefore, microfluidics provides many advantages for the experimental approach of cell biology, especially single cell analysis, such as patch clamp analysis, axon guidance and signal patch on the cell surface. On the other hand, our long-term cell culture systems available for cell-based biosensor. In fact, we integrate the microfluidic cell culture system that has an inline culture well with a shear horizontal surface acoustic wave (SH-SAW) as for cell-based biosensor could be used to assay cell-cell and/or cell-surface interaction. In addition to the biosensor, we are trying to improve the cell culture system to promote the differentiation of embryonic stem cells (ES cells).

[1] A. Takano, M. Tanaka, and N. Futai, On-chip CO<sub>2</sub> incubation for pocket-sized microfluidic cell culture, *Microfluidics and Nanofluidics*, **12**, 907-915 (2012)

### Non-invasive/destructive single cell purification method for re-cultivation of functionally identified specific cells using spot digestion of double alginate sol layers on a multi-electrode array chip.

H. Terazono<sup>1</sup>, H. Kim<sup>1</sup>, A. Hattori<sup>2</sup>, F. Nomura<sup>2</sup>, T. Kaneko<sup>2</sup>, K. Yasuda<sup>1,2</sup>; <sup>1</sup>On-chip Cellomics Project, Kanagawa Academy of Science and Technology, Kanagawa, Japan, <sup>2</sup>Biomedical Information, Tokyo Medical and Dental University Tokyo Medical and Dental University, Tokyo, Japan

#### 1. Objective

We have studied the meaning of community effect of cell networks using re-constructive approach from single cells such as creating artificial cell networks using individual cells set on a micropatterned biochip as a minimum functional unit. Hence, we have developed several techniques for studying above cell-to-cell communications, such as a non-destructive cell sorting method using digestive DNA aptamer equipped with an imaging flow cell sorting system, and a constructive cell network patterning method using stepwise spot heating with focused infrared laser on a thin agarose layer set on a multi-electrode action potential recording system for creating desired microchamber patterns even during cultivation. Adding to the developed

non-invasive/destructive purification of target cells using DNA aptamer, which identified target cells using the expressed surface proteins, we need to identify and purify the target cells from the viewpoint of their functions. To overcome this problem, a non-destructive method of collecting cultured cells after identifying their in situ functional characteristics has been developed using thin alginate sheet on a culture dish and multi-electrode array chip.

## 2. Methods

Primary hippocampal neurons, or beating human embryonic stem (hES) cell-derived cardiomyocytes are cultivated on an alginate layer in a culture dish or multi-electrode array dish, following released cells at the single-cell level by spot application of a calcium chelate buffer that locally melts the alginate layer.

## 3. Results

Primary hippocampal neurons, and beating human embryonic stem (hES) cell-derived cardiomyocytes cultivated on an alginate layer were first measured their field potential waveforms, and the target cells having particular field potential profile were successfully released from the substrate from single cell level, and collected using a micropipette. Then the collected target cells were re-cultivated on the other biochip from single cell level successfully maintaining their physiological function and their spatial patterns such as neurite patterns.

## 4. Discussion

We have developed a new approach of the non-invasive/destructive functional cell identification and purification method. This method can be expanded for further applications for phenotypic identification and re-cultivation combining with imaging technologies such as cell network pattern, and cell cycle state, which are not possible with commercialized fluorescence-activated cell sorting (FACS) methods.

927

## Microfluidic deformability cytometry is a high-throughput screening tool for stem cell pluripotency.

*M. Masaeli<sup>1,2</sup>, H. T. Tse<sup>1,2</sup>, D. R. Gossett<sup>1,2</sup>, A. T. Clark<sup>3</sup>, D. Di Carlo<sup>2</sup>; <sup>1</sup>Bioengineering, University of California, Los Angeles, Los Angeles, CA, <sup>2</sup>California NanoSystems Institute, Los Angeles, CA, <sup>3</sup>Department of Molecular, Cell and Developmental Biology, University of California, Los Angeles, Los Angeles, CA*

**Introduction:** Due to high risks of genetic and phenotypic instability associated with cell culture, quality control strategies to ensure proper and consistent human embryonic stem cells (hESC) functionality for potential use in regenerative medicine are vitally important. The expression of certain markers usually assessed by flow cytometry and the ability to form embryoid bodies and teratomas in mice are two main categories of assays used for quality control. In addition to variability of these tests between different labs and their limited robustness, these assays are highly costly and labor-intensive. Recent studies using atomic force microscopy (AFM) and micropipette aspiration have shown that cell mechanical properties could be a promising biomarker of pluripotency. However, AFM and other recent techniques are manual approaches severely limited in throughput and are not suitable for cell screening. Here we introduce microfluidic deformability cytometry as a screening tool for stem cell pluripotency that addresses the need for high throughput.

**Methods:** The microfluidic device was designed to apply uniform stretching forces to cells using an extensional flow. The positioned cells arrive one at a time at the extensional flow while they are continuously imaged using high-speed microscopic imaging and cell size and deformability are extracted by image analysis. Individual cells are plotted based on these parameters as points on color density plots.

**Results:** The deformability of three hESC cell lines was analyzed before and after induction to differentiation for up to 12 days. The density plots captured from the deformability cytometer

show that while the pluripotent cells exhibit a deformable, small diameter profile, they switch to a larger, less deformable state as they lose their pluripotency. We assessed pluripotency of live cells using conventional pluripotency markers, which consistently show down regulation of these markers following differentiation as expected. The high correlation between our mechanical measure and pluripotency markers ( $\geq 0.9$ , for the expression of Oct4 and Nanog) indicates the potential of deformability cytometry as a label-free assay of pluripotency.

Conclusions: The high information content (multiparameter mechanophenotype), low cost (elimination of antibody use with reduced sample preparation), and high throughput ( $> 1000$  cells/sec) of deformability cytometry technology provides further evidence for the feasibility of using deformability as a biomarker for routine screening of ESC quality and differentiation for research and clinical use.

928

**Light-induced inhibition of Src via LOV domain insertion into a conserved portion of the catalytic domain.**

*P-H. Chu<sup>1</sup>, A. V. Karginov<sup>1</sup>, D. G. Shirvanyants<sup>2</sup>, N. V. Dokholyan<sup>2</sup>, K. M. Hahn<sup>1</sup>; <sup>1</sup>Department of Pharmacology, University of North Carolina-Chapel Hill, Chapel Hill, NC, <sup>2</sup>Department of Biochemistry, University of North Carolina-Chapel Hill, Chapel Hill, NC*

Src is a non-receptor tyrosine kinase that couples with cellular receptors to participate in a diverse spectrum of signaling pathways, and has been implicated in numerous types of cancer. Src activation leads to increased invasiveness, increased motility and decreased cell adhesion in tumor cells. The interactions of Src with upstream activators and downstream targets is dependent on the subcellular localization and kinetics of activation, necessitating the use of live cell techniques to understand Src signaling. We demonstrate here a new genetically encoded approach, potentially broadly applicable to kinases, for light-induced inhibition of Src. The light oxygen voltage (LOV) domain of *Avena Sativa* phototropin undergoes light-induced conformational changes upon irradiation at wavelengths between 400 and 500 nm. We have identified a site in Src, highly conserved in kinases, where insertion of the LOV domain minimally perturbs Src in the dark, but inhibits catalytic activity upon irradiation. Molecular dynamics studies indicate a mechanism in which the unwinding of the LOV  $\alpha$  helix results in narrowing of the ATP binding site. The activation loop and beta-sheet move closer to each other, emulating the structure of the inactive state. Inhibiting Src activity through irradiation decreases migration rates in wound healing assays and alters protrusion behaviors. Cells transformed by overexpression of LOV-Src revert to a normal phenotype upon irradiation. Structural studies and insertion of other engineered folds into the Src site we have identified indicates that the same strategy can be applied to other kinases.

929

**Precise control of signal transduction in living cells by light.**

*K. Zhang<sup>1</sup>, L. Duan<sup>1</sup>, Z. Lin<sup>2</sup>, K. Sung<sup>3</sup>, Y. Osakada<sup>1</sup>, B. Cui<sup>1</sup>; <sup>1</sup>Department of Chemistry, Stanford University, Stanford, CA, <sup>2</sup>Department of Applied Physics, Stanford University, Stanford, CA, <sup>3</sup>Biophysics Program, Stanford University, Stanford, CA*

With a limited set of signaling pathways, cells exploit time control in order to ensure proper conversion of specific environmental stimuli into distinct cellular output. However, there are very limited means to control the temporal dimension of intracellular pathways with high accuracy. Here, we report a light-gated protein-protein interaction system that precisely regulates the activation and inactivation of the mitogen-activated protein kinase (MAPK) signaling pathway. We show that sustained MAPK activation through continuous light stimulation is sufficient to

induce significant neurite outgrowth in PC12 cells in the absence of nerve growth factor. Light-gated activation leads to an interesting discovery that MAPK alone is sufficient to account for neurite elongation, it only partially contributes to the full development of sodium channels in PC12 cells. The strategy of using light-gated protein interaction shows a great promise in dissecting detailed mechanisms of signal transduction in cells.

930

**Real-time light-driven temporal control of gene expression and protein concentration in *S. cerevisiae*.**

J. Melendez<sup>1</sup>, B. Oakes<sup>1</sup>, M. Noyes<sup>1</sup>, M. N. McClean<sup>1</sup>; <sup>1</sup>Lewis-Sigler Institute for Integrative Genomics, Princeton, NJ

Studies of signaling and transcriptional networks are limited by the tools currently available to systematically perturb and interrogate such networks. Standard genetic tools such as deletion, overexpression, and mutation are effective for identifying network components but less suitable for understanding kinetics and identifying feedback interactions. Here we describe the development of a system for real-time light-inducible control of gene expression in *S. cerevisiae*. Controlling transcription enables fine-tuned temporal modulation of protein levels useful for interrogating genetic networks.

Light-induction is achieved through fusion of the *Arabidopsis thaliana* proteins cryptochrome 2 (CRY2) and its interaction partner (CIB1) to appropriate DNA-binding and activation domains (1). CRY2 and CIB1 naturally dimerize on blue-light exposure, bringing the DNA-binding domain and the activation domain together to drive expression of the desired gene. We characterize the kinetics, off-target effects, and dose-response of this induction system and develop improved fusion proteins to allow for specific and controllable induction.

To implement real-time control we developed an integrated robotics system. Cells from a steady-state chemostat culture are continuously imaged for fluorescence. Information from this imaging is used to adjust the inducing light levels to vary the concentration of the fluorescently-tagged protein. By controlling the light-intensity, pulse frequency, and pulse duration we are able to maintain a steady-state protein concentration of our choosing. By modulating the inducing light we can produce dynamic protein level perturbations such as pulses and oscillations. This tool allows us to flexibly perturb protein levels to interrogate the kinetics and structure of genetic networks.

**Selective Differentiation of Human Neural Stem Cells via Spatial Exposure Control.**

C. Chen<sup>1</sup>, B. Miller<sup>1</sup>, P. Hung<sup>1</sup>; <sup>1</sup>R&D, CellASIC/EMD Millipore, Hayward, CA

Modeling *in vitro* neuronal culture system has been a challenging task because the model requires multiple cell types working together in order to approximate physiologic microenvironment. Co-culture has provided a method to look into various cell-cell interactions; however, the inability to precisely control the distribution of different cell types as well as the difficulty in spatially controlling the cellular placement significantly reduce the robustness and repeatability of co-culture experiments. Here we developed a method to create spatially distinctive populations of the neuronal cells, in this case, neurons and astrocytes, for studying neuronal cell-cell communications *in vitro*. Using a commercially available microfluidic platform, two extracellular matrices were selectively patterned on the top and bottom half of a circular

microchamber (3mm in diameter and 0.1mm in height) at the same time using the hydrodynamic focusing effect at micro-scale. We also used fluorescent green dye FITC and red dye Texas red with similar viscosity to validate and optimize the dual ECM coating profiles in the chamber. H9-derived human neural stem cells were then seeded into the chamber. After cells stabilized in the microchamber for 24 hours, the same hydrodynamic principle was applied again to allow two differentiation reagents to continuously perfuse through the top and the bottom half of the chamber, respectively.

Before the differentiation reagents were introduced, the cells were immunostained for the pluripotency markers Nestin and Sox2, as well as the astrocyte marker GFAP and neuron marker MAP2. After the differentiation reagents were applied to the neural stem cells, we continuously monitored the cellular morphology at the top and the bottom part of the microchamber for two weeks. At the end, the cells were again stained with the same set of the neural markers. Using Cell Profiler software for image analysis, we were able to obtain information on both the proliferation and the differentiation of the two spatially distinctive populations. In this study, we have created a novel system to distinctly differentiate the human hippocampal stem cells into two different types of neural cells in one culture chamber. This novel method has the potential to create co-culture methods for the multiple neural cell types through selective ECM patterning as well as spatially controlled differentiation reagent introduction.

**Rapid Feeder-Free Xeno-Free iPSC Generation using mRNA.**

*L. A. Warren<sup>1</sup>, Y. Ni<sup>1,2</sup>, J. Wang<sup>1</sup>, X. Guo<sup>2</sup>; <sup>1</sup>Allele Biotechnology, San Diego, CA, <sup>2</sup>Nanjing Maternity and Child Medical Institute, Nanjing, China*

“Footprint-free” methods for reprogramming somatic cells to pluripotency are essential if iPSC technology is to advance to the clinic. Currently, protocols based on non-integrating episomal DNA, Sendai virus, and messenger RNA vectors can meet the footprint-free requirement while still producing iPSCs with practical levels of efficiency. Of these methods, only the mRNA approach obviates screening and cleanup of derived iPSCs to eliminate risks associated with residual traces of the reprogramming vector. The main drawback to the mRNA method is the increased hands-on time needed to perform reprogramming, which arises from the need to resupply the short-lived mRNA vector every day for ~2 weeks in order to fully activate endogenous pluripotency circuitry. We sought to address this problem by increasing the potency of the reprogramming cocktail, and were able to show that use of a six-factor cocktail incorporating M3O – an engineered variant of Oct4 – along with Sox2, Klf4, c-Myc, Lin28 and Nanog significantly accelerates reprogramming relative to the established OSKM+Lin28 mRNA regimen. We leveraged these kinetic gains to define a xeno-free, feeder-free protocol for rapid reprogramming of human fibroblasts to pluripotency. The new protocol achieves efficient reprogramming with 9 days of transfection, and the transfection process itself has been streamlined so that RNA/vehicle cocktails can be stored for days and applied by simple supplementation of culture media prior to routine media changes. This novel methodology is readily applicable to high-throughput iPSC derivation and circumvents the inconvenience and uncertainty attending the main alternative approaches to footprint-free reprogramming.

### Combinatorial Application of Multiple MicroRNAs to Induce Non-Integrating Cell Fate Conversion on Microfluidic Chips.

N. Li<sup>1</sup>, B. Fowler<sup>1</sup>, A. Leyrat<sup>1</sup>, L. Warren<sup>1</sup>, J. Wang<sup>1</sup>, P. Chen<sup>1</sup>, J. Shuga<sup>1</sup>, D. Wang<sup>1</sup>, S. Weaver<sup>1</sup>, L. Szpankowski<sup>1</sup>, D. Toppani<sup>1</sup>, M. Norris<sup>1</sup>, M. Thu<sup>1</sup>, M. Wong<sup>1</sup>, B. Clerkson<sup>1</sup>, R. Lebofsky<sup>1</sup>, J. West<sup>1</sup>, A. May<sup>1</sup>, M. Unger<sup>1</sup>, R. C. Jones<sup>1</sup>; <sup>1</sup>Fluidigm Corporation, South San Francisco, CA

Since *in vivo* cell fate determination and cell-cell signaling involve multiple genes, extracellular factors, and intracellular signaling pathways, finding the right combinations for *in vitro* cell culture conditions is invaluable for studying fundamental cell biology questions and for cell-based therapies. However, using traditional cell culture systems, multi-factorial experiments are often laborious and difficult to reproduce. Microfluidic technologies allow for precise control of microenvironment of cells, facilitate studies of multi-factorial combinations, and enable development of robust, reproducible and chemically defined cell culture systems. We have designed and fabricated a prototype microfluidic chip and an automated instrument that can culture cells on chip for extended period of time and deliver multiple combinations of different factors to cells. Each chip includes 32 cell culture microchambers and 16 reagent inlets. Reagents can be automatically multiplexed to desired combinations and ratios at various pre-defined time points. Cells can also be harvested from the chip for continued off-chip culturing, single-cell genomic analysis, and/or functional assays. Culturing human BJ fibroblasts on chip, we have developed a safe non-integrating method for direct reprogramming of fibroblasts to neurons by dosing cells with combinations of synthetic microRNA mimics. The identities of cells were confirmed with immunostaining and gene expression profiling. This non-integrating approach of miRNA administration generated neurons with high efficiency and cell viability. The results were consistent with published reports and were confirmed in large well-dish format. In summary, the prototype automated microfluidic system reported here provides the potential to study and screen the precise combinatorial effects of multiple factors on cell culture maintenance, reprogramming and differentiation, hence could be a valuable tool for the cell biology research community.

### Transdifferentiation of Cells into Brown Adipose Tissue.

S. R. Taylor<sup>1</sup>, M. G. Markesbery<sup>1</sup>, P. A. Harding<sup>1</sup>; <sup>1</sup>Zoology, Miami University, Oxford, OH

**Objective.** Recently, investigators have focused on brown fat as a tool to combat obesity, which according to the Centers for Disease Control, more than one-third of Americans are obese and projections speculate 42% of Americans will be considered obese by the year 2030. The goal of this study is to transdifferentiate cells into a brown adipose tissue (BAT) phenotype by co-expression of heparin-binding EGF-like growth factor (HB-EGF) and a disintegrin and metalloprotease (ADAM) 12S. **Methods.** HB-EGF and ADAM 12S cDNAs were cloned, sequenced, and stably expressed in mammalian cells including mouse fibroblasts and human epidermoid carcinoma cells (A431) resulting in formation of oil droplets as evidenced by positive Oil Red O staining. In order determine whether the Oil Red O positive cells are BAT or white adipose tissue (WAT), we employed a quantitative real-time RT-PCR approach for known genes involved in the WAT pathway including peroxisome proliferator-activated receptor gamma (PPAR $\gamma$ ), CCAAT/enhancer binding protein alpha (C/EBP $\alpha$ ), and serine-threonine protein kinase (AKT-1) as well as genes involved in the BAT pathway including PR domain 16 (PRDM16) transcriptional coregulator, peroxisome proliferator-activated receptor gamma coactivator 1 alpha (PGC-1 $\alpha$ ) and uncoupling protein 1 (UCP-1). No significant differences in PPAR $\gamma$ , C/EBP $\alpha$ , or AKT-1 mRNA expression levels were present in all stable cell lines

examined, but were up-regulated in WAT 13-, 400- and 3.5-fold, respectively. PRDM16 mRNA levels were significantly up-regulated 12-fold in HB-EGF/ADAM 12S co-expressing cells and 138-fold in BAT compared to mouse fibroblasts, mock-transfected, HB-EGF, and ADAM 12S cell lines. PGC-1 $\alpha$  mRNA was significantly up-regulated 38-fold in ADAM 12S/HB-EGF co-expressing cells and 100-fold in BAT compared to other cell lines. Finally, UCP-1 mRNA was significantly up-regulated 5-fold and 7,322-fold in ADAM 12S/ HB-EGF co-expressing cells and BAT, respectively. In order to support these results, human adipogenesis PCR arrays were performed using RNA from A431 cells stably transfected with ADAM 12S and HB-EGF and resulted in increased expression of PGC-1 $\alpha$  (30-fold), Kruppel like factor 3 (Klf3) (5-fold), Klf4 (2-fold), and fibroblast growth factor (FGF-2) (4-fold) compared to mock transfected A431 cells. Further supportive of BAT transdifferentiation was down-regulation of the WAT marker genes C\EBP $\alpha$ , Lamin A/C (LMNA), and solute carrier family 2 (GLUT4) (-5, -2, and -2.7 -fold, respectively). In order to demonstrate BAT transdifferentiation in vivo, recombinant adenovirus vectors directing the expression of ADAM 12S and HB-EGF were engineered and used to co-infect A431 cells resulting in positive Oil Red O staining and upregulation of PGC-1 $\alpha$  (15.6-fold) and FGF-2 (4-fold) and down-regulation of C\EBP $\alpha$  and LMNA (-10.5 and -7.6 -fold respectively). **Conclusions.** Co-expression of ADAM 12S and HB-EGF stimulate adipogenesis utilizing the canonical BAT pathway while suppressing genes involved in the WAT pathway. The adenoviral vectors directing ADAM 12S and HB-EGF will be useful tools to demonstrate BAT synthesis in vivo.

#### Induced pluripotent cells derived from peripheral lymphocytes can be differentiated into functional neural cells.

T. Matsumoto<sup>1,2</sup>, N. Kuzumaki<sup>1</sup>, T. Ando<sup>3</sup>, R. Yamaguchi<sup>4</sup>, T. Ando<sup>1</sup>, H. Kurosawa<sup>3</sup>, N. Fusaki<sup>5</sup>, M. Nakanishi<sup>6</sup>, M. Ohyama<sup>7</sup>, M. Amagai<sup>7</sup>, W. Akamatsu<sup>1</sup>, H. Okano<sup>1</sup>; <sup>1</sup>Physiology, Keio university, Shinjuku-ku, Japan, <sup>2</sup>Frontier reserch labs, Ajinomoto co.,inc, Kawasaki city, Japan, <sup>3</sup>Human Environment Medical Engineering, University of Yamanashi (Japan), Yamanashi, Japan, <sup>4</sup>Dainippon Sumitomo Pharma Co., Ltd, Osaka, Japan, <sup>5</sup>Dnavec corporation, Ibaraki, Japan, <sup>6</sup>Research Center for Stem Cell Engineering, National Institute of Advanced Industrial Science and Technology, Tsukuba, Japan, <sup>7</sup>dermatology, Keio university, Shinjuku-ku, Japan

Human induced pluripotent stem cells (hiPSCs) derived from somatic cells of patients, are recognized as promising source for regenerative medicine and useful tool for disease modeling. Currently, most of hiPS clones are generated from dermal skin fibroblasts by inducing reprogramming factors. However, there are undeniable invasive risks of bleeding, infection, and scarring in skin biopsies. Although T-cell derived iPSCs (TiPS) (Seki et al., Cell Stem Cell, 2010) are perhaps the ideal cell source for patient-specific iPSCs due to the ease of obtaining patient samples, recent studies have indicated that iPSCs retain an epigenetic memory relating to their cell of origin that restricts their differentiation potential.

To investigate whether TiPS have ability to generate functional neural cells as well as fibroblast-derived iPSCs and can be used for the study of neural diseases, we established both TiPS and fibroblast-derived iPSCs from the same patient by various method including Sendai virus (SeV), retrovirus and episomal vectors. Although microarray and principal component analysis revealed that global gene expression of TiPS was significantly distinct from that of fibroblast-derived iPSCs from the same donor, all TiPS clones were able to differentiate three germ layers as well as fibroblast-derived iPSCs. While the efficiency of differentiation into neural lineage is significantly lower in TiPS, neural cells induced from TiPS were functionally similar to that from fibroblast-derived iPSCs. Therefore, we concluded that TiPS can be used as tools to study neural diseases.

**Profiles of genomic instability in high-carcinogenicity genetic disease cell lines collection by high-resolution array-based comparative genomic hybridization (aCGH).**

A. Kohara<sup>1</sup>, N. Hirayama<sup>1</sup>, M. Ozawa<sup>1</sup>, A. Ohtani<sup>1</sup>, N. Matsunaga<sup>1</sup>, M. Lemura<sup>1</sup>, S. Shioda<sup>1</sup>;

<sup>1</sup>National Institute of Biomedical Innovation, Osaka, Japan

**Introduction:** Genomic instability has been proposed to play an important role in cancer by accelerating the accumulation of genetic changes responsible for cancer cell evolution. Genomic aberrations in the form of subchromosomal DNA copy number changes including c-myc amplification are a hallmark of cell line. The goal of the present study was to analyze such aberrations in high-carcinogenicity genetic disease cell lines for scientific research at high resolution.

**Methods:** The patient origin cell lines of xeroderma pigmentosum (XP) and fanconi anemia (FA) was used for analysis. We employed high-resolution array comparative genomic hybridization with Affymetrix GeneChip SNP6.0 to analyze genomic aberrations in genetic disease cell lines. And also numerical chromosomal aberrations and rearrangements were analyzed by multicolor fluorescence in situ hybridization (mFISH) and G-banding.

**Results:** The detailed chromosome analysis result of XP group and FA group became clear by aCGH. The chromosomal region which changes in common was found out by comparing XP cell lines with FA cell lines mutually. The partial loss of chromosome 12 and 17 were non-random and was detected by analysis of microsatellites and single-nucleotide polymorphism (SNP)-based loss of heterozygosity (LOH). Also, DNA copy number aberrations identified in XP and FA cell lines. The relation of these aberration and clinical information is just going to be interesting very much.

**Conclusion:** High resolution CGH analysis of high-carcinogenicity genetic disease cell lines reveals powerful tool for detection of chromosomal aberrations and gene amplification. In the quality control and characterization of cell lines, the chromosome aberration is an important problem, and CGH might be useful a convenient and efficient screening method. Then, precise gene amplification analysis is important to elucidate a mechanism for oncogene amplifications for better understanding of tumor initiation or progression.

**Multiplexed High Content Hepatotoxicity Assays using Induced Pluripotent Stem Cell Derived Hepatocytes.**

O. Sirenko<sup>1</sup>, J. Hesley<sup>1</sup>, S. Einhorn<sup>2</sup>, V. Ott<sup>2</sup>, E. F. Cromwell<sup>1</sup>; <sup>1</sup>Molecular Devices, LLC, Sunnyvale, CA, <sup>2</sup>Cellular Dynamics International, Madison, WI

Hepatotoxicity is one of the main safety concerns in drug development. Highly predictive in vitro assays suitable for safety and efficacy testing are extremely important for improving the drug development process and reducing drug attrition. Accordingly, there is great interest in using stem cells as tools for screening compounds during early drug development. Human hepatocytes derived from stem cells can greatly accelerate the development of new chemical entities and improve drug safety by offering more clinically relevant cell-based models than those presently available. Such cells can express appropriate hepatocyte markers and demonstrate intrinsic hepatocyte functions similar to primary cells. We demonstrate several models for assessing general and specific hepatotoxicity that are well-suited for automated assays. First, multi-parametric image analysis using an automated microscope is used to monitor changes in cell viability (Calcein AM), nuclear shape (Hoechst), and mitochondria potential (Mitotracker Orange) associated with different types of toxicity. A number of known hepatotoxic compounds were evaluated using these assays and IC50 values determined. Other assay models targeting specific mechanisms of hepatotoxicity will also be presented.

Mitochondrial depolarization is an early signal for hypoxic damage or oxidative stress. Mitochondria membrane potential was monitored with the mitochondria active dye JC-10 on the ImageXpress Micro system. This assay can be used either as an end-point or live-cell real time assay. We evaluated the effect of apigenin, CCCP, and several other compounds and determined IC50 values with this assay. Phospholipidosis is a lysosomal storage disorder characterized by the excess accumulation of phospholipids in tissues. The increase in undigested materials results in the abnormal accumulation of multi-lamellar bodies (myeloid bodies) in tissues. Phospholipidolysis was detected using LipidTOX reagent with an automated microscope system. A dramatic increase in phospholipid levels was observed in response to treatment with Amiodarone, Cyclosporin A, Propranolol, and Chloroquine and IC50 values were determined. We have also monitored modulation of the autophagy pathway in hepatocytes by high content imaging using Cyto-ID dye. In disease, autophagy may function as a survival mechanism by removing damaged organelles and toxic metabolites to maintain viability during periods of stress. We have characterized several compounds that affect autophagy in hepatocytes, including chloroquine verapamil, and rapamycin. The results demonstrate that method has potentially significant value for compound screening and early safety evaluation in drug development process.

**Predictive Assays for High Throughput Assessment of Cardiac Toxicity and Drug Safety.**

*O. Sirenko<sup>1</sup>, C. Crittenden<sup>1</sup>, E. Cromwell<sup>1</sup>; <sup>1</sup>Molecular Devices, Sunnyvale, CA*

Assessing cardiotoxicity is important in the early stages of drug discovery to enable elimination of potentially toxic compounds from further development. There is a need for cardiotoxicity assays that use more biologically relevant cell-based models to aid development of new chemical entities and ensure drug safety. Accordingly, there is great interest in using stem cells as tools for screening compounds during early drug development. Stem cell derived cardiomyocytes are especially attractive for this because they express ion channels, and demonstrate spontaneous mechanical and electrical activity similar to native cardiac cells. We have developed methods for measuring the impact of pharmacological compounds on the beating rate of stem cell derived cardiomyocytes using imaging methods and FLIPR® Tetra cellular analysis system. Cardiomyocyte contractions rate and patterns characterized by monitoring changes in intracellular Ca<sup>2+</sup> measured using calcium sensitive dyes. Automated peak detection and analysis processes the data concurrently with acquisition and provides user selectable outputs. The assay allows characterization of deviations from normal contractions that include changes in beating rate and other characteristics such as spacing between peaks, peak width or pattern irregularities. Multi-parameter characterization of beating profiles provides additional insights into mechanisms of action indicating distinct characteristics of different types of receptor antagonists or ion channel blockers. We have characterized more than 100 known pharmacological compounds and detected concentration-dependent modulation of beating rate as well as atypical patterns caused by alpha and beta blockers, hERG inhibitors, ion channel blockers, kinase inhibitors, anti-cancer drugs, and other cardiotoxic compounds. Identifying these parameters early in the drug discovery process has the potential to identify a compound that should be failed as a pre-clinical candidate. For example, this assay may allow prediction of adverse cardiac effects such as elongated QT syndrome. We demonstrate that the IC50 values determined by FLIPR cardiac beating assay had significant rank correlation with published values determined by other cardiac models and also good concordance with reported human plasma C<sub>max</sub> values. Finally, we have estimated assay predictivity by testing the Screen-Well™ Cardiotoxicity library that consists of 131 compound representing different classes of cardiotoxicity. We found that estimated predictive value of the assay was greater than

80%, and therefore method could be very useful for compound screening and early safety evaluation in drug development process.

### **Image-Based Functional Assay to Screen Therapies for Inherited Heart Disease.**

*C. Simmons<sup>1,2</sup>, K. L. Zaleta-Rivera<sup>2,3</sup>, A. Ribeiro<sup>1,2</sup>, E. Ashley<sup>2,3</sup>, B. L. Pruitt<sup>1,2,4</sup>; <sup>1</sup>Mechanical Engineering, Stanford University, Stanford, CA, <sup>2</sup>Cardiovascular Institute, Stanford University, Stanford, CA, <sup>3</sup>Cardiovascular Medicine, Stanford University, Stanford, CA, <sup>4</sup>BioX, Stanford University, Stanford, CA*

Many single cell drug-screening technologies test changes in electrochemical properties of contractile heart cells (cardiomyocytes - CMs). However, as researchers and clinicians alike turn to stem cell-derived CMs for applications in pharmacology and tissue engineering, there is a need for rapid, easy-to-use mechanical functional assays of immature cells such as neonatal and stem cell-derived CMs. This paper reports a new image-based minimally invasive functional assay that quickly and rapidly quantifies cell contractility and detects changes in CM mechanical function in standard culture conditions.

While commercial image-based functional assays (IFAs) exist for adult CMs, their algorithms rely on mature sarcomeric structures and are thus unsuitable for immature cells like neonatal and stem cell-derived CMs. Researchers have created IFAs to study neonatal cardiomyocytes, but these algorithms only detect contraction frequency or effective mechanical contractility, not both. Our IFA routine utilizes three unique components to enable simultaneous frequency and mechanical contractility analysis: soft hydrogel substrates for cell culture that enable large cellular displacements, edge-finding algorithm for each frame of high-speed brightfield videos that facilitates velocity and contractility calculations, and Fourier transforms of the raw data to identify a characteristic frequency.

The poly(acrylamide-co-acrylic acid) hydrogels were functionalized with SulfoSANPAH followed by laminin. Neonatal cells were harvested from mouse pups and plated on gels the same day. Brightfield videos of single cells were captured six days later, before and after treatment with 10  $\mu$ M isoprenaline. Videos were then cropped and converted to AVI files using ImageJ. AVI files were read into MATLAB, and for a given video, each frame was processed to trace the outer border of the cell and the major axis recorded. Contraction and relaxation velocities were also calculated for the cell. Calculations of change in length, scaled by original length, yield an average contractility. Contractility has physiological correlation to the ability of the heart to pump blood. Discrete Fourier transforms of the major axis data identifies the dominant spontaneous beat frequency.

Using this method, statistically significant increases in contractility ( $p = 0.030$ ) and frequency ( $p = 0.002$ ) are detected in the presence of isoprenaline. Other techniques have not been able to generate this combined data with such robust statistical significance. We are currently using our IFA to identify changes in contractility due to inherited mutations in contractile proteins like Myosin Regulatory Light Chain (MYL2-N47K) and Myosin Heavy Chain (MYH7-R403Q) that cause hypertrophic cardiomyopathy.

Our mathematical and experimental approaches showed that our image-based functional technology was able to capture the fastest kinetic properties of the cells. The outcome of these studies shows a reliable new technology that can be used for single cell functional studies and drug screening for cardiovascular diseases.

**Cord blood platelet gel applications in thoracic surgery.**

L. Rosso<sup>1</sup>, V. Parazz<sup>2</sup>, F. Damato<sup>1</sup>, I. Righi<sup>3</sup>, L. Santambrogio<sup>1</sup>, P. Rebull<sup>2</sup>, S. Gatti<sup>4</sup>, S. Ferrero<sup>5</sup>, M. Nosotti<sup>1</sup>, L. Lazzari<sup>2</sup>; <sup>1</sup>Thoracic Surgery and Lung Transplant Unit, Fondazione Policlinico, Milano, Italy, <sup>2</sup>Cell Factory - Fondazione Policlinico, Milano, Italy, <sup>3</sup>General And Thoracic Surgery Unit, Legnano Hospital, Legnano, Italy, <sup>4</sup>Center for Surgical Research, Fondazione Policlinico, Milano, Italy, <sup>5</sup>Department of Pathology, Fondazione Policlinico, Milano, Italy

**Objective:** Prolonged air leak is the major cause of morbidity after pulmonary resection. In this study we tested an innovative approach based on the use of human umbilical cord blood platelet gel (CBPG) in repairing pleural damage through in vitro and in vivo experimental approaches.

**Methods:** In vitro, scratch assay was performed to test the tissue repair capability mediated by CBPG compared to the standard culture conditions using human primary mesothelial cells.

In vivo, a iatrogenic injury on the left lung of 54 Wistar rats was performed. CBPG was placed on the injured area only in treated animals and at different times histological changes and presence of pleural adhesions were evaluated. In addition, changes in the soluble inflammatory factor pattern were tested using a multiplex proteome array.

**Results:** In vitro, CBPG repaired the damage of mesothelial cells in a shorter time in comparison with the control (24 vs 35 hours, respectively). In vivo, formation of new mesothelial tissue and complete tissue recovery was observed at 45+1 and 75+1 hours in treated animals vs 130+2.5 and 160+6 hours in controls, respectively. Pleural adhesions were evident in 43% of treated animals compared to 17% of controls. No complication was observed.

Interestingly, some crucial soluble factors involved in inflammation were significantly reduced in treated animals.

**Conclusions:** CBPG accelerates the repair of pleural damage and stimulates the development of pleural adhesions. Both properties could be particularly useful in the management of prolonged air leak, and to reduce inflammation.

941

**Analysis of Neurotransmitters and Behavioral Responses in 835 MHz Radiofrequency Exposed Mice.**

J-K. Lee<sup>1</sup>, K-S. Lee<sup>1</sup>, J-H. Shin<sup>1</sup>, H-G. Kim<sup>1</sup>, H-R. Kim<sup>1</sup>; <sup>1</sup>Dept of Pharmacology, College of Medicine, Dankook University, Cheonan, Korea

Neurotransmitters (NTs) are signaling molecules, which play critical roles in neuronal communication of nervous system. The changes of NTs concentration in several brain regions have been known to involve many psychiatric diseases developments and neurodegenerative diseases progresses. Our lab has developed a simple and rapid liquid chromatography tandem mass spectrometry (LC-MS/MS) method for analyzing the level of major NTs in brain regions. By using this newly developed method, we measured various NTs of mouse brain regions following chronic exposure to 835 MHz radiofrequency radiation (RFR). We investigated the effect of chronic RF exposure on mice at 835 MHz with high energy (specific absorption rate: SAR=4.0 W/kg) for 4 weeks (10 hrs/day) by using determining NTs. We found that the levels of dopamine at striatum and midbrain were continuously decreased in parallel with the duration of radiofrequency exposures. The levels of serotonin and epinephrine in brain following radiofrequency exposure did not change at all brain regions in mice. Norepinephrine levels significantly decreased at brain stem region but increased at pituitary glands (PT) region in mice. Glutamate levels significantly decreased at PT and cerebellum (CB) regions and GABA levels increased at CB region in mice. The moving distances of RFR and rearing frequencies in

RFR exposed mice were significantly increased at the 2 or 3 weeks after exposure. These results suggest that RFR-exposed mice show the hyperactivities. The underlying mechanisms affecting RFR exposed mice behavior are under investigation. In summary, newly developed analytical method for NTs significantly improves assay performance characteristics and will be well-suited for many relevant studies to quantify the concentration of various NTs.

942

**Possible involvement of protein citrullination in the production of brain-reactive autoantibodies related to Alzheimer's disease pathology.**

*N. K. Acharya<sup>1,2</sup>, E. P. Nagele<sup>2</sup>, M. Han<sup>1,2</sup>, C. DeMarshall<sup>1</sup>, M. Kosciuk<sup>1</sup>, R. G. Nagele<sup>2</sup>; <sup>1</sup>GSBS, UMDNJ-Stratford, Stratford, NJ, <sup>2</sup>New Jersey Institute for Successful Aging, University of Medicine and Dentistry of New Jersey – School of Osteopathic Medicine (UMDNJ-SOM), Stratford, NJ*

Brain-reactive autoantibodies (BAs) in human sera, which are immunoreactive to antigens in the brain, may contribute to AD pathology. Some BAs have shown promise as biomarkers that can be used to diagnose AD. However, mechanisms involved in their generation are unknown. Here, we used immunohistochemistry and immunoblotting to investigate whether protein citrullination (PC) plays a role in this process. PC is a post-translational protein modification whereby arginine, a basic amino acid, is converted to citrulline, a neutral amino-acid. This is mediated by peptidyl arginine deiminases (PADs). Loss of basic charges can modify protein structure which can enhance antigenicity. PC leading to the generation of disease-specific autoantibodies is well established in rheumatoid arthritis. In the present study, we found selective expression of PAD4 and PAD2 in neurons and astrocytes, respectively, in human brain. In the cerebral cortex and hippocampus PAD4 was expressed selectively in pyramidal neurons. Although comparable levels of PAD4 expression were observed in AD and control brains, cortical expression of PAD2 was higher in AD brains compared to controls. PAD4 was localized to the neuronal perikaryon, but was also present in axons, dendrites and synapses. Similarly, PAD2 was localized in the cell body and processes of astrocytes. Localization of citrullinated proteins closely matched that of PADs in both cell types in AD and control brains. Co-localization of PAD4, citrullinated proteins and amyloid beta1-42 was consistently observed in pyramidal neurons, suggesting a link between PAD expression, protein citrullination and accumulation of amyloid during AD pathogenesis. Lastly, pentatricopeptide repeat domain 2, a potent diagnostic marker of AD, was citrullinated in human brain. We propose that protein citrullination has a vital function that remains unidentified in the brain. However, our results suggest that selective neuronal degeneration in AD brains releases citrullinated proteins into the blood that elicits an immune response and the appearance of BAs. Under conditions of blood-brain barrier compromise, extravasation of these BAs into brain could exacerbate AD pathology.

### Single Molecule Study of Thrombospondin-1 Receptor, CD36, In The Endothelial Cell Plasma Membrane.

*J. M. Githaka<sup>1</sup>, A. Chanda<sup>2</sup>, G. Danuser<sup>2</sup>, K. Jaqaman<sup>3</sup>, N. Touret<sup>1</sup>; <sup>1</sup>Department of Biochemistry, University of Alberta, Edmonton, AB, Canada, <sup>2</sup>Department of Cell Biology, Harvard Medical School, Boston, MA, <sup>3</sup>Department of Systems Biology, Harvard Medical School, Boston, MA*

Thrombospondin-1 (TSP-1), an endogenous extracellular matrix anti-angiogenic factor, is down-regulated in many tumors. CD36 is a key receptor transmitting the anti-angiogenic activity of TSP-1 through induction of endothelial cell apoptosis. The binding of multivalent ligand to CD36 (anti-CD36 immunoglobulin M (IgM)), similarly induces endothelial cells apoptosis, while divalent anti-CD36 immunoglobulin G (IgG) does not, suggesting that CD36 clustering is critical for this apoptotic signal. Our objectives are to examine the dynamic organization of CD36 into multimeric complexes upon TSP-1 binding, and determine the factors that regulate its reorganization and clustering upon TSP1 binding. To achieve this, we used single molecule and super-resolution imaging to assess the dynamics and spatial organization of CD36 in the plasma membrane of human dermal microvascular endothelial cells. We compared CD36 dynamics and organization in unstimulated and TSP-1 stimulated cells. Treatment with 10 nM TSP-1, which induced endothelial cell apoptosis, resulted in a significant increase in CD36 clustering and actin-guided organization and mobility. TSP-1 also induced phosphorylation of the Src family kinase Fyn in a CD36-dependent manner at focal adhesions along actin filaments. Based on our data, we propose that TSP-1 binding results in a change in CD36 dynamics, potentially mediated by actin, which facilitates CD36 clustering and subsequent downstream signaling.

<sup>5</sup>James Franck Institute, University of Chicago, IL-60637 Chicago, U.S.A.

The GTPase Dynamain polymerizes into a helical coat that constricts membrane necks of Clathrin-coated pits to promote their fission. However minimal requirements for fission are still debated as Dynamain constriction is necessary but not sufficient for fission. Here we show that fission occurs at the interface between the Dynamain coat and the uncoated membrane (Morlot et al., in press). At this location, the considerable change in membrane curvature increases

locally membrane elastic energy, reducing the energy barrier for fission. Fission kinetics depends on tension, bending rigidity and the Dynamin constriction torque. Indeed, we experimentally find that the time it takes for fission depends on membrane tension *in vitro* and during Clathrin-mediated endocytosis *in vivo*. By i) estimating the energy barrier from the increased elastic energy at the edge of the Dynamin coat, and ii) measuring the Dynamin torque, we show that the mechanical energy spent in Dynamin constriction can reduce sufficiently the energy barrier for fission to promote spontaneous fission.

These results allow us to quantitatively validate a membrane fission scenario in which Dynamin constricts fast (<few 100 ms), and waits a few seconds for spontaneous fission to occur.

### **Investigating the spatial correlation and dynamics of protein nanoclusters in live cells, using spatial statistics.**

A. Chessel<sup>1</sup>, J. Dodgson<sup>1</sup>, J. Boussier<sup>1</sup>, R. Carazo-Salas<sup>1</sup>; <sup>1</sup>Gurdon Institute, University of Cambridge, Cambridge, United Kingdom

Quantitative analysis of live fluorescence microscopy images is a key tool in the study of the intracellular localization and dynamics of proteins, and of the cellular components they are part of. However, significant advances in our understanding of cell biological processes can only be attained by linking that information with functional and/or biophysical models.

Here we present a mathematical framework based on spatial statistics to quantitatively assess punctate protein aggregate co-localisation and dynamics in cells, and relate them to biophysical models.

Punctate objects abound in cellular fluorescence microscopy (vesicles, protein clusters, exo- or endocytosis sites, etc) and the main question they raise concerns their spatio-temporal (co-)localisation, that is how given populations of points are distributed, either alone or with respect to one another, and how that changes with time. Co-localisation is often studied using a variety of ad-hoc techniques, and dynamics using Single Particle Tracking (SPT) methods. We use spatial statistics as a tool to tackle both problems in a unified way and ask: are the distributions of two proteins correlated in space? how do the spatial correlations between different pairs of proteins compare with one another? what biophysical or biological model(s) can best explain an observed correlation? In particular we are able, without particle tracking and using noisy data, to distinguish free diffusion from sub- or constrained diffusion and directed motion and compare experimentally observed spatio-temporal behaviour with the output of complex simulated systems.

Focusing on the protein machineries that regulate cell polarity in fission yeast (*S. pombe*) cells, we recently discovered that *S. pombe* polarity factors are not smoothly distributed at the cortex of cells but rather are organized in nanoscopic protein clusters [Dodgson, Chessel and al., under review]. We illustrate how using spatial statistics we have been able to shed light on the relative spatio-temporal distribution of polarity factor clusters in *S. pombe*, revealing the existence of several distinct but interacting (possibly cell-cycle regulated) polarity complexes as well as investigating their dynamics with the help of biophysical models.

**Multiscale Modeling of Lipid Droplet Formation.**

S. Katira<sup>1</sup>, P. Rangamani<sup>1</sup>, A. Benjamini<sup>1</sup>, G. Oster<sup>1</sup>, B. Smit<sup>1,2</sup>; <sup>1</sup>UC Berkeley, Berkeley, CA, <sup>2</sup>Lawrence Berkeley National Laboratory, Berkeley, CA

Lipid droplets (LD) are intracellular organelles containing neutral lipid esters enclosed in a lipid monolayer. They have long been thought of as passive globules for intracellular lipid storage. However, recent studies have shown that they are dynamic structures involved in fat metabolism and may have important roles in obesity, diabetes and atherosclerosis. Furthermore, viruses such as the hepatitis C virus are known to hijack LDs for their function. Despite the importance of LDs in many of these processes, very little is known about their structure, formation and regulation. Understanding the biogenesis of these organelles will provide new avenues in therapies for these diseases.

The canonical model of LD formation hypothesizes that neutral lipids accumulate between the leaflets of the endoplasmic reticulum membrane and subsequently bud off into vesicles. We are studying this problem using two different approaches—mesoscopic modeling and continuum mechanics. We use a coarse-grained lipid model, and hybrid Monte Carlo–dissipative particle dynamics simulations to study properties of individual lipids surrounding the droplet and the mechanism by which they facilitate budding of the LD. We model the contents of the LD as ‘super-hydrophobic’ particles secreted within the membrane.

Alongside the coarse-grained model, we are also developing continuum models of the membrane. We use lipid tilt as a key degree of freedom in our continuum model to capture not just the change in the shape of the membrane but also the change in the orientation of the lipids in response to the deformation caused by the LD. Our results show that the early stages of LD formation are ellipsoidal in shape. Furthermore, there is a change in the thickness of the lipid monolayer along the LD, indicating that the lipids in the membrane monolayer are adjusting their orientation to accommodate the LD. Ongoing studies are focused on understanding the different stages in the formation of the droplet and scission.

**Membrane curvature-induced sorting of transmembrane proteins.**

S. Aimon<sup>1</sup>, G. Toombes<sup>2</sup>, A. Callan-Jones<sup>3</sup>, P. Bassereau<sup>1</sup>; <sup>1</sup>PhysicoChimie Curie, Institut Curie, Paris, France, <sup>2</sup>Porter Neuroscience Research Center, NIH, Bethesda, MD, <sup>3</sup>Laboratoire Charles Coulomb, Université Montpellier II, Montpellier, France

The targeting of transmembrane proteins to specific cellular regions is essential for proper cell function. It depends upon both enrichment in trafficking vesicles, and lateral redistribution upon delivery to the plasma membrane or organelle of interest. Extensive work has been done to identify specific protein/protein interactions, active processes governing protein targeting as well as the contribution of hydrophobic mismatch. However, membranes such as transport intermediates, the dendrites of neurons or primary cilia can be highly curved, with curvature radii of tens of nanometers. Thus, the matching of protein shape to the underlying membrane curvature may also provide a targeting mechanism that was not demonstrated yet.

We have used a quantitative in-vitro assay to demonstrate that membrane curvature can strongly affect the lateral distribution of transmembrane proteins. We consider two proteins: a voltage-gated potassium channel, KvAP, and Aquaporin AQP0. The redistribution of these two proteins between flat and highly curved membranes is strikingly different. Our model system consisted of purified, fluorescently-labeled, proteins reconstituted into Giant Unilamellar Vesicles (GUV) with a typical diameter of ~10 μm. Using micromanipulation techniques, we

pulled membrane nanotubes from GUVs and measured the protein concentration via quantitative confocal fluorescence microscopy while varying the nanotube radii from 100 nm to 7nm.

We observe strong curvature-induced sorting of KvAP; up to a 10-fold enrichment of KvAP is measured on the tube compared to that of the GUV. This sorting is measured as a function of tube radius and protein density on the GUV. In addition, FRAP measurements on the nanotube confirm that proteins can freely diffuse between the quasi-flat GUV membrane and the highly curved membrane tube. Thus, the membrane nanotube neck does not act as a diffusion barrier. In contrast, no curvature-induced sorting of AQP0 has been observed.

The markedly different sorting of these two transmembrane proteins can be understood in terms of a theoretical model of the protein-imposed spontaneous membrane curvature. Thus, these measurements of curvature-induced sorting provide supra-molecular scale information about the shape of membrane-embedded proteins, which is usually not accessible using crystallographic methods.

In conclusion, our work shows a new sorting mechanism based on the shape of transmembrane proteins. Consequently, cells can sort proteins based on matching of their shape and the local membrane curvature; otherwise, active means or interactions with other cell constituents are necessary to efficiently create and maintain protein spatial inhomogeneities.

### **Bayesian imaging fluorescence correlation spectroscopy to resolve heterogeneity in cell membranes.**

*S-M. Guo<sup>1</sup>, X. Ma<sup>2</sup>, N. Bag<sup>2</sup>, N. Monnier<sup>1</sup>, J. He<sup>1</sup>, T. Wohland<sup>2</sup>, M. Bathe<sup>1</sup>; <sup>1</sup>Biological Engineering, MIT, Cambridge, MA, <sup>2</sup>Department of Chemistry and Centre for Bioimaging Sciences, National University of Singapore, Singapore, Singapore*

Fluorescence Correlation Spectroscopy (FCS) is a powerful tool to measure molecular dynamics with single molecule sensitivity, including transport mechanisms, local concentrations, and aggregation states. Due to its high spatial resolution and non-invasive nature, FCS has been widely used to probe the dynamics of various cellular processes in live cells. In contrast to single point detection in traditional confocal FCS, advances in EM-CCD camera technology and Total Internal Reflection Fluorescence Microscopy (TIRFM) now enable parallel measurements at hundreds to thousands of locations on the cell surface. However, inferring models from FCS measurements on biological samples is challenging due to noise from sampling limitations, heterogeneity present in the sample, and the often transient nature of biological processes. In addition, imaging FCS measurements contain up to thousands of temporal autocorrelation functions (TACFs) in a single acquisition, rendering manual data analysis and model selection impractical. Thus, automated, unbiased analysis procedures are required for proper data analysis and interpretation. Here, we present and apply a systematic Bayesian approach to multiple hypothesis testing of competing models for FCS datasets of multiple TACF curves or single intensity traces. By testing the approach with simulations and TIRF data of supported lipid bilayers, we demonstrate that this Bayesian approach selects the simplest model that can describe the observed data, thereby capturing heterogeneity in the sample while avoiding overfitting. Further, model probabilities provide a reliability test for the downstream interpretation of measured parameter values. Application of our approach to Epidermal Growth Factor Receptor (EGFR) indicates that diffusion of EGFR on the cell surface is more heterogeneous than the membrane marker Dil and requires at least two species to describe the data. These results demonstrate that Bayesian analysis offers a quantitative and unbiased approach for FCS data analysis and has broad applications in resolving heterogeneous dynamics in various cellular processes.

**Understanding heterogeneity of cellular responses in tumors by computational and systems biology.**

A. Gough<sup>1,2</sup>, D. Boltz<sup>1,2</sup>, T. Lezon<sup>1</sup>, C. Reese<sup>2</sup>, L. Verneti<sup>1,2</sup>, J. Grandis<sup>3</sup>, D. L. Taylor<sup>1,2</sup>;

<sup>1</sup>Computational & Systems Biology, University of Pittsburgh, Pittsburgh, PA, <sup>2</sup>Drug Discovery Institute, University of Pittsburgh, Pittsburgh, PA, <sup>3</sup>Otolaryngology, University of Pittsburgh, Pittsburgh, PA

Heterogeneity in the cellular make up and response to molecular signals and chemical challenges in micro and macro-domains of tumors has fundamental implications in understanding the dynamics of pathways and signaling, the development of predictive diagnostic and prognostic tests, and the optimal delivery of personalized therapeutics. The objective of this study is to relate heterogeneity in cellular activity, to variations in specific cellular pathways, using computational models. Our approach is based on large-scale cell biological analyses using multiplexed fluorescence with High Content Analysis (HCA). The present study pushes the limits of quantitative HCA by calibrating the "systems response" of the imaging platform using fluorescent dye solutions and bead standards for stability, sensitivity, dynamic range, and linearity, so that variations in the biological responses can be optimally interpreted. We have validated this approach by correlating the same measurements in both flow and image (HCA) cytometry. In addition, we are building a continuum of biological models including 2D arrays of relevant cancer cells, 3D arrays of tumor microenvironments and cohorts of patient tumor sections. We have demonstrated that the calibrated intensities of 2  $\mu\text{m}$  fluorescent beads, measured by imaging, exhibit a coefficient of variation (CV) of ca. 4%, which is comparable to the best CV's obtained by flow cytometry of ca. 3%. We used the cell cycle distribution as a key comparative parameter in validating measurements of heterogeneity. When a head and neck cancer cell line (Cal33), labeled with a fluorescent DNA probe, was analyzed, we demonstrated that with the optimal systems calibration a CV of ca. 8% for the G0/G1 peak and a fraction of S-phase of ca. 28% were obtained. This result compares well to a CV of ca. 6% and a ca. 31% fraction for the S-phase in the same cell samples measured by flow cytometry. The initial model system is focused on the Cal33 cells plated over a range of densities and relating key components of STAT3, STAT1 and NF $\kappa$ B pathways to the stage of cell cycle in normally cycling cells and in response to stimulation by IL-6, INF- $\alpha$ , TNF $\alpha$  and selected test compounds. Even in the simple 2D cell model, we have characterized significant heterogeneity of responses, for which we are developing network models to reveal finer details of sub-populations.

950

**Relating cellular heterogeneity to drug sensitivity.**

C. Wichaidit<sup>1</sup>, D. K. Singh<sup>1</sup>, C-J. Ku<sup>1</sup>, R. J. Steininger<sup>1</sup>, L. F. Wu<sup>1</sup>, S. J. Altschuler<sup>1</sup>; <sup>1</sup>University of Texas Southwestern Medical Center, Dallas, TX

Cancer is a disease associated with a high degree of cellular heterogeneity. Here, we show that quantification of pre-existing heterogeneity in H460 lung cancer clones can be used to predict drug response. Cellular heterogeneity within clones was described by mixtures of similarity of signaling states (i.e. colocalization patterns of signaling molecules from microscopy fluorescence images). Clones with similar ensembles appeared to have similar drug sensitivities, and relative similarity among the clones was largely independent of signaling readout. Our work suggests that measures of cellular heterogeneity can contain useful information for the diagnosis and treatment of cancer.

951

**Modeling the Cell Biology of the Heat Shock Response of Barley Aleurone Cells.**

*R. Heineman<sup>1</sup>, H. Nguyen<sup>1</sup>, M. R. Brod<sup>2</sup>; <sup>1</sup>Department of Mathematics, Trinity University, San Antonio, TX, <sup>2</sup>Department of Biology, Trinity University, San Antonio, TX*

When heat shocked, the secretory cells of barley aleurone layers reallocate cellular resources by combining heat shock and ER stress responses. Cells of the barley aleurone layer secrete endosperm-degrading hydrolytic enzymes in response to the phytohormone gibberellic acid which is sent by the germinating embryo. The hydrolases, chief among them  $\alpha$ -amylase, mobilize nutrients stored in the endosperm to support the growth of the embryo through the soil until it is capable of sustaining photosynthesis. Upon heat shock, secretory protein synthesis is suppressed by rapid and targeted destabilization of secretory protein mRNAs. The ER upon which these secretory protein mRNAs are translated into proteins undergoes major structural and compositional changes. In addition, signal recognition particles that ferry secretory protein-translating polysomes to translocons at the ER fail to release from the ER upon heat shock. We present a mathematical model to analyze how these elements interact to regulate  $\alpha$ -amylase synthesis in heat-shocked aleurone cells. Our model was created using the mass-action principle to transform biological reactions into differential equations. We then fit the model with our experimental data which measure protein concentrations at three different temperature schemes (plunge [heat shock], slow and fast ramps [heat stresses]). The computational simulations show good qualitative agreement with the literature and experimental data.  $\alpha$ -Amylase is most severely affected by the plunge temperature scheme but is not as drastically decreased in the heat stresses, since the ramping periods afford cells some time to adapt to the temperature stimulus. Continuing work is aimed at refining the model with deeper experimental data and introducing membrane fluidity into the model. We will test predictions about the ability of aleurone layers to maintain normal cellular function under heat stress conditions. This will provide important insights about the limits of plants to adapt to temperature extremes, insights important to addressing challenges imposed by global climate change. Supported by the NSF grant 0926702 and Trinity University.

**The temperature dependence of cell cycle timing.**

*M. L. Begasse<sup>1</sup>, F. Vazquez<sup>2</sup>, S. Grill<sup>1,2</sup>, A. A. Hyman<sup>1</sup>; <sup>1</sup>MPI-CBG, Dresden, Germany, <sup>2</sup>MPI-PKS, Dresden, Germany*

The timing of cell division and therefore the developmental timing of cold-blooded organisms is temperature (T) dependent. It is known that the rates (R) of many biological processes increase exponentially with the inverse of T, following the empirical Arrhenius equation. But consideration of the full viable T range often reveals more complex T dependence above a breakpoint temperature T\*, where R decreases with temperature, giving rise to asymmetric humped shapes in R vs T plots. We are interested in the origin of this non-monotonous T dependence of the speed of biological processes. Are cellular rates controlled by a master regulator that fails at higher temperatures, or can the high temperature behavior be explained by the network structure of a set of regulatory proteins?

One of the best-understood regulatory networks in cell biology is the CDK-1/APC feedback system that is believed to give rise to the stable oscillations underlying cell cycle progression. Based on models of the CDK-1/APC oscillatory network, we developed a protein network model that assumes Arrhenius-like T dependence of rates on the protein level and therefore accounts for the T dependence of cell cycle timing. We found that a three-node model that allows for

dynamic looping trajectories in the graph of network states shows the non-monotonous T dependence typical for physiological rates. To test our model we measured the timing of early embryonic cell cycles of the nematodes *C. elegans*, *C. briggsae* and *P. pacificus* at different temperatures and could show that the model successfully captures both aspects of the biological data, the asymptotic Arrhenius tail at low T, as well as the non-monotonous behavior at high T. This suggests that the T dependence of cell cycle rates is due to the network structure of regulatory proteins.

The formula obtained from the dynamics of the model, explains the temperature rate relationship observed for developmental processes. Besides adding temperature dependence to the current cell cycle models, our analysis gives accurate fits to the nematode data that allows us to address the question of how organisms adapt their cell cycle machinery to evolve to a different temperature niche.

**Wanted: a calibration standard for anomalous subdiffusion.**

*M. J. Saxton*<sup>1</sup>; <sup>1</sup>*Biochemistry & Molec Med, Univ of California, Davis, Davis, CA*

Much work is being done on anomalous subdiffusion in the plasma membrane, cytoplasm, and nucleus of cells, and in model systems. The main question: Is diffusion anomalous, transient anomalous, or normal? If it is anomalous, what are the exponent and the mechanism? If it is transient anomalous, what is the crossover time from anomalous to normal? The type of diffusion is of interest as a factor in reaction kinetics and as a probe of submicroscopic organization, unfortunately not uniquely invertible. The area is controversial, especially the hypothesis that crowding causes anomalous subdiffusion. There is strong experimental evidence supporting the hypothesis in model systems, but the problem is not yet well enough understood in terms of theory, simulation, and experiment to settle the question. Resolving the experimental question requires a calibration standard for anomalous subdiffusion, preferably one able to crosscalibrate the various optical (FRAP, FCS, single-particle tracking) and NMR measurements. A standard would provide a positive control to experimentalists who do not observe anomalous subdiffusion in cells, and a calibration point to those who do. The main requirements for a calibration standard are as follows. Diffusion must be anomalous over the length and time scales of the measurements, several  $\mu\text{m}$  and s for the optical measurements. The length scale is fundamental; the time scale can be tuned via the viscosity of the medium. The standard must be theoretically well understood, with a known anomalous subdiffusion exponent, ideally readily tunable. The standard must be simple, reproducible, and independently characterizable, say by electron microscopy for nanostructures. If subdiffusion is transient, the anomalous regime must extend over at least two or three orders of magnitude. Among the candidate experimental systems discussed are (1) obstructed motion in a supported lipid bilayer; (2) computer-driven physical trajectories in which a stable fluorophore is moved by a piezo stage; (3) continuum diffusion in a randomly ablated lattice of nanoscale obstacles, a novel percolation problem chosen to facilitate nanofabrication; and (4) transient anomalous diffusion in which the tracer is trapped by a hierarchy of binding sites, for example a transcription factor in a random DNA array. (Supported by NIH grant GM038133.)

**A Single-Molecule Hershey-Chase Experiment.**

*D. A. Van Valen<sup>1</sup>, D. Wu<sup>2</sup>, Y-J. Chen<sup>3</sup>, H. Tuson<sup>4</sup>, P. Wiggins<sup>5</sup>, R. Phillips<sup>1</sup>; <sup>1</sup>Applied Physics, California Institute of Technology, Pasadena, CA, <sup>2</sup>Medicine, University of Chicago, Chicago, IL, <sup>3</sup>Physics, California Institute of Technology, Pasadena, CA, <sup>4</sup>Biochemistry, University of Wisconsin, Wisconsin, WI, <sup>5</sup>Physics, University of Washington, Seattle, WA*

Ever since Hershey and Chase used phages to establish DNA as the carrier of genetic information in 1952, the precise mechanisms of phage DNA translocation have been a mystery. Although bulk measurements have set a timescale for in vivo DNA translocation during bacteriophage infection, measurements of DNA ejection by single bacteriophages have only been made in vitro. Here, we present direct visualization of single bacteriophages infecting individual *Escherichia coli* cells. For bacteriophage  $\lambda$ , we establish a mean ejection time of roughly 5 min with significant cell-to-cell variability, including pausing events. In contrast, corresponding in vitro single-molecule ejections are more uniform and finish within 10 s. Our data reveal that when plotted against the amount of DNA ejected, the velocity of ejection for two different genome lengths collapses onto a single curve. This suggests that in vivo ejections are controlled by the amount of DNA ejected. In contrast, in vitro DNA ejections are governed by the amount of DNA left inside the capsid. This analysis provides evidence against a purely intrastrand repulsion-based mechanism and suggests that cell-internal processes dominate. This provides a picture of the early stages of phage infection and sheds light on the problem of polymer translocation.

955

**Predicting rates of cell state change due to stochastic fluctuations using a data-driven landscape model.**

*D. Sisan<sup>1</sup>, M. Halter<sup>1</sup>, J. Hubbard<sup>1</sup>, A. L. Plant<sup>1</sup>; <sup>1</sup>Biochemical Science Division, NIST, Gaithersburg, MD*

We develop a potential landscape approach to quantitatively describe experimental data from a fibroblast cell line that exhibits a wide range of green fluorescent protein (GFP) expression levels under the control of the promoter for tenascin-C. Time lapse live cell microscopy provides data about short term fluctuations in promoter activity, and flow cytometry measurements provide data about the long term kinetics as isolated subpopulations of cells relax from a relatively narrow distribution of GFP expression back to the original broad distribution of responses. The landscape is obtained from the steady state distribution of GFP expression and is connected to a potential-like function using a stochastic differential equation description (Langevin/Fokker-Planck). The range of cell states is constrained by a “force” that is proportional to the gradient of the potential, and biochemical noise causes movement of cells within the landscape. Analyzing the mean square displacement of GFP intensity changes in live cells indicates that these fluctuations are described by a single diffusion constant in log GFP space. This allows application of the Kramers’ model to calculate rates of switching between two attractor states, and enables an accurate simulation of the dynamics of relaxation back to the steady state with no adjustable parameters. With this approach, it is possible to use the steady state distribution of phenotypes and a quantitative description of the short term fluctuations in individual cells to accurately predict the rates at which different phenotypes will arise from an isolated subpopulation of cells.

956

**The Thermodynamics of Prediction.**

S. Still<sup>1</sup>, D. A. Sivak<sup>2</sup>, A. J. Bell<sup>3</sup>, G. E. Crooks<sup>4</sup>; <sup>1</sup>Information and Computer Sciences, University of Hawaii, Manoa, Honolulu, HI, <sup>2</sup>Center for Systems and Synthetic Biology, University of California, San Francisco, San Francisco, CA, <sup>3</sup>Redwood Center for Theoretical Neuroscience, University of California, Berkeley, Berkeley, CA, <sup>4</sup>Physical Biosciences, Lawrence Berkeley National Laboratory, Berkeley, CA

Biological systems (such as organisms, cells or molecules) inhabit constantly-fluctuating environments. They learn and exploit environmental statistics. What governs their adaptation? Here we make concrete the connection between two important perspectives: the view that biological systems have evolved (in part) to predict their environment, and the view that biological systems have evolved to use energy efficiently. A system responding to a stochastically fluctuating environment can be interpreted as computing, by means of its dynamics, an implicit model of the environment. The system's state retains information about past environmental fluctuations, and a fraction of this information is predictive of future ones. The remaining nonpredictive information reflects model complexity that does not improve predictive power. We expose the fundamental equivalence between this model inefficiency and thermodynamic inefficiency, measured by the energy dissipated during the interaction between system and environment. Our results hold arbitrarily far from thermodynamic equilibrium and are applicable to a wide range of biomolecular systems. They highlight a profound connection between the effective use of information and efficient thermodynamic operation: any system constructed to keep memory about its environment and to operate with maximal energetic efficiency has to be predictive.

957

**Thermodynamic Metrics and Optimal Perturbation Paths.**

D. A. Sivak<sup>1</sup>, G. E. Crooks<sup>2</sup>; <sup>1</sup>Center for Systems and Synthetic Biology, University of California, San Francisco, San Francisco, CA, <sup>2</sup>Physical Biosciences, Lawrence Berkeley National Laboratory, Berkeley, CA

A fundamental question in biology is how a molecular-scale machine performs useful work in a cellular milieu, while operating away from thermal equilibrium without excessive dissipation. In particular, how can control be exerted to rapidly manipulate a microscopic substrate so as to minimize the work required and hence the metabolic burden? For example, how should a linear motor step through its mechanical cycle so as to translate its cargo with minimal energy wasted? To address this general question of optimal control, we derive a friction tensor that induces a Riemannian manifold on the space of thermodynamic states. Within the linear-response regime, this metric structure governs the dissipation of rapid perturbations, and bestows optimal perturbation protocols with many useful properties. We demonstrate the utility of this metric by solving for optimal control parameter protocols in a simple microscopic nonequilibrium model.

958

**Is transcriptional noise universal? Single cell readout of mRNA copy numbers in systematically designed promoters.***R. C. Brewster<sup>1</sup>, D. Jones<sup>1</sup>, R. Phillips<sup>1</sup>; <sup>1</sup>Applied physics, California Institute of Technology, Pasadena, CA*

Recent efforts have demonstrated the diverse and widespread importance of noise to biological function. Theoretical efforts to quantify transcription often uses the language of rates to describe how the relevant molecular players will interact with the various DNA target binding sites which constitute the promoter. The output of such a theory is a distinct prediction for the mean and noise in expression as a function of the promoter architecture and of the concentrations of those molecular players. An inescapable prediction from this theory is that for any transcriptional architecture one can model, the predicted dependence of both the mean and noise in expression on these parameters is unique to that architecture. On the other hand, recent experiments measuring the mRNA copy number from a collection of unrelated promoters suggests that the noise in expression is universal and fits a single phenomenological model which depends only on the mean. In an attempt to understand this discrepancy, we have used single cell mRNA fish measurements in *E. coli* to study the expression profile from constitutive promoters where we have systematically altered the affinity of RNAP binding to the promoter; a quantity that is directly relateable to a parameter in our theory. As a result we have constructed over a dozen constitutive promoters with mean expression levels varying over 3 decades from an identical architecture where the systematic tuning of the RNAP binding affinity acts as the sole parameter determining the expression.

959

**Comparison of the theoretical and real world evolutionary potential of a genetic circuit.***M. Razo-Mejia<sup>1,2</sup>, J. Boedicker<sup>1</sup>, R. Phillips<sup>1</sup>; <sup>1</sup>Applied Physics and Biology, California Institute of Technology, Pasadena, CA, <sup>2</sup>Biotechnological Engineering, National Polytechnic Institute, Silao de la Victoria, Mexico*

Many large scale genomic efforts aim to map genotypic variability among individuals. However, a simple model system where the link between genetic variability, gene regulation, and function can be studied in detail is missing. Here we implement a thermodynamic model of gene regulation in the wild type *lac* operon as the theoretical framework to explore the potential evolutionary pathways for this gene circuit. We used the model parameters controlling gene regulation (such as the number of *Lac* repressor molecules per cell, the binding energies of transcription factors encoded in the DNA, the propensity for the formation of secondary structures involved in gene regulation, and the RBS binding sites of the genes) to gain insight into the possible sources and patterns of variability among individuals. We then analyzed how this operon actually evolved in a collection of  $\approx 1000$  *E. coli* natural isolates from all over the world, measuring both the genetic and phenotypic diversity of the *lac* operon in each isolate in order to inquire into the paths of evolutionary change. Thus far we have shown a wide range of phenotypic potential within the natural isolates and have begun to correlate these changes with the evolutionary story of the *lac* operon in each individual strain.

960

**Heritable changes to network architecture in genetically rewired yeast**

L. S. Moore<sup>1,2</sup>, E. Stolovicki<sup>1,2</sup>, L. David<sup>3</sup>, E. Braun<sup>1,2</sup>; <sup>1</sup>Department of Physics, Technion-Israel Institute of Technology, Haifa, Israel, <sup>2</sup>Laboratory of Network Biology, Technion, Haifa, Israel, <sup>3</sup>Department of Animal Sciences, Hebrew University of Jerusalem, Rehovot, Israel

Genome rewiring events (recruiting genes to foreign regulatory systems) alter the network architecture of a cell resulting in major physiological changes that ultimately lead to the emergence of new phenotypes. Deciphering the mapping between genotype and phenotype is essential for many branches of biology, e.g. development and cancer and is at the basis of our understanding of evolution. We have developed an experimental system to study the ability of a cell to recover from a genome rewiring event by measuring the dynamics of various cell phenotypes (division rate, cell size, protein expression levels) over hundreds of generations using genetically rewired strains of the yeast *S. cerevisiae*. These cells have been modified to remove the essential gene HIS3 from its native context in the genome and place it under sole regulation of a promoter in the galactose metabolic system, which is isolated from the histidine pathway in wild type cells. Glucose-containing medium strongly represses the GAL genes and HIS3 resulting in a severe challenge to the rewired cells in this medium. Greater than 50% of the population overcome the challenge within 20 generations and the adapted state can propagate indefinitely. In our experiments, adaptation was due to a reorganization of the system architecture within many individual cells as a response to the environmental challenge and is not a result of selection of rare advantageous phenotypes. An induced response that resolves an environmental challenge, accessible to many cells but is nevertheless inherited extends the common evolutionary theory and attests to the adaptive potential of regulatory circuits. [Stolovicki et al 2006, David et al 2010] Here I will present new results that show that the adaptation process involves complex dynamics manifested both at the molecular and cellular levels. Using time-lapse microscopy, we show the surprising result that the adapting population is composed of cells spanning a broad distribution of growth rates and that the population dynamics are not simply driven by fixation of the fastest growing cells. The build-up of a stable adapted population thus relies on the ability of cells to inherit a stable growth phenotype and to transmit it for generations. These results suggest the existence of a wide variety of stable adaptation mechanisms, resulting in a new, robust regulatory system for the rewired genome in the initially challenging environment. It calls for a new framework for population dynamics based on epigenetic mechanisms.

962

**Bistable Switch in Glycolysis as a Control of Metabolic State.**

A. Yongky<sup>1</sup>, B. C. Mulukutla<sup>1</sup>, W-S. Hu<sup>1</sup>; <sup>1</sup>Chemical Engineering and Materials Science, University of Minnesota, Minneapolis, MN

Glycolysis may operate at two different states: a high flux state in which the majority of glucose consumed is converted to lactate and a low flux state in which most glucose consumed results in complete oxidation through the citric acid cycle. Different cells may operate at different flux states; for example quiescent cells are often at a low flux state, whereas upon oncogenic transformation cells metabolize glucose through the high flux state to produce lactate, known as the Warburg effect. In liver and muscle cells the metabolism may switch between a high and a low flux state depending on the hormonal state. To understand the regulation of the switch of the metabolic state, we developed a mathematical model based on mechanistic enzyme kinetics. We showed that the glycolytic pathway exhibits multiple steady states and that the steady state behavior is dependent on the make-up of glycolytic isozymes. With the isozymes

seen in quiescent tissues, glycolysis resides only at the low flux state in the physiological range of glucose concentration. Whereas in rapidly growing cells such as cancerous cells and embryonic stem cells, glycolysis resides at a high flux state. A bistable switch allows the change of flux state only at the “switch” concentration. Our modeling results show that in the physiological range of glucose concentration, the switch from a particular flux state is prevented in both quiescent cells and in fast growing cells. In contrast, in liver cells, the bistable behavior is determined by the ratio of kinase/phosphatase activity of PFKFB which is modulated by the hormones insulin/glucagon. Thus the change in the “switch concentration” under different K/P ratios allows the flux state to switch from a high flux state to a low flux state (gluconeogenesis) in the presence of glucagon.

A better understanding of the bistable behavior will enable a better control of metabolism under different disease conditions. We evaluated a number glycolysis inhibitors which have illicited interest in clinical applications. Some inhibitors shift the “switch concentration” while others change the flux level without affecting the bistable behavior fundamentally, thus potentially presenting different strategies and even efficacies in metabolic control. Insights from the switch behavior of glycolysis may reveal new means of metabolic intervention in the treatment of cancer and other metabolic disorders through suppression of glycolysis.

963

#### **The Response of Bacterial Growth Rate to Changes in Osmotic Pressure.**

*E. R. Rojas*<sup>1,2</sup>, *J. Theriot*<sup>2</sup>, *K. C. Huang*<sup>1</sup>; <sup>1</sup>Bioengineering, Stanford University, Stanford, CA, <sup>2</sup>Biochemistry, Stanford University, Stanford, CA

Several theoretical studies (e.g. Koch 1983, Huang 2011) have proffered osmotic pressure as an essential factor of bacterial cell growth, proposing that it is required to drive mechanical expansion of the stiff cell wall, but this idea has yet to be studied experimentally. Here, we combine microfluidics with high-resolution, time-lapse microscopy to measure the response of single-cell growth rate to repeated, rapid changes in osmolarity of the growth media. We find that while lowering the osmotic pressure of the Gram-negative bacterium *Escherichia coli* transiently lowers its growth rate, that these cells are capable of making up for this by exhibiting particularly rapid bursts of growth upon re-pressurization, thereby attaining the same size that they would have attained had they never been slowed. This suggests that it is actually wall synthesis, not osmotic pressure, that ultimately determines cell size in this species. On the other hand, the same phenomenon is not observed in the Gram-positive *Bacillus subtilis*. In *B. subtilis*, the retardation of growth in response to osmotic shock is longer-lived. Furthermore, *B. subtilis* cells that have experienced successive osmotic up- and downshocks are smaller than they would have been had they never been shocked. Thus, it appears that in Gram-positive species, growth depends critically on both wall synthesis and osmotic pressure and suggests a model where the cell wall behaves as a viscoelastic solid for which the yielding properties are dependent on synthesis and hydrolysis of wall cross-links. I will discuss these observations in the context of the co-evolution of cell wall ultrastructure, osmoregulation, and the proposed fundamental growth strategies associated with Gram-negative and Gram-positive organisms.

#### **Spatial gradients in bacteria.**

*C. Tropini*<sup>1</sup>, *E. Chen*<sup>2</sup>, *M. Laub*<sup>2</sup>, *K. C. Huang*<sup>1</sup>; <sup>1</sup>Stanford University, Stanford, CA, <sup>2</sup>Massachusetts Institute of Technology, Cambridge, MA

Establishment of spatial asymmetry is critical to development. One mechanism for generating asymmetry involves the localized synthesis of a regulatory protein that diffuses away from its

source, forming a spatial gradient. While gradients are prevalent in eukaryotes at both the tissue and intracellular levels, it has only recently been shown that gradients of freely diffusible proteins can form within bacterial cells despite their small size and the speed of diffusion.

We use mathematical modeling to investigate the biochemical and physical constraints on the generation of intracellular gradients by the asymmetric localization of a source and a sink [1]. Our results suggest that gradients are a robust and potentially common mechanism for providing intracellular spatial cues. We present two examples illustrating the importance of spatial asymmetry in bacteria. First, employing a combination of mathematical modeling, single-cell microscopy and genetic manipulation, we demonstrate that a gradient of the master cell-cycle regulator CtrA in *Caulobacter crescentus* robustly establishes the asymmetric fates of daughter cells prior to the compartmentalization resulting from cell division [2]. Second, we present a systematic computational analysis of the effects of changes in protein localization and abundance to determine whether localization of the histidine kinase PleC is required for correct developmental timing of the flagellar pole in *Caulobacter* [3].

Taken together, our results suggest that bacteria are able to create functional spatial gradients that are robust to perturbations in localization phenotypes, regulatory mechanisms and cellular morphology.

#### Quantitative characterization assisted design of novel pattern forming E coli.

X. Fu<sup>1</sup>, S. Li<sup>1</sup>, J. Hu<sup>2</sup>, C. Liu<sup>2</sup>, L. Liu<sup>2</sup>, P. Lenz<sup>3</sup>, T. Hwa<sup>4</sup>, X. Cui<sup>1</sup>, J-D. Huang<sup>2</sup>, W. Huang<sup>1,2</sup>;

<sup>1</sup>Physics, The University of Hong Kong, Pokfulam, Hong Kong, <sup>2</sup>Biochemistry, The University of Hong Kong, Pokfulam, Hong Kong, <sup>3</sup>Physics, University of Marburg, Marburg, Germany,

<sup>4</sup>Physics, University of California, San Diego, La Jolla, CA

Biological pattern formation is a process involving cell motion, growth and spatial gene expression regulation. A number of mechanisms has been identified using traditional reverse genetic method. We have taken a build-to-understand approach using synthetic biology to engineer E coli motion control. We have engineered a novel cell density suppression cell motility mechanism, and it leads to form a robust sequential and periodic stripe pattern. A key element to this area of study is to develop quantitative cell motion measurement with sufficient spatial and temporal resolution. We have developed a continuous fluorescent photobleaching method to measure the diffusion and drift coefficients of the engineered E coli strain. It enable us to identify an additional pattern forming motion regulation of engineered strains.

**Configurable tool for automated exocytotic events quantification.**

S-J. J. Lee<sup>1</sup>, Z. Kenyon<sup>1</sup>, T. Wadadekar<sup>1</sup>, H. Watanabe<sup>2</sup>, R. Numano<sup>3</sup>, T. Tsuboi<sup>4</sup>; <sup>1</sup>DRVision Technologies LLC, Bellevue, WA, <sup>2</sup>Nikon Instruments Company, Yokohama, Japan,

<sup>3</sup>Electronics-Inspired Interdisciplinary Research Institute, Toyohashi University of Technology, Toyohashi, Japan, <sup>4</sup>Life Sciences, University of Tokyo, Tokyo, Japan

**Background**

Exocytosis is one of the fundamental cellular processes. Many key molecules involved in exocytosis have been identified. However, its underlying mechanisms are complex and are still largely unknown. Total internal reflection fluorescence (TIRF) microscopy allows the direct imaging of the exocytosis dynamics. Using TIRF movies to quantify exocytosis event statistics, such as the types, occurrence counts and timings for different assay scenarios could provide a powerful tool in basic research and drug development for new discoveries in exocytosis processes.

**Challenges**

Exocytosis is generally a rare event among many vesicles in cells. In our study of 20 movies with a variety of assay scenarios, the exocytosis rate is < 1%. Therefore it is impractical (tedious, irreproducible) to quantify exocytosis statistics manually. There is a strong demand for automated exocytotic quantification. However, the kinetic profiles of exocytosis events vary significantly in TIRF images depending on factors such as cell types, probes, imaging systems, assays, etc. It is challenging to create a universal classifier for automated exocytosis event detection.

**Solutions**

We developed a tool that can be configured to automatically detect a variety of exocytotic events in TIRF images such as rapid emerging events, slow emerging events and gross events. The configuration parameters include event size, contrast and lasting durations. The tool is based on a spatiotemporal structure guided processing method. The method uniquely performs multi-duration event energy integration, event energy contrast detection, spatiotemporal event qualification and resulting event quantification.

**Objective**

The objective of this study is to assess the effectiveness of our tool for broad exocytosis detection.

**Studies** We performed a verification study to assess the exocytotic event detection accuracy using TIRF movies containing a variety of exocytotic events.

Study data: The study set includes 15 movies of endocrine cells (MIN6 and GLUTag) that were provoked with various secretagogues, resulting in rapid emerging, slow emerging, and gross exocytotic events.

Accuracy metrics: sensitivity and positive predictive value are used to assess the accuracy of the tool detection results. The exocytosis events were manually detected and independently confirmed as truth for the study.

**Results** The study results show high sensitivity:  $88.44 \pm 4.76\%$  (153/173) and high positive predictive values:  $91.07 \pm 4.31\%$  (153/168) for all exocytotic event types .

**Conclusion** Our configurable tool could automatically provide accurate statistics for the quantification of broad exocytosis events.

967

**The Conserved Domain Database (CDD) at NCBI.**

R. A. Yamashita<sup>1</sup>, A. Marchler-Bauer<sup>1</sup>, F. Chitsaz<sup>1</sup>, M. K. Derbyshire<sup>1</sup>, N. R. Gonzales<sup>1</sup>, M. Gwadz<sup>1</sup>, D. I. Hurwitz<sup>1</sup>, C. J. Lanczycki<sup>1</sup>, F. Lu<sup>1</sup>, G. H. Marchler<sup>1</sup>, J. S. Song<sup>1</sup>, N. Thanki<sup>1</sup>, C. Zheng<sup>1</sup>, S. H. Bryant<sup>1</sup>; <sup>1</sup>NCBI, NIH, Bethesda, MD

The Conserved Domain Database (CDD) at the National Center for Biotechnology Information (NCBI) is a collection of structure based multiple sequence alignments that represent ancient conserved domains. CDD provides annotation and tools for the rapid annotation of functional domains on protein and coding nucleotide sequences. In addition protein BLAST searches by default display the results of the CD-Search giving users a quick overview of the protein domains present. CDD includes high quality curated NCBI protein domain models as well as imported models from Pfam, SMART, TIGRFAM, and COG, combining data from several disjoint resources. DELTA-BLAST, the latest in an arsenal of BLAST tools relies heavily on PSSMs generated from CDD and offers the most sensitive protein search to date, outperforming BLASTP, PSI-BLAST, and CS-BLAST. Currently, over 92% of proteins with known 3D structure and over 76% of proteins with defined source organism are annotated by CDD in NCBI's Entrez database, and about 13,000 functional sites have been recorded on close to 5000 domain models, almost half of which are supported by direct evidence observed in 3D structures of protein complexes.

968

**The pSeg Library: A toolset for simplifying live-cell image analysis.**

A. Coster<sup>1</sup>, S. Altschuler<sup>1</sup>, L. Wu<sup>1</sup>; <sup>1</sup>Green Center for Systems Biology, UT Southwestern Medical Center, Dallas, TX

A thorough understanding of biochemical pathways requires knowledge of how pathway components change in time. Investigators have become increasingly aware of the importance of measuring pathway dynamics at the single cell level, as population-level approaches may average away interesting behaviors. Additionally, the single cell variability seen in pathway dynamics may itself be an important aspect of the underlying biology. Detailed cell-level studies require careful data collection of hundreds to thousands (or more) of cells, and so fluorescence microscopy is often used due to the wealth of information available in images (position, texture, intensity distribution, and hundreds more) and because single cells can be monitored over time. Automatic identification of cellular regions in an image, termed *segmentation*, is a difficult problem, requiring some level of expertise. Segmentation depends on fluorescence signals that separately identify a cell's nucleus and cytoplasm. Such signals are not readily available for live-cell studies. To simplify live-cell image analysis, we have developed a toolset consisting of two parts: (1) a library of *segmentation plasmids* (pSegs) for differentially labeling the cytosol and nucleus of live cells, and (2) software for intensity-based segmentation that is simple to use. Each pSeg includes both a cytosolic and a nuclear fluorescent protein expressed together for a total of over 20 color localization combinations. Finally, our software identifies the nuclei in fluorescence images based on a single parameter and outputs measurements of each nucleus along with the perinuclear pixels. We hope that this toolset will simplify single-cell studies by removing the requirement for image analysis expertise and by providing an efficient experimental foundation.

**Simple Physics and the Possible Origin of Life between Mica Sheets.***H. G. Hansma<sup>1</sup>; <sup>1</sup>Department of Physics, University of California, Santa Barbara, CA*

The origins of life require reliable energy sources. One feasible energy source has not been considered until recently. This is mechanical energy - work (1, 2). The spaces between moving muscovite mica sheets are the environment in which mechanical energy is hypothesized to have been involved in the origins of life. Mechanical energy from moving mica sheets has two main sources: 1. The open-and-shut motions of mica sheets in response to water movements in and out between the sheets, and 2. Thermal cycles of day and night acting on bubble 'defects' between mica sheets. This mechanical energy is hypothesized to have been involved in the formation (and breaking) of covalent bonds, the rearrangement of polymers and molecular aggregates, and the budding off of protocells, in the earliest form of cell division. Furthermore, it is hypothesized that: The mechanical energy from mica sheets moving open-and-shut is the source of the common open-and-shut motions of enzymes, originating from a protobiotic era when mechanical energy was plentiful and chemical energy was not yet available.

**unPAK: Developing an Undergraduate Research Network to Analyze Fitness Phenotypes of *Arabidopsis thaliana* Single Gene Knockout Lines.**

M. J. Wolyniak<sup>1</sup>, H. S. Callahan<sup>2</sup>, C. J. Murren<sup>3</sup>, K. O' Donnell<sup>2</sup>, M. T. Rutter<sup>3</sup>, A. E. Strand<sup>3</sup>, Y. Wieckowski<sup>3</sup>; <sup>1</sup>Hampden-Sydney College, Hampden-Sydney, VA, <sup>2</sup>Barnard College, New York City, NY, <sup>3</sup>College of Charleston, Charleston, SC

Providing an authentic research experience for undergraduates that reflects the collaborative nature of modern biology research is a consistent challenge for faculty. A solution to this challenge is the formation of research collaborative networks in which undergraduates directly work with one another in classroom or independent research settings and take the lead in the gathering and analysis of biological data. unPAK (**u**ndergraduates **P**henotyping **A**rabidopsis **K**nockouts) is a collaborative research network between the College of Charleston, Barnard College, Hampden-Sydney College, and the University of Georgia in which undergraduates phenotype and genotype single gene knockouts (SALK insertion lines) of the genetic model plant *Arabidopsis thaliana*. unPAK seeks to serve the *A. thaliana* research community by developing a comprehensive database with specific phenotypic and genotypic information for the SALK insertion lines. Several previous targeted investigations have not uncovered phenotypes in these mutant lines. The information gathered by unPAK researchers is expected to uncover a wide variety of phenotypes in these lines that are only revealed under specific environmental conditions that mimic natural ecological variation. Additionally, mutant phenotypes may be more likely to be found by screening complex fitness traits (i.e. germination, fruit production, plant size). Molecular analysis via conventional and quantitative PCR is expected to reveal which SALK lines contain multiple T-DNA insertions that have the potential to influence and complicate total phenotypic assessment. Undergraduates have, to date, grown more than 8000 plant lines encompassing over 1000 distinct SALK T-DNA lines for the development of seed stocks and tissue samples for genotyping. Fitness experiments are ongoing to phenotypically characterize each line. Undergraduate genotypic assessment of ~1000 distinct tissue samples have suggested that approximately half of these lines possess multiple T-DNA inserts across their genomes. As unPAK continues to develop and expand, it will serve as a model for the development of cross-campus undergraduate research collaboration, provide undergraduate research experiences both in and out of the classroom, and provide an invaluable resource for the study of plant genetics.

971

**Investigation of Benefits and Challenges of Mentoring Undergraduates from Underrepresented Groups.**

A. J. Prunuske<sup>1</sup>, J. Wilson<sup>1</sup>, M. Walls<sup>1</sup>, R. Regal<sup>1</sup>, G. Trachte<sup>1</sup>, B. Clarke<sup>1</sup>; <sup>1</sup>University of Minnesota, Duluth, MN

Mentors are critical in the development of an individual's career, and most mentors in the biological sciences have had little formal training in managing undergraduates. In order to understand the benefits and challenges associated with mentoring undergraduates, we conducted semi-structured interviews with 15 undergraduate mentors at the University of Minnesota Duluth. All of the mentors we contacted agreed to participate in the interview and the interviewed mentors represented a broad array of perspectives including an equal

representation of male and female mentors, mentors from underrepresented groups, mentors at different levels of their careers, and mentors from undergraduate and professional school departments. In addition, the mentors in our study had all served as mentors for the Pathways program, which is designed to increase the number of students from underrepresented groups in science careers. Themes we explored with the mentors included: What evidence suggests that the mentor-mentee relationship is working well? How does diversity contribute to your relationship with the mentee? How does mentorship of undergraduates affect professional development? Our interview data help to identify issues relevant to designing programs and courses focused on undergraduate student research.

### Using HeLa as an Organizing Theme for an Advanced Cell Biology Course.

M. L. Casem<sup>1</sup>; <sup>1</sup>Department of Biological Science, California State University Fullerton, Fullerton, CA

HeLa cells have had an enormous impact on the field of cell biology. The story behind the first immortalized human cell line also provides insights into the role of science in society. I have developed an upper division, undergraduate, cell biology course that uses HeLa as an organizing theme. Students explore a range of topics in cell biology through review of primary literature utilizing HeLa cells as a research model. In addition, students read and discussed *The Immortal Life of Henrietta Lacks* by R. Skloot. Discussions of the sociological and philosophical aspects of the HeLa story were supplemented through the inclusion of guest lectures by faculty from the College of Humanities and Social Science. Learning outcomes for the course included **scientific literacy** as demonstrated by the ability to access, read and evaluate primary literature as well as explain methodologies and derive independent interpretation of data; **application and integration of knowledge of cell biology** as evidenced by the ability to relate specific research problems to larger question in the field of cell biology, evaluate how methodology influences interpretation, and recognize science as a human endeavor; and **scientific communication** measured by the ability of students to present scientific literature and lead an effective discussion. Students also completed several writing assignments, including a 'mini-review' on a topic of their choosing. Student response to the structure and outcomes of the course was very positive. The involvement of colleagues from outside the College of Natural Sciences and Mathematics also provided an exciting opportunity for trans-disciplinary collaboration.

973

### The Genomics Education Partnership: An undergraduate team research experience.

M. J. Wolyniak<sup>1</sup>, K. L. Clase<sup>2</sup>, A. L. Goodman<sup>3</sup>, W. Leung<sup>4</sup>, D. Lopatto<sup>5</sup>, G. C. Regisford<sup>6</sup>, J. A. Roecklein-Canfield<sup>7</sup>, A. G. Rosenwald<sup>8</sup>, C. D. Shaffer<sup>4</sup>, A. Sreenivasan<sup>9</sup>, S. C. Elgin<sup>4</sup>;  
<sup>1</sup>Hampden-Sydney College, Hampden-Sydney, VA, <sup>2</sup>Purdue University, West Lafayette, IN, <sup>3</sup>California Polytechnic State University, San Luis Obispo, CA, <sup>4</sup>Washington University, St. Louis, MO, <sup>5</sup>Grinnell College, Grinnell, IA, <sup>6</sup>Prairie View A&M University, Prairie View, TX, <sup>7</sup>Simmons College, Boston, MA, <sup>8</sup>Georgetown University, Washington, DC, <sup>9</sup>California State University-Monterey Bay, Seaside, CA

Research into how students learn science has confirmed that inquiry-driven research experiences that address important biological questions are more successful at producing scientifically literate students with good critical thinking skills than traditional content-driven

laboratory classes. The Genomics Education Partnership (GEP), a consortium of faculty from over 90 colleges and universities with different characteristics and missions, uses comparative genomics to engage students in research within the regular academic year. GEP curriculum has been adapted to many different settings, from a short module in a genetics course to the core of a laboratory course. The current GEP research project focuses on the evolution of the Muller F element (a largely heterochromatic domain) in five *Drosophila* species (*D. melanogaster*, *D. erecta*, *D. ananassae*, *D. grimshawi* and *D. mojavensis*). GEP undergraduates work to improve the draft genomic sequences and/or annotate these improved sequences. More than 4.2 million bases of draft sequence have been improved and hundreds of gene models produced using evidence-based manual annotation, leading to student poster presentations and collaborative publications in the scientific literature. The flexibility in the way GEP materials can be used means that each faculty member can adapt the materials in a manner that best suits his or her unique pedagogical goals. Anonymous surveys of GEP faculty and students show a high level of satisfaction with this active-learning approach. GEP students show similar self-reported gains in scientific problem solving and data assessment when compared to students who have participated in traditional summer research, as well as comprehension gains on a quiz about genes and genomes. The GEP pedagogical model offers an exciting opportunity for institutions with limited genomics resources and/or expertise to engage undergraduates in a research experience that will more fully prepare them for future careers in the life sciences. We invite additional faculty to join us (no previous training in bioinformatics required; see <http://gеп.wustl.edu>; training workshops will be held summer 2013). Supported by HHMI grant # 52005780 to SCRE.

974

#### **Characterization of *C. elegans* capture by a nematophagous fungus in an undergraduate laboratory course.**

B. Sato<sup>1</sup>; <sup>1</sup>University of California, Irvine, Irvine, CA

Incorporation of discovery driven experiments into the undergraduate laboratory curriculum brings students one step closer to a true research experience. The purpose of this study is to assess whether a new undergraduate lab course exercise allows students to conduct novel scientific research while achieving the learning objectives established for the module. This experiment examines the regulation of *Caenorhabditis elegans* capture by *Arthrobotrys oligospora*, a nematophagous fungus. The protocol was generated by students in an advanced molecular biology lab course using the published literature as a guide. It has been adapted for a large TA instructed microbiology lab course consisting of eight sections (160 students total) per quarter. The students in this class are presented the background information regarding the experiment. Groups of four then conduct their own literature search to identify a variable, which may affect the efficiency of *C. elegans* capture by *A. oligospora*. Briefly, the experiment involves the addition of a known number of *C. elegans* to a plate of growing fungus. At two time points following *C. elegans* incubation (6 hours, 24 hours), students count the number of surviving worms and compare to a control plate lacking fungus. The percentage of surviving worms is then compared to the chosen variable. Following data collection, students write a lab report in the format of a primary research article. From this experimental module, students were able to produce results that agree with published data as well as add to the existing literature. A number of the established learning goals were achieved, with the students demonstrating a greater understanding of the subject material and an improved ability to apply the scientific method. From self-assessments, students expressed positive gains as well. Overall, these benefits demonstrate the utility of discovery driven experiments compared to traditional “cookbook” labs.

975

**A simple microscopy assay to teach the processes of phagocytosis and exocytosis.**

R. Gray<sup>1</sup>, A. Gray<sup>1</sup>, J. L. Fite<sup>1</sup>, R. Jordan<sup>1</sup>, S. Stark<sup>1</sup>, K. Naylor<sup>1</sup>; <sup>1</sup>Biology, University of Central Arkansas, Conway, AR

Phagocytosis and exocytosis are two cellular processes involving membrane dynamics. While it is easy to understand the purpose of these processes, it can be extremely difficult for students to comprehend the actual mechanisms. As membrane dynamics play a significant role in many cellular processes ranging from cell signaling, to division, to organelle renewal and maintenance, we felt that we needed to do a better job of teaching these types of processes. Thus, we developed a classroom-based protocol to simultaneously study phagocytosis and exocytosis in *Tetrahymena pyriformis*. Using simple compound microscopes and a pulse-chase set-up where the cells are supplied India Ink as the pulse and carmine dye as the chase, we quantified black and red vesicles over time in the presence and absence of cytoskeletal inhibitors. Here we present the results demonstrating that our undergraduate classroom experiment delivers results comparable to that acquired in a professional research lab. The students performing the experiment did learn the mechanisms of phagocytosis and exocytosis and finally, we demonstrate a mathematical exercise to help the students apply their data to the cell. Ultimately, this assay sets the stage for future inquiry-based experiments where the students develop their own experimental questions and delve deeper into the mechanisms of phagocytosis and exocytosis.

976

**Preparing Science & Math Undergraduate Majors to Teach in K-12 Classrooms.**

E. M. Stone<sup>1</sup>; <sup>1</sup>Cal Teach Program, University of California, Berkeley, CA

Recruiting, preparing, and retaining high quality K-12 teachers are critical issues for promoting scientific literacy for our nation's youth, particularly those from socially and economically disadvantaged backgrounds. Education leaders have advocated for teacher education programs to provide stronger preparation and support for beginning teachers. Proponents of innovation in teacher education pathways argue that in subject areas with severe teacher shortage problems, such as science and math, there should be a deliberate effort to open channels for attracting strong candidates such as science and math undergraduate majors into teaching. Cal Teach Berkeley is a new interdisciplinary teacher education program that allows undergraduate students to complete their degrees in life sciences, physical sciences, engineering and math while simultaneously earning a single-subject teaching credential with a focus on teaching in urban schools. We hypothesize that the integration of science and math disciplinary coursework with education coursework and simultaneous opportunities for apprentice teaching through multiple field placements in local K-12 classrooms will produce highly qualified science and math teachers. We present data that address the following research questions: (1) How does the integration of disciplinary coursework, education coursework, and field placements in urban classrooms the development of pedagogical content knowledge (PCK)? (2) How does this integration influence the development of productive beliefs about subject matter knowledge, teaching, and learning? (3) How are Cal Teach graduates able to translate their beliefs and PCK into classroom practices that promote pupil learning? In particular, we highlight a research methods course that provide research experiences for Cal Teach students so that they may gain an understanding of and comfort level with the process of research by engaging in in-depth, authentic research projects and subsequently engage their K-12 students in meaningful inquiry and problem-solving. We describe the Cal Teach Summer Research Institute and instruments we developed for measuring outcomes of this program. A

Knowledge Integration scoring rubric specific for the research process effectively measures conceptual understanding of research by analyzing open-ended responses from pre/post surveys. We show that the opportunity to engage in scientific research experiences provides participants with a deeper understanding of the process of experimentation and the nature of science, as well as strategies for teaching these concepts and skills to K-12 students.

977

**The flip-side of integrating research and teaching: the research laboratory as a classroom.**

*T. A. Frey<sup>1</sup>, L. J. Runyen-Janecky<sup>2</sup>, O. A. Quintero<sup>2</sup>; <sup>1</sup>Department of Biology, Dickinson College, Carlisle, PA, <sup>2</sup>Department of Biology, University of Richmond, Richmond, VA*

Undergraduate independent research projects provide opportunities to aid student growth towards the independence required for a professional career. In addition to producing publishable work, the goal of an independent study project is to help students transition from viewing knowledge as something that is provided to realizing that they can participate in the analysis, interpretation, and creation of new knowledge. Just like any other skill, the expertise required to become an effective scientist is learned. However, students accustomed to traditional courses can struggle when faced with less structured experiences like independent study. Even if a student is receiving course credit for an independent project, traditional coursework can seem more important because of the internal checkpoints (exams and assignments) by which a student can easily gauge success. Additionally, since the emphasis for independent research projects is often placed on the actual doing of experiments, students can be left without a proper understanding of the preparation, effort, and “skills away from the bench” required of an effective researcher. Here we describe student-centered approaches designed to aid students in transitioning from traditional coursework to independent research by overlaying a structure onto independent study. Projects are built around a formal syllabus. They also contain specific mechanisms to assess student progress, generating feedback useful in improving the experience for all involved. From the onset of the project, student involvement is key to developing an individualized plan that is tailored to the goals of both mentor and student. Written materials relevant to working as a scientist (such as searching the scientific literature, presenting one’s own research, and keeping a lab notebook) are provided to supplement oral instruction. To introduce students to the idea of external review and accountability, a portion of their final grade comes from an external reviewer. Assessments in the middle and at the end of the experience allow for the students and mentors to revise and improve the project for the next iteration. Student feedback indicates that participants have a realistic understanding of the complexity of the scientific endeavor, beyond what is necessary to complete their specific experiments. Those that choose to enter graduate programs are well prepared--those that have chosen other careers have developed a skill set that will help them to be successful professionals.

978

**Integrating research and teaching: The classroom as a research laboratory.**

*L. V. Paliulis<sup>1</sup>; <sup>1</sup>Biology Department, Bucknell University, Lewisburg, PA*

While new active pedagogies that expand student engagement and investment are common in the classroom environment, use of similar active pedagogies is not common in laboratory sections of many undergraduate courses. In addition, more students seek research experiences than are available, and faculty at primarily undergraduate institutions often have difficulty balancing large teaching loads with their desire to answer exciting research questions. I have addressed these issues by creating a research-and inquiry-based undergraduate

laboratory section of an advanced genetics course. The course focuses on chromosomes; their inheritance, their structure, their evolution, and chromosome-based sex determination. The reading material for the course consists of reviews and articles from the primary literature. The laboratory component of the course is a semester-long research project that establishes connections between course material and my own research. The research project evolves from year to year as the research question progresses. Topics have included meiosis in holocentric chromosomes, chromosome behavior on the spindle, and evolution of chromosome number, structure, and sex determination. At the beginning of each semester, students are instructed in the basic methods they will need to study their topic, and provided with all background literature. Lab groups of 2-4 students are then formed, I discuss with each group the approach they will take to studying their topic, and the students then design and analyze their own experiments. To assess whether the lab meets its learning goals, I used both course evaluations and the CURE (Classroom Undergraduate Research Experience) survey. Students reported gains in understanding the research process, in confidence that they could create hypotheses and design experiments to test those hypotheses successfully, and in critically interpreting and reporting research results. Students also reported learning about the struggles associated with science, e.g. when experiments fail to test their hypothesis, or when organisms die or are difficult to work with. As a faculty member and researcher, I have been impressed with the quality of student work, and have obtained publishable results each year I have taught this course, with the most recent version significantly enhancing my research program. The research projects designed for this laboratory could easily be altered and used as a laboratory for a non-majors biology class, or for an introductory genetics or cell biology class, and the critical thinking and analysis gains should carry into any situation.

979

### **Effectiveness of Supplementing Traditional Lecture with Animation.**

*M. K. Zanin<sup>1</sup>; <sup>1</sup>Biology, The Citadel Military College, Charleston, SC*

Many students are intimidated by courses in cell and molecular biology because these courses require them to conceptualize intangible processes. Illustrating these abstract concepts with textbook figures is helpful, but a mounting body of evidence indicates that presenting simple animations may improve learning outcomes, because it allows students to see a topic as a continuous process. In this study, student learning outcomes were compared following cell biology lessons taught with three different instructive strategies. One group was instructed with traditional written material and figures; another group was instructed with narrated animations; and a third group was instructed with both written material and with animations. Learning outcomes were measured using a pre-test/post-test analysis. Mean post-test score improvements for the three methods of teaching were compared pairwise using independent t-tests with 2 tails. No significant difference in learning outcomes was observed between students who learned from traditional written lessons as compared to those who learned from narrated animation lessons. In the post-study survey, many students reported anecdotally that they learned better from one method or the other, indicating that the best teaching strategy might be to incorporate both written lessons and animations into lessons, in order to accommodate multiple learning styles of students. Surprisingly, for three of the four topics taught in the study there was no significant improvement in outcomes for students who learned from both methods of instruction prior to taking the post-test as compared to outcomes for students who learned from only written lessons or from only narrated animation lessons. These results show that more studies are needed to determine if students who learn via multiple instructive strategies can achieve better learning outcomes than students who learn from only one method of teaching.

980

### **Integrating Inquiry-Based Laboratory Exercises throughout an Undergraduate Biology Curriculum.**

*V. Navas<sup>1</sup>, D. Siritunga<sup>1</sup>, R. Montalvo<sup>1</sup>, F. Carrero-Martinez<sup>1</sup>, N. Franz<sup>1</sup>, C. Acevedo<sup>1</sup>, A. Velez<sup>1</sup>, N. Diffoot-Carlo<sup>1</sup>; <sup>1</sup>Biology Department, University of Puerto Rico Mayaguez Campus, Mayaguez, PR*

It is nationally recognized that undergraduate students profit from exposure to research activities. Large undergraduate institutions that cannot accommodate all students in independent research projects due to financial and personnel constraints need to search for alternatives that effectively expose undergraduates to research endeavors. The Biology Department at the University of Puerto Rico Mayagüez Campus has developed an initiative (funded by HHMI) in which research has been successfully integrated into the curriculum involving all departmental undergraduate students (approximately 1,300 per year). In this approach, faculty researchers designed inquiry-based laboratory modules that have been integrated into undergraduate biology courses (General Biology, Microbiology, Genetics, Botany, Zoology, Immunology, Cell Biology, Microbial Ecology, Entomology and Plant Physiology). Each laboratory module comprises of 3-12 contact hours and focuses on molecular and/or structural research in the given course field. The lab module mimics as much as possible an authentic research environment within the constraints of the large undergraduate and teaching assistant populations. Students take a minimum of four inquiry-based lab modules as they progress through their undergraduate curriculum thus being exposed to multiple research projects in different disciplines prior to graduation. With this approach, our large undergraduate science population acquires research awareness and appreciation as well as research skills. Assessment conducted revealed that students, including those with independent research experiences, have learned novel research techniques and skills in the teaching labs of their biology courses. Our approach of impacting students early in their undergraduate careers, and doing so multiple times, also enhanced student's interest in pursuing other research activities and graduate / professional degrees. Each inquiry-based lab module was pilot tested, thoroughly assessed and modified accordingly, before permanent integration into the course lab schedule. Challenges encountered, especially at the beginning, included resistance-to-change attitude by lab technicians and coordinators, research faculties' general lack of experience in conducting assessment in education, as well as the intense coordination required for graduate teaching assistants training and for gathering of assessment data. We will describe in detail the process followed to design and integrate the modules in the courses, challenges encountered, assessment tools developed and the impact of this endeavor on our undergraduate population. Other science departments with large undergraduate student population as ours will find this initiative useful to further enrich their undergraduate student's research experiences.

981

### **Improving student performance in a first year biology course through an emphasis on learning strategies.**

*J. Sanjeevi<sup>1</sup>, H. Bryner<sup>1</sup>, B. Porter<sup>1</sup>, J. Fernandes<sup>1</sup>, P. Callahan<sup>1</sup>; <sup>1</sup>Zoology, Miami University, Oxford, OH*

Objective: Introductory courses are one of the major reasons for student attrition in the STEM majors. The U.S. Department of Education strongly recommends the development of stronger programs and customized approaches to increase student retention in the STEM majors. Undergraduate Research and Mentoring (URM) program at Miami University is funded by the NSF. The chief objective of the program is to increase diversity and retention in the biological sciences. . Introductory biology course, BMZ 115 is a large enrollment class aimed at teaching

basic biology concepts and is a gateway course designed primarily for biology majors. BMZ 115 is perceived by many students to be one of the weed-out courses at Miami University. The attrition rate for the course over the past 3 years is ~40%. The URM program designed and implemented a supplemental sprint course for BMZ 115 in fall 2011, emphasizing learning strategies to improve student performance and thereby retention in the biological sciences.

Description: The sprint course was offered for seven weeks during the second half of the semester. Students who had a C or lower grade in the first exam in BMZ 115 were encouraged to enroll in the sprint course. Sixty students enrolled in the course. The students in the sprint course focused on learning strategies based on Merlin C. Wittrock's generative learning theory which was derived from David Ausubel's assimilation theory. David Ausubel defined assimilation as a fundamental process involved in meaningful learning, where new concepts and propositions are hierarchically arranged and incorporated in to already existing cognitive structures. The strategies practiced in the sprint course were the following:

- Making outline before every lecture focusing on the significance of the material to be taught in relation to previously learned material
- Reorganizing lecture notes using concept maps and flow charts
- Developing the habit of asking questions while studying, to evaluate oneself on the learned material

Results: (1) Study habits of the students in the sprint course improved during the course (2) An achievement gap observed between the control and the sprint group in the first exam in BMZ 115 during the beginning of the sprint course, gradually decreased in the subsequent BMZ 115 exams and closed in the final exam.

982

**Connecting the Core: Comprehensive assessment model of basic concepts and research skills in a four-year undergraduate biology curriculum.**

*C. Chandrasekaran<sup>1</sup>, B. Benz<sup>1</sup>, M. A. Clark<sup>1</sup>, A. Roberts<sup>1</sup>; <sup>1</sup>Department of Biology, Texas Wesleyan University, Fort Worth, TX*

In 2004, the Department of Biology at Texas Wesleyan adopted a research-based curriculum for its undergraduate biology major in response to the call for reform by several noted educational groups (National Academy of Sciences, AAAS, etc). Based on these recommendations, the department designed a curriculum focused on developing analytical skills and emphasizing exposure to biological research techniques. Curricular changes included the introduction of inquiry-based laboratory explorations in all courses, and the implementation of a two-semester capstone course sequence for all biology majors to develop skills in independent research. We developed a comprehensive assessment approach that evaluated student performance in both concept acquisition and hands-on research skills, utilizing both tools designed specifically by the department and nationally standardized assessment tools. Our strategy is unique and notable because of its breadth (preliminary evaluations starting in the freshman year, with both mid-program and end-of program evaluations) and depth (specific tools developed to assess laboratory-based skills, analytical skills, and basic concept acquisition). We submit our curricular design and assessment efforts as a model of how to incorporate sustained evaluation throughout the curriculum, and present a novel method for assessment of laboratory skills and analytical abilities for students in the biological sciences.

983

**Integrating teaching and research in a research-based introductory biology laboratory curriculum: results of a three-year comparison evaluation.**

*S. E. Brownell<sup>1</sup>, M. J. Kloser<sup>1</sup>, T. Fukami<sup>1</sup>; <sup>1</sup>Biology, Stanford University, Stanford, CA*

National reports including Bio2010 and Vision and Change have emphasized the positive impact that a research-based curriculum can have on undergraduate biology laboratories. However, few research-based curricula have been implemented in large introductory laboratory courses at research-intensive institutions due to logistical challenges and few incentives for faculty to dedicate time to teaching rather than research, with teaching and research often perceived as competing demands.

We present an introductory ecology-based lab course implemented at a research-intensive institution that has many of the hallmarks of authentic research – a single longitudinal question, research questions with unknown answers, the use of modern ecological and molecular techniques in the field and in the laboratory, experimental designs and protocols that are not pre-determined, and collaboration among lab peers.

As part of the assessment of this lab course, we compared students enrolled in the research-based ecology course to students enrolled in a traditional “cookbook” lab course using pre- and post-course Likert-scale surveys. The first year assessment using a matched-pair design comparing volunteers in the new course with matched students in the traditional course revealed that the new course had a significant positive effect on student attitudes regarding authentic research practices, student perceptions of their ability to do lab-related tasks, and student interest in pursuing future research. The second year assessment using a randomized study design showed that the new course compared to the cookbook course had a significant positive effect on student attitudes regarding authentic research practices, but there were no differences in either student perceptions of their ability to do lab-related tasks or student interest in pursuing future research. The third year assessment using a randomized study design that scaled the number of students up to over 100 showed similar results to the second year assessment, specifically gains in student attitudes towards authentic research practices.

Notably, this curriculum goes beyond its pedagogical functions to provide a source of novel data that can have an epistemic function. For example, student-collected data are being used to answer research questions that are the subject of research-based manuscripts from the professor’s research lab.

The success of this curriculum serves as a case study showing that, by merging research and teaching, a research-based curriculum can provide a mutual benefit to undergraduates and faculty. Based on our experience and formal assessment, we provide general ideas and specific protocols that can be easily applied to implement similar curricula elsewhere, in particular at research-intensive institutions where instruction has often taken a backseat to research.

984

**Improvisation: Building and Understanding Environments for Creative Learning.**

*R. M. Holmes<sup>1,2</sup>, S. Hug<sup>3</sup>; <sup>1</sup>Center for Cell Analysis and Modeling, U.Conn Health Center, Farmington, CT, <sup>2</sup>improvscience, Boston, MA, <sup>3</sup>A.T.L.A.S, U.Colorado at Boulder, Boulder, CO*

Recent research in learning suggests that people learn and develop expertise through social interaction, and it is the qualitative aspects of those interactions that affords learning (Vygotsky,

1976; Bransford, Brown, Cocking, 1999; Holzman, 2009) It is also increasingly recognized that an integral component of collaborative learning environments is improvisational conversation (Sawyer, 2007).

Yet, scientists and science educators are rarely invited to learn and practice the social-cultural skills involved in building environments of cooperative communication and interdependent, collaborative work. In contrast, actors in improvisational (improv) theatre explicitly learn how to develop such environments, to experiment with different performances and interactions, and to take risks. Both groups are challenged to collectively create an ensemble of individuals from diverse disciplinary, ethnic and socio-economic backgrounds to work together.

We created improv theater workshops to 1) teach the principles of improv, 2) engage scientists in developing their abilities for group creativity and 3) discover if and how improv theater training affects learning and creativity within computational biology. The 90 minute workshops used improv theater exercises that focus on the development of the ensemble, accepting and giving “offers”, and active listening.

The evaluation of this effort is accomplished through socio-cultural research questions focused on workshop participants’ perspectives of creativity in science, production of creative ideas, opportunities to practice creative thought in collaboration, and abilities to project their creativity in their future research. Our findings suggest improvisational theater training can help participants to create a social environment and a perspective on interaction practices that provide new ways of building community within working groups and a new view of the discursive practices that may be common to science professions. Specifically, participants: 1) realized interpersonal relationships affect learning and creativity within interdisciplinary research teams, 2) learned about their own and others’ perceptions of their field through discussions with individuals from various disciplines, 3) reexamined their notions of learning, and 4) identified having a supportive, collaborative environment as most valuable experience of improvisational training for computational biology.

985

### **Jumpstarting STEM Careers.**

*D. P. Baluch<sup>1</sup>, K. Traynor<sup>1</sup>, A. Cease<sup>1</sup>, M. Coloumbe<sup>1,2</sup>, V. Stout<sup>1</sup>, K. Sweazea<sup>1,3</sup>; <sup>1</sup>School of Life Sciences, Arizona State University, Tempe, AZ, <sup>2</sup>College of Liberal Arts and Sciences, Arizona State University, Tempe, AZ, <sup>3</sup>School of Nutrition and Health, Arizona State University, Tempe, AZ*

A successful career in science, technology, engineering and mathematics requires not only a great education and research experiences but also extensive training and preparation with dedicated and enthusiastic mentors and role models. To help promote this preparation, initiatives by the National Science Foundation, National Institutes of Health and other funding institutions now require that post-doctoral mentoring plans be incorporated into funded research proposals to maintain a pipeline of future professionals. Women and minorities are especially affected by low rates of career advancement. Although a similar number of women obtain high-level degrees as compared to men, it appears that women do not continue within academia in proportion to their male contemporaries; such that, significantly fewer women occupy higher ranked, tenured and tenure-track positions. For example, recent statistics show that women received over 40 percent of all BA/BS degrees awarded by U.S. 4-year colleges and universities in the life sciences and that the proportion of women with doctorates has exceeded 40 percent for the last two decades with some reports as high as 60 percent in the biomedical fields. However, in the basic science departments of most medical schools and universities, the

proportion of women associate professors is still below 30 percent, and the proportion with rank of full professor is only 20 percent. In an effort to address these concerns, the Central Arizona Chapter of the Association for Women in Science, based at Arizona State University, and in collaboration with colleagues from George Washington, Gallaudet and Ottawa Universities, has developed a program to help prepare graduate students, post docs and early faculty for a career in stem. This nsf advance funded program tackles the problem of low career advancement of women and minorities by hosting a series of career development seminars and workshops to provide training, mentoring and networking opportunities to graduate students and post docs as they progress through their program of study. Such career training programs that include mentoring and networking will help address the complex problem encountered by women and minorities and thus will aid in restoring a pipeline of diverse stem professionals.

986

**Abstract art can enhance student learning about quantitative measurements of cells in biological tissues.**

*F. Lakhani<sup>1</sup>, P. Selz<sup>2</sup>, T. M. Elul<sup>1</sup>; <sup>1</sup>Dept. of Basic Sciences, Touro University California, Vallejo, CA, <sup>2</sup>Dept. of Art History, University of California, Berkeley, Berkeley, CA*

To enhance the histology and embryology curriculum for first year medical students at Touro University California, paintings of the abstract expressionist artist Sam Francis that resemble, and may have been inspired by, biological images, were also presented to the students. We then developed a research project in which a student performed a mathematical comparison between shapes of cell-like forms in the paintings and shapes of cells in these biological images. Our analyses showed that the shapes of cells in Sam Francis paintings are more varied than those of biological cells. Cell like forms in the Sam Francis painting 'Red in Red' were more diverse in elongation (measured as Length to Width (LW) ratio) than red blood cells in a Blood Smear slide. In addition, cells in the Sam Francis painting 'Abstraction' varied more in their skewness (measured as Kurtosis) than cells from an image of embryonic tissue undergoing morphogenesis. This underscores the unconstrained aspect of Sam Francis paintings compared to nature, as well as the variability of cell shapes between different paintings of Sam Francis. This also shows that art can be used as an effective tool to enhance medical student learning about histology and embryology, and quantitative morphometric techniques common in contemporary bio-informatics research in cell and developmental biology.

987

**The SUN Project Significantly Improves High School Biology Students' Knowledge of Biological Energy Transfer Relative to Cluster-Randomized Controls.**

*A. Batiza<sup>1</sup>, M. Gruhl<sup>2</sup>, B. Zhang<sup>3</sup>, W. Luo<sup>3</sup>, T. Harrington<sup>4</sup>, M. Roberts<sup>5</sup>, D. LaFlamme<sup>6</sup>, M. Haasch<sup>7</sup>, J. Knopp<sup>8</sup>, G. Vogt<sup>9</sup>, D. Nelson<sup>10</sup>; <sup>1</sup>Applied Research and Grants, Milwaukee School of Engineering, Milwaukee, WI, <sup>2</sup>Gruhl Education Consultants LLC, Washburn, WI, <sup>3</sup>Educational Psychology, University of Wisconsin-Milwaukee, Milwaukee, WI, <sup>4</sup>Bacon Academy, Colchester, CT, <sup>5</sup>Concordia University, Mequon, WI, <sup>6</sup>St. Dominic School, New Berlin, WI, <sup>7</sup>Wauwatosa School District, Wauwatosa, WI, <sup>8</sup>International Baccalaureate, Cardiff, Wales, <sup>9</sup>Center for BioMolecular Modeling, Milwaukee School of Engineering, Milwaukee, WI, <sup>10</sup>Biochemistry, University of Wisconsin-Madison, Madison, WI*

The SUN (Students Understanding eNergy) Project has developed a new approach to learning about biological energy transfer. During the SUN teacher workshop, a series of experiences emphasizes the role of moving electrons in both abiotic and biotic instances of energy release

and capture. The common terminology of ultimate electron donor and electron acceptor allows one to highlight this physical basis for energy transfer in both a hydrogen fuel cell and in the mitochondria and chloroplasts of living things. This terminology also allows one to conceive of life forms that do not require oxygen (that have a different ultimate electron acceptor) or that use electrons from an atypical source (not a carbon compound) as the ultimate electron donor. Our physical manipulatives, now with some digital support, are designed to help learners understand how electrons move in the chloroplast and mitochondrion, what gets them moving, and how some of the energy released can be stored in a usable form as a result. Previously we reported significant effects of this approach on teacher knowledge and self-efficacy demonstrated both in a traditional exam and in a drawing with explanation assessment. Here we report significant effects upon regular biology students from a cluster-randomized controlled trial. Importantly, students were assayed at the beginning and end of the course, not at the beginning and end of instruction. We found that when pre-scores, SES (free lunch eligibility), GPA and gender were controlled, the SUN participants demonstrated significantly higher scores with a medium effect size of .44. Interestingly ANOVA analysis demonstrated no significant gain in knowledge by control students, which supports a plethora of data regarding student difficulty learning this topic. We will discuss additional data that explore the affordances of these manipulatives, and also propose a learning progression that highlights fundamental laws and applies them to biological energy transfer.

988

### **Turning Grandparents on to Content Based Cell Biology.**

*M. R. Kasschau<sup>1</sup>; <sup>1</sup>CALL, Keene State College, Keene, NH*

The Cheshire Academy for Lifelong Learning (CALL) program at Keene State College is organized around classes that are 90 minutes long and run for eight weeks. Having 12 hours of class time over an extended period allows one to teach content based science courses with time to allow the "students", or in this case 55+ year old grandparents, to build an understanding of the early parts of the course before progressing to the more complicated content near the end of the course. The courses I have taught to this group have been highly successful to the extent that I have developed a following of about 20 students who take every new course I offer. Another 20 to 30 additional students have taken one or two of my courses. Courses I have taught for the CALL program include: The A, B, C's of Cell Biology, Cancer Cell Biology, Understanding Genetics and How Animals Work. Toward the end of each class I have, when possible, tied the course to relevant information in the news. Feedback from "students" indicates that they better understand biological topics they read about in the news, can talk with their grandchildren regarding their new understanding of cell biology, and have a better understanding of their own bodies and health.

989

### **From lab to classroom: Science with mobile phone microscopes.**

*E. M. Schmid<sup>1</sup>, O. Höller<sup>2</sup>, S. Khan<sup>3</sup>, C. Reber<sup>1</sup>, S. Eistetter<sup>1</sup>, E. Röttinger<sup>4,5</sup>, A. Amiel<sup>4,5</sup>, D. A. Fletcher<sup>1</sup>; <sup>1</sup>UC Berkeley, Berkeley, CA, <sup>2</sup>University of San Francisco, San Francisco, CA, <sup>3</sup>San Francisco Friends School, San Francisco, CA, <sup>4</sup>University of Hawaii, Honolulu, HI, <sup>5</sup>KahiKai, Honolulu, HI*

Microscopy is a critical tool for biological and clinical research, but high-quality microscopes are typically confined to well-equipped laboratories. We recently developed a mobile phone-based microscope for disease diagnostics in developing countries that enables high-resolution imaging outside traditional laboratory environments. After a chance encounter with a middle school

science teacher in San Francisco, we introduced these mobile phone microscopes, called CellScopes, to students at the San Francisco Friends School and found that they could provide new educational opportunities in the classroom and motivate middle school students to pursue discovery-based learning. Over the course of a year, students used a set of CellScopes to carry out a 'Micro : Macro' project in which they took the microscopes outside the classroom to take macroscopic and microscopic pictures of objects in their homes, gardens, parks and playgrounds. The images were displayed in real time on the touchscreen of the phone and could be viewed by multiple students simultaneously, which allowed for interactive discussions among students and teachers. Image modifications and annotations were performed directly on the smartphone screen and results were subsequently posted to social media platforms for further discussions. This project required both students and academic researchers to be actively involved, take initiative, and think creatively about the microscopic world around them. We are now extending the use of CellScope to educational outreach activities with researchers from the University of Hawaii where the microscopes are taken to the beach and students participate in plankton diversity monitoring.

990

**Foldscope: Origami based print and fold paper microscopes.**

*J. Cybulski<sup>1</sup>, J. Clements<sup>2</sup>, M. Prakash<sup>2</sup>; <sup>1</sup>Mechanical Engineering, Stanford University, San Francisco, CA, <sup>2</sup>Bioengineering, Stanford University, San Francisco, CA*

Here we describe Foldscope, a fully functional microscope printed and folded out of paper. Foldscope utilizes the principles of origami to implement bright field, multi-fluorescence, polarization, dark-field and projection microscopy. Foldscopes are manufactured in a roll-to-roll process where all the optical components including lenses, apertures and illumination electronics are directly printed on paper. Novel optical components including spherical GRIN lenses and integrated micro-apertures are also introduced. Panning and focus stage are implemented as a flexure mechanism in paper. The entire microscope can be assembled in minutes, includes no mechanical moving parts, is extremely light (paper), packs in a completely flat configuration in a very small volume, operates with no external power, can be dropped from a 5-story building or stomped upon by a person and can be incinerated if required. We describe several potential applications of foldscope in ultra low cost "use and throw" microscopy for field diagnostics of diseases including malaria, chagas, giardiasis. Costing less than a dollar, Foldscopes can bring microscopy out of the lab and into the hands of citizen scientists enabling large-scale hands-on life science education opportunities.

991

**Teaching Cellular and Molecular Biology with a Video Game, Evaluation Results and Game Development.**

*M. A. Stegman<sup>1</sup>, C. Slayden<sup>2</sup>, A. Slayden<sup>2</sup>; <sup>1</sup>Learning Technologies, Federation of American Scientists, Washington, DC, <sup>2</sup>Medical and Scientific Animation, Cosmocyte, Inc., Savage, MD*

Immune Attack is a third person shooter that is designed for Advanced Placement (AP) biology students in high school to learn about the immune system, cell to cell communication, and how proteins are required to mediate the signals that allow the immune system to function. We have developed an assessment of cellular immunology knowledge gained as well as confidence with the graphical presentation of the subject matter, and correlated these scores with the amount of time players report spending on video games, how much of the game students finished in the time allotted, whether the students understood the game mechanism, and whether they found the game difficult to play. Our short, 3 day, protocol allowed us to collect a large data sample,

N=180 for each group: middle school, Immune Attack, middle school control, high school Immune Attack and high school control. Classes were each divided randomly into Immune Attack or control groups to ensure that the teacher quality, subjects covered, socio economic status were controlled. Additionally, parental consent was obtained, as well as student assent. Our results show that students gain confidence with the material regardless of how much of the game they play through or how much they play games in general. Additionally, we found that middle school students also enjoyed the game, learned cellular immunology concepts and gained confidence with the graphical representations of cellular immunology, despite the fact that the material covered in the game was at the AP level. Using the results from our evaluation and play testing, we built a sequel game called Immune Defense. Immune Defense is a two dimensional game that can be downloaded and played on Macintosh and PC computers and in browser windows online. The game is a real time strategy style game, in which players must strategically deploy cells of the innate and adaptive immune system to destroy ever more difficult Pathogens. Our evaluation of how well Immune Defense teaches cellular immunology is ongoing. It will include a comparison of the game versus a video on the same topics. We will also investigate whether students learn more when they watch the video before or after playing the game.

992

**Rising to the challenge of 'Vision and Change in Undergraduate Biology Education'**

*S. M. Wick<sup>1</sup>, R. Wright<sup>2</sup>, D. Matthes<sup>2</sup>; <sup>1</sup>Plant Biology, University of Minnesota, St. Paul, MN, <sup>2</sup>Genetics, Cell Biology and Development, University of Minnesota, Minneapolis, MN*

In 2009 AAAS published a call for reform in undergraduate biology education based on several guiding recommendations: Integrate Core Concepts and Competencies throughout the Curriculum, Focus on Student-Centered Learning, Promote a Campuswide Commitment to Change, and Engage the Biology Community in the Implementation of Change. The College of Biological Sciences at the University of Minnesota-Twin Cities has established courses and programs to meet several aspects of the recommendations found in the Vision and Change report. We provide coursework that emphasizes student-centered learning, problem solving, team responsibilities, and core concepts and competencies both at a foundational biology and in some upper division courses, including cell biology. Other instructors are noticing the increased preparation and critical thinking skills of students who have participated in student-centered courses, and graduates of these courses report they are better prepared for upper division work, lab research and graduate school than students in traditional lecture courses. We established a series of Conversations on Teaching and Learning as one element of a commitment to creating a community of biology scholars dedicated to improving undergraduate courses and contributing to the teaching and learning literature. We also have begun a Scientific Teaching Program for advanced graduate students and postdocs in biology as a way to introduce them to principles of effective teaching that include classroom diversity, active learning and assessment, as informed by current literature. All participants practice what they have learned by working on a team to create a small instructional module in their sub-discipline. As current or former teaching assistants, they typically recognize the power of this education reform and are eager to put its principles into action as the next generation of biology educators.

993

### **An In-class Activity that Promotes Understanding of Experimental Design for Undergraduates.**

A. Crowe<sup>1</sup>, S. Freeman<sup>1</sup>, O. Okoroafor<sup>1</sup>, M. Koval<sup>1</sup>, R. Theobald<sup>1</sup>, M. Wenderoth<sup>1</sup>; <sup>1</sup>University of Washington, Seattle, WA

Understanding experimental design is essential to all fields of science. This fundamental skill is taught beginning in elementary school and continuing through to the college classroom. Although students quickly grasp the general idea of creating an experiment to test a hypothesis, they are frequently unable to put these ideas into practice. Our aim was to develop a twenty minute in-class group activity suitable for the large lecture hall which would promote student understanding of experimental design. We designed two alternative activities to test the hypothesis that analysis of well-designed and confounded experiments would be more effective at teaching experimental design than creating a new experiment. Students in an introductory biology course were randomly assigned one of the two activities which they completed in groups of two to four during the same class period. To assess the effectiveness of these alternative interventions we measured student performance using the open-ended experimental design ability test (EDAT) administered before and after the in-class activity. The EDAT and scoring rubric were expanded in order to capture students' ability to justify their proposed experimental design. Comparison of change in pre/post EDAT scores using a general linear model to control for student academic ability and ethnicity revealed no significant differences between the two interventions. However, both activities increased student understanding of experimental design relative to a control group which received a traditional lecture in place of the activities (effect size = 0.25;  $p = 0.047$ ). Moreover, the median performance of students who received either activity exceeds the median performance of graduate students on the same test ( $p = 0.01$ ). Thus, creating a well-controlled experiment and justifying the design elements remains a challenge for entry-level Ph.D. students in biology.

994

### **Promoting Understanding of Scientific Literature among College Students.**

R. Lee<sup>1</sup>, V. Ayukaev<sup>2</sup>, N. Vo<sup>1</sup>, H. Hu<sup>1</sup>, J. Knight<sup>1</sup>; <sup>1</sup>College of Biological Sciences, University of Minnesota, Minneapolis, MN, <sup>2</sup>College of Science and Engineering, University of Minnesota, Minneapolis, MN

The current system of undergraduate education in science fields often includes a limited amount of training in understanding professional research publications. The pursuit of a higher educational degree, however, requires this training. We conclude that there can be an academic gap between undergraduate training and postgraduate expectations in biomedical professional schools.

With this in mind, we undergraduates have created the Health and Biological Research (HBR) News Foundation, which serves to increase undergraduate students' understanding of scientific publications. Our goals include education of young scientists, especially college students, by encouraging them to read contemporary biological research and write and report summaries of their applications. We aim to create working professional relationships within a team of motivated individuals through interactive groups and peer-to-peer review. We also want to further worldwide dissemination of biological knowledge by publishing our works and translations of them on our website. To ensure scientific quality of our articles, our members use primary scientific literature from journals such as Nature and Science, and send their works to authors of the original publications for revision and approval. Another goal is to create an online

database where other college students and the general public can receive updates on the latest biological and medical discoveries.

To accomplish our goals, the Foundation established its first chapter at the University of Minnesota. This chapter also serves as a model as we strive to establish more at other universities. So far our colleagues at Tufts and Pennsylvania State University have agreed to establish a chapter at those campuses.

After eight months, the results show that students who participated in our chapter at the University of Minnesota have succeeded in their general biology courses, developed a better understanding of biology, sharpened their scientific reading and writing skills, and actively engaged in scientific discussions. Members report that they have discovered more biological areas of interest through reading and writing about various research articles. In addition, members enjoy the scientific, peer-reviewed, and professional environment within the chapter. Our website consistently has more than 60 unique viewers every day, 200 every week, and 700 every month.

995

### **Strategies to improve time management and content retention in undergraduate Biology majors.**

*N. T. Ahmed<sup>1</sup>; <sup>1</sup>Department of Biology, St. John Fisher College, Rochester, NY*

Current undergraduate students expect immediate access to information on any topic, due in large part to advances and accessibility of technology. As a consequence, this generation struggles with tasks that require a consistent commitment over a long period of time. These tasks can include acquiring and retaining a set of information over a semester or completing a multi-week long project. To help students improve their time management skills in Cell Techniques, a laboratory-based course, a large project was broken down into small tasks with intermediate deadlines. Students kept a log of the time they spent completing all laboratory assignments over the course of the semester. On the six-week project with intermediate deadlines, students spent on average 2.8 hours per week in addition to the scheduled lab time and 3.5 hours the week before the final due date. In contrast, on a four-week single deadline project, students spent 2.7 hours per week for the first three weeks of the project and 5.0 hours of outside time the week before the project was due. Students were more consistent in the amount of time they spent each week completing a project with multiple deadlines than they were in completing a single deadline project. To help students improve their retention of information and time management skills in Genetics, a content-centered course, reading worksheets were designed and evaluated for effectiveness. These reading worksheets forced students to read the assigned material on time, produce a tangible product that could be used for studying for the exams, focus on information the instructor deemed important, and engage in higher order thinking. Student learning was evaluated using pre and post unit assessments. For example, on the pre-unit I assessment, only 22% of students could demonstrate they knew how many chromatids would be in a cell at prophase I of meiosis. On the unit I exam, 68% of students demonstrated knowing this concept and 93% of students answered the question correctly on the final exam. Student feedback was solicited using an anonymous survey. Ninety-three percent of the students who completed the survey found the reading worksheets helpful and ninety-seven percent recommended that I continue to use reading worksheets in the future offerings of the course. Improved student learning, content retention, and satisfaction support the continued use of instructor-designed reading worksheets.

996

**How Does Active Learning Influence Student Learning in Large-Enrollment Introductory Biology Courses?***C. A. Saunders<sup>1</sup>, S. Kazmi<sup>1</sup>, M. D. Withers<sup>1</sup>; <sup>1</sup>Biology, West Virginia University, Morgantown, WV*

The goal of this study was to begin to understand which aspects of an active learning classroom, level of engagement or level of alignment between the assessments used for the course and for evaluation, contribute most to improvements in student learning. To do this, we calculated learning gains for freshmen science majors in three large introductory biology classes using pre-/post-tests composed of validated concept inventory questions. We used timing analysis and the Reformed Teaching Observation Protocol (RTOP) to quantify the level of interactivity and student-centeredness, respectively, of each class. We used the Blooming Biology Tool to determine the Bloom's level of cognitive processing for both the course exams and the pre-/post assessments. We then compared the average Bloom's cognitive levels of each topic to determine the level of alignment between the course exams and the course evaluation, i.e. pre-/post-tests. Finally, we compared the level of interactivity and level of alignment with the magnitude of student learning gains for each topic to determine which had the biggest impact. Preliminary findings suggest that alignment may be more important for student learning than level of interactivity.

997

**Science, Biotechnology and Society: A Novel Introductory Course in which Non-STEM Undergraduates Engage in Active Learning Performing Molecular Biology Laboratory Experiences.***G. Arroyo-Cruzado<sup>1</sup>, J. Rodríguez-Echegaray<sup>1</sup>, C. I. Ayarza-Real<sup>1</sup>; <sup>1</sup>Biological Sciences Department, General Studies College, UPR-Río Piedras Campus, San Juan, Puerto Rico*

Since August 2010, the Department of Biological Sciences (DBS) of the University of Puerto Rico, Río Piedras Campus (UPR-RP), is offering a novel course to introduce non-STEM undergraduates to biotechnology and the new trends in this scientific field. The course was designed with the 7E model strategy described by Eisenkraft (The Science Teacher, 2003), as the strategy for "the transfer of learning". Scientific Methodology, Chemistry of Life, Cell Physiology, Molecular Biology and Biotechnology are the main topics presented using an interdisciplinary approach, through the discussion of technical papers related to the biotechnological evolution. The students are engaged in active learning, introducing themselves in the discussion of current socioeconomic, environmental and bioethical issues related to biotech. In the laboratory, students execute a sequence of experiences in basic microbiology and DNA technology resembling a research simulation. These experiences provide to the students the opportunity to learn how scientists do science while develop research skills. Pre-post tests show students significant outcomes in knowledge and comprehension about DNA structure, gene expression, recombinant DNA, gene cloning, stem cell resources and DNA technology fundamentals. The next objective in the evolution of this course is to integrate non-science majors in authentic research activities.

998

**Closing the Loop—Assessing a Mandatory Research Course in an Undergraduate Biology Curriculum.***H. G. Kuruville<sup>1</sup>; <sup>1</sup>Science and Mathematics, Cedarville University, Cedarville, OH*

Scientists learn much of what they know about methods of science by practicing those methods in a research setting. However, getting undergraduates to add research experiences to an already busy schedule can be challenging. In order to ensure that our students receive firsthand exposure to scientific research, Cedarville University currently requires that all of our B.S. majors (biology, environmental science, and cellular and molecular biology) complete a research requirement. Students may choose to pursue either a one-semester on-campus research experience, or may elect to do a 10-week summer internship. The research program has four stated learning goals: 1. students will investigate a research problem and state an appropriate hypothesis, 2. students will read and critically evaluate published research and write a review of the literature related to the research question, 3. students will participate in research design, data collection, and hypothesis testing using appropriate instruments and tests, and 4. students will perform appropriate data analyses, interpretations, and representations. Using Survey Monkey, I surveyed all 39 of our senior students to determine whether these learning goals had been met. Twenty four students answered the survey. The results indicated that most learning goals have been met; however, students are not receiving consistent exposure to the literature in terms of writing a literature review. In response to this data, the biology faculty are working to further standardize our expectations for this research experience. I also found that more than half of our students were asked about their research during an interview, and that of these, the vast majority (87%) felt that they could communicate effectively about their research during the interview. We plan to continue making research a mandatory part of our biology curriculum at Cedarville University.

999

**Quantitative Biology Laboratory for Transfer Students.***A. K. Wilson<sup>1</sup>, R. Rylaarsdam<sup>1</sup>, K. Kelly<sup>2</sup>; <sup>1</sup>Biological Sciences, Benedictine University, Lisle, IL, <sup>2</sup>Psychology, Benedictine University, Lisle, IL*

Transfer students often cite issues with the process of transferring, especially from a two year institution to a four year university. Benedictine University provides articulation and advising services through our New Student Advising Center but does not offer a formal orientation for transfer students as it does for incoming freshmen. Because optional orientation activities rarely work, we now offer a “transfer’s lab” to these students. This lab offers students the chance to 1) learn/brush up on lab skills required for upper level labs, 2) a formal orientation to key persons, offerings and expectations in the College of Science and more specifically, the Department of Biological Sciences and 3) discussions of University policies and academic advising concerns. This course counts as a 200 level biology elective towards the major. Assessment has confirmed the need for addressing lab skills such as micropipetting, calculating and making solutions and dilutions, proper methodology to collect observational, quantitative, and qualitative data along with statistical analyses and interpretation of that data and the use of equipment such as electronic balances, compound light microscopy, spectrophotometers, and gel electrophoresis. Students have responded favorably to the orientation and advising components of the course.

**Biology Undergraduate Mentoring Program (BUMP) at Central Michigan University.***C. K. Damer<sup>1</sup>, D. L. Linton<sup>1</sup>, A. K. Monfils<sup>1</sup>; <sup>1</sup>Biology, Central Michigan University, Mount Pleasant, MI*

We have created an undergraduate research opportunity funded by the National Science Foundation at Central Michigan University (CMU) called Biology Undergraduate Mentoring Program (BUMP). The goal of BUMP is to increase the diversity of individuals pursuing graduate studies in biological research. BUMP recruits students from historically underrepresented groups, engages them in high-quality research projects mentored by our faculty, and prepares them for graduate school. Students in the program receive financial support for two years and begin the program in their first or second year. Starting in 2009, BUMP has recruited three cohorts of ~ five students. In addition to being closely mentored by a faculty member in research, students in the program take several courses to introduce them to careers in biological research, to develop their scientific communication skills, and to prepare them for the GRE. BUMP students are supported by and integrated into the University, scientific, and local communities through collaborations and partnerships. These include collaborations with the Biology Department, the Multicultural Education Center, GEAR-UP, and the McNair Program on campus. Outside of CMU, BUMP students interact with scientific professionals in the community, volunteer at the Chippewa Nature Center, and mentor students from Holmes Middle School. Although it is too soon to determine the overall impact of the program, the self-efficacy surveys completed by students in the new courses suggest that students had a significant increase in self-efficacy, a clear perspective on career opportunities in biological research, and a realistic plan for their career pathway into biological research.

**The Open Learning Initiative: development and evaluation of free online content delivery system for introductory and advanced biology courses.***A. L. Goodman<sup>1</sup>, A. M. Barra<sup>2</sup>, W. Riggs<sup>3</sup>, M. Brown<sup>4</sup>, G. Rule<sup>4</sup>; <sup>1</sup>California Polytechnic State University, San Luis Obispo, CA, <sup>2</sup>National University, Costa Mesa, CA, <sup>3</sup>College of the Redwoods, Eureka, CA, <sup>4</sup>Carnegie Mellon University, Pittsburgh, PA*

The Open Learning Initiative (OLI; <https://oli.web.cmu.edu/openlearning/>) provides a robust content delivery platform used with a variety of instructional approaches, including traditional and inverted classrooms, and hybrid and online instruction. OLI offers three levels of biology courses. (1) Introductory Biology, developed specifically to meet the needs of students at community colleges, has minimal prerequisite knowledge and covers wide range of topics from molecular and cellular biology to evolution and ecology. (2) Modern Biology, a more advanced course, emphasizes cell and molecular biology. (3) Biochemistry is designed for advanced students studying biochemistry and biotechnology. All courses are available as open-and-free versions that contain all course materials, with the exception of graded activities. Instructors who use the courses can customize the content to specifically meet the needs of their students.

The OLI environment offers a wide range of educational materials including text with imbedded assessments, static drawings, Flash-based animations, molecular simulators, three-dimensional images of biological structures using Jmol, and quizzes aligned to learning objectives. The rich assessment environment in OLI provides feedback to the student and reports student progress to the instructor. Student performance on the interpretation of 3D models was improved using Jmol-based ungraded quizzes and mini-tutors. In a student survey, the majority of respondents (68%) recommended using a combination of OLI materials and a traditional textbook. When asked to evaluate individual components of the OLI learning

environment, students found the following aspects helpful: simulations and dynamic figures (71%), ungraded quizzes (68%) and mini-tutors (61%). All of these features offer immediate feedback to students. Graded quizzes, in the same format as ungraded quizzes, were endorsed as helpful by only 32% of the students. Written comments revealed that students valued immediate feedback from the ungraded quizzes as a learning tool, but considered graded quizzes too stressful.

We are looking for partner institutions and instructors to further evaluate and improve the OLI materials, as well as use common assessment tools to investigate effectiveness of pedagogical approaches like the inverted classroom (contact email: oli-participate@andrew.cmu.edu)

1002

**Identifying insect species using taxonomy and DNA Barcoding: a research experience that bridges two undergraduate courses.**

*J. Bassong<sup>1</sup>, A. D'Costa<sup>1</sup>; <sup>1</sup>Biology, Georgia Gwinnett College, Lawrenceville, GA*

As part of GGC's 4-year undergraduate research experience (4-yr URE), students are exposed to research in all 4 years of their undergraduate career. These course-embedded research experiences provide students the research skills needed for independent research projects in their senior year and later. The goal of this project is to measure insect biodiversity on our campus, and has students in multiple sections of Introductory Biology and Cell biology courses collaborating over a semester. Students in Introductory Biology set up insect traps at three locations on campus. In lab, they sort and classify the insects, usually down to "order", using traditional taxonomic techniques. Each student picks a specimen and researches its distinguishing morphological features, life cycle, and other important characteristics. The insects are then handed over to students in Cell biology to DNA barcode ([www.barcodeoflife.org](http://www.barcodeoflife.org)). DNA barcoding involves first extracting DNA and then amplifying a region of the cytochrome oxidase subunit I gene (CO1) using PCR. Apart from learning the PCR technique, we cast our own agarose gels, and learn to trouble-shoot to obtain a PCR product. The PCR products are sent off campus for sequencing. We learn basic bioinformatics, and aligned our sequences in the NCBI and Barcode of Life databases to identify our insect down to the "species" level. Information from each specimen (morphological characteristics, taxonomic and barcode) is catalogued in an online biodiversity database. Pre and post content assessments and surveys to determine students' attitudes towards science are administered, and assessment data will be presented, along with my experiences and as a student and a peer mentor.

**Figure Facts: Encouraging undergraduates to take a data-centered approach to reading primary literature.**

*J. E. Round<sup>1</sup>, A. M. Campbell<sup>1</sup>; <sup>1</sup>Biology, Davidson College, Davidson, NC*

The ability to comprehend and interpret experimental data is essential to understanding and participating in the process of scientific discovery. Reading primary research articles can be a frustrating experience for many undergraduate biology students because they have very little experience interpreting data. To enhance their analytical skills, students used a template called "Figure Facts" to assist them with primary literature-based reading assignments in an advanced cellular neuroscience course. The Figure Facts template encourages students to adopt a data-centric approach, rather than a text-based approach, to understand research articles. Specifically, Figure Facts requires students to focus on the experimental data presented in each figure and identify specific conclusions that may be drawn from those results. Students who used Figure Facts for one semester increased the amount of time they spent analyzing figures in a primary research article, and regular examination of primary literature was associated with

improved student performance on a data analysis skills test. Students reported decreased frustration associated with interpreting data figures, and their opinions of Figure Facts were overwhelmingly positive. Here, we present Figure Facts for others to adopt and adapt, with reflection on its implementation and effectiveness to improve undergraduate science education.

1005

**Genome Solver: Genome Analysis for 21st Century Faculty.**

*A. G. Rosenwald<sup>1</sup>, G. Arora<sup>1</sup>, R. Madupu<sup>2</sup>, J. Roecklein-Canfield<sup>3</sup>, J. Russell<sup>4</sup>; <sup>1</sup>Biology, Georgetown University, Washington, DC, <sup>2</sup>J. Craig Venter Institute, Rockville, MD, <sup>3</sup>Chemistry, Simmons College, Boston, MA, <sup>4</sup>Center for New Designs in Learning and Scholarship, Georgetown University, Washington, DC*

The face of biology education is changing rapidly, becoming more interdisciplinary and using larger datasets, in keeping with the recommendations of influential documents such as Vision and Change in Undergraduate Biology. However, faculty trained in the mid-20th century may not be equipped to teach courses involving 21st century techniques, such as genomics and bioinformatics. To address this gap, we, in collaboration with bioinformatics specialists at the J. Craig Venter Institute, have developed workshops to teach faculty to mine the rich data sources being created by the Human Microbiome Project (HMP). The aims of the faculty workshops are several-fold: (1) To teach faculty to use open-source bioinformatics tools, (2) to teach faculty where to obtain HMP data, and (3) to develop a faculty community to discuss curriculum ideas and best practices. The workshops in turn help support the networking possible through our parallel on-line community at [www.genomesolver.org](http://www.genomesolver.org). Here we report on the outcomes of our first two workshops, held in the summer of 2012.

1006

**Are There Cell-Cycle Dependent Variations in Cadherin-Mediated Cell Adhesion?**

*M. Cimpean<sup>1</sup>, Y. Yu<sup>1</sup>, K. Belberska<sup>1</sup>, B. LaPerle<sup>1</sup>, W. Thomas<sup>1</sup>; <sup>1</sup>Colby-Sawyer College, New London, NH*

Cell adhesion makes possible the development and maintenance of tissues and organs. It has thus been an important topic in biomedical research, cancer research in particular. One method used to quantify cell adhesion, the dual pipette assay, has uncovered considerable variability in the force required to separate pairs of adherent cells. This variability, persistent despite strict protocols and assay automation, has necessitated high numbers of replicate trials to obtain statistically valid data. We are using FUCCI (fluorescence ubiquitination cell cycle indicator) to determine if cell-cycle dependent changes might account for the observed variability in separation force. The FUCCI technique involves antiphase oscillating proteins that mark the cell-cycle transitions with corresponding fluorescent probes. Initial comparison of fluorescence distributions in aggregated and unaggregated FUCCI E cad cells showed no preferential accumulation in aggregates of cells in a particular stage of the cell cycle. Work continues with recently acquired equipment of higher sensitivity to improve the resolution and reproducibility of the tests. Positive results could lead to enhanced efficiency of the dual pipette assay.

1007

**New tools that enable blind students to tactilely visualize image data.**

A. N. Gonzales<sup>1</sup>, L. Harris<sup>1</sup>, E. Hasper<sup>1</sup>, R. Brubaker<sup>1</sup>, R. A. Windhorst<sup>1</sup>, D. P. Baluch<sup>1</sup>; <sup>1</sup>Arizona State University, Tempe, AZ

In the fields of microscopy and astronomy items that are either too small or distant are visualized through optics and this image data is captured through pictures, but not everyone is capable of seeing pictorial information. In the United States there are approximately 21.5 million people that are either totally blind or vision impaired. Recent studies have shown that by the age of 16 years old, the average vision impaired student is 3 years behind in subjects such as mathematics in comparison to their peers. From the population of individuals who have STEM (science, technology, engineering and mathematics) careers, less than 5% will be held by those who have some form of vision disability. There is no evidence that individuals who are blind lack the necessary analytical abilities to pursue a STEM career but the lack of opportunities to develop and use those abilities impedes both their educational and employment advancement in these disciplines. Since almost all aspects of life are vision based this creates an unintentional bias because the mechanisms for doing most anything rely on sight. STEM fields are image based, and image rich content must be converted into a tactile format to enable the visually impaired student to have the same access to course materials as their peers. Within the 3D IMAGINE project, we are addressing the issue of low participation in STEM courses by creating 3D tactile prints and models that will help the blind “visualize” images that are critical in understanding key concepts or interpreting data. We are incorporating these tactile displays into entry level STEM classes to assist blind students with learning image rich material. Various technologies are used to create projected tactile surfaces such as printing using raised ink and swell paper or changing 2D images into height field 3D surface geometries that are used to create HDPE (high-density polyethylene) boards or rapid 3D prototype models. Through the development of these pilot courses which are enriched with tactile image displays, we are exploring the limitations encountered by those who are visually impaired and are working to develop new technologies that will make it possible for these students to overcome image based obstacles and have the opportunity to learn and find their place in the STEM community.

**Group Assignment for a 200-level cell biology class that integrates the arts to express and explore basic concepts.**

J. J. Fernandes<sup>1</sup>; <sup>1</sup>Zoology, Miami University, Oxford, OH

Students in a 200-level Cell biology course were involved in a semester-long assignment on “Cells and Disease” to allow for an opportunity to apply the basic concepts in an out-of-class activity. The assignment had 3 parts- (1) using popular science articles to learn about an assigned cell and a diseased condition, (2) using research articles and reviews to develop disciplinary knowledge about the cell and its disease, (3) in keeping with the “year of the arts” at the institution, a final assignment was to develop two formats to communicate basic concepts to a middle school audience. The objective of the final assignment was for students to express themselves creatively in a science classroom and to target it to a middle school audience. Students developed two formats- choice of comic strip/poem/artwork/trading cards/other, and choice of Short story/Learning unit/video or animation/Other. The assignment had the following additional components- (i) a narrative that discussed why particular formats were chosen (ii) reflective statements that commented on the role that art/visuals play in understanding science concepts, how the assignment engaged students with the scientific content they read/learned about, and an examination of the importance of communicating science to the non-scientist/middle school audience. Students were polled to determine which assignment engaged

them the most. Greater than 75% of students indicated it was the creative assignment. Qualitative comments were solicited about the learning experiences of the creative assignment. Greater than 40% of responses indicated an awareness of/the ability to communicate science to a lay audience. Examples of student work will be presented. Future directions of this project include the use of student generated material in teacher professional development workshops.

## **Kinesins: Regulation and Activity**

1009

### **Tuning Multiple Motor Travel via Single Motor Velocity.**

*J. Xu<sup>1</sup>, Z. Shu<sup>2</sup>, S. J. King<sup>3</sup>, S. P. Gross<sup>2</sup>; <sup>1</sup>UC Merced, Merced, CA, <sup>2</sup>UC Irvine, Irvine, CA, <sup>3</sup>University of Central Florida, Orlando, FL*

Microtubule-based molecular motors often work in small groups to transport cargos in cells. A key question in understanding transport (and its regulation in vivo) is to identify the sensitivity of multiple-motor-based motion to various single molecule properties. Whereas both single motor travel distance and microtubule binding rate have been demonstrated to contribute to cargo travel, the role of single-motor velocity is yet to be explored. Here, we recast a previous theoretical study, and make explicit a potential contribution of velocity to cargo travel. We test this possibility experimentally, and demonstrate a strong negative correlation between single-motor velocity and cargo travel for transport driven by two motors. Our study thus discovers a previously unappreciated role of single-motor velocity in regulating multiple-motor transport.

1010

### **Quantitative optical trapping on single cellular organelles in cell extract.**

*P. K. Barak<sup>1</sup>, A. Rai<sup>1</sup>, P. Rai<sup>1</sup>, R. Mallik<sup>1</sup>; <sup>1</sup>Department of Biological Science, Tata Institute of Fundamental Research, Mumbai, India*

Molecular motors transport many cargos such as Endosomes, Lysosomes and Lipid Droplets inside cells. How motor-function on an organelle is modulated in response to metabolic or cellular signaling is under intense investigation. One way to address these questions is by utilizing optical trapping to measure the force exerted by motors on cellular organelles in response to different metabolic stimuli. However, cellular organelles vary in size from hundreds of nanometers to few microns. Since the force exerted by an optical trap depends on the size of trapped object, this makes calibration of the trap difficult for cellular organelles.

Here we present and validate a simple method that uses motion generated by the motors to precisely calibrate the optical trap for force measurements on cargos of unknown size in a cell extract. This permits the extension of quantitative optical trapping to cellular organelles in controlled assays to understand how motors and motor-associated proteins function. We first validate this method using kinesin-coated beads to confirm a force of  $5.7 \pm 1.1$  pN for kinesin-1. We then use this method to measure kinesin-1 forces driving lipid droplets isolated from rat liver. A histogram of stall forces shows a single kinesin force peak at  $7.1 \pm 1.4$  pN and a second peak at  $13.2 \pm 1.5$  pN. Using the same methodology we further show that kinesin-1 activity reduces on lipid droplets isolated from 16hr fasted rat liver. This apparent change in kinesin-1 activity as a function of metabolic state of the liver will be a subject of future investigation.

1011

**Traffic control: Serine 176 phosphorylation attenuates kinesin's stall force and biases bidirectional transport.**

H. A. DeBerg<sup>1</sup>, B. H. Blehm<sup>1</sup>, J. Sheung<sup>1</sup>, A. R. Thompson<sup>2</sup>, S. F. Torabi<sup>3</sup>, C. L. Berger<sup>2</sup>, Y. Lu<sup>3,4</sup>, P. R. Selvin<sup>1</sup>; <sup>1</sup>Physics, University of Illinois at Urbana-Champaign, Urbana, IL, <sup>2</sup>Molecular Physiology & Biophysics, University of Vermont, Burlington, VT, <sup>3</sup>Biochemistry, University of Illinois at Urbana-Champaign, Urbana, IL, <sup>4</sup>Chemistry, University of Illinois at Urbana-Champaign, Urbana, IL

In neurons, microtubule motor driven transport is crucial for communication between processes and the cell body. Disruptions in transport are associated with a variety of neurodegenerative diseases. Recent studies implicate phosphorylation of serine 176, a conserved residue found in all three isoforms of kinesin-1 in the impaired axonal transport associated with Huntington's disease. In isolated squid axoplasm, introduction of pathogenic huntingtin protein activates the kinase, JNK3, which specifically phosphorylates kinesin at S176[1]. The mechanism by which S176 modification leads to impaired transport is not very well understood and it is not known whether phosphorylation of kinesin alone is sufficient to cause impaired cargo transport. To investigate the isolated effect of residue 176 on kinesin transport, we use optical trapping and single-molecule fluorescence imaging to study purified kinesin. We employ two constructs, S176A and S176D, truncated at residue 888 to remove the autoinhibition domain, resulting in constitutively active motors. There is no significant difference in the processivity or ATPase activity of the phosphomimetic S176D construct or the non-phosphorylatable S176A construct. However, we do find that S176D has an attenuated stall force (5pN) compared to S176A (7 pN). Furthermore, polystyrene bead cargos coated with dynein and S176D are transported preferentially in the minus direction in comparison with cargos coated with equivalent concentrations of dynein and S176A. We also perform phosphorylation assays using JNK3 on both 888-truncated and full-length wild-type kinesin in which radiolabeling is used to quantify the percentage of protein phosphorylated in the assay. The pattern of stall force attenuation observed for the S176D mutant is also observed in JNK3 phosphorylated samples in which 60-80% of the wild type protein has been phosphorylated by the kinase. These results show that modification of serine 176 alone is sufficient to alter the behavior of kinesin. Efforts are currently underway to investigate the effect of S176 phosphorylation in PC-12 cells as model for neuronal traffic via tracking of up-conversion nanoparticles (UCNP) in neurite growth factor induced processes. UCNP are excitable by two photon processes and do not photobleach, making them ideal for tracking on long timescales. Understanding how modification of this kinesin residue affects transport will allow us to better model the molecular events associated with the development of Huntington's disease.

1012

**In Vivo Optical Trapping Reveals Kinesin Drags Dynein During Intracellular Transport.**

B. H. Blehm<sup>1</sup>, T. A. Schroer<sup>2</sup>, K. M. Trybus<sup>3</sup>, Y. R. Chemla<sup>1</sup>, P. R. Selvin<sup>1</sup>; <sup>1</sup>Physics Department and Center for Physics of the Living Cell, University of Illinois, Urbana-Champaign, Urbana, IL, <sup>2</sup>Department of Biology, Johns Hopkins University, Baltimore, MD, <sup>3</sup>Department of Molecular Physiology and Biophysics, University of Vermont, Burlington, VT

Kinesin and dynein are fundamental components of intracellular transport, but their interactions when simultaneously present on cargos are unknown. We have built an optical trap that can be calibrated in vivo to measure forces in living cells. By comparing directional stall forces in vivo and in vitro, we found that cytoplasmic dynein is active during minus- and plus-end directed

motion, while kinesin(s) is only active in the plus-end direction. In vivo, we found that outward ( $\approx$  plus-end) stall forces range from 2-7 pN, significantly less than the 5-7 pN stall force measured in vitro for single kinesin molecules. In vitro measurements on beads with both kinesin-1 and dynein bound revealed a similar distribution, implying that an interaction between these opposite polarity motors causes the reduction in kinesin stall force. Finally, inward ( $\approx$  minus-end) stalls in vivo were 2-3 pN, higher than the 1.1 pN stall force of a single dynein, implying multiple active dynein.

1013

**Investigating properties of kinesin-2 motors optimized for bidirectional transport.**

*W. O. Hancock<sup>1</sup>, D. Arginteanu<sup>1</sup>; <sup>1</sup>Bioengineering, Penn State University, University Park, PA*

Kinesin-2 and dynein motors transport intracellular cargo bidirectionally along both axonemal and cytoplasmic microtubule. These motor activities underlie intraflagellar transport, melanosome dynamics and other vital transport functions in cells, but the mechanism by which the activities of these oppositely-directed motors are coordinated is not well understood. One important question is whether the properties of kinesin-2 motors are specifically tuned for bidirectional transport rather than long-distance plus-ended transport. Consistent with this, kinesin-2 motors were found to detach much more readily than kinesin-1 under hindering loads, and also to rapidly rebind and continue stepping following detachment (slipping behavior). To test the hypothesis that kinesin-2 motors are specifically tuned for bidirectional transport, we carried out stopped-flow and steady-state biochemical studies of monomeric and dimeric kinesin-1 and kinesin-2. In solution, kinesin-2 motors were found to have a 30-fold higher affinity for mantADP than unmodified ADP, presumably due to the hydrophobic nature of the mant moiety. While this feature complicates experimental interpretations, it also offers a new tool to study the role of ADP dissociation in the kinesin-2 chemomechanical cycle. Extrapolated ADP off-rates in the presence of microtubules indicated that for unlabeled nucleotide, ADP dissociation is not rate limiting for either kinesin-1 or kinesin-2. Microtubule pelleting experiments indicated that in the ADP state, monomeric kinesin-2 motor domains have a 10-fold higher microtubule affinity than kinesin-1 motor domains. However, this increased microtubule affinity does not translate into enhanced processivity of dimeric kinesin-2 when compared to kinesin-1. This result suggests that kinesin-2 spends a larger fraction of its hydrolysis cycle in the ADP state and thus is more prone to detaching under hindering loads, but following detachment it readily rebinds to the microtubule. This behavior results in a more dynamic competition with dynein that avoids the cargo coming to a complete standstill due to motor stalling. Supported by NIH.

1014

**The kinesin catalytic motor domains possess a plus-end directionality.**

*M. Yamagishi<sup>1</sup>, Y. Toyoshima<sup>1</sup>, J. Yajima<sup>1</sup>; <sup>1</sup>Department of Life Sciences, Graduate School of Arts and Sciences, The University of Tokyo, Tokyo, Japan*

*Drosophila* kinesin-14, Ncd, moves toward the minus-end of microtubules. Ncd has a neck region between the C-terminal motor domain, the catalytic core of ATPase, and the N-terminal stalk domain, the dimerizing region. The neck is composed of a rigid coiled-coil structure. The widely accepted model of its force-producing mechanism is the power-stroke model in which Ncd strokes its N-terminal neck region as a rigid lever-arm around the motor domain as a pivot in the direction to the minus-end of microtubules. (Thomas et al., EMBO, 2002) Here, to test the power-stroke model, we have engineered Ncd that is fused to a gelsolin protein or a biotinylated tag sequence (Avi-tag) at the C-terminus. These C-linked Ncds are able to be fixed to a glass

surface or a biotin-coated quantum dot via their C-terminus respectively, leaving the N-terminal coiled-coil structure hanging free. We found that these C-linked Ncd molecules slid microtubules or moved along immobilized microtubules with robust processivity at similar rates to N-linked Ncds (wild type), thereby ruling out models in which the rigid coiled-coil structure is the only element able to exert or transmit force. Instead, our findings indicate another force-generating mechanism that shifts both the N and C terminus of the head, so that force can almost equally well be exerted by either the N or C terminus of the head. We also found that these C-linked Ncds are the plus-directed motors as is Kinesin-1. It was previously reported that a chimera Ncd whose C-terminus was replaced with kinesin-1 neck slid microtubules with the minus-end leading when it was attached to the glass surface at its C-terminus (Henningsson and Schliwa, *Nature*, 1997), showing the relative movement of these Ncds toward the plus-end of microtubules. This implied that the kinesin-1 C-terminal neck was a critical part in determination of the directionality. But our result of the plus-ended directionality of C-linked Ncds, leaving the N-terminal coiled-coil structure hanging free, indicates that the Kinesin-1 neck is not needed for the plus-ended directionality. It means that the kinesin motor domains would possess a 'default' plus-ended directionality.

1015

**Exaggerating the switch - a chimeric Kinesin-tetramer with fulsome motile features.**

S. Lakämper<sup>1,2</sup>, C. Thiede<sup>2</sup>, A. D. Wessel<sup>2</sup>, C. F. Schmidt<sup>2</sup>; <sup>1</sup>D-MAVT, ETH Zürich, Zürich, Switzerland, <sup>2</sup>Drittes Physikalisches Institut, Georg-August Universität Göttingen, Göttingen, Germany

Mitosis is driven by a fundamental rearrangement of cytoskeletal structures and the concomitant activity of a wealth of motor-proteins. The tetrameric Kinesin-5 Eg5 has been shown to cross-link antiparallel microtubules and drive long-range uni-directional and plus-end directed relative sliding (on-state). This activity is required in the spindle mid-zone during spindle elongation. When interacting with a single microtubule, however, Eg5 displays a less effective mode of activity (off-state), most likely consisting of a ATP-independent diffusive component (type-1) and a ATP-dependent directional component (type-2), as shown by MSD-analysis. To understand the switch between on and off-state as well as the factors influencing transitions between type 1 and type-2-interactions, it is desirable to be able to directly observe transitions between and quantify the contributions of both interaction types to Eg5-motility. Given the inherently slow speed and short processive run-length of Eg5 quantitative information is very difficult to obtain. To accentuate the transition between type-1- and type-2-interactions, we exchanged the motor-domain and neck-linker of Eg5 with corresponding parts of Kinesin-1. Single molecule fluorescence assays of this chimeric model system, DK4mer, directly confirm the alternation of type-1 and type 2 interactions. Using a truncated chimera we find that characteristics of type 2 interactions are predominantly determined by the motor domain and the initial, dimeric coiled coil of the neck. Thoroughly investigating the influence of ionic strength on the motility of DK4mer on single microtubules and in relative sliding assays, we find that type 2 interactions dominate over type 1 interactions, but also that Type 1 interactions are likely to be required for the initiation of type 2 interactions. This study of our chimeric model system lays the base for a more detailed understanding of motility and regulation of Kinesin-5 motors, representing important players in Mitosis, but also development of cellular polarity.

1016

**Force transduction by the kinesin motors.**

H-L. Liu<sup>1</sup>, M. A. Haller<sup>2,3</sup>, S. A. Endow<sup>1,3</sup>; <sup>1</sup>Cell Biology, Duke University Medical Center, Durham, NC, <sup>2</sup>Biochemistry, Duke University Medical Center, Durham, NC, <sup>3</sup>Program in Structural Biology & Biophysics, Duke University Medical Center, Durham, NC

Kinesin motors use ATP to do work by coupling steps of nucleotide hydrolysis to microtubule binding to produce force. Large conformational changes, detected in previous structural studies, have led to the proposal that the central beta-sheet of the motor plays an essential role in force transduction by the motor. We now find that an invariant beta-sheet residue has large, unexpected effects on force transduction by a kinesin motor. Amino acid changes in this residue greatly affect the ability of the motor to hydrolyze ATP and bind to microtubules – force production by the motor is increased, as indicated by motility assays and effects on spindles in oocytes. The spindle effects can be reproduced by simulations of assembly, indicating that they arise because of the altered motor properties. The findings show that the residue is involved in mechanotransduction by the motor. Movements by the residue in different states of the ATP hydrolysis cycle could trigger conformational changes in the motor that store and release free energy, producing strain that leads to force generation.

1017

**Characterization of Hereditary Spastic Paraplegia-Causing Mutations in Kinesin Kif5A.**

D. Carter<sup>1</sup>, D. Nathan<sup>1</sup>, T. Huckaba<sup>1</sup>; <sup>1</sup>Department of Biology, Xavier University of Louisiana, New Orleans, LA

Hereditary Spastic Paraplegias (HSPs) are a group of neurodegenerative disorders that arise from the progressive degeneration of corticospinal tract axons, causing lower limb spasticity and weakness. An autosomal dominant form of HSP (AD-HSP) is caused by mutations in Kif5A, a neuronally enriched form of the kinesin-1 family of cellular transport motors. While nineteen separate AD-HSP-causing missense mutations in Kif5A have been mapped, eighteen are in the motor domain, suggesting a deficit in catalytic activity as the mechanistic cause of the disease. We have mutated the wild type Kif5A gene with each of the separate AD-HSP-causing mutations and have begun to test the mechanical properties of these recombinantly-expressed mutant motors in a series of *in vitro* biochemical and biophysical assays. Here we report the results of four separate mutations in the ATP binding and hydrolysis pocket (S202N, S203C, R204W, and V231L) and one mutation in the L11 loop predicted to be at the microtubule interface (E251K). Performing microtubule pelleting assays in the presence of saturating levels of ATP, we found that S202N and S203C had a significantly higher microtubule affinity than wild type Kif5A or the other mutants. Conversely, in the presence of the non-hydrolyzable ATP analog AMPPNP, R204W, V231L and E251K had a significantly lower microtubule affinity than wild type and the other mutants. In microtubule gliding assays, wild type Kif5A moved microtubules at a rate of  $0.47 \pm 0.02$   $\mu\text{m}$  per second. The S203C mutant moved microtubules at a 60-fold slower rate of  $0.0074 \pm 0.0028$   $\mu\text{m}$  per second, while the S202N, R204W, and E251K mutants bound microtubules to the glass surface in rigor and the V231L mutant was unable to recruit microtubules from solution. These contrasting results suggest that AD-HSP may be caused by a variety of different mechanical deficits in the kinesin catalytic core. We will report the results of our ongoing studies to parse the deficits involved in each of the AD-HSP-causing mutations in Kif5A.

**The ubiquitous kinesin KIF5B binds light chain heterodimers in human cells.**

Z. Maliga<sup>1</sup>, R. Klemm<sup>2</sup>, M. Junqueira<sup>3</sup>, A. Shevchenko<sup>1</sup>, A. A. Hyman<sup>1</sup>; <sup>1</sup>MPI-CBG, Dresden, Germany, <sup>2</sup>Department of Cell Biology, Harvard Medical School, Boston, MA, <sup>3</sup>Brazilian Center for Protein Research, Department of Cell Biology, University of Brasilia, Brasilia, Brazil

Conventional kinesin (Kinesin-1a) is a ubiquitously expressed molecular motor transporting a variety of cargoes towards microtubule plus-ends. However, the molecular details of cargo discrimination and destination choice are poorly understood. The Kinesin 1a holoenzyme consists of two heavy chains (KIF5B) and two regulatory light chains encoded by one of four kinesin light chains (KLC) genes, each encoding multiple splice variants. Whether the cellular ensemble of Kinesin-1a is associated only with KLC homodimers, or also heterodimers, impacts the diversity of motors in the cell and how they might be regulated. To study this question in detail, we combined the sensitivity of reciprocal affinity-purification mass spectrometry (rAP-MS) with the advantages of recombinant bacterial artificial chromosome (BAC) transgenes because these vectors contain native non-coding cis-regulatory information to express proteins at wild-type levels. Western blot analysis showed that stable HeLa lines express native levels of KIF5B and the correct KLC isoforms. Recombinant KIF5B and KLC1 also bind light membranes by density-gradient centrifugation, indicating the tagged proteins bind cargo. As a final demonstration of biochemical function, all 4 KLCs are captured by recombinant KIF5B and all recombinant KLC transgenes capture endogenous KIF5B by AP-MS. We found that recombinant KLC1 selectively captures endogenous KIF5B and a short, endogenous KLC1 isoform. Systematic AP-MS using all tagged KLCs further revealed that only KLC3, the most divergent member of this protein family, is uniquely homodimeric in the context of the Kinesin-1a holoenzyme. This study demonstrates that asymmetric Kinesin-1a motors, containing different light chains, exist in cells expressing multiple light chain genes. Although not all species contain multiple KLC genes, we propose that Kinesin-1a light chain asymmetry is a general phenomenon in mammals and highlights a previously unexplored regulatory mechanism in cells.

**Molecular mechanisms of kinesin-8 regulation in budding yeast.**

C. Mieck<sup>1</sup>, S. Opravič<sup>2</sup>, K. Mechtler<sup>2</sup>, S. Westermann<sup>1</sup>; <sup>1</sup>The Research Institute for Molecular Pathology (IMP), Vienna, Austria, <sup>2</sup>Protein Chemistry, The Research Institute for Molecular Pathology (IMP), Vienna, Austria

Accurate segregation of the duplicated genetic material during mitosis not only requires the essential load-bearing bridge between kinetochores and microtubules, but also elements that fine-tune microtubule dynamics and spindle behavior. While none of the four nuclear kinesins in yeast is individually required for viability, nevertheless several important mitotic functions are performed by these motors. The family of kinesin-8 motors combines plus-end directed motility with depolymerization activity to provide length-dependent regulation of microtubules (Varga et al., 2006). Recent studies have indicated important roles for the non-motor carboxyterminal domain of the yeast kinesin-8 Kip3 in allowing full motor activity (Su et al., 2011). How the cell spatially and temporally coordinates the activities of microtubule polymerases and depolymerases to allow spindle morphogenesis remains an important open question.

We show here that mutations within the carboxyterminal tail of the yeast kinesin-8 Kip3 have differential effects on motor activity. While large truncations of the c-terminal domain interfere with dimerization and behave similar to Kip3 deletion alleles, truncations of the extreme carboxyterminus have the opposite effect and lead to increased benomyl-sensitivity and shortened anaphase spindles in vivo. This suggests that this domain has an important role in

restricting Kip3 activity. Interestingly, several cell-cycle dependent phosphorylation sites map to this region, suggesting a possible mode of regulation. We will present biochemical and cell biological experiments to gain further insights into the regulation of a major microtubule-depolymerizing enzyme in the cell.

#### **Huntington-associated phosphorylation of kinesin-1 enhances autoinhibition in a phosphomimic.**

*D. D. Hackney<sup>1</sup>, Y. Yeo<sup>1</sup>; <sup>1</sup>Carnegie Mellon University, Pittsburgh, PA*

One of the consequences of the triplet expansion in Huntington's disease is inhibition of fast axonal transport (FAT). Phosphorylation of Ser176 in human kinesin-1 by JNK3 has been implicated in this inhibition (Morfini, et al., *Nature Neuro*. 12, 866 (2009)). To investigate the molecular basis for the inhibition of FAT, we have generated the S182E phosphomimic of the homologous residue in *Drosophila* kinesin-1. The S182E mutation produces only a modest 30% decrease in the maximum rate of microtubule-stimulated ATPase rate for a short dimer of motor domains, indicating that direct inhibition of MT-stimulated ATPase activity is not likely to be the cause of the pronounced inhibition of FAT. However, free kinesin is known to be autoinhibited through the binding of a tail domain to a dimer of motor domains (heads) and the Ser182 phosphorylation site is near the tail binding site on the heads (Kaan, et al., *Science* 33, 883 (2011)) where it could influence autoinhibition. One possibility is that the increased negative charge on the heads due to phosphorylation of Ser182 could produce a stronger interaction with the positively charge tail domain that would strengthen autoinhibition and inhibit FAT. To test the effect of the phosphomimic on autoinhibition, the kinetics of binding for a monomeric tail domain to a dimer of motor domains was determined using a FRET assay. In 100 mM KCl, the binding rates were 61 and 117  $\mu\text{M}^{-1}\text{s}^{-1}$  and the dissociation rates were 65 and 35  $\text{s}^{-1}$  for the wild type and phosphomimic respectively. These rates predict  $K_d$  values for the tail-motor domain interaction of 1.1 and 0.3  $\mu\text{M}$  for the wild type and mutant respectively, indicating that the phosphomimic motor domains bind tail domains 3-fold more tightly. The increased affinity of tails for motor domains in the phosphomimic suggests that reversal of autoinhibition is more difficult for phosphorylated kinesin and that this may be a significant factor in inhibition of FAT.

**KIF17 activity is regulated by its C-terminal tail domain and by EB1.**

B. R. Acharya<sup>1</sup>, J. Morgan<sup>1</sup>, G. Kreitzer<sup>1</sup>; <sup>1</sup>Cell and Developmental Biology, Joan and Stanford I. Weill Medical College, Cornell University, New York, NY

KIF17 is a kinesin-2 family, plus-end directed microtubule (MT) motor that interacts with EB1 and APC and contributes to MT stabilization and polarization in epithelial cells. To gain insight into the mechanism by which KIF17 participates in MT stabilization, and to elucidate the functional significance of its interaction with EB1, we analyzed KIF17 activities in the absence or presence of EB1 *in vitro*. Purified, full-length EB1 enhanced the steady-state MT-stimulated ATPase activity of KIF17 motor domain 2.0 fold and increased the number of motility events as observed in MT gliding assays. This EB1-mediated increase in ATPase and MT gliding activity was abrogated by addition of purified KIF17 Tail domain, consistent with a role of head-tail interactions in regulating kinesin activity. Interestingly, we found EB1 and the KIF17 tail domain compete for binding to the KIF17 catalytic motor domain. In two *in vitro* assays, the KIF17 catalytic domain was sufficient to protect MTs from depolymerization. This MT stabilizing activity was also enhanced by EB1 but was unaffected by the KIF17 tail domain. Consistent with *in vitro* MT stabilization assays, we also found that overexpressed KIF17 motor domain was sufficient to stabilize MTs in MDCK epithelial cells. As expected, the KIF17 motor domain co-sedimented with MTs. Unexpectedly however, we also found that the KIF17 tail domain co-sediments with MTs and indeed, bound with higher affinity to MTs than the motor domain. This suggests that the KIF17 tail, in addition to regulating the ATPase activity of the motor, may also contribute to binding of the holoenzyme to MTs. Furthermore, the KIF17 tail domain also interacts with soluble tubulin heterodimers, suggesting this kinesin could potentially regulate MT dynamics by dual mechanisms in cells. In support of this, we also found that expression of the KIF17 tail domain in cells transiently attenuated MT regrowth after washout of MT depolymerizing drugs, possibly by sequestering tubulin dimers. The emerging role of various kinesins in disease raises the possibility of using them as targets for treatment and therapy but very little is known about the intrinsic biochemical properties of each kinesin contribute to determining patterns of motility and patterns of microtubule dynamics within eukaryotic cells. Our result suggested some unique control of KIF17 motor and tail domain over MT growth and stabilization needs further research to explore its novel regulation in microtubule dynamics.

1022

**Src kinase regulates the human kinesin-5, Eg5, by phosphorylating tyrosines in the motor domain of Eg5.**

J. S. Waitzman<sup>1</sup>, T. Poor<sup>2</sup>, M. Gonzalez<sup>1</sup>, K. Gifford<sup>1</sup>, S. E. Rice<sup>1</sup>; <sup>1</sup>Cell and Molecular Biology, Northwestern University, Chicago, IL, <sup>2</sup>Molecular Biosciences, Northwestern University, Evanston, IL

The human kinesin-5, Eg5, is required to establish and maintain the mitotic spindle. While Eg5 localization is regulated by phosphorylation and protein-protein interactions, it is unclear if any endogenous cell mechanisms directly regulate the motor's activity. Using *in silico* and *in vitro* methods, we show that the Eg5 motor domain contains a previously unidentified SH3-binding motif that allows the Src kinase to phosphorylate tyrosine residues near the nucleotide pocket of Eg5. Characterization of phosphomimetic and non-phosphorylatable Eg5 mutant proteins reveals that two of these phosphorylation events slow ATPase activity and microtubule sliding. Src phosphorylation of Eg5 represents a novel regulatory mechanism for a human kinesin, which may be of particular interest as both Src and Eg5 are antimitotic drug targets.

**Protein kinase Darkener of Apricot and microtubule-binding protein EF1- $\gamma$  are global regulators of transport along microtubules.**A. S. Serpinskaya<sup>1</sup>, L. Rabinow<sup>2</sup>, V. I. Gelfand<sup>1</sup>;<sup>1</sup>Cell and Molecular Biology, Northwestern University Feinberg School of Medicine, Chicago, IL,<sup>2</sup>Centre de Neurosciences de Paris Sud, Université Paris Sud 11, Orsay Cedex, France

Regulation of organelle transport along microtubules is important for proper distribution of membrane cargo in the cytoplasm. We used RNAi-mediated knock-down in cultured *Drosophila* S2 cells to study the role of microtubule-binding proteins in this regulation. Our results demonstrate that two microtubule-binding proteins, a unique isoform of Darkener of apricot (DOA) protein kinase and its substrate, translational elongation factor-1 $\gamma$  (EF1 $\gamma$ ) negatively regulate transport of several classes of membrane organelles along microtubules. Inhibition of transport by EF1 $\gamma$  requires its phosphorylation by DOA on Serine 294. Together, our results indicate a new role for two proteins that have not been previously implicated in regulation of the cytoskeleton and suggest that the biological role of some of the proteins that bind to microtubule track is to mediate cargo transport along these tracks.

1024

**The microtubule-binding protein ensconsin is an essential cofactor of kinesin-1.**K. Barlan<sup>1</sup>, V. I. Gelfand<sup>1</sup>; <sup>1</sup>Cell and Molecular Biology, Northwestern University, Chicago, IL

Kinesin-1 is a major microtubule motor that drives transport of a multitude of cellular cargoes toward the plus-ends of microtubules. In the cell, kinesin-1 exists primarily in an inactive, autoinhibited state, and motor activation is thought to occur upon binding to cargo or adaptors through the C-terminus. Using RNAi-mediated depletion in *Drosophila* S2 cells, we demonstrate that kinesin-1 requires ensconsin (MAP7, E-MAP-115), a ubiquitous microtubule-associated protein, for its primary function of organelle transport. A “hingeless” mutant of kinesin-1, which mimics the active conformation of kinesin-1, does not require ensconsin, suggesting that ensconsin acts to promote unfolding of the autoinhibited motor on the microtubule. Surprisingly, an ensconsin truncation that cannot bind microtubules is sufficient to activate organelle transport by kinesin-1, indicating that this activating domain functions independently of microtubule binding. Our study demonstrates that cargo-binding alone is insufficient to activate kinesin-1 for transport and indicates that ensconsin is an essential cofactor for kinesin-1 in organelle transport.

**Kinesin as a Small G-protein, with CK2 as an Exchange Factor.**M. K. Mattson<sup>1</sup>, Y. Jun<sup>1</sup>, S. K. Tripathy<sup>1</sup>, B. J. Reddy<sup>1</sup>, A. Strawn<sup>1</sup>, S. P. Gross<sup>1</sup>; <sup>1</sup>Developmental and Cell Biology, University of California, Irvine, Irvine, CA

The kinesin motor protein is required for proper function and organization of the cell; loss of function leads to neurodegeneration and death. Currently, the dominant model for how kinesin is regulated involves head-tail auto-inhibition, which is believed to be relieved upon cargo binding. However, cellular cargos can change motion (and force production) without a change in the amount of cargo-bound kinesins, suggesting the existence of additional kinesin regulatory mechanisms. Recently, Xu et al. discovered that kinesin inactivates over time and activity can be rescued with treatment of the signaling kinase casein kinase 2 (CK2), but the mechanism was unknown. Here, we provide a mechanistic understanding of kinesin's inactivation. Kinesin

shares structural homology with small G-proteins, and we find that when inactive, kinesin is in a previously unknown stable ADP-bound state, and unable to release the ADP. Methods used to characterize GEFs were modified for use with kinesin, and nucleotide movement was monitored. We find that CK2 promotes release of ADP, essentially acting as a nucleotide exchange factor for kinesin. Because this process requires only the kinesin head domain, with many family members share structural homology, this mechanism will likely turn out to be quite general, with potentially different exchange factors contributing to regulation of different motors.

## Actin and Actin-Associated Proteins II

### The role of the actin-bundling protein fascin in cell motility.

Y. Oak<sup>1</sup>, K. Lee<sup>1</sup>, J. D. Tytell<sup>1</sup>, G. Danuser<sup>1</sup>; <sup>1</sup>Department of Cell Biology, Harvard Medical School, Boston, MA

Fascin is an actin binding protein that cross-links filamentous actin into tightly packed parallel bundles. In normal mammalian tissues, it is the most highly expressed in neuronal and glial cells, microcapillary endothelial cells, and antigen-presenting dendritic cells but is largely absent or present in very low levels in epithelial cells. After the initial observation that GFP-fascin is very highly localized to filopodia, fascin has been the most intensely studied within the framework of filopodia dynamics.

More recently, it has been established that high fascin expression is correlated with poor prognoses and high rates of metastases in many cancers. Because fascin is highly expressed in cancer cells but not in normal epithelia, it is emerging as an attractive novel therapeutic target. Although it has been shown that drugs targeting fascin are able to suppress metastasis, very little is known about the exact nature of the relationship between fascin and cell motility.

To study the role of fascin in cell motility, we use PTK-1 as well as HCT116 and HT29 colon cancer cell lines. HCT116 expresses fascin at high levels while HT29 expresses very little fascin. In a wound healing assay, the migration rate of HCT116 was fourfold larger than that of HT29. In a transwell migration assay, the migration rate of HCT116 was also higher, by a factor of 2.5, than the one of HT29. This difference could be partially reduced by knocking down fascin in HCT116 with shRNA, confirming fascin's central role as a positive regulator of cell motility.

We then employed high-resolution imaging of PTK-1 and HCT116. From movies of cells expressing fluorescent proteins or fluorescently-tagged cells, we are able to segment a cell, define probing windows that dynamically adapt to the changing shape of a migrating cell, and thus follow local variations in protein recruitment relative to the local cell motion. Such analyses allowed us to positively correlate fascin localization with protruding lamellipodia, suggesting that fascin may play essential roles in regulating actin dynamics outside filopodia. Further experiments showed that increased fascin expression may be correlated with increased maximum protrusion velocity and decreased total retraction distance in both cell lines. This could be interpreted as fascin bundling increasing the mechanical persistence of the entire protrusive actin network structures. We are currently consolidating these initial data and continue to systematically probe non-filopodia related functions of fascin.

**Actin crosslinking by *V. cholera* ACD toxin: kinetic parameters and the role of high-energy glutamyl-phosphate intermediate.***E. Kudryashova*<sup>1</sup>, *C. Kalda*<sup>1</sup>, *D. S. Kudryashov*<sup>1</sup>; <sup>1</sup>*Chemistry and Biochemistry, Ohio State University, Columbus, OH*

Actin Crosslinking Domain (ACD) is produced by several life-threatening Gram-negative pathogenic bacteria (*V. cholerae*, *V. vulnificus*, and *A. hydrophila*) as an effector domain in larger MARTX and VgrG toxins. ACD together with other effector toxins contributes to the inactivation of macrophage cells, intestinal inflammation, and bacterial colonization of intestinal epithelium. Upon intracellular delivery, ACD disrupts the actin cytoskeleton by irreversible covalent crosslinking of cytoplasmic actin. At the molecular level, ACD-catalyzed formation of an intermolecular amide bond between E270 and K50 residues of actin (Kudryashov, D.S. (2008) Proc. Natl. Acad. Sci. USA 105, 18537-18542) leads to the accumulation of polymerization-deficient actin oligomers, ultimately resulting in structural and functional failure of the actin cytoskeleton in affected cells.

In the present study, we determined the pH optimum for the reaction catalyzed by MARTX ACD, measured the kinetic parameters of the enzyme for both of its substrates (actin and ATP), and deciphered the role of the nucleotide in the ACD catalyzed actin crosslinking.

The optimal pH for ACD activity was in the range of 7.0-9.0. We established that similar to ATP, GTP also supports the crosslinking reaction by ACD, but the kinetic parameters ( $K_M=8\mu\text{M}$  and  $50\mu\text{M}$  for ATP and GTP, respectively) suggest that ATP is the primary substrate of ACD *in vivo*. ACD showed sigmoidal, non-Michaelis-Menten kinetics for actin ( $K_{0.5}=30\mu\text{M}$ ) reflecting involvement of two actin molecules in a single crosslinking event. Furthermore, we found that the actin crosslinking reaction proceeds via formation of a high-energy acyl-phosphate intermediate. First, the  $\gamma$ -phosphoryl group of ATP is transferred to the E270 residue of actin resulting in the formation of an activated glutamyl phosphate derivative. Subsequently, this high-energy intermediate is hydrolyzed and the energy of hydrolysis is utilized for the formation of the amide bond between actin subunits. The elucidated kinetic mechanism of ACD toxicity adds to understanding of complex mechanisms of host-pathogen interactions.

**Electron microscopy and 3D reconstruction reveals Filamin Ig-domain binding to F-actin.***W. Suphamungmee*<sup>1</sup>, *F. Nakamura*<sup>2</sup>, *J. Hartwig*<sup>2</sup>, *W. Lehman*<sup>1</sup>; <sup>1</sup>*Department of Physiology & Biophysics, Boston University School of Medicine, Boston, MA*, <sup>2</sup>*Department of Medicine, Brigham & Women's Hospital, Harvard Medical School, Boston, MA*

Filamin A (FLNa) is an actin-binding protein that cross-links F-actin into networks of orthogonally branched filaments. FLNa also directs the networks to integrins while responding to mechanochemical signaling pathways. Elongated, 80 nm long FLNa molecules are subunits of a dimer and contain an N-terminal calponin-homology/actin-binding domain connected by a series of 24 immunoglobulin (Ig) repeats to a dimerization site at their C-terminal end. Whereas the CH-homology domains' contribution to F-actin affinity is weak ( $K_a \sim 10^5$ ), the binding of the intact protein to F-actin is strong ( $K_a \sim 10^7$ ), suggesting involvement of additional parts of the molecule in this association. Indeed, previous results indicate that Ig-repeats along FLNa contribute significantly to the strength of the actin filament interaction. In the current study, we have used electron microscopy and three-dimensional reconstruction to elucidate the structural basis of the Ig-repeat – F-actin binding. We find that FLNa density is clearly delineated in reconstructions of F-actin complexed with either a 4 Ig-repeat segment of FLNa containing Ig-repeat 10 or with IgFLNa10 alone. The mass attributable to IgFLNa10 lies peripherally along the actin-helix over the N-terminus of actin subdomain 1. The interaction appears to be specific,

since no other fragment of the FLNa molecule or individual Ig-repeats examined, besides ones with CH-domains or IgFLNa10, decorated F-actin filaments or were detected in reconstructions. We conclude that the combined interactions of CH-domains and the IgFLNa10 repeat provide the binding strength displayed by the whole FLNa molecule and propose a model for the association of filamin on actin filaments.

1029

### **New Structural Units in the Actin Cross linking Protein Filamin C.**

*R. Sethi<sup>1</sup>, J. Ylanne<sup>1</sup>; <sup>1</sup>University of Jyväskylä, Jyväskylä, Finland*

Dynamic nature of actin cytoskeleton is essential for cell division, adhesion, migration, signal transduction and various other cellular processes. The nucleation, polymerization and organization of the actin filament network is mediated by a number of proteins. Filamins are actin cross-linking proteins composed of two 290 kDa subunits. Each subunit is composed of N terminal actin binding domain followed by a flexible rod region containing 24 Immunoglobulin-like domains. We have earlier found that in the C-terminal rod-2 part of filamin there are three closely interacting pairs of immunoglobulin-like domains. Two of these domains pairs can serve as mechanically regulated binding sites for Integrins, other transmembrane receptors and for cytoplasmic adaptor proteins. This provides a way how mechanical contraction of actomyosin cytoskeleton can regulate cell adhesion and signaling. To find out whether other areas of Filamins have similar structures we expressed all possible two immunoglobulin-like domain fragments of the rod-1 region from human Filamin C. We found three compact two-domain pairs. Of these, we have crystallized the fragment consisting of immunoglobulin domains 4 and 5. This fragment shows a novel type of domain-domain interaction, where the two domains form a loop-like structure with large interaction surface. While the previously characterized domain pairs of the Filamin rod 2 region interact through the edge of a beta-sheet, the domains 4-5 interact face-to-back along their beta-sheets. This kind of structure could be easily opened by mechanical force and we are currently investigating if this provides a new functional site in Filamins.

1030

### **Visualizing the exposure of filamin A's cryptic binding sites in living cells.**

*F. Nakamura<sup>1</sup>; <sup>1</sup>Medicine, Brigham and Women's Hospital/Harvard Medical School, Boston, MA*

Filamin A (FLNA) is a ubiquitous actin-crosslinking and scaffold protein consisting of 24 Ig-like repeats that bind and modulate multiple intracellular signaling effectors. Structural studies of repeats 19-21 of FLNA indicate that the integrin-binding site on repeat 21 is sterically masked by strand A of repeat 20, and that mechanical/chemical stimuli are required to unmask this cryptic site. We have previously shown that mechanical straining of actin-FLNA networks *in vitro* induces a conformational change in FLNA that successfully exposes its integrin binding site. Here we have engineered a novel photoquenching fluorescence resonance energy transfer (PQ-FRET)-based system (sensor cassette) that reports on this conformational change in cells. Fluorescence emission of the monomeric enhanced green fluorescent protein (mEGFP) is diminished by ~ 73% when the quencher, sREACH, is attached to its C-terminus. Insertion of the two tandem FLNA repeats 1-2 (and even only one repeat) between the FRET pair obliterates this quenching. However, insertion of the FLNA repeats 20-21, generates a structure that quenches mEGFP fluorescence intensity by ~50%, confirming the repeats to posit the probes on the two molecule ends near one another. We then expressed recombinant FLNA containing RFP as an internal control and the FRET pair sensor cassettes in HEK-293 and COS-7 cells. We tested sensor cassettes containing either the "stretchable" FLNA repeats (20-

21) or the control repeats (1-2) between the FRET pairs. Ratio imaging (mEGFP vs RFP) of FLNA molecules in cells having the stretch-detecting repeat 20-21 cassette report that the delivery of FLNA to F-actin enriched regions of cells and the mechanical opening of FLNA molecules can occur in separate steps. By contrast, no changes in fluorescence intensity were observed in FLNA molecules carrying the control sensor cassette (containing repeats 1-2). Time-lapse cell imaging further demonstrates that opening the cryptic binding site is associated with motile activity at the leading edge of cells. These data confirm that FLNA-mediated mechanotransduction occurs in motile cells and that the stretch-detecting PQ-FRET probe is capable of revealing important conformational changes.

1031

**Catch bond behavior of alpha-actinin in vivo.**

A. J. Ehrlicher<sup>1,2</sup>, D. Weitz<sup>1</sup>, M. Pollak<sup>2</sup>; <sup>1</sup>Harvard University, Cambridge, MA, <sup>2</sup>Beth Israel Deaconess Medical Center, Boston, MA

Our cells are subjected to an incredible variety of static and dynamic forces; the correct chemical and mechanical responses of cells to these stimuli are essential, and when incorrect can cause medical disorders. The actin cytoskeleton's ubiquitous nature and connectivity enables it to sustain & transmit forces rapidly over large distances, implicating it in these physiological and pathological responses. At the core of actin mesh dynamics are actin-binding proteins, which can crosslink the network and set its mechanical properties. Here we find that the actin-binding protein, alpha-actinin (ACTN4), an essential crosslinker displays unique behavior under stress in vivo; under stress, ACTN4 binds more tightly, which is in stark contrast to the behavior of most binding interactions. To study this behavior, we transfect GFP tagged ACTN4 into cells cultured on deformable substrates with Young's moduli of 1-30 kPa. Cell spreading and internal stresses increase on stiffer materials, and we use this to stress the cells as a function of substrate stiffness. Using Fluorescence Recovery After Photobleaching (FRAP), we demonstrate that ACTN4 binds an order of magnitude longer to actin under greater stress. Additionally, we impose an external strain on the substrate, which stretches the cells a precise amount, confirming the strain-mediated increase in binding affinity. We hypothesize that this strain-dependent binding is mediated by the CH1 & CH2 domains opening and either exposing an additional actin binding site, or by removing a steric hindrance. We verified the specificity of the strain-dependent binding with a series of ACTN4 point mutations which constitutively open or close the CH1-CH2 conformations, and disrupt the putative additional actin binding site. These results may have immediate bearing on renal medical disorders; we find that in kidney disease (Focal segmental glomerulosclerosis) an ACTN4 variant (K255E), is a severe disease causing mutation. In vivo K255E binds substantially longer than the wildtype, suggesting that interrupting or increasing ACTN4's strain dependent binding may underlie certain diseases.

1032

**CAS-2, a second cyclase-associated protein isoform in *C. elegans*, regulates ADF/cofilin-dependent actin filament dynamics in an ATP-dependent manner.**

K. Nomura<sup>1</sup>, K. Ono<sup>1</sup>, S. Ono<sup>1</sup>; <sup>1</sup>Pathology, Emory University, Atlanta, GA

Cyclase-associated protein (CAP) is a conserved actin-monomer binding protein that regulates actin dynamics. In particular, CAP enhances actin filament turnover in the presence of ADF/cofilin. In multicellular organisms, multiple CAP isoforms are expressed in a tissue-specific manner, but their functional differences are not clearly understood. Mammals have CAP1 (a non-muscle isoform) and CAP2 (a muscle isoform). Recently, we have reported that CAS-1 is a muscle isoform of CAP in *C. elegans* and is essential for sarcomeric actin organization in

striated muscle (Nomura et al., 2012). In addition, *C. elegans* has CAS-2, a second isoform of CAP, which remains uncharacterized. CAS-2 is 41 % identical to CAS-1. *cas-2*-null worms were homozygous viable and showed disorganized actin cytoskeleton in the distal gonad. Although we have been unsuccessful in localizing the CAS-2 protein in worms, gonadal expression of *cas-2* mRNA has been demonstrated in the NextDB *in situ* hybridization database (National Institute of Genetics, Mishima, Japan) and is consistent with the observed phenotypes. These results strongly suggest that CAS-2 is a non-muscle CAP isoform in *C. elegans*. To understand the actin-regulatory function of CAS-2, we produced recombinant CAS-2 protein and characterized its biochemical properties *in vitro*. CAS-2 bound to G-actin without strong preference to either ATP-actin or ADP-actin and sequestered it from polymerization when CAS-2 was present at high concentrations. CAS-2 strongly enhanced the rate of exchange of actin-bound ATP/ADP. Although UNC-60A, a non-muscle ADF/cofilin isoform, inhibited exchange of actin-bound nucleotides, substoichiometric concentrations of CAS-2 was able to enhance nucleotide exchange in the presence of UNC-60A. The C-terminal half of CAS-2 was necessary and sufficient for G-actin binding and enhancement of nucleotide exchange and had nearly as strong activities as the full-length CAS-2 protein. UNC-60A promoted depolymerization of F-actin and inhibited polymerization. However, substoichiometric concentrations of CAS-2 antagonized UNC-60A and promoted actin polymerization in the presence of ATP but not in the presence of ADP or in the absence of nucleotides. These results suggest a role of CAS-2 to load ATP onto UNC-60A-bound ADP-actin to promote their dissociation and a new round of actin polymerization and depolymerization.

**Swiprosin-1 modulates membrane dynamics by regulating cofilin accessibility to F-actin.**

Y-H. Huh<sup>1</sup>, S-H. Kim<sup>2</sup>, K-H. Chung<sup>1,2</sup>, S. Oh<sup>2</sup>, D-H. Kim<sup>2</sup>, W-K. Song<sup>1</sup>; <sup>1</sup>Bio Imaging and Cell Dynamics Research Center, Gwangju, Korea, <sup>2</sup>School of Life Sciences, Gwangju Institute of Science and Technology (GIST), Gwangju, Korea

Membrane protrusions, like lamellipodia, and cell movement are dependent on actin dynamics, which are regulated by a variety of actin binding proteins acting cooperatively to reorganize actin filaments. Here we provide evidence that Swiprosin-1, a recently identified actin bundling protein, modulates lamellipodia formation and cell motility by regulating the accessibility of F-actin to cofilin. Overexpression of Swiprosin-1 increased lamellipodia formation and cell motility in B16F10 melanoma cells, whereas knockdown of Swiprosin-1 inhibited EGF-induced lamellipodia formation and cell motility, and led to a loss of actin stress fibers at the leading edges of cells but not in the cell cortex. Swiprosin-1 strongly facilitated the formation of F-actin that was closely packed into parallel or entangled bundles, which made the F-actin inaccessible of cofilin. Taken together, these findings suggest that Swiprosin-1 is a novel molecule that regulates actin dynamics by modulating the pattern of cofilin activity at the leading edges of cells.

**Cofilin uses intrinsic zones of instability within F-actin to disrupt the actin filament.**

V. E. Galkin<sup>1</sup>, A. Orlova<sup>1</sup>, A. Solodukhin<sup>1</sup>, E. Egelman<sup>1</sup>; <sup>1</sup>University of Virginia, Charlottesville, VA

Actin plays a major role in many cellular processes including cell motility, cell division, endocytosis, and exocytosis. Recently, we showed that frozen-hydrated actin filaments contain a multiplicity of different structural states. We also reported an unconventional structural state of actin (tilted actin or T-actin) where the interaction between the actin protomers weakens

compared to “canonical” F-actin. To evaluate the role of T-actin in the stability of the actin filament we analyzed the structural composition of individual frozen hydrated filaments. We show that within regions of actin filaments enriched with T-actin the majority of neighboring actin protomers have their subdomain 2 completely disordered. The coupling in the spatial distributions of the two structural modes that possess less connectivity between subunits suggests an existence of intrinsic zones of instability within the actin filament. Cofilin/ADF proteins depolymerize actin filaments to maintain the pool of monomeric actin. To evaluate the role of the proposed intrinsic zones of instability within the actin filaments in presence of ADF/cofilin proteins we analyzed individual frozen hydrated actin filaments partially decorated with cofilin-2. We show that the bare zones between the regions of F-actin occupied by cofilin are structurally similar to the intrinsic zones of instability found in pure F-actin. The weakening of the contacts between actin subunits in those zones reaches its maximum at 50%-75% occupancy by cofilin-2. Our data show that at substoichiometric concentrations ADF/cofilin proteins boost the frequency of intrinsic zones of instability within the actin filament. We provide a structural explanation for the maximal depolymerization activity of ADF/cofilin proteins when bound at low stoichiometry to actin filaments.

### **Mammalian CAP1 (adenylyl Cyclase-Associated Protein 1) Regulates Cofilin function, the Actin Cytoskeleton and Cell Adhesion.**

H. Zhang<sup>1</sup>, P. Ghal<sup>1</sup>, J. Field<sup>2</sup>, G-L. Zhou<sup>1,2</sup>; <sup>1</sup>Department of Biological Sciences and Arkansas Biosciences Institute, Arkansas State University, Jonesboro, AR, <sup>2</sup>Department of Pharmacology, University of Pennsylvania, Perelman School of Medicine, Philadelphia, PA

**Background:** CAP (adenylyl Cyclase-Associated Protein) was first identified as a yeast protein that participates in the regulation of both the actin cytoskeleton and the Ras regulation of cAMP. While the role in Ras signaling does not extend beyond yeast, CAP regulates actin in all eukaryotes. *In vitro* biochemical assays and knockdown experiments have shown that mammalian CAP1 and its yeast homologue facilitate cofilin-driven actin filament turnover. However, it remains unclear whether mammalian CAP participates in other cellular functions.

**Methods and Results:** We efficiently knocked down CAP1 in HeLa cells using stable knockdown with vector-based shRNA constructs. Imaging and fractionation assays show that depletion of CAP1 led to larger cell size, cell protrusions and accumulation of filamentous (F) actin. We suggest that loss of CAP1 function in sequestering actin monomers is responsible for the actin filament phenotype. Moreover, we unexpectedly found that CAP1 knockdown led to activation of FAK (Focal Adhesion Kinase) and enhanced cell spreading. We further demonstrated that CAP1 forms complex with adhesion molecules FAK and Talin, which may explain the increases in adhesion and spreading of the CAP1 knockdown cells. Knockdown of CAP1 in HeLa cells also led to substantially elevated cell motility and invasion through Matrigel. Finally, our studies showed biochemical and functional interactions between CAP1 and cofilin as well as the underlying mechanisms; CAP1 depletion in cells caused cofilin dephosphorylation and accumulation into aggregates, and CAP1 facilitates cofilin phosphorylation by LIM kinase in *in vitro* biochemical assays. We also mapped cofilin binding to the N-terminus of CAP1 by GST-cofilin pull-down. In summary, in addition to further establishing the role of mammalian CAP1 in actin dynamics, we identified a novel cellular function for CAP1 in regulating cell adhesion signaling.

1036

**Cortactin directly targets nascent actin filament branch junctions to synergize with N-WASp and activate branching nucleation by Arp2/3 complex.***L. Helgeson<sup>1</sup>, A. Wagner<sup>1</sup>, B. Nolen<sup>1</sup>; <sup>1</sup>Institute of Molecular Biology, University of Oregon, Eugene, OR*

Arp2/3 complex is a critical actin regulatory protein that nucleates branched actin filaments in response to cellular signals. Cortactin has been shown to regulate Arp2/3 and is required for assembly of actin filaments in podosomes and invasive actin structures in cancer cells called invadopodia. Cortactin acts synergistically with WASp/Scar family proteins, the prototypical Arp2/3 complex activators, to dramatically increase branching nucleation by the complex. Cortactin has an actin filament binding domain and no actin monomer binding region, suggesting it uses a distinct mechanism of activation compared to WASp/Scar proteins. Despite its critical role in regulating actin, how cortactin synergistically activates the Arp2/3 complex is unknown. Here we show that neither the previously proposed actin filament recruitment model nor the WASp displacement/cycling model can account for cortactin-mediated synergy. Instead, our data supports an obligatory displacement model in which cortactin actively displaces N-WASp from nascent branch junctions as a prerequisite for branching nucleation. Our data show that the oligomerization state of N-WASp, the number of actin monomer binding regions it harbors, and its affinity for actin monomers (and Arp2/3 complex) are all critical determinants in synergy. We find that the N-terminal acidic (NtA) region of cortactin alone is sufficient for synergy. By mapping regions of NtA required for synergy we show that it is functionally distinct from the acidic region of N-WASp. In contrast to previously published data, we demonstrate that high concentrations of cortactin do not inhibit branching. Using single-molecule TIRF microscopy we show that cortactin has a 150-fold preference for binding branches over filament sides, explaining how nascent branches are directly targeted by cortactin, a prediction of the obligatory displacement model. Using kinetic rate constants derived from our single molecule studies, we built mathematical models which show that an obligatory displacement model but not the cortactin-mediated WASp cycling or filament recruitment models can account for synergy observed in our bulk actin polymerization assays. These results have important implications for understanding how cortactin cooperates with other Arp2/3 complex regulators to control branching nucleation.

1037

**Arg/Abl2 modulates the affinity and stoichiometry of cortactin binding to F-actin.***S. M. MacGrath<sup>1</sup>, A. J. Koleske<sup>2</sup>; <sup>1</sup>Molecular Biophysics and Biochemistry, Yale University, New Haven, CT, <sup>2</sup>Molecular Biophysics and Biochemistry, Interdepartmental Neuroscience Program, Department of Neurobiology, Yale University, New Haven, CT*

The Abl family nonreceptor tyrosine kinase Arg/Abl2 interacts with cortactin, an Arp2/3 complex activator, to promote actin-driven cell edge protrusion. Both Arg and cortactin bind directly to filamentous (F-) actin. While protein:protein interactions between Arg and cortactin have well-characterized downstream effects on the actin cytoskeleton, it is unclear whether and how Arg and cortactin affect each other's actin binding properties. We employ actin cosedimentation assays to show that Arg increases the stoichiometry of cortactin binding to F-actin at saturation. Using a series of Arg deletion mutants and fragments, we demonstrate that the Arg C-terminal calponin homology (CH) domain is necessary and sufficient to increase the stoichiometry of cortactin binding to F-actin. We also show that interactions between Arg and cortactin are required for optimal affinity between cortactin and the actin filament. In summary, our data suggest a mechanism for Arg-dependent stimulation of cortactin binding to F-actin, which may facilitate cortactin recruitment to sites of local actin network assembly.

**Effects of actin binding proteins on polarizing cortical flow mechanics.**

S. Naganathan<sup>1</sup>, S. Fürthauer<sup>2</sup>, S. W. Grill<sup>1,2</sup>; <sup>1</sup>Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, Germany, <sup>2</sup>Max Planck Institute of Physics for Complex Systems, Dresden, Germany

The establishment of cell polarity is crucial for many developmental processes. In *C. elegans* one-cell embryos, cellular polarization and anteroposterior axis establishment is facilitated by actomyosin cortical flows (Mayer M *et al.*, 2010, Goehring N *et al.*, 2011). Flows proceed on scales that are comparable to the size of the cell. Describing flows requires the identification of mesoscale physical properties of the actomyosin cytoskeleton, such as active stresses, active torques, 2D viscosity of the cortex and friction with the cell membrane and the intracellular cytosol (Mayer M *et al.*, 2010). However, how large-scale actomyosin flow and associated physical properties depends on molecular functions of actin binding proteins (ABPs) and other cortex-associated proteins remains unknown. Here, we devised a candidate RNAi screen of ABPs and inferred the molecular regulation of large scale flow by performing a systematic comparison to a mesoscale hydrodynamic description of the cortex. Interestingly, our candidate-based RNAi screen yielded only a reduced spectrum of flow phenotypes. This points towards a type of mechanical redundancy, with diverse molecular mechanisms affecting a limited number of mesoscale physical properties. In summary, by applying the hydrodynamic model on molecular perturbation experiments performed on a developing *C. elegans* embryo, we reveal the molecular links that give rise to emergent flow properties of the actomyosin cortex.

1039

**Slings enable leukocyte rolling during inflammation.**

P. Sundd<sup>1</sup>, A. Groisman<sup>2</sup>, K. Ley<sup>1</sup>; <sup>1</sup>La Jolla Institute for Allergy and Immunology, La Jolla, CA, <sup>2</sup>University of California, San Diego, La Jolla, CA

Leukocyte recruitment to the sites of inflammation involves leukocyte rolling along the inflamed venules. Rolling is mediated by P-selectin on the endothelium binding to P-selectin glycoprotein ligand-1 (PSGL-1) constitutively expressed on leukocytes. Most leukocytes can roll along the walls of venules at low shear stress (1 dyn/cm<sup>2</sup>), but neutrophils have the ability to roll at 10-fold higher shear stress in microvessels in vivo. Although the shear-resistant neutrophil rolling is known to be facilitated by cell flattening and pulling of long membrane tethers, the mechanisms that enable neutrophil rolling during inflammation are poorly understood. Isolated mouse bone marrow neutrophils stained with an intercalating membrane dye (Dil or DiO) were allowed to roll on a P-selectin (20 molecules/μm<sup>2</sup>) coated cover slip in a microfluidic device at a shear stress of 6 to 10 dyn/cm<sup>2</sup> and footprints recorded using dual-color quantitative dynamic footprinting (DqDF). Epifluorescence intravital microscopy was used to observe rolling of neutrophils in the mice cremaster venules. As anticipated, rolling neutrophils formed long membrane tethers (> 10 μm) at the rear. However, following detachment these long tethers did not retract as postulated, but instead persisted and appeared as 'slings' at the front of rolling cells. Rolling neutrophils formed slings in a model of acute inflammation in vivo and on P-selectin in vitro, where PSGL-1 was presented as discrete sticky patches (1.6 μm apart) while LFA-1 was expressed over the entire length on slings. As neutrophils rolled forward, slings wrapped around the rolling cells and underwent a step-wise peeling from the P-selectin substrate. As each PSGL-1 patch failed, the rolling neutrophil was unable to accelerate because a new downstream patch on the same sling was already lined up and became load-bearing. LFA-1 on the sling interacted with inter-cellular-adhesion-molecule (ICAM)-2 on the neutrophil surface in trans to facilitate wrapping of slings and blocking this interaction resulted in less efficient wrapping and thus, reduced rolling velocity

on P-selectin substrate. The discovery of slings provides a mechanism by which neutrophils rolling at high shear stress pave their own way for enhanced rolling. Besides stabilizing rolling, slings are unique structures that also enable rolling neutrophils to present LFA-1 to its ligand ICAM-2 in trans. This study was supported by the NCRP-Scientist Development Grant 11SDG7340005 from the American Heart Association (P.S.) and NIH EB02185 (K.L.).

**Degradation of E-cadherin by aspartyl proteases secreted by *Candida albicans* causes changes in F-actin dynamics and disruption of epithelial adherens junctions.**

T. Woellert<sup>1</sup>, P. Sundstrom<sup>2</sup>, G. M. Langford<sup>1</sup>; <sup>1</sup>Biology, Syracuse University, Syracuse, NY, <sup>2</sup>Microbiology and Immunology, Dartmouth Medical School, Hanover, NH

Pathogenic *Candida albicans* invade human epithelia by a complex mechanism that allows them to penetrate the protective outer layer. E-cadherin has been identified as one of the epithelial cell receptors for the host-cell association with *C. albicans*. In a previous study, we showed that secreted aspartyl proteases (Saps) that contribute to the virulence of *C. albicans* affected E-cadherin-mediated cell-cell adhesions in cultures of human oral keratinocytes and decreased E-cadherin levels in a time-dependent manner during coculture with *C. albicans*. The mechanism by which *C. albicans* induces epithelial cell damage is incompletely understood but Saps most likely contribute to this process. To determine the effects on epithelial adherens junctions by individual Sap4-6, keratinocytes were treated with single *SAP4-6* and *SAP4-6*-deficient mutants. We used OKF6/TERT-2 cells, an immortalized cell line of human oral keratinocytes cocultured with hyphae-forming *C. albicans*. The cellular dynamics of proteins that form cell-cell adhesions was determined at defined time intervals by multi-mode high-resolution microscopy and quantitative image analysis.

OKF6/TERT-2 cells exposed to wild-type *C. albicans* showed that E-cadherin mediated cell-cell adhesions were compromised compared to untreated cultures. Coculture with *C. albicans* initially stimulated formation of cell-cell adhesions at early time intervals (0 – 6 hours). At longer intervals of coculture (12 – 24 hours) cell-cell adhesions began to disintegrate and were disrupted completely after 24 hours. Fluorescence intensity profiles illustrated both the dynamics of cell-cell adhesion proteins and their colocalization with the actin cytoskeleton. Exposure of OKF6/TERT-2 cells to individual tetracycline-inducible *SAP4-6* promoter strains and triple *SAP4-6* mutants were found to elicit attenuated changes in keratinocyte responses compared to those that were cocultured with wild-type *C. albicans*. Disruption of cell-cell adhesions by *C. albicans* was blocked by the anti-fungal drug fluconazole. In addition, affinity binding studies using GST-E-cadherin and purified Saps showed binding between these proteins, which resulted in the degradation of E-cadherin. We, therefore, conclude that the binding of Sap4-6 to epithelial E-cadherin caused its degradation and led to the simultaneous reorganization of the actin cytoskeleton. The degradation of E-cadherin by Sap4-6 may be important for *C. albicans* to invade epithelial surfaces by active penetration between epithelial cells.

**F-actin during mitosis: how spindle-associated F-actin contributes to mitotic spindle structure and function.**

A. Kita<sup>1</sup>, S. Woolner<sup>2</sup>, W. Bement<sup>1</sup>; <sup>1</sup>Cellular and Molecular Biology Program, University of Wisconsin, Madison, WI, <sup>2</sup>University of Manchester, Manchester, United Kingdom

Mitotic spindles are microtubule-based structures responsible for partitioning genetic information into each new daughter cell. The role of microtubules and microtubule-associated proteins in

this process has been well characterized, however whether or not F-actin is required—or is even present—within the spindle has long been controversial. In this work we examine spindle-associated F-actin in the intact *Xenopus laevis* epithelium. Imaging of fluorescently labeled phalloidin revealed F-actin at spindle poles, F-actin cables extending from poles towards the cortex, and F-actin cables spanning between poles within the spindle. Similar localization patterns are detected with gamma-actin antibodies. Live imaging experiments corroborated these results and highlighted the dynamic nature of these actin cables as they move within and around the spindle throughout mitosis. In addition, treatment with the formin inhibitor SMIFH2 resulted in a loss of spindle-associated F-actin and mitotic spindle defects, while cortical F-actin remained intact. Collectively, these results show that a) mitotic spindles in intact vertebrate epithelia contain a substantial amount of F-actin structures; b) these structures form coincident with spindle assembly, and; c) spindle F-actin, rather than cortical F-actin, may be essential for proper mitotic spindle structure and function.

### **Drosophila dorsal closure as a model for actin regulation.**

*S. H. Nowotarski<sup>1</sup>, C. G. Bilancia<sup>1</sup>, M. Peifer<sup>1</sup>; <sup>1</sup>Biology, University of North Carolina at Chapel Hill, Chapel Hill, NC*

From bundled myofibrils in muscle cells to dynamic filopodia and lamellipodia in migratory axons, proper development requires cells in different tissues, or cells within the same tissue at different times, to build distinct actin-based structures. Each structure presumably arises from different underlying actin geometries, created by the action of different suites and levels of actin regulators. We are using *Drosophila* morphogenesis, and in particular dorsal closure, as a model for understanding in-vivo mechanisms of actin regulation both within the same and across different tissue types. Dorsal closure is a highly dynamic process that results in enclosing the embryo in epidermis, through both the dorsalward migration of contralateral epidermal sheets, and apical constriction of central amnioserosa cells. These two cell types produce morphologically and dynamically distinct suites of actin-based protrusions. We are comparing the structure and dynamics of these protrusions, and identifying their underlying suite of actin regulators. We started by exploring the contribution and relationship of the actin elongation and filopodia promoting factors, Enabled (Ena) and Diaphanous (Dia), in formation and persistence of filopodia within and between these two cell types. Our preliminary data suggest that while both Ena and Dia can promote filopodia, the nature and dynamics of these filopodia differ significantly. Further, our data suggest that Ena binds and inhibits Dia in vitro, in cultured cells, and in vivo in the epidermis. While elongation factors are required to promote filopodia formation at the tip, the shaft is comprised of bundled actin. We thus are extending our assessment of the role of actin regulators by determining the requirement of actin bundling for morphology and persistence of filopodia, by removing zygotic fascin. Taken together these experiments will help us understand the mechanistic differences that drive these two very distinct sets of actin-based structures contributing to the same developmental process.

1043

### **Cell Adhesion Assemblies and the Origins of Multicellularity.**

*R. O. McCann<sup>1</sup>, A. Oliver<sup>2</sup>, A. Lowrey<sup>1</sup>; <sup>1</sup>Division of Basic Medical Sciences, Mercer University School of Medicine, Macon, GA, <sup>2</sup>Department of Biology, Mercer University, Macon, GA*

The emergence of multicellular eukaryotes is one of the major transitions in the evolution of life. Multicellularity presented eukaryotic organisms with novel challenges. Principal among these are: (1) Cell Adhesion: How do individual cells in the multicellular organism interact with one another and their environment within the organism, and (2) Cell Signaling: How do cells

communicate with each other and sense their extracellular environment within the organism? Despite its fundamental importance in eukaryote evolution, relatively little is known about the origins of multicellular animals (Metazoa) at the cellular level. Completion of the genome sequences of several unconventional model organisms (e.g., Choanoflagellates, Basal Fungi, Apusozoa, and Filasterea) has provided the foundation for addressing this question. These model genomes have revealed that several adhesion/signaling complex proteins are ubiquitous, or nearly so, in close unicellular relatives of animals. These include talin, which is found in all unicellular taxa closely related to animals, and is essential for cell adhesion and cell motility in these organisms. Vinculin and integrin, which are physiological partners of talin in metazoans, are also present in these organisms. Given that talin, integrin, and vinculin have essential roles in cell adhesion and signaling in multicellular organisms, the identification of the molecular and cellular roles of these conserved proteins in unicellular relatives of animals may reveal fundamental information about the origin of multicellularity in the Metazoa. We have performed extensive phylogenetic and bioinformatic analyses of talin, vinculin, and beta-integrin from the choanoflagellates *Monosiga brevicollis* and *Salpingoeca rosetta*, the apusozoan *Thecamonas trahens*, the filasterean *Capsaspora owczarzaki*, and the basili fungi *Spizellomyces punctatus* and *Allomyces macrogynus* and have identified the putative functional domains of these conserved, modular proteins. The phylogenetic affinities of these proteins are congruent with the conventional phylogenies of these taxa. Molecular and cellular analyses of these protein domains have revealed functional conservation, e.g., actin binding, between the proteins from these largely unicellular organisms thought to be representative of the immediate ancestor(s) of multicellular organisms and those from model metazoan organisms. While it is not possible to study the last common ancestor of unicellular organisms and animals and directly characterize the transition to multicellularity, the comparative approach described here should allow us to define the structure and function of the putative simple ancestral states of multicomponent adhesion assemblies such as the focal adhesion complex and the adherens junction. These results may then provide a foundation for understanding how the subsequent evolution of the extant complex derived state of these adhesion assemblies contributed to the emergence of multicellular organisms.

#### **Enabled antagonizes Actin Capping Protein function to regulate growth of motor nerves in the *Drosophila* embryo.**

L. Kotlyanskaya<sup>1,2</sup>, S. Nowotarski<sup>3</sup>, M. Peifer<sup>3</sup>, E. Giniger<sup>1</sup>; <sup>1</sup>National Institute of Neurological Disorders and Stroke, National Institutes of Health, Bethesda, MD, <sup>2</sup>Neurobiology Curriculum, University of North Carolina at Chapel Hill, Chapel Hill, NC, <sup>3</sup>University of North Carolina at Chapel Hill, Chapel Hill, NC

During neural development, axons migrate to their targets by responding to guidance cues in the environment. In response to transmembrane receptor activation of signaling cascades, the growth cone of the axon builds actin-based cell protrusions including filopodia and lamellipodia that help determine the speed and direction of axon growth. Enabled (Ena), a member of the Ena/VASP/EVL family of proteins, promotes formation of filopodia *in vitro* and is essential for many aspects of neuron migration and axon guidance *in vitro* and *in vivo*. Ena has several biochemical activities including promoting actin polymerization, preventing capping of actin filaments, bundling actin filaments and anchoring actin to the cell cortex. In the *Drosophila* embryo, Ena is required for pathfinding of the Intersegmental Nerve b (ISNb) motor nerve. In *ena* mutants, the axons of this nerve fail to defasciculate from the Intersegmental Nerve after exiting the CNS, causing them to “bypass” their target muscles. Based on experiments in cell culture it has been hypothesized that the anti-capping function of Ena is particularly important

for motility, but this has not been tested in axon guidance *in vivo*. We manipulated levels of Ena and Actin Capping Protein (CP) to test this hypothesis. Our data suggest that suppressing CP activity is an essential aspect of Ena function in ISNb motor nerves. Using Fasciclin II as an axonal marker, we compared the nervous system defects in *ena* and *cp* single mutants with those in mutants deficient in Ena and with reduced Capping Protein. Strikingly, reducing the dose of *cp $\beta$*  by half in *ena* mutants produces substantial rescue of the ISNb “bypass” defect. This supports the importance of the anti-capping function of Ena in promoting ISNb motor axon guidance. In our future experiments we will selectively inactivate functional domains of Ena required for its other biochemical activities to assess their contributions to Ena-dependent axon guidance.

1045

### **Capturing the Action: Visualizing *in vivo* Actin Dynamics in the *Drosophila* Ovary.**

A. J. Sprackeln<sup>1</sup>, K. Lovander<sup>1</sup>, T. L. Tootle<sup>1</sup>; <sup>1</sup>Anatomy and Cell Biology, University of Iowa Carver College of Medicine, Iowa City, IA

*Drosophila* oogenesis is comprised of 14 morphologically defined stages of egg or follicle maturation. Late in this maturation process, the 15 germline-derived support cells, termed nurse cells, rapidly transfer their cytoplasmic contents to the oocyte in a process termed nurse cell dumping. Nurse cell dumping requires the nurse cells to undergo dramatic actin cytoskeletal remodeling. Specifically, the nurse cells must increase their cortical actin to provide the contractile force necessary for dumping while forming a series of parallel actin filament bundles extending from the nurse cell membranes inward towards the nuclei. This developmental model has been used to elucidate the function of numerous actin-binding proteins and their interacting partners. Despite decades of study, *in vivo* actin dynamics in the *Drosophila* germline have not been examined. In order to visualize actin dynamics during nurse cell dumping, we have recently generated transgenic flies expressing either Lifeact::mEGFP or Ftractin::mEGFP/tdTomato under the control of the UASp/Gal4 system. Additionally, we have obtained Utrophin-GFP transgenic flies (UASp and *sqh* promoter driven). Here we compare the utility of these actin labeling tools by assessing colocalization with phalloidin, live imaging capability, and affects on nurse cell dumping and female fertility.

## **Higher-Order Actin-Based Structures**

### **Functions of Nonmuscle Myosin IIA and IIB in Assembly of the Cellular Contractile System.**

M. Shutova<sup>1</sup>, C. Yang<sup>1</sup>, J. M. Vasiliev<sup>2</sup>, T. Svitkina<sup>1</sup>; <sup>1</sup>University of Pennsylvania, Philadelphia, PA, <sup>2</sup>Blokhin Cancer Research Center, Moscow, Russia

The contractile system of nonmuscle cells consists of interconnected actomyosin networks and bundles anchored to focal adhesions. The initiation of the contractile system assembly is poorly understood structurally and mechanistically, whereas system’s maturation heavily depends on nonmuscle myosin II (NMII). Using platinum replica electron microscopy in combination with fluorescence microscopy, we characterized the structural mechanisms of the contractile system assembly during spreading or recovery from blebbistatin treatment and investigated roles of NMII in general, as well as specific roles of NMIIA and NMIIIB isoforms, at early stages of this process. We show that inhibition of NMII by blebbistatin, in addition to known effects, such as disassembly of stress fibers and mature focal adhesions, also causes transformation of

lamellipodia into unattached ruffles, loss of immature focal complexes, loss of cytoskeleton-associated NMII filaments and peripheral accumulation of activated, but unpolymerized NMIIA and NMIIIB. After blebbistatin washout, assembly of the contractile system begins with quick and coordinated recovery of lamellipodia and focal complexes that occurs before reappearance of NMII bipolar filaments. The initial formation of focal complexes and subsequent assembly of NMII filaments, preferentially NMIIA, occurred in association with filopodial bundles and concave actin bundles formed by filopodial roots at the lamellipodial base. Over time, accumulating NMII filaments composed of both NMIIA and NMIIIB help to transform the precursor structures, focal complexes and associated thin bundles, into stress fibers and mature focal adhesions. However, semi-sarcomeric organization of stress fibers develops at much slower rate with parallel accumulation of alpha-actinin. Together, our data suggest that activation of NMII motor activity by light chain phosphorylation occurs at the cell edge and is uncoupled from NMII assembly into bipolar filaments. We propose that activated, but unpolymerized NMIIA initiates focal complexes, thus providing traction for lamellipodial protrusion. Subsequently, the mechanical resistance of focal complexes activates a load-dependent mechanism of NMIIA and NMIIIB polymerization in association with attached bundles, leading to assembly of stress fibers and maturation of focal adhesions.

**Live cell, 3-D SIM reveals a myosin II-based, actin arc contractile system operating on the dorsal surface of migrating cells.**

*D. T. Burnette<sup>1</sup>, L. Shao<sup>2</sup>, C. Ott<sup>1</sup>, R. Fiolka<sup>2</sup>, M. W. Davidson<sup>3</sup>, C. Waterman<sup>4</sup>, E. Betzig<sup>2</sup>, J. Lippincott-Schwartz<sup>1</sup>; <sup>1</sup>Cell Biology and Metabolism Program, Eunice Kennedy Shriver National Institute of Child Health and Human Development, NIH, Bethesda, MD, <sup>2</sup>Janelia Farms Research Campus, Howard Hughes Medical Institute, Ashburn, VA, <sup>3</sup>National High Magnetic Field Laboratory and Department of Biological Science, Florida State University, Tallahassee, FL, <sup>4</sup>National Heart, Lung and Blood Institute, NIH, Bethesda, MD*

The actin cytoskeleton provides a dynamic structural scaffold that frames the cell and propels its motion. To gain better insight into how this system operates in migrating cells, we employed live-cell structured illumination microscopy (SIM), which doubles both the lateral (x,y) and axial (z) resolution compared with conventional fluorescence techniques. Using 3-D SIM, we observed a novel myosin II-based, contractile system comprised of actin arcs operating on the top surface of migrating cells. The actin arcs glided along the dorsal cell surface, shortening as they moved toward the top of the cell (near the perinuclear region), where they recycled their components. Arranged parallel to the plasma membrane and perpendicular to dorsal actin stress fibers, the arcs contained most of the myosin IIA within cells (up to 80%), with dorsal stress fibers (contacting focal adhesions) having virtually no myosin IIA. Using 3-D SIM we were able to distinguish the myosin IIA motor domain from the coiled-coil domain of individual molecules tagged with mEmerald (N terminus) and mApple (C terminus). This resulted in a distinctive green-red-green (i.e., head-tail-head) pattern that could be used to reveal myosin IIA-filament orientation. We found that myosin IIA-filaments had their long axis oriented parallel to the leading edge. Notably, the myosin II filaments were separated from each other by alpha-actinin, suggesting a sarcomeric arrangement reminiscent of the arrangement in muscle myofibrils. This pattern was acquired by specific recycling of alpha-actinin along the lengths of newly formed actin arcs at sites of myosin IIA filament formation. By revealing a myosin IIA-based, actin arc contractile system at the dorsal surface of cells, our data suggest a model in which a contractile force generated from the top of the cell is used to move the cell forward. This scenario may be particularly relevant for understanding how a cell moves in a more complex 3-D environment, where large ventral stress fibers are not apparent and focal adhesions are small.

1048

**3D PALM shows distinct distributions of Z-disc proteins with the Z-discs in cardiomyocytes.**

*M. Peckham<sup>1</sup>, Y. Takagi<sup>2</sup>, D. Ushakov<sup>1</sup>, X. Ma<sup>2</sup>, K. Temprine<sup>2</sup>, H. Shroff<sup>2</sup>; <sup>1</sup>University of Leeds, Leeds, UK, <sup>2</sup>National Institutes of Health, Bethesda, MD*

Z-discs are important structural and signalling structures that form the boundaries of each muscle sarcomere in striated muscle. Within the Z-disc, electron microscopy indicates that actin filaments, arranged in an anti-parallel organization, are cross-linked by  $\alpha$ -actinin dimers arranged at ~20 nm intervals. At least 30 different proteins reside in the Z-disc, and their organisation is not well understood. Conventional light microscopy cannot resolve the localisation of proteins within it as it is too narrow, ~100 nm wide.

We have developed the use of 3-D Photoactivated Localisation Microscopy (PALM [1,2]) to image two specific proteins within the Z-disc;  $\alpha$ -actinin2, and Lasp-2 (LIM and SH3 containing protein 2), which binds to  $\alpha$ -actinin2.  $\alpha$ -actinin2 and LASP fused to mEos2 were expressed in cultured embryonic mouse or isolated adult rat cardiomyocytes. Fixed cells were imaged using PALM, in which a weak cylindrical lens in the light path between the specimen and the camera was used to obtain 3D information from a single 2D plane.

The resulting images show individual molecules of mEos2- $\alpha$ -actinin2 and mEos2-LASP within the Z-disc, using light microscopy, for the first time. The localization precision was 20nm (X,Y) and 50nm in Z. The density of mEos2- $\alpha$ -actinin2 molecules was higher than that for mEos2-LASP, and the densities of both molecules was non-uniform throughout the Z-disc structures. A quantitative analysis of these molecules provides new insight into the organisation of these molecules within the Z-disc structure. These results demonstrate that PALM can be used to localise specific proteins within the narrow Z-disc and thus it has great potential for investigating the organisation of component proteins within this structure.

**Reconstitution of lamellipodium-like structure using micropatterning.**

*C. Suarez<sup>1</sup>, A. Kawaska<sup>1</sup>, T. Klar<sup>1</sup>, J-L. Martiel<sup>1</sup>, L. Blanchoin<sup>1</sup>, M. Théry<sup>1</sup>, R. Boujemaa-Paterski<sup>1</sup>; <sup>1</sup>Laboratoire de Physiologie Cellulaire et Végétale, Institut de Recherches en Technologies et Sciences pour le Vivant (iRTSV), Grenoble, France*

Cells move, change shape, divide by a dynamic control of their architecture maintained by the actin cytoskeleton and orchestrated by regulatory proteins. The identification of biochemical, biophysical and physical laws that govern this dynamics in cells is rendered difficult by the complexity of life. To reduce this complexity, we have developed new biomimetic experimental systems that reproduce, in simplified terms, the behavior of the cellular actin cytoskeleton. Using this approach, we reconstituted an actin network crosslinked structure similar to that present in the lamellipodium of motile cells. By varying the geometry and the density of the actin nucleation zones, we were able to show that the actin network size, but not its density, affects the lamellipodium-like growth rate. We showed that denser lamellipodia are more rigid and density gradients of actin network orient lamellipodia growth. This work unveils how kinetic and

mechanical properties of growing actin networks can control the overall properties of lamellipodium-like growth and governs force production and cell motility.

**Embryonic Wound Healing Mechanisms Investigated by Experiment and Computer Modeling.**

*M. A. Wyczalkowski<sup>1</sup>, L. A. Taber<sup>1</sup>; <sup>1</sup>Biomedical Engineering, Washington University in St. Louis, St. Louis, MO*

The healing of embryonic wounds can yield insight into the mechanical forces which shape a developing organism. Here we characterize the healing of wounds in the epithelia of early stage chick embryos, and use a newly developed computational model to investigate the underlying cellular-level mechanisms.

Early stage (HH4) chick embryos were harvested and cultured *ex ovo*. At this stage the embryo consists of planar epithelial sheets two to three cell layers thick. Circular and slash wounds (~100µm in size) were made in the tissue and allowed to heal. The healing process was captured with time lapse microscopy, and wound area and shape were characterized as functions of time. We found that the closure rate of embryonic wounds displayed a two-phase behavior, with rapid constriction lasting about a minute, followed by a period of more gradual contraction until the wound closed. Fluorescent staining revealed that about ten seconds after wounding a broad, faint ring of contractile actin and myosin-II encircles the wound. By one minute post wounding this structure gives way to a narrow actomyosin band at the wound border, consistent with a “purse string” healing mechanism observed in other embryonic systems. We hypothesize that contraction of the broad ring is responsible for the initial, rapid phase of wound closure, and that the narrow purse string drives the later slower phase.

To test the proposed wound healing mechanisms, we implemented both types of contractile response in a finite element computational model. Considering both circular and elliptical wounds, we found that the rapid initial phase of wound closure is consistent only with an isotropic contraction of the broad ring surrounding the wound, and that the slower phase can be accounted for by the formation and circumferential contraction of actomyosin-like fibers at the wound margin. Together, these two mechanisms can quantitatively reproduce the observed wound healing dynamics.

The results of this integrated experimental and computational investigation suggest that a new mechanism, the isotropic contraction of cells in a broad ring around the wound, works together with an actomyosin contractile ring to close an embryonic wound.

**Actin filament cross-linking proteins Daam1 and Fascin share an integrated and essential role in filopodia formation.**

*R. Jaiswal<sup>1</sup>, D. Breitsprecher<sup>1</sup>, B. L. Goode<sup>1</sup>; <sup>1</sup>Department of Biology, Brandeis University, Waltham, MA*

Filopodia are slender, finger like projections that dynamically form at the leading edge of motile cells with important roles in cell migration and environment sensing. Each filopodium contains a dense bundle of parallel actin filaments that grow rapidly from their tips. The molecular basis for the formation of these structures is still not well understood, but in part involves the coordinated actin-assembly activities of Ena/VASP proteins, formins, and Arp2/3 complex. In addition, the

rigid architecture of filopodia depends on the filament bundling protein fascin, which localizes all along the filopodium shaft. Here, we report that the formin Daam1 (Disheveled associated activator of morphogenesis 1) plays a critical role in filopodia formation. Unlike other formins, which localize to the tips of filopodia, endogenous Daam1 localized along the entire filopodial shaft in B16F1 cells, similar to fascin. RNAi silencing of Daam1 caused reduced numbers of filopodia and loss of their structural integrity, similar to fascin silencing. Co-silencing of fascin and Daam1 virtually abolished filopodia formation, suggesting that fascin and Daam1 have related roles in establishing and maintaining filopodial structure. Consistent with this view, purified Daam1 strongly bundled actin filaments in vitro, and dual-color TIRF microscopy revealed that fluorescently labeled Daam1 molecules are recruited to the sides of fascin-bundled filaments. Further, fascin-silencing disrupted Daam1 localization to filopodial shafts but not to tips. Taken together, these results demonstrate a closely intertwined and essential role for the actin crosslinking proteins fascin and Daam1 in filopodia formation.

#### **Drosophila septins bundle and curve actin filaments.**

*M. Mavrikis<sup>1</sup>, Y. Azou<sup>1</sup>, F-C. Tsai<sup>2</sup>, J. Alvarado<sup>2</sup>, A. Bertin<sup>3</sup>, G. Koenderink<sup>2</sup>, T. Lecuit<sup>1</sup>; <sup>1</sup>Institut de Biologie du Développement de Marseille Luminy, CNRS, Aix-Marseille University, Marseille, France, <sup>2</sup>FOM Institute AMOLF, Amsterdam, Netherlands, <sup>3</sup>Institut de Biochimie et de Biophysique Moléculaire et Cellulaire, CNRS, Université Paris-Sud, Paris, France*

During cell division, actin filaments and myosin motor proteins form a membrane- anchored contractile ring that constricts the cell midzone to give rise to two daughter cells. A conserved core of about 20 proteins is involved in animal cytokinesis. However, the structural organization and assembly of the actomyosin network remain outstanding questions. Here we focus on septins, one of the conserved core components of cytokinesis. Although septins bind independently membranes, Anillin and nonmuscle Myosin-II in different model systems, the role of septins in the organization of actomyosin is not understood, and their precise biochemical function remains unknown. During *Drosophila* embryo cellularization actomyosin assembles into a cytokinesis-like ring at the tips of invaginating membranes. Pnut/hSep7 depleted embryos fail to accumulate and stabilize actomyosin during cellularization, whereas actomyosin fails to assemble into ring- like structures and instead forms a loose coat beneath the cell membrane, suggesting that septins are involved in compacting or/and curving actomyosin. In vitro reconstituted actin filaments in the presence of purified *Drosophila* septin complexes are bundled and organize in rings and curved bundle clusters. Septins decorate specifically actin filament bundles as opposed to single actin filaments, and appear as stitches along curved actin filament bundles. We provide in vivo and in vitro evidence that *Drosophila* septins constitute a novel actin crosslinker that bundles and curves actin filaments.

#### **Roles of mammalian profilin1 in cell migration.**

*S-I. Kojima<sup>1</sup>; <sup>1</sup>Dept. of Life Sci., Gakushuin Univ., Tokyo, Japan*

Biochemical analyses have revealed that profilin, one of G-actin binding proteins, regulates actin dynamics in several different manners, namely blocking polymerization at the minus ends of actin filaments, inhibiting spontaneous actin nucleation and acceleration of ATP/ADP exchange of G-actin. We applied retrovirus-mediated RNA interference (RNAi) to profilin1 (Pfn1), the major isoform of mammalian profilin, to better understand cellular roles of profilin. RNAi of Pfn1 in mouse neuroblastoma N2A cells caused significant reduction of filopodia number and length at the leading edges. On the other hand, immunofluorescence with several

lamellipodial markers revealed that lamellipodia formation was enhanced by RNAi of Pfn1. Live cell imaging using mCherry-actin indicated that actin filaments polymerized and depolymerized normally in lamellipodia of the Pfn1 knockdown cells. Though Pfn1 knockdown cells could migrate similarly to the control cells, they were frequently rounded up on the substrate, suggesting that cell-substrate adhesion was affected. We also analyzed RNAi of Pfn1 in Rat2 cells and rat embryonic fibroblasts (REFs), which showed polarized cell migration. By RNAi of Pfn1, lamellipodia became bigger and thicker and contained less filopodia compared to the control cells. Normally these fibroblasts formed the long tails containing F-actin bundle at the rear region during cell migration. RNAi of Pfn1 shortened the rear tails in both Rat2 and REF, resulting that their cell shapes became more round and unpolarized. Interestingly, we could not observe obvious defects caused by RNAi of Pfn1 in cytokinesis or stressfiber formation in either of three tested cell lines. Another mammalian profilin isoform, profilin2, was expressed in these cell lines in that the actin machinery other than lamellipodia and filopodia might not be so severely affected by RNAi of Pfn1. In summary, our results indicate Pfn1 is primarily responsible for balance between lamellipodia versus filopodia formation, probably by cooperating with formin proteins. We also hypothesize that filopodia formation is likely important for subsequent cell-substrate adhesion to establish the cell polarity during cell migration.

#### **CP and N-WASP cooperate to organize barbed end orientation at the leading edge.**

X. Hu<sup>1</sup>, J. R. Kuhn<sup>1</sup>; <sup>1</sup>Biological Sciences, Virginia Tech, Blacksburg, VA

Motile cells orient actin filament at the leading edge such that fast-growing barbed ends face the membrane. We used *in vitro* motility assays with N-WASP WWCA coated nanofibers and total internal reflection fluorescence (TIRF) microscopy to determine how WWCA domains, capping protein (CP), and arp2/3 generate this barbed end orientation. In the absence of CP, arp2/3 nucleates barbed ends that grow away from the nanofiber surface and branches remain stably attached to their WWCA tethers. CP addition causes barbed ends to pivot toward the nanofiber. CP-mediated reorientation is accompanied by both the shedding of short branches from the nanofiber and barbed end capture by the nanofiber. On drifting nanofibers, reoriented branches pivoted at their barbed end, showing specific barbed end tethering rather than branch-point attachment. Barbed end retention by nanofibers correlated to capping, and barbed end rapidly detached from the nanofiber upon the resumption of growth. These observations indicate that WWCA and CP bind simultaneously to barbed ends. We used filament pull-down assays and fluorescence anisotropy to confirm cooperative binding of WWCA and CP to barbed ends in the absence of arp2/3. In pull-down assays, GST-WWCA coated beads captured an average of 8-9 barbed ends as counted by TIRF microscopy. CP addition lead to a biphasic response with a peak of 13 filaments captured per bead at 5 nM CP and a reduction to ~4 ends per bead at 200 nM CP – half the number captured by WWCA alone. We used bulk WWCA binding assays to measure WWCA affinity for mechanically sheared filament barbed ends. End concentration was estimated from seeded pyrene-actin polymerization assays and WWCA binding was measured in parallel by fluorescence anisotropy. We found that labeled WWCA bound to barbed ends with an affinity of 14 pM and unlabeled WWCA with an affinity of 75 pM, similar to the known 80 – 100 pM affinity of CP for barbed ends. CP addition increased WWCA binding slightly at low CP concentrations and decreased WWCA binding to 50% at high CP concentrations. Reduction of WWCA binding by half in both assays shows that CP competes with the terminal WWCA binding site at the barbed end but does not preclude WWCA binding to the penultimate actin subunit. Molecular models of CP and WH2 domains bound respectively to the terminal and penultimate actin subunit showed no overlap between the two molecules and that CP

orientation might blocks WWCA dissociation from the penultimate subunit. We propose that simultaneous binding of CP and WWCA to barbed ends is essential to the establishment of filament orientation at the leading edge. Rapid CP association limits growth of arp2/3 nucleated barbed ends away from the leading edge. Subsequent N-WASP binding to capped barbed ends causes arp2/3 at the nearby branch junction to detach from N-WASP, pivoting the branch to point in the direction of productive motility. Cooperative CP/N-WASP binding thus presents a new mechanism that refines our understanding of dendritic nucleation at the leading edge.

### **Correlation of cross-linked actin network formation and elastic moduli of human trabecular meshwork cells.**

J. T. Morgan<sup>1</sup>, K. C. Murphy<sup>1</sup>, J. A. Wood<sup>1</sup>, C. J. Murphy<sup>1,2</sup>, P. Russell<sup>1</sup>; <sup>1</sup>Department of Surgical and Radiological Sciences, University of California, Davis, School of Veterinary Medicine, Davis, CA, <sup>2</sup>Department of Ophthalmology and Vision Science, University of California, Davis, School of Medicine, Davis, CA

**Objective:** Cross-linked actin networks (CLANs) are  $\alpha$ -actinin rich polygonal actin networks observed in human trabecular meshwork (HTM) cells *in vivo* and *in vitro*. They have been observed with increased incidence in glaucomatous tissue and have been associated with glaucomatous phenotypes *in vivo*. We have recently reported glaucomatous HTM exhibit increased elastic moduli (E) and that Latrunculin B (Lat B), a potential glaucoma therapeutic, can induce transiently increased E in HTM cells *in vitro*. We wished to investigate the role CLANs play in the increased E of Lat B treated HTM cells and to determine if this finding was unique to Lat B, or more broadly a consequence cytoskeletal disrupting agents.

**Methods:** We treated HTM cells with either 2  $\mu$ M Lat B or 100  $\mu$ M Y-27632 (a Rho-associated protein kinase inhibitor) and their appropriate vehicle controls for 30 min. After 30 min, the cells were allowed to recover for 0-270 min and their compliance (E) was measured via atomic force microscopy (AFM) or they were fixed and assayed for CLANs.

**Results:** Both Lat B and Y-27632 treatment resulted in complete ablation of actin stress fibers after 30 min. During recovery, we observed the formation of circumferential cross-linked actin structures after Lat B treatment. We verified that these structures were rich in  $\alpha$ -actinin, and identified these as a non-canonical presentation of CLANs. These structures were present in 32.48% $\pm$ 6.29% (mean $\pm$ SEM; n=9) of cells at 90 min and declined to 11.03% $\pm$ 5.18% of cells by 270 min, in close agreement to the previously published timeline of transient increases in E following Lat B treatment. Y-27632 treated cells did not exhibit these structures, nor did they exhibit transient increases in E.

**Conclusions:** These results suggest this non-canonical presentation of CLANs following Lat B treatment may increase the stiffness of HTM cells, and this effect seems specific to Lat B. Given the recent correlation between stiffness and glaucoma, this behavior is an important consideration when testing therapeutics that target the cytoskeleton of HTM cells.

**Monitoring Actin Cortex Thickness In Live Cells.**

A. G. Clark<sup>1</sup>, K. Dierkes<sup>2</sup>, E. Paluch<sup>1</sup>; <sup>1</sup>Max Planck Inst - CBG, Dresden, Germany, <sup>2</sup>Max Planck Inst - PKS, Dresden, Germany

Animal cell shape is determined primarily by the actomyosin cortex, a thin layer of proteins that directly underlies the plasma membrane. The cortex regulates cell shape by controlling the physical properties of the cell, including contractile tension and elasticity, which arise from interactions between actin filaments, myosin motors and other actin binding proteins. The thickness of the cortical network is a key determinant of a cell's physical properties, and modulation of cortex thickness over space and time can drive cell shape changes. Thus, understanding how thickness is controlled is essential to understanding cellular morphogenesis. However, because cortex thickness is on the order of the resolution limit of the light microscope, it is too thin to be measured directly by conventional light microscopy. To address this, we developed an assay to measure cortex thickness based on dual-color sub-resolution localization. We measured cortex thickness by determining the distance between the center of the actin cortex and the plasma membrane, which we labeled with different colored fluorophores. Using a simple theoretical description of cortex geometry, we established a functional definition of cortex thickness that we could use to compare cortices across different experimental conditions. Furthermore, we used this model to account for artificial shifts in the apparent position of the cortex inherent to microscopic imaging. We tested the validity of this model and of our image analysis tools using synthetic images of the actin cortex generated in silico. Applying our technique to living cells, we measured an average cortex thickness of ~130 nm in mitotic HeLa cells and observed an increase in cortex thickness following treatments that prevent F-actin disassembly. We could also follow physiological changes in cortex thickness in real time by monitoring actin cortex regrowth in cellular blebs. Our data demonstrate that our method is sufficiently precise to detect differences in cortex thickness across experimental treatments and during shape changes in living cells. We are currently investigating how changes in cortex thickness contribute to cell deformations during cell division.

**Compliance and Elasticity of Actin Networks from Motile Fish Keratocytes.**

M. A. Tsuchida<sup>1</sup>, J. A. Theriot<sup>2</sup>; <sup>1</sup>Howard Hughes Medical Institute, Stanford University, Stanford, CA, <sup>2</sup>Howard Hughes Medical Institute, Department of Biochemistry, and Department of Microbiology and Immunology, Stanford University, Stanford, CA

Cells undergo actin-based crawling motility by continuously building, reorganizing, and disassembling an actin network. These processes are driven and coordinated by a series of biochemical reactions and mechanical forces. Because the actin cytoskeleton is a large structure permeating the cell, knowledge of the mechanical properties of this network is crucial in understanding how the cell coordinates a large-scale process like crawling motility. Because the cytoskeleton of a live cell is highly specifically (albeit stochastically) organized, it is possible that their mechanical properties differ from reconstituted protein gels or even among different regions of a cell.

We have used detergent-extracted actin-rich cytoskeletons from fish epithelial keratocytes to directly measure the response to forced deformation by a micromanipulator. When stretched by a microneedle, the thin (approximately 200 nm) lamellipodium stretched extensively, up to several-fold its original dimensions. Deformation propagated through the lamellipodial network, indicating that the cytoskeleton can behave as a coherent sheet and can transduce forces over long distances. At moderate strains, the deformation was almost completely reversible, indicating that the network is highly elastic, at least over the measured timescale (0.2 s to 30 s).

These observations suggest that there is strong mechanical coupling within the cytoskeleton over distance scales close to the whole cell, and may serve as a constraint on physical models of crawling motility.

1058

**Protocadherin-24 and mucin-like protocadherin interact to form inter-microvillar adhesion links that are required for normal enterocyte brush border assembly.**

S. W. Crawley<sup>1</sup>, D. A. Shifrin<sup>1</sup>, A. E. Benesh<sup>1</sup>, S. Mao<sup>1</sup>, J. E. Heuser<sup>2</sup>, Q. Y. Zheng<sup>3</sup>, M. J. Tyska<sup>1</sup>; <sup>1</sup>Cell and Developmental Biology, Vanderbilt University Medical Center, Nashville, TN, <sup>2</sup>Department of Cell Biology and Physiology, Washington University School of Medicine, St. Louis, MO, <sup>3</sup>Department of Otolaryngology- Head and Neck Surgery, Case Western Reserve University, Cleveland, OH

Intestinal epithelial cells (IECs) possess a highly ordered, densely packed apical array of actin-based, membrane protrusions known as microvilli. Collectively, these microvilli form the brush border, which is known to play a key role in both nutrient absorption and host defense. Despite being critical for proper gut function, little is known about the molecular mechanisms underlying brush border assembly during IEC differentiation. Using the CACO-2<sub>BBE</sub> cell culture model system, we observed that microvilli cluster together during IEC differentiation, interacting with each other at their distal tips to form 'tepee'-shaped structures. High magnification images of these clusters revealed that microvilli are physically connected to one another by thread-like links. Similarly, electron microscopy of native intestinal tissue revealed an extensive network of inter-microvillar links that exists within a mature brush border. Towards the goal of identifying the constituent(s) of these links, we have identified and characterized the functional role and binding partners of a cadherin superfamily member, protocadherin-24 (PCDH24), which exhibits striking enrichment at the tips of microvilli from IECs. Over-expression of PCDH24 in CACO-2<sub>BBE</sub> cells correlated with tight microvillar clustering, while knockdown impaired brush border assembly and resulted in structures with loosely packed microvilli of variable length. Deletion of the cytoplasmic tail of PCDH24 resulted in degradation of the protein suggesting that cytoplasmic binding partners are required for stability. Pull-down experiments using a tagged PCDH24 cytoplasmic domain demonstrated interactions with the scaffold protein harmonin-a and the molecular motor myosin-7b (Myo7b). Both harmonin-a and Myo7b colocalized with PCDH24 at the tips of microvilli of CACO-2<sub>BBE</sub> cells and native tissue. Furthermore, we found that harmonin-a and Myo7b interact directly and knockdown of PCDH24 resulted in loss of both harmonin-a and Myo7b from the brush borders of CACO-2<sub>BBE</sub> cells. These data indicate that PCDH24, harmonin-a and Myo7b form a tripartite complex at the tips of IEC microvilli. The physiological significance of this complex is highlighted by ultrastructural analysis of harmonin KO mice intestinal tissues, which exhibit severe defects in brush border formation and villus morphology. Analysis of the adhesion capacity of PCDH24 using bead aggregation and protein pull-down assays revealed relatively weak *trans*-homophilic bond formation. Strikingly, these assays demonstrated strong *trans*-heterophilic interaction between PCDH24 and mucin-like protocadherin (MLPCDH), another cadherin that localizes specifically to the tips of IEC microvilli. We propose that PCDH24 is targeted to the tips of IEC microvilli through complex formation with harmonin-a and Myo7b. At the tips, PCDH24 interacts in *trans* with MLPCDH to form inter-microvillar adhesion links that promote the tight packing and uniform length of microvilli during brush border assembly.

**Palladin regulates actin stress fiber assembly via VASP-dependent mechanism**G. Gateva<sup>1</sup>, S. Tojkander<sup>1</sup>, S. Koho<sup>2</sup>, O. Carpen<sup>3</sup>, P. Lappalainen<sup>1</sup>;<sup>1</sup>Institute of Biotechnology, University of Helsinki, Helsinki, Finland, <sup>2</sup>Institute of Biomedicine and Medicity research laboratories, University of Turku, Turku, Finland, <sup>3</sup>Department of Pathology, University of Turku and Turku University Central Hospital, Turku, Finland

Cell motility, adhesion and cytokinesis are key cell features critical for major developmental processes and pathological conditions like metastasis. The ability of cells to move or divide is strictly dependent on a dynamic cytoskeleton characterized by a complex protein composition. A unique protein, actin, is one of the major building blocks of the cytoskeleton. Actin is an extraordinary protein, because it can polymerize into highly dynamic filaments, characterized by rapid assembly and disassembly cycles regulated by physiological stimuli. Actin filaments build up stress fibers which constitute the contractile acto-myosin machinery of non-muscle cells. The assembly of these actin structures is regulated by various actin-binding proteins, but the mechanisms controlling stress fiber stability, organization and contractility are largely unknown. Palladin, like  $\alpha$ -actinin, is an abundant stress fiber-associated actin-binding protein, but its exact function in stress fibers remains elusive.

We demonstrated that palladin regulates stress fiber architecture likely via the recruitment of VASP (vasodilator-stimulated phosphoprotein) to stress fiber structures. FRAP (Fluorescent Recovery After Photobleaching) experiments revealed that palladin and VASP display similar highly dynamic rates of association with stress fibers, distinct of the dynamics of classical crosslinking proteins like  $\alpha$ -actinin. Depletion of palladin by siRNA caused abnormal actin stress fiber network and over-expression of palladin in 2D and 3D cell cultures resulted in formation of very thick and stable actin stress fibers. Interestingly, the thick actin bundles induced by palladin over-expression resembled the phenotype induced by over-expression of proteins involved in actin filament nucleation and elongation like mDia1 and VASP. Furthermore, we showed by site-directed mutagenesis that the interaction between palladin and VASP was crucial for VASP recruitment to stress fibers and stress fiber stabilization, demonstrated by the formation of thick stress fibers. All our data indicate that palladin acts as a scaffolding protein to promote actin filament assembly in stress fibers at least partially through VASP-dependent actin filament polymerization.

1060

**Effect of Palladin on the mechanical force responses of tumor-associated fibroblasts.**M. Azatov<sup>1</sup>, B. J. Grooman<sup>1</sup>, S. Zhang<sup>1</sup>, S. Goicoechea<sup>2</sup>, C. A. Otey<sup>2</sup>, R. F. Hwang<sup>3</sup>, A.Upadhyaya<sup>1</sup>; <sup>1</sup>University of Maryland, College Park, MD, <sup>2</sup>UNC School of Medicine, Chapel Hill, NC, <sup>3</sup>University of Texas M.D. Anderson Cancer Center, Houston, TX

Pancreatic tumor-associated fibroblasts (TAFs) have been shown to promote the progression of pancreatic tumors. Mechanisms by which these cells stimulate invasiveness and metastasis of cancer cells are not well understood. It is known that the actin-crosslinking protein, palladin, is upregulated in TAFs, but the precise role of palladin in these cells is unknown. Several lines of evidence suggest that the misregulation of actin reorganization resulting from enhanced palladin levels may contribute to aberrant cellular behavior. In this study we use human pancreatic TAFs to investigate the role of palladin in regulating the plasticity of the actin cytoskeleton in response to alterations in substrate stiffness and externally applied local forces. To investigate the cellular response to external forces, we used a magnetic trap device to apply point forces on the cell surface. We detected an increase in stress fiber contraction and displacement after the application of force. We have developed software to track points on the stress fibers to

measure local strain rates within the stress fibers. We found an increase in cellular activity, usually three minutes after the initial force application, and that the force pulses applied must be at least two minutes long to exert this effect. Traction force microscopy revealed that TAFs are sensitive to substrate stiffness, exerting stronger forces on stiffer substrates. Cells knocked down (KD) in palladin by shRNA displayed a similar sensitivity to substrate stiffness in terms of exerted traction forces. However, KD cells exerted higher forces on stiff substrates (20 kPa gels) as compared to wild type or GFP-palladin cells. Finally, we found that palladin KD cells are more sensitive to inhibition of myosin II – treatment with Blebbistatin leads to a greater disruption of force compared to WT cells. However, removal of blebbistatin leads to a greater degree of force recovery in KD cells. Biophysical characterization of the interactions between TAFs and the external mechanics of the surroundings is likely to yield important new insights into the mechanisms that underlie the metastasis-promoting activity of these cells.

## Actin-membrane Interactions

1061

### Analysis of synergies between Aip1p and capping protein during clathrin-mediated endocytosis by quantitative microscopy, new alignment methods and mathematical modeling.

*J. Berro<sup>1</sup>, T. Pollard<sup>1</sup>; <sup>1</sup>Molecular, Cellular and Developmental Biology, Yale University, New Haven, CT*

Actin filament dynamics play a major role in reshaping the plasma membrane into vesicles during clathrin-mediated endocytosis. Elongation of actin filament barbed ends in endocytic patches is regulated by at least two classes of capping proteins, heterodimeric Acp1p/Acp2p capping protein and Aip1p. We used quantitative microscopy of live fission yeast cells to count the absolute numbers of protein molecules that assemble to and disassemble from sites of endocytosis. These temporal quantitative data have great potential for improving our understanding of the precise molecular mechanisms of clathrin-mediated endocytosis. However, their collection, analysis and interpretation require advanced theoretical and computational methods to take full advantage of the data.

First, we developed a new, generally applicable method to increase the time resolution of any dataset below the acquisition rate. This new alignment method allowed us to limit many artifacts that appear when averaging datasets such as errors in estimating average values, standard deviations and assembly and disassembly profiles. This method also allowed us to measure more accurately endocytic patch movement and show that actin is not directly involved in propelling the endocytic vesicle but only in its formation. In addition, we built a mathematical model to infer the biochemical mechanisms of clathrin-mediated endocytosis. Reconciliation of simulations of the model with observations showed that dendritic nucleation by the Arp2/3 complex is crucial for a fast assembly and severing filaments from the network by ADF/cofilin is crucial for fast disassembly. This model also predicted quantitative biochemical properties of the actin cytoskeleton in vivo that were later proven experimentally.

Now we have applied our computational and theoretical tools to study synergies between capping protein and Aip1p during endocytosis. The experiments and mathematical models showed that in cells lacking Aip1p capping protein can cap the filaments normally capped by Aip1p. However, Aip1p cannot compensate for the absence of one or both capping protein subunits. In addition, the experiments showed that Acp2p alone has another previously

unknown function, independent from its ability to partner with Acp1p to cap actin filament barbed ends. Indeed Acp2p and Aip1p are individually involved in setting proper polarization of endocytic sites in interphase cells. Strikingly, Acp1p, Acp2 and Aip1p are not involved in the polarization during cytokinesis. Therefore, our data suggest that independent polarization pathways exist during interphase and cytokinesis.

1062

**Severing of actin filaments by cofilin contributes to both assembly and disassembly of endocytic actin patches in fission yeast.**

Q. Chen<sup>1</sup>, T. D. Pollard<sup>1,2</sup>; <sup>1</sup>MCDB, Yale University, new haven, CT, <sup>2</sup>MB&B, Yale University, New Haven, CT

We used a mutant cofilin with defects in severing actin filaments to test the proposal that cofilin severs actin filaments during endocytosis in fission yeast cells. We used quantitative fluorescence microscopy to track GFP-tagged proteins, including early endocytic adaptor proteins, activators of Arp2/3 complex and actin filaments. Consistent with the hypothesis, actin patches disassembled far slower in cells depending on severing-deficient cofilin than wild type cells. Even more interesting, actin patches assembled slowly in these cofilin mutant cells. Adaptor proteins End4p and Pan1p accumulated and persisted at the endocytic sites more than 10 times longer than in wild type cells, followed by slow put persistent recruitment of activators of Arp2/3 complex, including WASP and myosin-I. Given the selective severing defect of these cofilin mutants, the slow assembly of actin patches may be due to a lack of short actin filaments normally produced by severing that diffuse out of actin patches to serve as mother filaments to stimulate Arp2/3 complex in adjacent patches to nucleate actin filaments. An investigation of actin patch proteins that might recruit these mother filaments revealed that actin filament binding sites on both Pan1p and End4p plays a role in initiating actin polymerization in actin patches.

**Native dynamics of dynamin, actin and cortactin during clathrin-mediated endocytosis revealed by real-time imaging in genome-edited cells.**

A. T. Cheng<sup>1</sup>, A. Grassart<sup>1</sup>, F. Zhang<sup>2</sup>, N. Zense<sup>2</sup>, D. Malkov<sup>2</sup>, D. G. Drubin<sup>1</sup>; <sup>1</sup>Molecular and Cell Biology, University of California, Berkeley, Berkeley, CA, <sup>2</sup>Cell-Based Assays/Reporter Cell Lines, Sigma-Aldrich Research Biotech, St. Louis, MO

Clathrin-mediated endocytosis (CME) is the best-studied endocytic pathway. Numerous molecular actors have been identified, and live-cell imaging studies have revealed the sequence and timing of their recruitment during cargo uptake. Recent application of high precision microscopy and quantitative analysis of clathrin-coated structure (CCS) dynamics during endocytosis revealed high heterogeneity. While the origin of this heterogeneity remains unclear, it also complicates faithful analysis of endocytic protein functions. Recently, we have overcome problems caused by protein overexpression by using zinc finger nuclease (ZFN) technology to express RFP- and GFP-tagged fusions of clathrin and dynamin, respectively, preserving their endogenous levels and stoichiometry. Here, we extend our analysis to explore the function and dependency of the actin machinery relative to dynamin during CME.

Our measurements revealed that dynamin dynamics are highly regular during the last step of CME. We observed that dynamin's arrival is strongly dependent on CCS maturation. Moreover, dynamin lifetime, kinetic accumulation and disappearance are highly predictable despite CCS heterogeneity. Together, these data suggest that early steps of endocytosis are the source of heterogeneity in CCS dynamics, and that the terminal step is highly regular. Interestingly, the

actin cytoskeleton has been proposed to play multiple roles at multiple stages of CME. However, direct imaging of the actin machinery during CME is notoriously challenging. Therefore, understanding the dependency on actin and coordination of its assembly with dynamin recruitment are far from complete. Here, we generated genome-edited cell lines expressing fluorescent protein fusions of actin and cortactin and combined these with fusions of clathrin or dynamin. Strikingly, we observed that actin is consistently recruited before dynamin during CME and is essential for normal dynamin recruitment and function.

**Investigating the function of class-I myosin motors during endocytosis in *Saccharomyces cerevisiae*.**

*E. B. Lewellyn<sup>1</sup>, D. G. Drubin<sup>1</sup>; <sup>1</sup>Molecular and Cell Biology, University of California, Berkeley, Berkeley, CA*

Many aspects of the clathrin-mediated endocytosis (CME) pathway are conserved among eukaryotes, but a prominent difference between species and cell types is the requirement for class-I myosin activity. The class-I myosins, Myo 3 and 5 (Myo3/5), are essential for CME in the yeast *S. cerevisiae*, while the requirement for a class-I myosin in other eukaryotes less absolute and varies depending on the cell type. Learning the role of myosins in CME would provide important insights into this process overall and may reveal important differences between species. In this study, we use *S. cerevisiae* as a model for studying myosin-dependent endocytosis. Myo3/5 are known to have at least two discrete functions. The CA domain at the carboxy terminus stimulates Arp2/3-mediated actin filament branching. At the N-terminus is a motor domain with high homology to other myosin motors. It has been previously shown that while the CA domain contributes to endocytosis, it is partially redundant with other activators of the Arp2/3 complex, and endocytosis still occurs when the CA domain is deleted. In contrast, complete deletion of Myo3/5 or introduction of a point mutation that blocks ATP binding and prevents actin filament release (rigor mutation) causes a substantial growth defect and abolishes endocytosis. Here we report that deletion of the entire motor domain was actually less deleterious to growth than the rigor point mutation, although CME was still significantly impaired. Furthermore, motor mutants that were engineered to eliminate actin translocation while preserving actin-dependent ATPase activity had growth and CME phenotypes similar to motor domain deletion. We next determined whether these mutants localized properly by GFP-tagging each myosin variant. We found that complete deletion of the motor domain greatly diminished localization at endocytic sites, suggesting that the motor domain contributes to myosin localization. In contrast, both the rigor mutant and actin translocation mutants were recruited to endocytic sites. Taken together, these findings suggest that the motor domains of Myo3/5 are important for at least two roles. First, the motor domain helps recruit myosin to endocytic patches. Second, translocation of actin by the motor domain appears to be required for CME. Moreover, this study suggests that actin polymerization alone is not sufficient for one or more steps of CME, but that forces generated by the Myo3/5 motor domains are also needed.

**Modulation of Ena/VASP processivity by a membrane tethered actin binding protein.**

*S. D. Hansen<sup>1</sup>, D. Mullins<sup>1</sup>; <sup>1</sup>CMP, Univ California San Francisco, San Francisco, CA*

Actin polymerases of the Ena/VASP protein family promote actin filament barbed end elongation. They are dynamically localized to leading edge membranes where they play an important role in determining the architecture of the underlying actin network. Although Ena/VASP proteins are intrinsically processive actin barbed end polymerases in vitro, this activity is not sufficient for membrane targeting in vivo. Instead, the combined presence of

growing actin filament barbed ends together with a membrane tethering protein are required for persistent membrane association of Ena/VASP proteins in vivo. The molecular mechanisms by which growing barbed ends and membrane tethering proteins synergistically contribute to Ena/VASP protein localization, lifetime, and/or activity at the plasma membrane, however, remain unclear. We present evidence that Lamellipodin, a membrane-associated Ena/VASP tethering protein, can autonomously bind to and organize actin filaments in vitro. In addition, Lamellipodin can enhance Ena/VASP barbed end processivity in vitro by a clustering independent mechanism that requires the interaction with filamentous actin. We propose that the filament binding activity of Lamellipodin acts as part of a “barbed end sensor” that rapidly and efficiently delivers Ena/VASP proteins to growing filament ends. To test this hypothesis, we characterized interactions between Lamellipodin, VASP, and actin filaments in vivo and in vitro, using biomimetic assays of varying degrees of complexity. This work provides insight about how membrane tethered actin barbed end polymerases control the assembly of the actin cytoskeleton during cell migration and morphogenesis.

#### Active membrane organization by dynamic actin filaments.

S. Ghosh<sup>1</sup>, S. Saha<sup>1</sup>, J. Mathew<sup>1</sup>, R. Chandran<sup>1</sup>, S. Mayor<sup>1</sup>; <sup>1</sup>National Centre for Biological Sciences, Bangalore, India

The plasma membrane (PM) of a living cell is more than just a selective barrier from the outside environment. The PM harbours platforms for signaling, maintains ion and nutrient balance and undergoes diverse structural changes associated with activities like endocytosis, secretion, cell polarization, locomotion and cytokinesis. All these activities require regulated segregation of both membrane proteins and lipids, creating structural and functional platforms which are often highly dynamic, and below optical resolution. For example, several lipid anchored proteins such as glycosylphosphatidylinositol-anchored proteins (GPI-APs) and Ras molecules form dynamic nanocluster assemblies which are of functional consequence to the cell. We have previously shown that the spatio-temporal dynamics of nanoclusters of GPI-APs are actively generated<sup>1</sup>. They are sensitive to cortical acto-myosin dynamics. To explain these observations we have recently put forward a theoretical framework<sup>2</sup>, involving the active hydrodynamics of short, dynamic actin filaments coupled to the PM to explain the experimentally observed properties of GPI-APs and other membrane components. Using single molecule imaging and FCS based diffusion measurements we find highly dynamic, and short lived (< 1s) actin filaments near the PM which associate with stable GPI-AP nanocluster enriched domains. To further probe into the molecular basis of the generation of these actin filaments, we undertook specific molecular perturbations of the actin nucleation and polymerization machinery and the cofilin based actin depolymerization machinery. We found that perturbing these two arms of actin turnover significantly affected the GPI-AP nanoclustering and the formation of the dynamic actin filaments. These results therefore strongly support the idea that PM components are locally organized by active processes driven by a regulatable actomyosin dynamics, which potentially can be regulated by the cell in response to specific stimuli and functional needs.

**A Septin-Containing Barrier Differentially Restricts Inheritance of a Yeast Prion and Mitochondria.**A. M. Tartakoff<sup>1</sup>; <sup>1</sup>Case Western Reserve University, Cleveland, OH

Fusion of haploid cells of *S. cerevisiae* generates zygotes. Their initial terminal buds inherit only a single mitochondrial genome and therefore provide an example of asymmetric cell division. We observe that the zygote midzone includes a septin annulus that restricts both mitochondria and supramolecular complexes (polysomes and the [PSI<sup>+</sup>] prion form of Sup35p-GFP). These complexes equilibrate only several minutes after cell fusion and do so slowly. Establishment of contact between parental mitochondria is further delayed until septins relocate to the bud site, thereby causing a single mitochondrial genome to have preferential access to nearby buds. By contrast, in [psi<sup>-</sup>] x [PSI<sup>+</sup>] genetic crosses all buds receive Sup35p-GFP [PSI<sup>+</sup>]. Thus, septin-containing barriers restrict entities that are not limited to the cell cortex; [PSI<sup>+</sup>] inheritance is the norm; and biased inheritance of mitochondria is promoted by a septin-dependent checkpoint. The rate of redistribution of complexes and organelles determines whether their inheritance is symmetric.

**Spatial organization of actin and intermediate filaments on the nuclear envelope.**J. Usukura<sup>1</sup>, S. Minakata<sup>2</sup>; <sup>1</sup>EcoTopia Science Institute, Nagoya University, Nagoya, Japan, <sup>2</sup>Graduate School of Engineering, Nagoya University, Nagoya, Japan

Current study aims to reveal the spatial organization of cytoskeletal actin filaments in the periphery of nuclear envelope. Cytoskeletal actin filaments in living cell have been investigated so far exclusively with fluorescent light microscopy. Therefore, observation was restricted on the stress fiber with relatively strong fluorescence and at ventral side of the cell. In order to detect real spatial structure of cytoskeleton, high voltage TEM (1000 KV), high resolution SEM and immuno-freeze etching technique were applied to unroofed whole cells.

Nuclear envelope was supplied with many cytoskeleton including intermediate filaments, actin filaments and microtubules. In particular, intermediate filaments, vimentin, extending from nuclear pore like a rosette formed complicated meshwork and covered the total surface. Many actin filaments were attached to nuclear envelope as well. Since S1 decoration showed both pointed and barbed ends clearly in the surface of nucleus, there seemed to be the terminations and origins of actin filaments on the nuclear envelope. Unfortunately, however, we were not able to trace entire actin filaments on the nuclear envelope, because all actin filaments were associated or covered with vimentin filaments on the surface of nucleus. Under careful observation of many electron micrographs, many actin filaments appeared to extend from nuclear pores. Indeed, Nesprin 1, actin binding protein, was detected in the periphery of nuclear pores. Actin filaments extending from nuclear envelope were bundled gradually to form stress fibers. These are completely new concept on nuclear related actin filaments.

**Apical targeting of the Formin Diaphanous in *Drosophila* tubular epithelia.**T. Rousso<sup>1</sup>, A. Shewan<sup>2</sup>, K. Mostov<sup>2</sup>, E. D. Schejter<sup>1</sup>, B-Z. Shilo<sup>1</sup>; <sup>1</sup>Molecular genetics, Weizmann Institute of Science, Rehovot, Israel, <sup>2</sup>Department of Anatomy, University of California, San Francisco, CA

Apical secretion in epithelial tubes of the *Drosophila* embryo was shown to be mediated by the Formin family protein Diaphanous (Dia) (Massarwa et al., 2009). Apical F-actin cables that are generated by Dia serve as tracks for MyosinV-based trafficking of vesicles that will be secreted to the tube lumen. Apical localization and activity of Dia is at the core of generating apical F-actin in this system. In this work we aimed to identify and characterize the molecular machinery(s) responsible for apical localization of Dia-based actin polymerization in *Drosophila* tubular epithelia.

We show that the open conformation of Dia, which is relieved from the auto-inhibited state, facilitates efficient apical targeting, probably by exposing the N-terminal domain that is critical for localization. Moreover, binding to Rho1 mediates not only opening of Dia, but also serves as one of the physical anchors of Dia at the apical membrane.

*Drosophila* Dia maintained apical localization in the mammalian tubular model system of MDCK cells, and could be relocalized to the baso-lateral membranes immediately after incorporation of PI(4,5)P2 into these membranes. Consistent with this, using live imaging we show that PI(4,5)P2 as well as the PIP5 kinase, Skittles, that catalyses its production, are enriched in apical membranes of *Drosophila* tubular organs. In addition, Dia apical targeting is sensitive to PI(4,5)P2 levels in these organs. Finally, we show that the basic amino-acid composition of the Dia N-terminal domain is crucial for apical localization, suggesting that it mediates the direct binding to PI(4,5)P2.

Our results demonstrate that the tight apical localization of Dia is achieved by combining apical-biasing cues, each of which provides only very partial targeting. The ability to distinguish between apical targeting by Rho1 and PI(4,5)P2 allows to establish the hierarchy between them. While Rho1 binding alone provides partial targeting, no apical targeting by alternative cues is observed in its absence. Binding to activated Rho1 may thus facilitate the initial interaction of Dia with the apical membrane. Physical proximity to the membrane can now overcome low affinity restrictions, and allow interaction of Dia with PI(4,5)P2 that stabilizes its association with the apical membrane.

**RANKL-induced Myo1b localizes to sites of dynamic actin-membrane remodeling and is required for osteoclast formation and function.**

P. Ng<sup>1</sup>, E. Landao-Bassonga<sup>1</sup>, E. Coudrier<sup>2</sup>, T. S. Cheng<sup>1</sup>, J. Xu<sup>3</sup>, H. J. Knölker<sup>4</sup>, M. H. Zheng<sup>1</sup>, N. J. Pavlos<sup>1</sup>; <sup>1</sup>Centre for Orthopaedic Research, The University of Western Australia, Nedlands, Australia, <sup>2</sup>Morphogenèse et signalisation cellulaires, Institut Curie, Paris, France, <sup>3</sup>School of Pathology and Laboratory Medicine, The University of Western Australia, Nedlands, Australia, <sup>4</sup>Department Chemie, Technische Universität Dresden, Dresden, Germany

Osteoclasts (OCs) are large multinucleated cells whose exquisite function is the resorption of bone. To achieve this, OCs boast a specialized cytoskeleton that is unique amongst all eukaryotic cells. The necessity of a highly dynamic cytoskeleton is borne out of cyclical requirements for motility and the generation of a polarized phenotype. Despite the obvious importance of the 'membrane-cytoskeleton interface' in the establishment of OC polarization, the nature and identity of molecules that directly link the OC plasma membrane with the underlying cytoskeleton remain largely obscure. Utilizing state-of-the-art transcriptional profiling we have systematically screened for novel actin-coupling molecules that are robustly up-regulated in OCs during RANKL-driven differentiation. Among the candidates identified, we uncovered myosin 1b (Myo1b), a member of the Class-I family of small actin-based mechano-sensitive motors, as a prominent RANKL-responsive gene. Up-regulation of Myo1b expression was confirmed both at the mRNA and protein level by quantitative PCR and immunoblotting. Consistent with its involvement in supporting membrane tension and deformation, Myo1b

specifically localized to dynamic sites of actin remodelling and membrane ruffling during OC motility and bone resorption. To begin to exploit the functional contribution of Myo1b (and other class I myosins) in OC formation and function, we employed the natural compound Pentachloropseudilin (PCIP), a specific and allosteric inhibitor of myosin-I ATPase activity. We demonstrate that blockade of myosin-I motor function dose-dependently attenuates OC formation and bone resorptive capacity *in vitro*, an effect that correlates with morphological disturbances in F-actin ring organization and membrane polarization. Collectively, our findings uncover Myo1b as a novel regulator of OC formation and function, most likely serving to bridge the actin-membrane interface at dynamic sites of membrane turnover.

**Actin controls the I-BAR-membrane interaction.**

*K. Futó<sup>1</sup>, E. Bódis<sup>1</sup>, L. M. Machesky<sup>2</sup>, M. Nyitrai<sup>1</sup>, B. Visegrady<sup>1</sup>; <sup>1</sup>Department of Biophysics, Medical School, University of Pécs, Pécs, Hungary, <sup>2</sup>Beatson Institute for Cancer Research Glasgow University College of Medical, Veterinary and Life Sciences, glasgow, UK*

The Inverse BAR (I-BAR) domain is the N-terminal 250 amino acid of the IRSp53 protein that induce negative membrane curvature both *in vitro* and in cells. Generation of membrane curvature by I-BAR proteins often works together with actin dynamics. I-BAR shares its function between actin bundling and membrane binding but it is still obscured what molecular mechanisms are responsible for these functions. The aim of our project is to investigate the detailed membrane binding properties of the I-BAR of IRSp53 and its relations to the actin cytoskeleton. *In vitro* FRET experiments and fluorescence quenching studies were carried out between the I-BAR and liposomes made up from different lipid constructs. We have found that the I-BAR has preference to bind to the negatively charged lipids ( $K_d = 1-2 \mu\text{M}$ ) however it can also bind to the uncharged lipids. The fluorescence quenching studies reflected that the accessibility of the I-BAR surface was higher toward the negatively charged lipids than for the uncharged ones. The I-BAR membrane interaction is controlled by the polymerization state of actin where filamentous actin stabilizes while the globular actin disrupts their interaction. The I-BAR domain influences the actin polymerization, the affect depends on the I-BAR concentration. Our results suggest that the I-BAR-actin interaction may have a crucial role in filopodia formation and regulation.

**Structure of the ZU5-ZU5-UPA-DD tandem of ankyrin-B reveals interaction surfaces necessary for ankyrin function.**

*C. Wang<sup>1</sup>, C. Yu<sup>1</sup>, Z. Wei<sup>1</sup>, M. Zhang<sup>1</sup>; <sup>1</sup>Division of Life Science, Hong Kong University of Science and Technology, Hong Kong, China*

Ankyrin-R/B/G (encoded by ANK1/2/3 respectively) are a family of very large scaffold proteins capable of anchoring numerous receptors and ion-channels to specific, spectrin-containing membrane micro-domains. Hereditary mutations of ankyrins are known to be associated with diseases including spherocytosis, cardiac arrhythmia, and bipolar disorder in humans, although the underlying molecular bases are poorly understood. The middle spectrin-binding domain of ankyrins contains highly conserved ZU5-ZU5-UPA-DD domains arranged into the ZZUD tandem. Curiously, most of the disease-causing mutations in the tandem have no apparent impact on the spectrin binding of ankyrins. The high resolution structure of the ankyrin-B ZZUD tandem determined here reveals that the ZU5-ZU5-UPA domains form a tightly packed structural supramodule, whereas DD is freely accessible. Although the formation of the ZZU supramodule does not influence the spectrin binding of ankyrins, mutations altering the inter-

domain interfaces of ZZU impair the functions of ankyrin-B&G. Our structural analysis further indicates that the ZZU supramodule of ankyrins has two additional surfaces that may bind to targets other than spectrin. Finally, the structure of the ankyrin ZZUD provides mechanistic explanations to many disease-causing mutations identified in ankyrin-B&R.

### **MICAL1 an F-actin-disassembly factor links membrane repair.**

K. Miyake<sup>1</sup>, Y. Egami<sup>1</sup>, C. Matsuda<sup>2</sup>, M. Hamada<sup>1</sup>, Y. K. Hayashi<sup>3</sup>, P. L. McNeil<sup>4</sup>, N. Araki<sup>1</sup>;  
<sup>1</sup>Histology and Cell Biology, Kagawa University, Faculty of Medicine, Kagawa, Japan,  
<sup>2</sup>Biomedical Research Institute, AIST, Tsukuba, Japan, <sup>3</sup>Neuromuscular Research, National Institute of Neuroscience, NCNP, Tokyo, Japan, <sup>4</sup>CBA & IMMAG, Georgia Health Science University, Augusta, GA

Plasma membrane disruption is a common form of cell injury in mammalian tissues under physiological conditions. Cell survival depends on the initiation of a rapid (second time-scale) resealing response that is mounted only in the presence of physiological levels of extracellular Ca<sup>2+</sup>. Vesicle-vesicle and vesicle-plasma membrane fusion events occurring in cortical cytoplasm surrounding the defect are thought to be a crucial element of the resealing mechanism. We have previously shown that a requisite prelude to this fusion is the disassembly in local cell cortex of the physical barrier constituted by filamentous actin. However, the identity of the proteins involved in this disassembly event remained unknown. Recently, the MICAL family of enzymes have been found to associate with the cytoplasmic domain of plexins, which are large cell-surface semaphorin receptors. MICAL thereby functions as an F-actin-disassembly factor mediating actin remodeling in a variety of cell responses. We expressed MICAL1/actin -GFP in culture cells or mice muscle fibers and then subjected them to a plasma membrane disruption created by a laser. Subsequent confocal imaging revealed a striking wave and rapid (second time-scale) accumulation of MICAL1-GFP at the disruption site, followed by actin depolymerization (second time-scale). We also observed, for the first time in living cells responding to a membrane disruption, vesicle fusion events at the disruption site. We hypothesize that localized filamentous actin disassembly mediated by MICAL1 removes a cortical barrier standing in the way of the membrane-membrane contacts leading to the homotypic and exocytotic fusion events required for repair.

## **Cytokinesis II**

1074

### **Regulation of spindle-pole-body duplication and cytokinesis by the centrin-binding protein Sfi1 in fission yeast.**

I-J. Lee<sup>1</sup>, N. Wang<sup>1</sup>, W. Hu<sup>2</sup>, J. Bähler<sup>3</sup>, J. R. Pringle<sup>4</sup>, L-L. Du<sup>2</sup>, J-Q. Wu<sup>1</sup>; <sup>1</sup>The Ohio State University, Columbus, OH, <sup>2</sup>National Institute of Biological Sciences, Beijing, China, <sup>3</sup>University College London, London, United Kingdom, <sup>4</sup>Stanford University, Stanford, CA

Cytokinesis partitions a mother cell into two daughter cells. The fission yeast *Schizosaccharomyces pombe* is a powerful model organism to study cytokinesis because both key regulators and the overall mechanism involving an actomyosin contractile ring are conserved. Nevertheless, many regulators of cytokinesis remain to be identified. By sequencing the genome of a mutant previously denoted as *M46*, we identified a mutation in *sfi1*, a conserved essential gene encoding a centrin-binding protein. Some *sfi1-M46* cells exhibit defects in spindle-pole-body (SPB) duplication and spindle formation, similar to those of *S.*

*cerevisiae sfi1* mutants. However, the majority of fission yeast *sfi1-M46* cells can form bipolar spindles and undergo mitosis. Interestingly, cytokinesis is misregulated in *sfi1-M46*. In wild-type cells, the two daughter cells separate after constriction of the contractile ring and formation of the septum. In *sfi1-M46*, some cells assemble a second contractile ring immediately and form another septum next to the first one. Contractile-ring assembly and septum formation in fission yeast are regulated by the septation-initiation network (SIN). Because both Sfi1 and SIN components localize to the SPBs, we hypothesize that Sfi1 regulates cytokinesis via the SIN pathway. Indeed, *sfi1-M46* has synthetic lethal/sick genetic interactions with many SIN mutations. Using Cdc7-EGFP as a marker, we find that the inactivation of SIN is delayed by *sfi1-M46*, and prolonged SIN activity results in the multi-septated phenotype in *sfi1-M46*. Our results indicate that in addition to its role in SPB duplication, the centrin-binding protein Sfi1 also regulates cytokinesis. This study opens up a new direction in investigating the functions of centrin and centrin-binding proteins in yeast and higher eukaryotes.

1075

#### **Polar expansion during cytokinesis.**

H. F. Gudejko<sup>1</sup>, L. M. Alford<sup>1</sup>, D. Burgess<sup>1</sup>; <sup>1</sup>Boston College, Chestnut Hill, MA

Vesicle trafficking and new membrane addition at the cleavage furrow have been extensively studied. Less clear, however, is the old idea that expansion at the cell poles occurs during cytokinesis. Previous studies using the adherence of kaolin or charcoal particles to the surface of a dividing a cell to track membrane dynamics showed that the poles expands during the later stages of mitosis, and this expansion was attributed to a “stretching” of the plasma membrane. We have monitored movement of lipid rafts, which migrate during cytokinesis into the furrow membrane, in dividing echinoderm eggs. While the rafts are found to be immobile by FRAP analysis throughout the cell cycle, we document bulk flow of the membrane rafts away from the poles into the furrow. We have re-examined this phenomenon and find that new membrane is added to the cell poles, likely via exocytosis, during anaphase causing the original raft rich plasma membrane to be “pushed” from the poles to the furrow coincident with the constriction of the contractile ring. This membrane addition is dependent on actin and astral microtubules and occurs significantly earlier during mitosis than membrane addition at the furrow. The membrane that is added at the polar regions is compositionally distinct from the original cell membrane in that it is devoid of GM<sub>1</sub>, a component of lipid rafts. These results suggest that polar expansion, via new membrane addition, may provide a force for moving the plasma membrane to the furrow during cytokinesis.

1076

#### **Self-organization of taxol-stabilized microtubules by spindle and midzone mechanisms.**

T. J. Mitchison<sup>1,2</sup>, P. A. Nguyen<sup>1,2</sup>, M. Coughlin<sup>2</sup>, A. Groen<sup>1,2</sup>; <sup>1</sup>Whitman Fellow, Marine Biological Laboratory, Woods Hole, MA, <sup>2</sup>Systems Biology, Harvard Medical School, Boston, MA

Adding Taxol to mitotic cytosol forces microtubule nucleation and stabilization, allowing analysis of organization mechanisms that act on stabilized microtubules. The Karsenti group used this approach to discover that dynein clusters microtubules, and aligns minus ends, to form taxol asters, and inferred similar mechanisms for spindle pole assembly (Verde et al 1991 J Cell Biol. 112: 1177-87). The Compton group used taxol asters to discover new proteins involved in spindle pole organization (Mack and Compton 2001 Proc Natl Acad Sci U S A. 98:14434-9.). We revisited this approach using mitotic cytosol from *Xenopus* eggs supplemented with glycogen to preserve physiological metabolic activity (Groen et al 2011 Mol Biol Cell. 22:3139-51). We observed self-organization of highly organized assemblies consisting of parallel bundles of microtubules arranged in circles and paired lines, that we called pineapples.

Microtubule minus ends, marked by NUMA, were always on the outside. Plus ends, marked by Aurora B, were on the inside. Both minus and plus ends were globally aligned. Based on localization of cell division proteins and response to perturbation, we believe pineapples assemble using a combination of metaphase spindle and cytokinesis midzone mechanisms. We are focusing on how plus ends cluster and align. These processes depended on the midzone kinase Aurora B, which is part of the Chromosome Passenger Complex (CPC), and the midzone kinesin Kif4, which blocks plus end polymerization in midzones, and probably other factors. We are currently trying to distinguish between three models for plus end alignment based on (i) motor-driven sliding of plus ends, (ii) maximization of bundling energy, and (iii) sideways interactions between capping complexes. We are also using pineapples to explore how the microtubule-bound proteome in mitotic cytosol responds to perturbation, and correlate this with altered morphology.

1077

**The minus-end directed kinesin KifC1 interacts with nucleoporin Nup153 and is required for targeting the spindle assembly checkpoint proteins Mad1 and Mad2 to kinetochores.**

G. Chatel<sup>1</sup>, N. Nilles<sup>1</sup>, I. Mossaid<sup>1</sup>, B. Fahrenkrog<sup>1</sup>; <sup>1</sup>IBMM, Université Libre de Bruxelles, Charleroi, Belgium

Cytokinesis is the final event in the cell cycle, when the segregated genome, the organelles and the plasma membrane are partitioned into two physically distinct daughter cells. It requires an intricate interplay between cytoskeletal, chromosomal, and cell cycle regulatory pathways, but also a broad range of other cellular processes, for example protein and membrane trafficking, and signalling pathways. We have previously shown that over-expression as well as knock down of the nuclear pore protein Nup153 lead to abnormal mitoses including cytokinesis failure. In search for putative Nup153 target proteins important for cytokinesis we have now identified the minus-end directed kinesin KifC1 as Nup153 binding partner. Both proteins interact directly *in vitro* and *in vivo* and co-purify in a complex isolated from human cells. The depletion of KifC1 from HeLa cells by siRNAs leads to abnormal spindles, but interestingly also to failed recruitment of the spindle checkpoint proteins Mad1 and Mad2 to kinetochores in prometaphase cells. Together our data suggest that the interplay between Nup153 and KifC1 is important for spindle organization, spindle checkpoint activity and in turn successful cytokinesis.

1078

**Analysis of late cytokinetic defects in cells lacking an organized central spindle.**

J. Hancock<sup>1</sup>, S. Shrestha<sup>1</sup>, M. Karki<sup>1</sup>, C. B. Shuster<sup>1</sup>; <sup>1</sup>Department of Biology, New Mexico State University, Las Cruces, NM

Upon anaphase onset, cells assemble an antiparallel array of microtubules termed the central spindle that is essential for the completion of cytokinesis. Two heterodimeric complexes act as the principle organizers: Centralspindlin (comprised of MgcRACGAP and MKLP1) and PRC1/KIF4A. Disruption of either complex results in disorganization of the central spindle and cleavage failure. However, these cells are still capable of initiating and ingressing a cleavage furrow. In a better effort to understand the mechanics of cleavage failure in cells with disrupted central spindles, we examined the structure and function of cleavage furrows in cells depleted of PRC1, KIF4A or MKLP1. Measurement of furrow ingression revealed that cells depleted of PRC1 or KIF4A ingressed at the same rate as controls, whereas MKLP1-depleted cells furrowed with slightly slower velocities. Depletion of PRC1 resulted in an elongated cytoplasmic bridge that failed to form a proper Flemming body, resulting in cleavage failure within two hours. Additionally, PRC1 was required for the normal midzone localization of key cytokinetic factors,

which instead were spread throughout the intercellular bridge. MKLP1 depletion displayed similar effects, whereas midzone components were largely localized correctly in KIF4A-depleted intercellular bridges. And while these extended intercellular bridges contained microtubules, brief treatments with high concentrations of nocodazole (to reveal stable microtubules) revealed that both MKLP1 and PRC1 were required to maintain microtubule stability during late cytokinesis. Taken together, these findings suggest that PRC1 and MKLP1 play a prominent role in maintaining the native midbody architecture and normal recruitment of cytokinetic factors at the midbody.

1079

**Interphase fission maintains genomic integrity after failure of cytokinesis in human cells.**

A. Choudhary<sup>1</sup>, R. Lera<sup>1</sup>, M. Martowicz<sup>1</sup>, J. Laffin<sup>2</sup>, B. Weaver<sup>3</sup>, M. E. Burkard<sup>1</sup>; <sup>1</sup>Medicine, University of Wisconsin, Madison, WI, <sup>2</sup>Wisconsin State Laboratory of Hygiene, University of Wisconsin, Madison, WI, <sup>3</sup>Cell and Regenerative Medicine, University of Wisconsin, Madison, WI

The century-old Boveri hypothesis predicts that failure of cytokinesis leads to aberrant cell divisions, aneuploidy, and cancer. We used modern single-cell techniques to investigate the fate of human epithelial cells after failed cytokinesis. To do this, we established a uniform population of binucleate interphase RPE1 cells that had previously segregated chromosomes (karyokinesis) but failed to divide into daughters (failed cytokinesis). After minimizing effects of DNA damage, we found a third of binucleate cells generate viable progeny. Strikingly, the majority of the progeny are euploid, with a karyotype that matches the parental line, and only a small fraction are near tetraploid. We performed confirmatory experiments that unambiguously demonstrate that euploid colonies are derived from single binucleate cells. To elucidate the mechanism of this process, we performed timelapse videomicroscopy. This revealed that binucleate cells can execute cytoplasmic fission to segregate nuclei without intervening mitosis. This fission echoes a primitive adhesion-dependent process reported in lower organisms such as *Dictyostelia*. Using fluorescent Cdt1, we demonstrate that the fission occurs during the G1 phase. The fission event does not require canonical components required for cytokinesis, demonstrating a distinct mechanism. Similar results were found in other human epithelial cell types including MCF10a breast epithelial cells and HCT116 colorectal cancer cells. Interphase fission can explain previous reports that polyploid multinucleate hepatocytes can resolve to euploid hepatocytes. We conclude that human cells have a failsafe mechanism to maintain euploidy in the face of cytokinesis failure, making subsequent aneuploidy less frequent than envisioned by Boveri.

**Proteomic Identification Reveals That FLJ25439 Overexpression-Induced Cellular Tetraploidization Is Associated with Changes in Stress-Related Protein Profiles.**

Y-T. Chan<sup>1</sup>, P. Ouyang<sup>1,2</sup>; <sup>1</sup>Anatomy, Chang Gung University, Taoyuan, Taiwan, <sup>2</sup>Gene-Engineering Mouse Core lab, Chang Gung University, Taoyuan, Taiwan

Cell cycle progression must be precisely regulated by checkpoint. It has been reported that malfunction of checkpoint mechanism would lead to aneuploidy through formation of tetraploid or polyploid cells, hallmarks of tumorigenesis. In cancer cells, the tetraploid cells may contribute to abnormal mitotic progression, which may be associated with cytokinesis failure. Tetraploidy would lead to genomic instability due to centrosome and chromosome over-replication. Until now, the mechanism of how the cells maintain the tetraploid status is unknown. Here, we identify a novel protein FLJ25439 localized to the centrosome in interphase cells and

at the midbody during cytokinesis. To investigate the function of FLJ25439, we established stable cell lines overexpressing FLJ25439. FLJ25439-overexpressers grew slower than its normal counterpart and showed dysregulated expression of p53, pRb and p21, suggesting a defect in cell cycle progression. In addition, cells with FLJ25439 overexpression displayed a tetraploid DNA content as compared to its diploid parental cells. To explore the molecular mechanism responsible for FLJ25439 over-expression, we analyzed the global protein expression profile between wild type and over-expressers using proteomics and bioinformatics approaches. Protein category profiling indicated FLJ25439 would be involved in pathways which reflect in stress, protein folding, cell cycle, and cytoskeleton regulation. Specifically, genotoxic-stress related chaperone proteins and tubulin-regulated proteins are greatly contributed to the FLJ25439 overexpression phenotypes. The results of this study pave a fundamental avenue for our further understanding of the role of this novel cytokinesis-related protein in protecting cells from environmental stress and tetraploid formation.

### **Role of Mitosis-Specific Translation in *S. cerevisiae* Cytokinesis.**

M. Onishi<sup>1</sup>, D. M. Klass<sup>2</sup>, P. O. Brown<sup>2</sup>, J. R. Pringle<sup>1</sup>; <sup>1</sup>Genetics, Stanford, Stanford, CA, <sup>2</sup>Biochemistry, Stanford, Stanford, CA

It has long been known that chromosome condensation during mitosis is associated with a global repression of transcription. Indeed, by using the Pol-II mutant *rpb1-1*, we verified in *S. cerevisiae* that mRNA transcription during this phase is not required for mitosis or cytokinesis. This has left the unanswered questions of how, where, and when the proteins required during this interval of cell cycle are synthesized. It has been widely assumed that such proteins are all synthesized before the shutdown of transcription. To test this hypothesis, we arrested cells in metaphase (with nocodazole) or late anaphase (with *cdc15*) and treated them after release with the translation-elongation inhibitor cycloheximide (CHX). In the CHX-treated cells, many of known cytokinesis proteins were present at normal or near-normal levels; however, depending on when the drug was added, the cells failed to execute mitotic exit, cytokinesis, and/or abscission despite an apparently normal progression of mitosis, suggesting that synthesis of one or more proteins involved in these events is regulated by translation. Similar effects were observed with a mutation in a core subunit of eIF3 (*prt1-1*), but not with a mutation of the cap-binding protein eIF4E (*cdc33-E17*), suggesting that the translation during mitosis may be initiated by a cap-independent mechanism. Current evidence suggests that the Polo kinase Cdc5 may be a target of the putative translation regulation that is responsible for many, but not all, of the above phenotypes: in CHX-treated cells, Cdc5 was rapidly degraded despite the apparent loss of APC activation, and it disappeared from the division site; Cdc5-dependent release of Cdc14 from the nucleolus was also blocked. Interestingly, a premature release of Cdc14 induced by *pds1f $\phi$*  bypassed the mitotic-exit and cytokinesis defects but not the abscission defect, suggesting the presence of an additional gene(s) involved in this step. Our attempt to identify such genes by polysome profiling suggests that yeast may regulate translation of genes encoding ER and Golgi proteins in anaphase to meet the increased demand for membrane trafficking during division.

1082

**Mitochondria in Cytokinesis.**

*E. J. Lawrence*<sup>1</sup>, *C. A. Mandato*<sup>1</sup>; <sup>1</sup>*Anatomy & Cell Biology, McGill University, Montreal, QC, Canada*

Cytokinesis is the final stage of cell division in which one parent cell is physically separated into two distinct daughter cells. In order to execute cytokinesis, the cell assembles a contractile ring at the equatorial cortex, which then constricts and eventually leads to division. One can imagine that such constriction and fission of the cell equator is an active event requiring energy and metabolites. Since mitochondria are organelles that function in energy production, calcium homeostasis, ROS production and lipid metabolism, we asked whether mitochondria play an active role in cytokinesis. To address this question, we performed live imaging of mammalian cell lines to observe the distribution of mitochondria during cell division. We show that mitochondria localize to the cleavage furrow after anaphase onset and remain enriched at the cell equator until the end of cytokinesis. Using small molecule inhibitors of cytoskeleton dynamics we show that the equatorial localization of mitochondria is dependent on microtubules but not actin. Furthermore, depletion of Miro1, an outer mitochondrial membrane protein that links mitochondria to microtubules, leads to mitochondrial mislocalization during division. This project will establish novel roles for mitochondria in cytokinesis and provide critical insights into the molecular basis of cytokinesis. Such work is crucial for the development of improved cancer therapies.

1083

**Phosphorylation of MyoGEF at Thr-544 by aurora B creates a docking site for Plk1.**

*Q. Wei*<sup>1,2</sup>, *D. Wu*<sup>3</sup>, *M. Asiedu*<sup>4</sup>, *F. Matsumura*<sup>5</sup>; <sup>1</sup>*Department of Biological Sciences, Fordham University, Bronx, NY*, <sup>2</sup>*Department of Biochemistry, Kansas State University, Manhattan, NY*, <sup>3</sup>*Department of Biochemistry, Kansas State University, Manhattan, KS*, <sup>4</sup>*Department of Surgery, Mayo Clinic, Rochester, MN*, <sup>5</sup>*Department of Molecular Biology and Biochemistry, Rutgers University, Piscataway, NJ*

We previously reported that Plk1 activates MyoGEF by phosphorylating MyoGEF at Thr-574, the phosphorylation of which promotes the localization of MyoGEF at the central spindle. It is known that binding of Plk1 to its substrates requires a docking site (S-\*S-P or S-\*T-P) that is phosphorylated by priming kinases, such as CDK1/cyclin B. Analysis of the MyoGEF sequence revealed that there are two potential Plk1 docking sites in MyoGEF, i.e., Thr-544 (S-\*T-P) and Ser-697 (S-\*S-P). Although in vitro kinase assays showed that Cdk1/cyclin B phosphorylated MyoGEF, point mutations of Thr-544 or Ser-697 to Ala did not substantially change Cdk1 phosphorylation of MyoGEF, suggesting that Cdk1 did not phosphorylate Thr-544 and Ser-697. Interestingly, in vitro kinase assays showed that aurora B could phosphorylate a MyoGEF fragment that contains Thr-544 and Ser-697. Mutation of Thr-544 (but not Ser-697) to Ala completely abrogated the phosphorylation of the MyoGEF fragment by aurora B. In addition, co-immunoprecipitation experiments showed that the T544A point mutation decreased the interaction between MyoGEF and Plk1. Our results suggest that phosphorylation of MyoGEF by aurora B can create a Plk1 docking site in MyoGEF.

1084

### Mutations in *Cog7* affect Golgi structure, meiotic cytokinesis and sperm development during *Drosophila* spermatogenesis.

G. Belloni<sup>1</sup>, S. Sechi<sup>1</sup>, M. Riparbelli<sup>2</sup>, M. T. Fuller<sup>3</sup>, G. Callain<sup>2</sup>, M. G. Giansanti<sup>1</sup>; <sup>1</sup>Istituto di Biologia e Patologia Molecolari, Dipartimento di Biologia e Biotechnologie Università di Roma Sapienza, CNR, Roma, Italy, <sup>2</sup>Dipartimento di Biologia Evolutiva, Università di Siena, Siena, Italy, <sup>3</sup>Departments of Developmental Biology and Genetics, Stanford University School of Medicine, Stanford, CA

The Conserved Oligomeric Golgi (COG) Complex plays essential roles for Golgi function, vesicle trafficking and glycosylation. Deletions of human *COG7* are associated with a rare multisystemic congenital disorder of glycosylation causing mortality within the first year of life. We have characterized the *Drosophila* ortholog of *COG7* (*Cog7*). Loss-of-function *Cog7* mutants are viable but male sterile. *Cog7* is enriched in both the Golgi stacks and the Golgi derived structures throughout spermatogenesis. Mutations in *Cog7* disrupt Golgi architecture and reduce the number of Golgi stacks in primary spermatocytes. During spermiogenesis, loss of *Cog7* impairs the assembly of the Golgi-derived acroblast in spermatids and affects axoneme architecture. Similarly to the *Cog5* homologue Four way stop (*Fws*), *Cog7* enables furrow ingression during cytokinesis. We show that the recruitment of both the small GTPase *Rab11* and the phosphatidylinositol transfer protein *Giotto* (*Gio*) to the cleavage site requires the wild type function of *Cog7*. In addition *Gio* coimmunoprecipitates with both *Cog7* and *Rab11* in testes. Together our results implicate *Cog7* as an upstream component in a *gio-Rab11* pathway controlling membrane addition during cytokinesis.

1085

### Chemical genetics to Polo-like kinase inhibition in *Trypanosoma brucei*

A. Lozano<sup>1</sup>, K. Ikeda<sup>2</sup>, G. Warren<sup>3</sup>, C. de Graffenried<sup>1</sup>;

<sup>1</sup>Max F. Perutz Laboratories, University of Vienna, Vienna, Austria, <sup>2</sup>Max F. Perutz Laboratories, Medical University of Vienna, Vienna, Austria, <sup>3</sup>Max F. Perutz Laboratories, University of Vienna and Medical University of Vienna, Vienna, Austria

The protist parasite *Trypanosoma brucei* (*T. brucei*) is a unicellular flagellated organism that causes African trypanosomiasis in humans and livestock. *T. brucei* multiplies by binary fission and this is a highly coordinated process in time and space. Polo-like kinases (PLKs) are known to regulate different cell cycle stages in eukaryotes. We became interested in understanding how the single PLK homolog in *T. brucei* (*TbPLK*) participates in the replication of the bilobe, a cytoskeletal structure of yet unclear function, and the closely associated Flagellar Attachment Zone (FAZ), which keeps the flagellum adhered to the cell body. With the help of chemical genetics tools, we designed a mutant *TbPLK* kinase that can be selectively and quickly inhibited using a small-molecule inhibitor, whereas all other kinases are not affected. Acute *TbPLK* inhibition resulted in rapid cell growth arrest and led to replication defects in both bilobe and FAZ. During the cell cycle, *TbPLK* localizes to both structures but, upon inactivation, the kinase was not able to migrate to the FAZ anymore. We then wondered whether *TbPLK* inhibition affects FAZ assembly directly or as a consequence of bilobe replication impairment. By introducing a synchronization method based on centrifugal elutriation, we found out that *TbPLK* regulates both bilobe and FAZ replication and is necessary for FAZ length extension.

1086

### Leukemia-associated RhoGEF (LARG) is a Novel RhoGEF in Mitosis and Required for the Proper Completion of Abscission.

M. K. Martz<sup>1</sup>, E. Grabocka<sup>1</sup>, N. Beeharry<sup>2</sup>, T. Yen<sup>2</sup>, P. Wedegaertner<sup>1</sup>; <sup>1</sup>Biochemistry, Thomas Jefferson University, Philadelphia, PA, <sup>2</sup>Fox Chase Cancer Center, Philadelphia, PA

Proper completion of mitosis requires the concerted effort of multiple RhoGEFs. Here we show that leukemia-associated RhoGEF (LARG), a RhoA specific RGS-RhoGEF, is required for abscission, the final stage of cytokinesis wherein the intercellular membrane is cleaved between daughter cells. LARG co-localizes with  $\alpha$ -tubulin at the spindle poles before localizing to the central spindle. During cytokinesis, LARG is condensed in the midbody where it colocalizes with RhoA. HeLa cells depleted of LARG display apoptosis during cytokinesis with unresolved intercellular bridges, and rescue experiments show that expression of siRNA-resistant LARG prevented this apoptosis. Moreover, live cell imaging of LARG-depleted cells revealed greatly delayed fission kinetics in abscission wherein a population of cells with persistent bridges undergo abscission-related apoptosis. The formation of a Flemming body and secondary ingression sites in cells depleted of LARG is consistent with a defect in late abscission, just prior to fission. In contrast to studies of other RhoGEFs, particularly Ect2 and GEF-H1, LARG depletion does not result in cytokinetic furrow regression nor does it affect internal mitotic timing. These results show that LARG is a novel and temporally distinct RhoGEF required for the completion of abscission.

1087

### How do fission yeast cells sense their size?

K. Z. Pan<sup>1</sup>, T. Saunders<sup>2</sup>, M. Howard<sup>3</sup>, F. Chang<sup>1</sup>; <sup>1</sup>Microbiology and Immunology, Columbia University, New York, NY, <sup>2</sup>EMBL, Heidelberg, Germany, <sup>3</sup>John Innes Centre, Norwich, UK

To maintain a certain cell size, cells often grow to a certain size before committing to cell division. A key question in this process is how do cells sense their own size? In the rod-shaped fission yeast *S. pombe*, wildtype cells grow to 14 microns long before entering mitosis. Genetic analysis has identified a pathway involved in cell size control, in which the pom1p kinase inhibits the cdr2p kinase, which inhibits wee1p. A current model for cell length sensing is that a protein gradient of pom1 emanating from cell tips regulates a "sensor" of cdr2p located in dots at the medial cortex. Here, to test this model, we pursue a quantitative analysis of pom1p and cdr2p using fluorescence intensity measurements of fluorescent protein fusions in vivo. Our data suggest that contrary to the previous model, the gradient of pom1p is not used to sense cell length. Pom1 levels do not decrease at the medial cortex as cells grow longer. Further, a pom1 mutant with an altered gradient distribution does not result in abnormal cell length. Instead, cdr2p itself may act as a sizer. Cdr2p accumulates in dots at the medial cortex overlying the nucleus; its local concentration increases with cell length, even though its total concentration does not change. The dosage of cdr2p determines the length of cells at division. Pom1p may be required primarily to restrict cdr2p to the medial cortex. Thus, we propose a new model in which the cell size is regulated by the local concentration of cdr2p near the nucleus. As cells grow to 14 microns long, a critical concentration of cdr2p at the medial cortex may contribute to triggering entry into mitosis. This system illustrates how the localization of sizer to a discrete structure (such as the medial cortex) allows the cell to sense its size.

1088

**A novel role for Blt1p in regulation of the Septation Initiation Network.***J. W. Goss<sup>1</sup>, T. Pollard<sup>1</sup>; <sup>1</sup>MCDB, Yale University, New Haven, CT*

Cytokinesis is the final step in the cell cycle during which a dividing cell separates into individual daughter cells. While many of the proteins involved in this process have been identified, the manner in which they interact with one another and coordinate their functions is largely unknown. One such protein identified in *S. pombe* is Blt1p, which functions prior to the onset of cytokinesis to ensure recruitment of the regulatory GEF, Gef2p, to the division plane and ensure proper placement of the contractile ring. This was believed to be its only function, however, I have recently found that Blt1p also interacts with proteins involved in the septation initiation network (SIN) that are required for completion of cytokinesis and septation in fission yeast. Specifically, Blt1p directly binds to the NDR-family kinase activator Mob1 and regulates its localization to the division plane prior to the onset of septation and completion of cytokinesis. This dual role early in mitosis and late in cytokinesis suggests that Blt1p could be an important regulator throughout cell division.

1089

**Regulation of Rho GEF Gef2 by the adaptor protein Ger1 in fission yeast cytokinesis.***Y. Zhu<sup>1</sup>, J-Q. Wu<sup>1</sup>; <sup>1</sup>Molecular Genetics, The Ohio State University, Columbus, OH*

Cytokinesis is the last step of the cell-division cycle for successful cell reproduction, which requires precise control and regulation to ensure genomic stability. Rho GTPases and Rho guanine nucleotide exchange factors (Rho GEFs) are among the key regulators of cytokinesis. In higher eukaryotes, activated Rho GEFs and GTPases facilitate division-site positioning and promote contractile-ring formation during early cytokinesis. However, such roles had not been identified in fission yeast. Our lab recently found that putative Rho GEF Gef2 helps define the division site by coordinating with Polo kinase Plo1 to recruit anillin-like protein Mid1 to the medial cortex. Here we show that a novel Gef2-related protein Ger1 shares high similarity with the COOH-terminus of Gef2. Ger1 colocalizes with Gef2 in the contractile ring and its precursor nodes at stoichiometric ratio of 1:1. Like *gef2* deletion, *ger1* deletion has genetic interactions with various cytokinesis mutants such as *plo1* and *mid1*, suggesting a role of Ger1 in early cytokinesis. However, sequence analysis finds that Ger1 has no GEF domain. Thus, Ger1 may regulate cytokinesis through Gef2 as an adaptor protein. We found that the two proteins are interdependent on their COOH-termini for the localization to cortical nodes. Furthermore, Ger1 and Gef2 interact through their COOH-termini in yeast two hybrid and Co-IP assays. We propose that the Ger1-Gef2 interaction is crucial for Gef2 localization and function during early cytokinesis in fission yeast. These and other results will highlight the existence and importance of Rho GEF adaptor proteins in regulating Rho GEF functions.

1090

**Analysis of Cellulose Synthase Trafficking and New Cell Wall Biosynthesis During Plant Cytokinesis.***C. T. Anderson<sup>1</sup>, C. Somerville<sup>2</sup>; <sup>1</sup>Biology, The Pennsylvania State University, University Park, PA, <sup>2</sup>Energy Biosciences Institute, University of California Berkeley, Berkeley, CA*

Unlike animal cells, plant cells accomplish cytokinesis by building a double-sided wall to separate new sister cells. Plant cytokinesis involves an orchestrated series of vesicle trafficking, membrane remodeling, and wall polymer biosynthetic events, all of which can occur in less than 60 minutes in the model plant *Arabidopsis thaliana*. However, many molecular details of how

new wall synthesis is carried out and regulated remain unknown. By monitoring the subcellular localization of cellulose synthase (CESA) and microtubules in vivo using spinning disk confocal microscopy, we determined the location and trafficking patterns of CESA over time in dividing cells at high temporal resolution. We discovered that CESA is depleted from the cortical plasma membrane during mitosis and cytokinesis and becomes highly enriched at the cell plate, an intermediate structure that gives rise to the new cell wall. These results suggest that CESA secretion is largely diverted from the cortical plasma membrane to the division plane during cytokinesis. Using drug treatments to inhibit specific trafficking pathways and cell plate maturation steps during cytokinesis, we found that CESA is delivered to the cell plate well before the earliest stage at which cellulose is detectable in this compartment, suggesting that in contrast to the case at the cortical plasma membrane, CESA becomes active long after its initial delivery to the cell plate. We also determined that CESA is mainly delivered to the cell plate via a de novo secretory pathway, that normal CESA distribution in the cell plate requires an intact actin cytoskeleton and Brefeldin A-sensitive trafficking events, and that inhibitors of CESA activity do not prevent the delivery of CESA to the cell division plane. In combination with rapidly accumulating knowledge of membrane trafficking events during plant cytokinesis, these results elucidate how cellulose-producing proteins are trafficked and regulated to help build new plant cell walls, which can serve as renewable sources of food, materials, and bioenergy.

1091

**Translocation of the Chromosomal Passenger Complex to the central spindle in anaphase requires deacetylation of INCENP.**

*A. van der Horst<sup>1</sup>, M. S. van der Waal<sup>1</sup>, M. J. Vromans<sup>1</sup>, S. M. Lens<sup>1</sup>; <sup>1</sup>Medical Oncology, University Medical Center Utrecht, Utrecht, Netherlands*

The Chromosomal Passenger Complex (CPC) is required for error-free chromosome segregation and for proper execution of cytokinesis. To coordinate nuclear division with cytoplasmic division, the CPC has to translocate from centromeres to the overlapping anti-parallel microtubules of the central spindle in anaphase. How this translocation is regulated is not fully understood. We found that it requires the microtubule-binding capacity of the coiled-coil (CC) domain of INCENP. An INCENP mutant lacking the coiled-coil domain localized to the cell cortex but failed to translocate to the midzone microtubules in anaphase. Cortical localization of INCENP- $\Delta$ CC promoted cleavage furrow ingression in anaphase, but gave rise to midbodies with reduced amounts of Aurora B in telophase. Importantly, central spindle localization and midbody accumulation of Aurora B was restored when the INCENP coiled-coil domain was replaced by an alternative microtubule-binding domain. Interestingly, in recent proteomics screens, INCENP was found being acetylated and the identified acetylated lysine residues appeared to reside in the coiled-coil domain of INCENP. We reasoned that the microtubule binding capacity of the INCENP coiled-coil is suppressed in (pro)metaphase by acetylation that neutralizes the positive charge of the lysine residues. Indeed, mutation of the lysine residues into glutamine to mimic constitutive acetylation, perturbed INCENP translocation to the central spindle. We therefore propose that translocation of the CPC to the central spindle in anaphase not only requires dephosphorylation, as shown before, but also deacetylation of INCENP.

1092

**Microvilli are disassembled to provide membrane for cleavage furrow ingression.**

*L. R. Figard<sup>1</sup>, H. Xu<sup>1</sup>, I. Golding<sup>1</sup>, A. M. Sokac<sup>1</sup>; <sup>1</sup>Baylor College of Medicine, Houston, TX*

Cell shape change often requires cell surface growth, but the source of new membrane fueling this growth is in many cases unknown. A decades-old hypothesis proposes that unfolding

microvilli can provide new membrane for cell surface growth during cytokinesis, phagocytosis, wound healing, and cell spreading, although this has never been definitively demonstrated. Here we show that microvilli serve as a membrane source for cleavage furrow growth during cellularization, the first complete cytokinetic event in the *Drosophila* embryo. We have characterized the density and morphology of microvilli that coat the embryo surface at the start of cellularization by scanning electron microscopy (SEM), and we calculate that microvilli contain enough membrane to support all furrow growth. Accordingly, we see many microvilli before cellularization, but almost none after. Using 3D imaging of live cells over time, we find that microvillar membrane is depleted slowly at the start of cellularization and is depleted rapidly later in the process. Remarkably, the rate of microvillar membrane depletion follows the biphasic kinetics of furrow ingression. Finally, quantitative analysis correlating our SEM and live-cell imaging data shows that microvillar membrane depletion and microvilli density decrease linearly as furrow length increases throughout cellularization. To then directly show that microvillar membrane contributes to furrow growth, we labeled and tracked microvillar membrane as it moved along the cell surface and into ingressing furrows. This work shows that microvilli are disassembled to provide membrane for furrow ingression and suggests that the rate of microvillar disassembly may govern furrow ingression kinetics.

1093

**Global lipid profiling of dividing cells reveals the significance of sphingolipids during cytokinesis and at the midbody.**

*G. E. Atilla-Gokcumen<sup>1,2</sup>, E. Muro<sup>3</sup>, S. Sasse<sup>2,4</sup>, A. Bedigian<sup>1,2</sup>, U. Eggert<sup>1,3</sup>; <sup>1</sup>Dana-Farber Cancer Inst, Boston, MA, <sup>2</sup>Harvard Med. School, Boston, MA, <sup>3</sup>King's College London, London, United Kingdom, <sup>4</sup>Westfälische Wilhelms-University Münster, Munster, Germany*

Although cells undergo dramatic shape changes during cytokinesis, the role of the plasma membrane and lipids is poorly understood. It is known that a few lipids localize to the cleavage furrow, and that the specific distribution of these lipids is necessary for cleavage. However, the full spectrum of lipids that may be involved in cytokinesis, and their functions are still unclear. Therefore, to identify further lipids that are involved in cytokinesis, we employed LC-MS based global lipid profiling. Specifically, we synchronized HeLa cells at cytokinesis and S-phase. We compared the lipid profiles of cells at S-phase and cytokinesis and identified lipids that change during cytokinesis. To gain insights into the role of lipids during late stages of cytokinesis, we also analyzed the lipid content at the midbody region, which is where cleavage occurs. We isolated midbodies and compared the lipid content of this region to that of cell lysate and cells at cytokinesis. This analysis revealed primarily accumulation of different dihydroceramides, and ceramides during cytokinesis as well as in the midbody region. In a parallel study to address the functional roles of lipids in cytokinesis, we assembled a small library of small molecules that inhibit different steps of lipid biosynthesis and evaluated their effects on cytokinesis. We found that inactivation of glucosyl ceramide synthase (GCS), either with the small molecule PPMP or by RNAi, causes failure of cleavage furrow ingression. We identified individual lipids that are enhanced or depleted due to GCS inhibition. We found that PPMP treatment primarily causes accumulation of C16- and C22-ceramide whereas siGCS treatment causes depletion of glucosyl ceramide species. We show that GCS inhibition results in the mislocalization of actin and the ERM proteins, key cytoskeletal proteins that connect the plasma membrane to the actin cortex. We propose that an imbalance between ceramides and glucosylated ceramides can trigger cortical changes, possibly mediated by interactions between ceramides and ERM proteins, which can in turn cause changes in the actin cytoskeleton. Our data provide evidence linking ceramides and other ceramide-related lipids to cytokinesis, and add a new class of lipids to the growing list of membrane components that play a role in cell division.

1094

**G-protein-coupled receptors participate in cytokinesis.**

X. Zhang<sup>1,2,3</sup>, W. wang<sup>3</sup>, A. V. Bedigian<sup>1</sup>, U. Eggert<sup>1,2,4</sup>; <sup>1</sup>Dana-Farber Cancer Institute, Boston, MA, <sup>2</sup>Harvard Medical School, Boston, MA, <sup>3</sup>High Magnetic Field Lab, Chinese Academy of Sciences, HeFei, China, <sup>4</sup>King's College, London, United Kingdom

Cytokinesis, the last step during cell division, is a highly coordinated process that involves the relay of signals from both the outside and inside of the cell. We have a basic understanding of how cells regulate internal events, but how cells respond to extracellular cues is less explored. In a systematic RNAi screen of G-protein-coupled receptors (GPCRs) and their effectors, we found that some GPCRs are involved in cytokinesis. RNAi knockdown of these GPCRs caused increased binucleated cell formation, and live cell imaging showed that most formed midbodies but failed at the abscission stage. OR2A4 localized to cytokinetic structures in cells and its knockdown caused cytokinesis failure at an earlier stage, likely due to effects on the actin cytoskeleton. Identifying the downstream components that transmit GPCR signals during cytokinesis will be the next step and we show that GIPC1, an adaptor protein for GPCRs, may play a part. RNAi knockdown of GIPC1 significantly increased binucleated cell formation. We also found that RNAi of Dopamine receptor D3 (DRD3) inhibits endocytic sorting as well as cytokinesis. The antihypertensive drug Prazosin stabilizes a normally transient interaction between DRD3 and the coatamer COPI, a complex involved in membrane transport, and shifts endosomal morphology entirely to tubules, disrupting cargo sorting. Understanding the molecular details of GPCRs and their interaction proteins in cytokinesis regulation will give us important clues about GPCRs signaling as well as how cells communicate with their environment during division.

1095

**The epigenetic basis of centromere identity and maintenance.**

D. Fachinetti<sup>1</sup>, D. Folco<sup>1</sup>, Y. Nechemia-Arbely<sup>1</sup>, L. Valente<sup>2</sup>, K. Nguyen<sup>1</sup>, Q. Zou<sup>3</sup>, I. M. Verma<sup>3</sup>, A. Desai<sup>1</sup>, L. E. Jansen<sup>2</sup>, D. W. Cleveland<sup>1</sup>; <sup>1</sup>UCSD-LICR, La Jolla, CA, <sup>2</sup>Gulbenkian Institute, Oeiras, Portugal, <sup>3</sup>The Salk Institute for Biological Studies, La Jolla, CA

The basic element for chromosome inheritance, the centromere, is specified in mammals by an undefined epigenetic mark rather than by DNA sequence. Using targeted replacement in human cells and fission yeast, centromere position is shown to be maintained indefinitely by chromatin assembled with CENP-A, the histone variant that replaces histone H3 at functional centromeres. Chromatin containing the CENP-A or histone H3 carrying the CENP-A targeting domain (CATD) is shown to template its cell cycle-dependent replication through action of the chaperone/chromatin loader HJURP/Scm3. Nucleation of kinetochore assembly onto CENP-A chromatin is shown to require either direct recruitment of CENP-C by CENP-A's short carboxy-terminal tail or stabilizing binding other components, including CENP-B, by CENP-A's amino-terminal-most tail. Thus, a conserved, two-step mechanism for is identified for both human and fission yeast in which CENP-A-containing chromatin is the epigenetic mark of centromere identity by templating its own replication and nucleating subsequent kinetochore assembly.

1096

**Analysis of the function of the chromosomal passenger complex in regulating spindle and central spindle formation in *Drosophila*.**

P. D. Jones<sup>1</sup>, S. Li<sup>2</sup>, J. A. Noble<sup>2</sup>, J. Wakefield<sup>1</sup>; <sup>1</sup>Biosciences, University of Exeter, Exeter, United Kingdom, <sup>2</sup>Department of Engineering Science, University of Oxford, Oxford, United Kingdom

The Chromosomal Passenger Complex (CPC), consisting of the Aurora B kinase and three regulatory subunits Borealin, Survivin/Deterin and INCENP, is a highly conserved complex which is required for regulating many distinct aspects of cell division, such as mitotic chromosome structure, spindle assembly and disassembly, kinetochore-microtubule attachment, central spindle formation and cytokinesis. We are investigating the functions of the CPC during cell division in *Drosophila*, primarily its role in central spindle formation and cytokinesis.

Quantitative analyses of the spatio-temporal properties of GFP-fusions to each of the four *Drosophila* CPC homologues confirms their similar cell cycle regulated distribution in embryonic mitoses, highlighting the presence of a population of the CPC on the mitotic spindle between prometaphase and metaphase, and the dramatic redistribution of the CPC from centromeres to interpolar microtubules at the onset of anaphase.

In order to dissect the specific role of the CPC on the spindle, we have utilised a microinjection approach. Previous work in humans has identified a region of INCENP required for targeting the CPC to the spindle. Injection of a polypeptide corresponding to this region of DmINCENP into syncytial embryos expressing AuroraB-GFP confirms a delay in the accumulation of the CPC on the spindle around the site of injection and a gradation of effects further from the injected area. Injection of the polypeptide into embryos expressing  $\alpha$ -Tubulin-GFP line also demonstrates a reduction in the amount of microtubule nucleation within the spindle. This is consistent with the known role of the CPC in promoting spindle formation and demonstrates that injection of this domain provides a tool for further investigating how the CPC contributes to this process.

We are also using the GFP-CPC embryos to understand the molecular details by which the CPC redistributes to interpolar MTs at anaphase onset. We have developed a method, based on incubation of GFP-CPC embryos with inhibitors of cell cycle progression, to isolate embryos in a metaphase- or anaphase-like state, subjecting these extracts to co-immunoprecipitation and mass spectrometry. Through this, we have identified putative novel interactors of the CPC. We are currently analysing the function of these proteins and their localisation during mitosis.

**Functional states of bivalent kinetochores during prometaphase congression.**

J. R. LaFountain<sup>1</sup>, J. Brady<sup>1</sup>, C. Cohan<sup>1</sup>, R. Oldenbourg<sup>2</sup>; <sup>1</sup>University at Buffalo, Buffalo, NY, <sup>2</sup>Marine Biological Laboratory, Woods Hole, MA

To achieve metaphase alignment, bivalent chromosomes in meiotic crane-fly spermatocytes typically move slowly at maximal velocities of  $\sim 0.5\mu\text{m}/\text{min}$  from off-equator positions to the spindle equator during the course of prometaphase. In such congression, the leading kinetochores of one homologue move toward (P) a distant pole, and the trailing kinetochores of the other homologue move away (AP) from a near pole. Crane-fly bivalents do not exhibit directional instability (oscillating back and forth between P and AP movement), characteristic of chromosomes during congression in vertebrate mitosis. Hence, our objective was to determine

the applicability of the mechanism of congression in well-studied vertebrate mitosis to non-oscillating bivalents. Specifically, we wanted to ascertain whether leading kinetochores engage in P motility and trailing AP partners are in a neutral state, as observed in vertebrate mitosis by Khodjakov and Rieder (1996. *J Cell Biol.* 135:315-327). We used a laser microbeam to cut one of the three prometaphase bivalents of spermatocytes into two “univalents”, each having the two sister kinetochores of their homologue plus attached chromatin that varied in size, depending on the location within the bivalent where the cut was made. Live cell imaging following the cut and frame-by-frame analysis of digital movies revealed new findings about released kinetochores. Both sets of bivalent kinetochores (one pair of sisters to one pole, and the other pair to the opposite pole) exhibit rapid P movement immediately after the operation. There was no detectable difference in the motile capabilities of leading kinetochores and trailing kinetochore subsequent to the operation. Moreover, rapid-than-normal post-op P velocities are suggestive that univalent kinetochores had converted from a functional state in which microtubule polymerization takes place at kinetochore microtubule plus ends to a depolymerization state consistent with pac-man motility. Maximal P movement of normally congressing bivalent kinetochores is slower [ $\sim 0.5\mu\text{m}/\text{min}$  to the pole] than the average flux rate [ $\sim 0.8\mu\text{m}/\text{min}$ ], whereas P movement of released univalent kinetochores is faster [ $\sim 2.0\mu\text{m}/\text{min}$ ] than the flux rate. Thus, in crane-fly spermatocytes, where chromosome movement is dominated by traction fiber mechanics, the release of bi-oriented kinetochores from their normal bipolar tension during prometaphase caused conversion to a pac-man state. For related work, see LaFountain, et al, 2012. *MBoC* 23(16):3133-3142.

**A quest for proteins that bind the flared ends of microtubules.**

*P. Grissom*<sup>1</sup>, *N. Renganathan*<sup>1</sup>, *I. Weidenfeld*<sup>1</sup>, *W. Old*<sup>2</sup>, *N. Ahr*<sup>2</sup>, *J. R. McIntosh*<sup>1</sup>; <sup>1</sup>M.C.D. Biology, University of Colorado, Boulder, CO, <sup>2</sup>Chemistry and Biochemistry, University of Colorado, Boulder, CO

Electron tomography suggests that fibrils form direct connections between centromeric chromatin and the flaring plus ends of kinetochore-associated MTs. We have therefore sought proteins that bind better to curled oligomers of tubulin than to normal MTs. Using Vinblastine to polymerize tubulin into “curls” and Taxol to stabilize normal MTs, we have examined the proteins that can be pulled down from lysates of human cell with these two forms of assembled tubulin. Electrophoresis shows that both sets of proteins are complex, but liquid chromatography and mass spectrometry have allowed the identification and approximate quantification of large numbers of proteins from each kind of pull-down. Extracts of either U2OS or RPE1 cells were prepared from both log-phase cultures and from populations enriched for mitotic cells by Nocodazole arrest and mitotic shake-off. Extracts, proteins pulled down by tubulin polymers, and proteins released from the pull-downs by high salt were subjected to extensive tryptic digestion, chromatographic separation on an Acquity UPLC system, and then analysis with an Orbitrap mass spectrometer. MS/MS data were searched against a human protein database using MASCOTT, and the abundance of each protein identified was estimated by spectral counting. Among the thousands of proteins pulled down, we have focused on components of the cytoskeleton. Several actin-binding proteins clearly prefer tubulin curls to MTs, as do a few kinesins and MT-associated proteins. Centromere Binding Protein F (CENPF) is prominent in the latter group, and given its known properties as an important kinetochore protein that contains long stretches of alpha-helical coiled coil, we have focused our principal attention here. c-DNAs that encode parts of the CENPF molecule have been expressed in bacteria or SF9 cells. Polypeptides from the N-terminal region of the protein bind better to curls than to MTs, while the C-terminal region of the protein prefers MTs. We are working to characterize these

binding reactions and to learn the impact of protein fragment expression on the growth of human cells in culture.

**Formin mDia3 regulates kinetochore movements in mitosis.**

C. Liu<sup>1,2</sup>, C. Kim<sup>2</sup>, Y. Mao<sup>2</sup>; <sup>1</sup>Integrated Program in Cellular, Molecular & Biomedical Studies, Columbia University, New York, NY, <sup>2</sup>Department of Pathology and Cell Biology, Columbia University College of Physicians & Surgeons, New York, NY

The mammalian diaphanous-related (mDia) formin proteins are well known for their actin-nucleation and filament-elongation activities in mediating actin dynamics. They also directly bind to microtubules and regulate microtubule stabilization at the leading edge of migrating cells. By using mammalian cultured cells, we have profiled spatiotemporal dynamics of the formin mDia3 in mitosis and have found that mDia3's kinetochore association is important for metaphase chromosome alignment, a process in which kinetochores form stable attachments with growing and shrinking microtubules. In addition, with high resolution live imaging and quantitative analysis of kinetochore movements, we have observed apparently altered kinetochore oscillations in cells expressing a phosphomimetic mDia3 mutant that has reduced ability to bind to microtubules, suggesting that the formin mDia3 could contribute to the regulation of kinetochore-bound microtubule dynamics, via its own microtubule-binding activity, and/or in coordination with its interaction partners at microtubule plus ends.

**Dissecting the kinetochore throughout *Toxoplasma gondii* mitosis and cell cycle.**

M. C. Farrell<sup>1</sup>, I. Cheeseman<sup>2</sup>, M.-J. Gubbels<sup>1</sup>; <sup>1</sup>Biology, Boston College, Chestnut Hill, MA, <sup>2</sup>Whitehead Institute for Biomedical Research, Cambridge, MA

The obligate intracellular parasite *Toxoplasma gondii* exhibits closed mitosis, as chromosome segregation occurs within an intact nuclear envelope. In addition, the nucleolus is maintained and condensation of chromosomes is restricted, as such distinct structural changes are absent during mitosis. Moreover, the kinetochores are clustered and the chromosomes remain anchored to the spindle poles through their centromeres throughout the cell cycle. This persistent clustering and anchoring is likely functioning in maintaining a full set of chromosomes throughout division. This phenomenon appears to be critical for bona fide chromosome segregation, yet the mechanism by which this is organized remains unknown. Thus, in an effort to define kinetochore-mediated clustering and anchoring of chromosomes, we are focusing on two microtubule-binding proteins, TgNuf2 and its binding partner TgNdc80, subunits of the Ndc80 complex. A conserved kinetochore component from yeast to humans, the Ndc80 complex is an essential component of the kinetochore, required for the establishment of stable microtubule attachments, chromosome segregation, and kinetochore assembly. We are currently investigating the role of these proteins during *T. gondii* cell division, specifically focusing on chromosome anchoring and segregation. The generation of a conditional TgNuf2 knockout revealed this kinetochore component is essential for proper chromosome segregation, as demonstrated by the loss of the nucleus at a high incidence. Moreover, the conditional knockout revealed the spindle pole remains intact. Loss of TgNuf2 revealed microtubules are required for the anchoring of chromosomes during mitosis, but are dispensable for kinetochore clustering. Additionally, we are in the process of mapping the *T. gondii* kinetochore proteome through affinity purification, using strains expressing TgNdc80 and TgNuf2 fusions, to fully characterize the composition of the kinetochore. TgNuf2 and TgNdc80 were isolated in reciprocal immunoprecipitations, demonstrating their interaction, while we are validating

potential additional kinetochore proteins. These findings will contribute to a greater understanding of chromosome anchoring and segregation.

**A Nuclear-Derived Proteinaceous Matrix Embeds the Microtubule Spindle Apparatus during Mitosis.**

C. Yao<sup>1</sup>, U. Rath<sup>2</sup>, H. Maiato<sup>3</sup>, D. Sharp<sup>2</sup>, J. Girton<sup>1</sup>, K. M. Johansen<sup>1</sup>, J. Johansen<sup>1</sup>; <sup>1</sup>Roy J Carver Department of Biochemistry, Biophysics & Molecular Biology, Iowa State University, Ames, IA, <sup>2</sup>Department of Physiology & Biophysics, Albert Einstein College of Medicine, Bronx, NY, <sup>3</sup>Institute for Molecular & Cell Biology, University of Porto, Porto, Portugal

The concept of a spindle matrix has long been proposed; however, whether such a structure exists and its molecular and structural composition has remained controversial. In *Drosophila* we have recently identified two nuclear proteins, Chromator and Megator, from two different nuclear compartments that interact with each other and that redistribute during prophase to form a molecular complex that persists in the absence of polymerized tubulin. Chromator is localized to polytene chromosome interbands during interphase whereas Megator occupies the nuclear rim and the intranuclear space surrounding the chromosomes. Chromator has no known orthologs in other species; however, Megator is the homolog of mammalian Tpr. The Megator/Tpr family of proteins is highly conserved through evolution and structural homologs are present from yeast to humans. Moreover, Megator and human Tpr have been demonstrated to have a shared function as spatial regulators of spindle assembly checkpoint proteins during metaphase. In this study using a live imaging approach in *Drosophila* syncytial embryos we demonstrate that these nuclear proteins reorganize during mitosis to form a highly dynamic, viscous spindle matrix that embeds the microtubule spindle apparatus, stretching from pole-to-pole. We show that this "internal" matrix is a distinct structure from the microtubule spindle and from a Lamin B containing spindle envelope, and by injection of 2000 kDa dextrans, that the disassembling nuclear envelope does not present a diffusion barrier. Furthermore, when microtubules are depolymerized with colchicine just prior to metaphase the spindle matrix contracts and coalesces around the chromosomes suggesting that microtubules act as "struts" stretching the spindle matrix. Additionally, we demonstrate that the spindle matrix protein Megator requires its coiled-coil amino-terminal domain for spindle matrix localization suggesting that specific interactions between spindle matrix molecules are necessary for them to form a complex confined to the spindle region. The demonstration of an embedding spindle matrix lays the groundwork for a more complete understanding of microtubule dynamics and of the visco-elastic properties of the spindle during cell division. Supported by NSF grant MCB0817107.

**Regulation of a microtubule depolymerizing kinesin by importin  $\alpha$  contributes to spindle size scaling during *Xenopus* development.**

J. D. Wilbur<sup>1</sup>, R. Heald<sup>1</sup>; <sup>1</sup>University of California Berkeley, Berkeley, CA

Early development of many animals is characterized by rapid cell divisions in the absence of growth, generating progressively smaller cells during embryogenesis. The mitotic spindle must adapt to the changing cell dimensions in order to properly segregate chromosomes to daughter cells, but how spindle size and architecture are modified is not understood. To identify physiological mechanisms that operate during development of the frog *Xenopus laevis*, we prepared cytoplasmic extracts from embryos at different developmental stages that are capable of reconstituting mitotic spindle assembly in vitro. Large spindles ~40  $\mu\text{m}$  in length formed in extract derived from stage 3 (4 cell) embryos, while stage 8 (~4000 cell) extract spindles were ~20  $\mu\text{m}$ , recapitulating the scaling of spindle size observed in vivo. Mixing of the two extracts

generated spindles of intermediate size, further indicating the existence of a biochemical scaling mechanism that is not the direct result of physically confining the spindle. We found that microtubules in stage 8 extract undergo catastrophe more frequently than those in stage 3 extract, and stage 8 spindles specifically recruit the microtubule depolymerizing kinesin-13 kif2a, suggesting that a decrease in microtubule stability contributes to spindle scaling during development. Interestingly, kif2a contains a nuclear localization sequence and interacts with the transport receptor importin  $\alpha$ , which inhibits its microtubule depolymerizing activity in vitro. In vivo, postranslational modifications lead to a redistribution of importin  $\alpha$  to a membrane fraction of stage 8 embryos. This suggests that the increasing ratio of plasma membrane to cytoplasm during development may act as a sink to sequester importin  $\alpha$  and concomitantly increase kif2a activity, thereby reducing spindle size. In support of this model, manipulating kif2a or importin  $\alpha$  levels in developing embryos could decrease spindle size in stage 3 blastomeres or increase spindle size in stage 8 blastomeres. Small spindles became randomly oriented in large cells, highlighting the importance of spindle scaling for polarized cell divisions during development.

**Spindle assembly requires suppression of microtubule plus-end dynamics by the unprocessive kinesin-8 Kif18B.**

Y. Du<sup>1</sup>, Y. Shin<sup>2</sup>, M. Wagenbach<sup>3</sup>, M. Lang<sup>2</sup>, L. Wordeman<sup>3</sup>, R. Ohi<sup>1</sup>; <sup>1</sup>Department of Cell and Developmental Biology, Vanderbilt University School of Medicine, Nashville, TN, <sup>2</sup>Department of Chemical and Biomolecular Engineering, Vanderbilt University, Nashville, TN, <sup>3</sup>Department of Physiology and Biophysics, University of Washington, Seattle, WA

During mitosis, a bipolar spindle is assembled from dynamic microtubules to segregate a replicated set of chromosomes among two daughter cells. Spindle bipolarity is established by motor proteins that act on both interpolar and astral microtubules to push and pull spindle poles apart, respectively. Whether compressive forces generated by the interaction of astral microtubules with the cell cortex inhibit spindle formation is largely unexplored. Here, we show that the kinesin-8 Kif18B is required for efficient bipolar spindle assembly, characterize its motile properties and ability to regulate microtubule plus-end dynamics. Kif18B is a human kinesin-8 that concentrates at astral microtubule plus-ends by hitchhiking with the +TIP EB1. Using a single molecule TIRF assay, we find that Kif18B is unlike canonical kinesin-8s in that it is highly unprocessive, shows periods of fast diffusive movement, and interacts only weakly with the microtubule lattice. Despite these properties, Kif18B shows striking enrichment at the extreme plus-end of some astral microtubules where the motor locates in front of EB1 comets. By analyzing the effect of Kif18B on the behavior of dynamic microtubules, we show that Kif18B, like the related motor Kif18A, suppresses microtubule plus-end dynamics in a manner potentiated by EB1. In cells, Kif18B depletion causes abnormal elongation of astral microtubules and an increase in the number of cells with monopolar spindles. This phenotype is exacerbated by pharmacological inhibition of kinesin-5/Eg5, a motor that pushes spindle poles apart. Collectively, these data suggest that Kif18B facilitates spindle formation by suppressing the growth of astral microtubules which in turn allows for efficient spindle pole separation by plus-end-directed motors that slide interpolar microtubules apart.

**Temporally distinct roles for TACC3/ch-TOG/clathrin microtubule crosslinkers during mitosis.***L. Cheeseman<sup>1</sup>, I. Prior<sup>1</sup>, S. Royle<sup>1</sup>; <sup>1</sup>Cellular and Molecular Physiology, University of Liverpool, Liverpool, United Kingdom*

Equal segregation of chromosomes between daughter cells during mitosis is essential to avoid aneuploidy, a hallmark of cancer. A TACC3/ch-TOG/clathrin complex was recently found to crosslink and stabilize kinetochore fiber (K-fiber) microtubules (MTs), thereby contributing to efficient mitosis. TACC3 and ch-TOG were described previously to promote MT nucleation and polymerization in early mitosis, but it is unclear whether this function is clathrin-independent.

Here, we distinguish between roles of the complex at early versus late mitosis by using 'knock-sideways' (KS), a rapamycin-based removal technique to rapidly reroute specific proteins to the mitochondria.

KS of TACC3 resulted in complete removal of the protein from the metaphase spindle within 10 minutes of rapamycin application. Its mitotic partners ch-TOG, clathrin and GTSE1 were also removed and localized to the mitochondria, whereas the unrelated spindle proteins NuMA, HURP and Eg5 were unaltered. Similarly, rerouting of clathrin light chain fully removed TACC3 and associated proteins, indicating that there is no clathrin-independent TACC3 on the metaphase spindle.

KS of TACC3 at early mitosis caused severe delays in chromosome alignment, with most cells failing to achieve metaphase within 3 hours of rapamycin application. Spindle regrowth following nocodazole treatment indicated that this delay was likely due to reduced MT polymerization.

Intriguingly, KS of TACC3 at metaphase (after a normal prometaphase) delayed anaphase, indicating that the TACC3/ch-TOG/clathrin complex has an ongoing function in K-fibers after fiber maturation and chromosome alignment. In these cells, we found that the spindle checkpoint was reactivated. Furthermore, inter-kinetochore distance was reduced by ~40%, suggesting a partial loss of K-fiber tension. Correlative light-electron microscopy of metaphase K-fibers 10 and 30 minutes post-rapamycin application revealed a loss of MT crosslinkers. Interestingly, K-fiber MT numbers and spacing remained unaltered. These results suggest that tension may contribute to silencing the spindle checkpoint independently of kinetochore attachment.

Our results show that the TACC3/ch-TOG/clathrin complex contributes to spindle function in several ways: firstly, by promoting MT nucleation and polymerization at early mitosis to mature K-fibers, secondly by maintaining K-fiber tension, thereby silencing the spindle checkpoint. We also demonstrate the advantages of rapid methods for removal of spindle proteins over slower methods, such as RNAi.

1105

**Modeling the dynamics and structure of the mitotic spindle.***J. Bruges<sup>1</sup>, D. Needleman<sup>1</sup>; <sup>1</sup>Harvard University, Cambridge, MA*

The mitotic spindle is an array of microtubules that segregate chromosomes during cell division. It has been difficult to validate models of spindle assembly due to a lack of quantitative measurements in these structures. To understand the spindle architecture and dynamics, we experimentally test different models for spindle assembly, by quantitatively comparing measured and predicted spatio-temporal correlation functions of microtubule density, orientations, and internal stresses. These measurements are precise enough to formulate a complete theory for the dynamics and structure of the spindle. Our theory quantitatively predicts the overall shape of the spindle, the orientation and polarity of microtubules. Our results show that the spatial

regulated microtubule nucleation and a local interaction of microtubules are sufficient to account for spindle morphogenesis.

1106

**Evolution and Genetic Architecture of the First Mitotic Spindle in *C. elegans*.**

*D. J. Needleman<sup>1</sup>, R. Farhadifar<sup>1</sup>, G. Fabig<sup>1</sup>; <sup>1</sup>Harvard University, Cambridge, MA*

The architecture and dynamics of sub-cellular structures show remarkable variations between species, but little is known about the evolutionary or mechanistic basis of this diversity. Examining intraspecies variation can provide valuable evolutionary insights because differences between species arise from differences between individuals within species, but the extent of intraspecific variation of sub-cellular traits is unknown. Mutations are the ultimate source of variation between individuals. Understanding how spontaneous mutations effect sub-cellular processes shows what phenotypes are evolutionary accessible and provides a “baseline” of how these traits would change in the absence of selection.

We are using the first embryonic division in *C. elegans* to study the evolution of the mitotic spindle. We developed a high-throughput microscopy platform and automated image analysis software that allows us to obtain quantitative information on the structure and dynamics of the spindle from thousands of embryos in hundreds of lines. We have found extensive standing genetic variation among natural isolates of *C. elegans* for all traits we have measured including: cell size; the size and motion of pronuclei; the length, motion, and speed of elongation of the spindle; the size of centrosomes; the positioning of the cleavage plane. We are studying the genetic architecture of these traits by performing a genome wide association analysis (aided by Erik Anderson, Princeton), by characterizing a panel of recombinant inbred advanced intercross lines (aided by Matt Rockman, New York University), and by investigating these same traits in a previously performed genome wide RNAi screen (Sonnichsen, et al, Nature 2005).

We are also studying how spontaneous mutations modify the spindle by characterizing cell division in a panel of mutation accumulation (MA) lines - created by propagating an initially genetically identical set of lines at low effective population size for ~250 generations (aided by Charlie Baer, University of Florida). Comparing the spectrum of variations in MA lines to the spectrum of variations we observe among natural isolates allows us to draw inferences about how selection and population dynamics combine with raw mutational inputs to shape the spindle in *C. elegans*.

Our preliminary results are very promising and suggest that combining cell biology, biophysics, and quantitative genetics will produce novel evolutionary and mechanistic insights.

1107

**Towards a MAP interactome: Using a predictive logistic regression model to identify novel *Drosophila* mitotic MAPs.**

*F. Khan<sup>1,2</sup>, C. Deane<sup>2</sup>, J. Wakefield<sup>1</sup>; <sup>1</sup>Biosciences, University of Exeter, Exeter, United Kingdom, <sup>2</sup>Statistics, University of Oxford, Oxford, United Kingdom*

The nucleation, length and dynamics of microtubules (MTs) that constitute the mitotic spindle are determined by MT associated proteins (MAPs). Our lab recently undertook a multi-disciplinary study, combining proteomics, functional screening and bioinformatics, to find proteins capable of binding to and altering the properties of MTs during mitosis in the early *Drosophila* embryo. However, although this work identified 270 MAPs, 2D gel analysis showed the presence of at least 600 MAPs in this tissue suggesting our list of MAPs is far from complete. In addition, in order to progress from a list of MAPs to an understanding of the way in

which they determine spindle self-organisation, the way in which these MAPs interact with one another in the cell needs to be determined.

To move towards this goal, we have used reciprocal BLAST to identify *Drosophila* homologues of MAPs originally found through biochemical techniques in other model species (humans, mouse, rat and *A. thaliana*), interrogating the BIOGRID protein-protein interaction (PPI) database with this list to produce a single PPI network containing 1134 putative *Drosophila* MAPs. In order to predict the likelihood of each of these proteins binding MTs and having a function during mitosis we have developed a logistic regression model that uses multiple features such as protein interactions, gene expression data, domain composition, along with data from a compilation of genome-wide mitotic RNAi screens, training the model against both positive and negative datasets.

The final output of this model is a ranked list of predicted MAPs with uncharacterised roles in mitosis. Strikingly, thirteen of the top fifty putative MAPs interact directly or indirectly with one another, and sub-cluster with protein kinases that have known roles in cell cycle regulation, and with other putative MAPs in our list. A functional analysis of this cluster of proteins using RNAi in *Drosophila* S2 cells demonstrates roles for at least ten of the high-ranking putative MAPs in the regulation of spindle formation, centrosome number and chromosome segregation, strongly suggesting that we have identified previously unrecognised mitotic MAPs with related function.

1108

**A novel and essential asymmetric centrosome protein in *Drosophila*.**

S. Marks<sup>1</sup>, T. Megraw<sup>1</sup>; <sup>1</sup>Biomedical Sciences, Florida State University College of Medicine, Tallahassee, FL

Asymmetric cell division is critical during development. It is the mechanism by which stem cells renew themselves while at the same time produce a population of differentiated cells with the potential to make multiple cell types. Asymmetric cell division involves complex coordination between the cellular cortex, centrosomes and the mitotic spindle. Centrosomes in mitotic cells are inherently asymmetric because one cell will inherit the older (mother) centrosome while the other cell will inherit the newer (daughter) centrosome. During stem cell divisions the asymmetry of the centrosomes is coordinated directly with the asymmetry of cell fate. Neural stem cells (neuroblasts, NB) inherit the daughter centrosome at each division. Conversely, male germline stem cells (GSC) inherit the mother at each asymmetric division. We have identified a novel *Drosophila* centrosomal protein that associates specifically with daughter centrosomes in asymmetrically dividing NBs and GSCs. In NBs this protein localizes to the centriole. In contrast, distribution of this protein is not asymmetric in symmetrically dividing cells. In symmetrically-dividing ganglion mother cells (GMCs) and cells of the embryo, it localizes to the periphery of the pericentriolar matrix (PCM) as defined by Cnn staining. We screened for EMS-induced mutations, and identified a nonsense deletion in the middle of the ORF. This mutation appears to be a null allele. Mutation of the gene and RNAi knockdown cause mislocalization of asymmetric determinants in larval NBs and lethality at early pupal stages. Together, these results show that this novel asymmetric centrosome protein is essential for asymmetric division and animal development.

1109

**Examining the Spatial Organization of the Centromere Throughout the Cell Cycle.**

C. J. Fuller<sup>1</sup>, A. F. Straight<sup>1</sup>; <sup>1</sup>Department of Biochemistry, Stanford University, Stanford, CA

The kinetochore is the primary microtubule-binding site on the chromosome and governs accurate chromosome segregation during cell division. Kinetochores form during mitosis on a specialized chromatin domain called the centromere. In higher eukaryotes, the location of the

centromere is thought to be epigenetically specified; the proteins that comprise the centromere determine its identity independent of the DNA sequence upon which it is built. The centromere is a large multiprotein complex. Understanding how these proteins act in concert to maintain the identity of the centromere through rounds of cell division and how the cell reads out the location of the centromere remain open questions. Understanding centromere and kinetochore function requires knowing how individual protein subunits of the centromere and kinetochore are spatially arranged and how this organization changes over the course of the cell cycle.

We present a technique called Colocalization and In-situ Correction of Aberration for Distance Analysis (CICADA) and use it to examine the spatial organization of the centromere and how it changes through the cell cycle at 10 nm length scales using standard widefield fluorescence microscopy. In particular, we examine centromeres before DNA replication, just after DNA replication and in metaphase of mitosis in order to understand how centromere organization might influence its major functions of self-propagation and providing a platform for mitotic kinetochore assembly.

1110

### **ILLUMINATING AURORA A'S *in vivo* BIOCHEMISTRY.**

R. Grant<sup>1</sup>, H. Rangone<sup>1</sup>, D. M. Glover<sup>1</sup>, C. Lindon<sup>1</sup>; <sup>1</sup>Department of Genetics, University of Cambridge, Cambridge, United Kingdom

Aurora kinase A (AurA) is a member of the Aurora family of mitotic serine/threonine kinases first discovered in a *Drosophila* mutagenesis screen for activities regulating the centrosome cycle. As a major player in the control of mitosis, AurA has many roles including regulating asymmetric cell division, mitotic entry, centrosome maturation, centrosome dependent and independent microtubule nucleation and organisation and anaphase spindle dynamics. Although AurA's activation and role in bipolar spindle assembly are known to be dependent on its interactions with TPX2 and CEP192 in mammalian systems, generally, however, the *in vivo* biochemistry underpinning many of AurA's cellular functions has yet to be elucidated. Here we have utilised a co-immunoprecipitation and mass spectrometry approach to identify potential cell cycle phase specific regulators of AurA activity, localisation and degradation in a comparative study between synchronised populations of human cells and *Drosophila* embryos and cell culture. Over 600 novel AurA-specific interactors have been identified, many of which in the human screen are specific to a single cell cycle phase, allowing us to infer how AurA functions change as the cell cycle progresses. In addition, the *Drosophila* screen identified a potentially significant interphase AurA function in regulating muscle and neuron development. A selection of interactors from both screens are now being validated and studied in detail in order to investigate the physiological role of their interaction with AurA.

1111

### **FUNCTIONAL SIGNIFICANCE OF POLO-LIKE KINASE 1 PHOSPHORYLATIONS REVEALED BY CHEMICAL GENETICS.**

A. L. Lasek<sup>1</sup>, M. E. Burkard<sup>1</sup>; <sup>1</sup>University of Wisconsin-Madison, Madison, WI

Mitosis is coordinated by carefully regulated phosphorylation and protease activity. Polo-like kinase 1 (Plk1) is a core regulator of mitosis. We previously developed a chemical genetic system to allow specific interrogation of Plk1 function in human cells. Here, we extend this system using genetic complementation to evaluate the functional significance of previously identified Plk1 phosphorylation sites *in vivo*. With this method, we are able to specifically target one of the Plk1 alleles using chemical inhibition. The other allele is resistant to treatment and

can be mutated to test the functionality of this mutated version of Plk1. In our experiments, we mutated Plk1 at known phosphorylation sites to examine their ability to rescue known roles of Plk1. As a control, we showed that wildtype Plk1 is able to rescue normal functions of Plk1. Surprisingly, Plk1 mutations at most phosphorylation sites were also able to rescue including: T6V, S103A, S330A, S375A, S450A, S461A, T464V, and T498V. Interestingly, cells containing the Plk1- S450A, S461A, T464V, and T498V mutants preferentially expressed this mutated Plk1 over other alleles, suggesting that the inability to phosphorylate these residues increased protein stability.

Plk1-T214V, however, was unable to rescue multiple Plk1 functions: cells grow and proliferate more slowly, are unable to progress normally through mitosis, have defective spindle maturation, and have a reduced ability to enter mitosis following DNA damage. We next sought to identify the kinase responsible for this posttranslational modification. T214 is immediately followed by a proline, making Cdk1 an attractive upstream candidate kinase. However, two assays have indicated that Cdk1 is not responsible. First, *in vitro*, Cdk1 did not significantly phosphorylate purified Plk1. Also, when the proline is mutated to alanine, normal mitotic functions of Plk1 are not affected, indicating that the upstream kinase is not proline-directed as suspected. We next will determine when this site is phosphorylated in cells.

Previously, T210 was considered to be the essential phosphorylation site for Plk1 activation; however, our results demonstrate that multiple phosphorylation events are essential for regulation of this kinase. A threonine at corresponding residues to T214 is widely conserved in kinase T-loops. Identification of additional regulators of Plk1 will have implications in our understanding of how kinases and other proteins are regulated in the cell cycle.

1112

#### **Novel mitotic signalling crosstalk between PI3K-Akt pathway and Plk1.**

H. Goto<sup>1,2</sup>, K. Kasahara<sup>1,3</sup>, I. Izawa<sup>1</sup>, T. Kiyono<sup>4</sup>, N. Watanabe<sup>5</sup>, S. Elowe<sup>6</sup>, E. A. Nigg<sup>7</sup>, M. Inagaki<sup>1,2</sup>, <sup>1</sup>Div Biochem, Aichi Cancer Ctr Res Inst, Nagoya, Japan, <sup>2</sup>Dept Cell Oncol, Nagoya Univ Grad Sch Med, Nagoya, Japan, <sup>3</sup>Dept Oncol, Grad Sch Pharma Sci, Nagoya City Univ, Nagoya, Japan, <sup>4</sup>Div Virol, Natl Cancer Ctr Res Inst, Tokyo, Japan, <sup>5</sup>Chem Biol Core Fac., Chem Biol Dept, Riken ASI, Wako, Japan, <sup>6</sup>Centre de Recherche du CHUQ, boulevard Laurier, QC, Canada, <sup>7</sup>Biozentrum, Univ Basel, Basel, Switzerland

Polo-like kinase 1 (Plk1) controls multiple aspects of mitosis, whereas a kinase cascade from phosphatidylinositol 3-kinase (PI3K) to Akt regulates cell growth, proliferation, survival and motility. Here, we report an unexpected role of the PI3K-Akt signalling pathway in regulating mitotic Plk1 function. We demonstrated that Plk1 is phosphorylated at Ser99 in a manner that requires the activities of PI3K and Akt. This phosphorylation occurs specifically in mitosis but independently of Plk1-Thr210 phosphorylation, a process essential for Plk1 activation. Plk1-Ser99 phosphorylation creates a docking site for 14-3-3 $\gamma$  and binding of 14-3-3 $\gamma$  stimulates the catalytic activity of Plk1. 14-3-3 $\gamma$  silencing or the replacement of wild-type Plk1 by a Ser99-phospho-blocking mutant leads to a prometaphase/metaphase-like arrest due to the activation of the spindle assembly checkpoint (SAC). These results suggested that PI3K-Akt pathway facilitates Plk1-Ser99 phosphorylation, which stimulates Plk1 catalytic activity through the formation of a Plk1-14-3-3 $\gamma$  complex. This activation pathway is required for proper progression from metaphase to anaphase.

1113

**A transition between two types of oscillators during the *Xenopus laevis* early embryonic cell cycle.**

T. Y-C. Tsai<sup>1,2,3</sup>, J. A. Theriot<sup>2,3</sup>, J. E. Ferrell Jr.<sup>1</sup>; <sup>1</sup>Chemical and Systems Biology, Stanford University, Stanford, CA, <sup>2</sup>Biochemistry, Stanford University, Stanford, CA, <sup>3</sup>Howard Hughes Medical Institute, Stanford, CA

During *Xenopus laevis* early embryonic development, the first cell cycle is long and the subsequent 11 cycles are short and highly accurate, raising the question of how an oscillator can be initially tunable yet precise afterwards. By reconstructing the oscillatory dynamics from single embryos, we found that the positive feedback is much stronger in the first cycle, but becomes minimal in the subsequent cycles, supporting a transition between a positive-plus-negative feedback oscillator to a negative-feedback-only oscillator. The negative feedback is highly ultrasensitive and could contribute to the robustness of the oscillator when the positive feedback is weakened. It is critical for the first cycle to be sufficiently long, as the embryos with shorter first cycle period upon drug treatment have dramatically reduced viability. This reduction in viability can be rescued by co-treatment with cycloheximide to extend the first cycle period back to its normal length. Using a mathematical model that fits our experimental data, we compared the systems level properties of the two oscillator design. The presence of positive feedback in the first cycle allows the oscillatory period to be tunable without changing the amplitude of Cdk1 activity, and down-regulating the positive feedback in the subsequent cycles helps to increase the precision of the oscillatory period. Thus, embryos may be altering the underlying architecture of cell cycle feedback regulation to meet two different developmental objectives during early development.

1114

**Resolution of the yeast septin ring reorganization by single molecule microscopy.**

C. Kaplan<sup>1</sup>, J. Ries<sup>2</sup>, G. Shtengel<sup>3</sup>, A. S. Gladfelter<sup>4</sup>, H. F. Hess<sup>3</sup>, H. Ewers<sup>1</sup>; <sup>1</sup>Institute of Biochemistry, ETH Zurich, Zurich, Switzerland, <sup>2</sup>European Molecular Biology Laboratory, Heidelberg, Germany, <sup>3</sup>Janelia Farm, Howard Hughes Medical Institute, Ashburn, VA, <sup>4</sup>Dartmouth College, Hanover, NH

The septins are a family of cytoskeletal GTPases with conserved essential functions in cell division and polarization. Heteromeric nonpolar octamers of yeast septin proteins localize to a ring-like structure at the mother-bud neck in dividing yeast cells. During cell division, this ring-structure separates several cell compartments of the mother cell from the daughter cell and ensures asymmetric cell division.

Emerging first as a ring at the future bud site, the structure assumes an hourglass-like arrangement during bud growth. At the onset of cytokinesis the hourglass-like structure splits into two rings that are distributed to the daughter and mother cell.

The dynamics and organization of this process are regulated by cell signaling and the respective terminal protein in the individual complexes. Fluorescence polarization measurements suggest that individual complexes within the structure undergo a 90-degree shift during reorganization. Electron tomography data on the other hand point towards a coexistence of two populations of differently organized filaments. How this essential structure that is paradigmatic for septin assembly in all cells is assembled and reorganized from individual complexes remains unclear.

Here we imaged both ends of the 35 nm long individual septin complexes in the septin structure at the yeast mother-bud neck by two- and three-dimensional single molecule super-resolution

microscopy. We could gather thousands of individual localizations at the septin ring and found dramatic changes in septin organization at different points during the cell cycle.

We find that the initial septin ring has an opening of around 382 nm (+/- 70 nm), which then widens to around 659 nm (+/- 50nm) before splitting into two rings. Our results reveal previously inaccessible insight into how this gigantic multiprotein complex is assembled from individual, 35 nm long septin octamers and changes during cell cycle progression.

**An essential mitotic role for the DNA replication protein, Cdt1.**

*D. Varma<sup>1</sup>, S. Chandrasekaran<sup>2</sup>, L. J. Sundin<sup>3</sup>, K. T. Reidy<sup>4</sup>, X. Wan<sup>1</sup>, D. D. Chasse<sup>5</sup>, K. R. Nevis<sup>2</sup>, J. G. DeLuca<sup>3</sup>, E. D. Salmon<sup>1</sup>, J. G. Cook<sup>2</sup>; <sup>1</sup>Biology, University of North Carolina at Chapel Hill, Chapel Hill, NC, <sup>2</sup>Biochemistry & Biophysics, University of North Carolina at Chapel Hill, Chapel Hill, NC, <sup>3</sup>Biochemistry & Molecular Biology, Colorado State University, Fort Collins, CO, <sup>4</sup>Curriculum in Genetics & Molecular Biology, University of North Carolina at Chapel Hill, Chapel Hill, NC, <sup>5</sup>Duke Institute for Genome Sciences and Policy, Duke University Medical Center, Durham, NC*

The cell division cycle requires complete and precise duplication of the entire genome in S phase followed by accurate chromosome segregation in mitosis. The formation and stability of kinetochore-microtubule (kMT) attachments during mitosis depends on the Ndc80 complex, Ndc80 (hsHec1), Nuf2, Spc24 and Spc25. In the approximate middle of the central coiled-coil rod domain of the complex is a "hinge" site produced by a ~40 amino acid loop in Hec1. We have identified the Cdt1 DNA replication licensing protein as an essential partner for Ndc80 during prometaphase through interaction with the Hec1 loop domain.

Cdt1, a protein first identified for its critical role in DNA replication origin licensing during G1 phase, is normally degraded during S phase but re-accumulates in G2. We now demonstrate that human Cdt1 has a distinct and essential function in prometaphase. We employed multiple strategies to temporally separate Cdt1's replication function from this new mitotic function to ensure that the mitotic arrest in Cdt1-depleted cells cannot be attributed to incomplete DNA replication. G2-specific depletion of Cdt1 arrests cells in late prometaphase due to abnormally unstable kinetochore-microtubule attachments and Mad1-dependent spindle assembly checkpoint activity. Cdt1 localizes to kinetochores during mitosis through interaction with Hec1. Cdt1 binds the unique loop extending from the rod domain of Hec1, and this loop is also required for kinetochore-microtubule attachment. Mutation of the loop prevents Cdt1 kinetochore localization and arrests cells in prometaphase. High resolution fluorescence microscopy indicates that Cdt1 binding to the Hec1 loop domain is required for a large microtubule-dependent conformational change in the Ndc80 complex in vivo. Thus Cdt1 binding to Hec1 represents a novel form of Ndc80 regulation in vertebrates essential for kinetochore-microtubule attachment. The Hec1 binding domain in Cdt1 overlaps with regions involved in binding some of Cdt1's replication partners such as geminin and Cdc6. These findings suggest that Cdt1 participates in multiple independent interactions that are separated both temporally and spatially. We suggest that the acquisition of multiple essential cell cycle functions by Cdt1 facilitates coordinated cell cycle progression to preserve genome stability.

**Cortical nodularity controls signaling pathways to link cell growth and division.**L. Deng<sup>1</sup>, J. B. Moseley<sup>1</sup>; <sup>1</sup>Department of Biochemistry, Dartmouth Medical School, Hanover, NH

Cell cycle progression is coupled to cell growth, but the molecular connections between these processes are largely unknown. In fission yeast, the kinases Cdr1 and Cdr2 promote mitotic entry and receive upstream cues related to polarized cell growth. To define the molecular connections between Cdr1/2 and cell polarity, we performed a comprehensive pair-wise yeast two-hybrid screen. From the resulting interaction network, we found that the protein Skb1 interacted with both Cdr1 and the Cdr1 inhibitory target Wee1. Consistent with these physical interactions, Skb1 inhibited mitotic entry through negative regulation of Cdr1 in genetic epistasis experiments. Skb1 localized to the cytoplasm and to stable nodes at the cell cortex, similar to Cdr1 and Cdr2. Surprisingly, Skb1 nodes were distinct structures from Cdr1/2 nodes, and artificial targeting of Skb1 to Cdr1/2 nodes delayed entry into mitosis. Thus, distinct cortical nodes prevent the inhibitory interaction of Skb1 and Cdr1 to ensure proper cell cycle progression. Moreover, we identified a novel protein Slf1 that co-localized and physically interacted with Skb1. We found that the number of cortical Skb1 nodes scaled with cell size and Slf1 promoted both Skb1 node formation and mitotic entry in a dosage-dependent manner. This suggests that regulation of Slf1 during cell growth may promote node formation and mitotic entry by sequestering Skb1 from its inhibitory target Cdr1. From these results, we propose that the formation of stable node structures in the cell cortex controls signaling pathways to link cell growth and division.

1118

**Mitofusin 1 is degraded at G2/M phase through ubiquitylation by MARCH5.**Y-Y. Park<sup>1</sup>, H. Cho<sup>1</sup>; <sup>1</sup>Department of Biochemistry, Ajou university, Suwon, Korea

Background: Mitochondria exhibit a dynamic morphology in cells and their biogenesis and function are integrated with the nuclear cell cycle. In mitotic cells, the filamentous network structure of mitochondria takes on a fragmented form. To date, however, whether mitochondrial fusion activity is regulated in mitosis has yet to be elucidated.

Findings: Here, we report that mitochondria were found to be fragmented in G2 phase prior to mitotic entry. Mitofusin 1 (Mfn1), a mitochondrial fusion protein, interacted with cyclin B1, and their interactions became stronger in G2/M phase. In addition, MARCH5, a mitochondrial E3 ubiquitin ligase, reduced Mfn1 levels and the MARCH5-mediated Mfn1 ubiquitylation were enhanced in G2/M phase.

Conclusions: Mfn1 is degraded through the MARCH5-mediated ubiquitylation in G2/M phase and the cell cycle-dependent degradation of Mfn1 could be facilitated by interaction with cyclin B1/Cdk1 complexes.

1119

***Cryptococcus neoformans* can undergo cell enlargement and reversible ploidy change during infection.**M-S. Fu<sup>1</sup>, K. Nielsen<sup>1</sup>; <sup>1</sup>Department of Microbiology, University of Minnesota, Minneapolis, MN

*Cryptococcus neoformans* is a major life-threatening human fungal pathogen that grows as a budding yeast. Recently, we showed that *C. neoformans* can enlarge its total cell size 5-10 fold during infection. These enlarged cells are defined as "titan" cells. Normal-size cryptococcal cells are haploid, but titan cells have an increased ploidy (tetraploid or octoploid) with single nucleus.

We hypothesize that titan cell production involves a process similar to endoreduplication or endomitosis, performed by plants and animals, in which mitosis is precluded or cytokinesis is not completed and the cells undergo extra rounds of DNA replication resulting in polyploidy and cell enlargement. Normally, endoreduplicated plant and animal cells rarely return to mitotic division. However, titan cells are able to undergo cell division and generate small daughter cells with cell size similar to normal-size cryptococcal cells. Interestingly, flow cytometric analysis showed that the majority of the progeny cells contained 1N DNA content (haploid) when titan cells isolated from mice were grown in standard laboratory conditions. These results showed that polyploid titan cells were able to give rise to haploid daughter cells. A similar phenomenon of endoreduplication and depolyploidization has also recently been observed in mammalian tumor cells upon exposure to chemotherapy. In the studies presented here, the nuclear division of normal-size and titan cells was visualized by fluorescent-labeling with mCherry or GFP fusions to the nucleolar protein (Nop1), alpha tubulin (Tub1), and DNA using histone H4. In normal-size cryptococcal cells, a single nucleolus was co-localized with DNA during interphase. However, the Nop1 signal was diffuse and did not localize with DNA during metaphase, suggesting an open or semi-open mitosis similar to mammals and in contrast to the model yeast *Saccharomyces cerevisiae*. Interestingly, titan cells were classified into two groups based on their nucleolar localization. The majority of titan cells contained a single nucleolus, but unlike normal-size cells, the Nop1 signal did not become diffuse and was co-localized with DNA in daughter cells during mitosis. A small fraction of titan cells contained two distinct nucleoli within long tube-shaped DAPI signal not associated with budding. These data suggest that titan cells have an unusual nucleus and may not follow the typical nuclear division seen in normal-size cryptococcal cells. This unusual nucleus in *C. neoformans* titan cells may allow an atypical division that produces haploid daughter cells from polyploid mother cells.

### **Constitutively Active-RSK2 induces chromosomal instability through diverse mechanisms.**

C-R. Park<sup>1</sup>, Y-Y. Park<sup>1</sup>, J-H. Lee<sup>1</sup>;

<sup>1</sup>Department of Biochemistry and Department of Molecular Science and Technology, Ajou university, Suwon, Korea

The 90KDa ribosomal S6 Kinases (RSKs) are family of Ser/Thr kinases that lie downstream of the Ras-MAPK cascade and they are found to play an important role in cancer progression. In relation to cancer, RSK2 expression was shown to be elevated in breast and prostate tumor samples. To investigate the involvement of RSK2 in tumorigenesis and tumor development, we took advantage of two different constitutively active RSK2 (CA-RSK2) constructs. We hypothesized that increased activity of RSK2 might induce chromosomal instability (CIN) which further contributed to tumorigenesis and tumor progression. We first analyzed the activities of two CA-RSK2 forms. In spite of inhibition of MEK by treatment with U0126, we observed an increase in the level of highly phosphorylated RSK2 at Ser380 in both CA-RSK2 construct transfected cells. As expected, we observed that cells expressing CA-RSK2 showed increase in number of chromosome bridge and lagging chromosome during anaphase. In addition, we observed that expression of CA-RSK2 increased micronuclei after mitosis. These results indicate that CA-RSK2 induced mis-segregation of chromosomes resulting in increase of CIN. Consistently, we observed that CA-RSK2 expression enhanced abnormal chromosome number in HeLa cells. Regarding underlying mechanism of CIN, we first analyzed the Spindle Assembly Checkpoint (SAC) protein activity by treating the cells with Nocodazole, an inducer of microtubule depolymerization, and found out that CA-RSK2 decreased mitotic cells as compared with that of control, suggesting partial impairment of SAC activity. In addition, when MCAK and CA-RSK2 were co-transfected, we observed that MCAK decreased CA-RSK2-

induced lagging chromosome and chromosome bridge of anaphase, suggesting the involvement of kinetochore microtubule here. Further investigating on the mechanisms underlying the chromosomal instability caused by CA-RSK2 is undertaken.

**The Histone-fold CENP-T-W-S-X complex induces positive supercoils into DNA.**

*K. Takeuchi<sup>1</sup>, T. Nishino<sup>1</sup>, K. Mayanagi<sup>2</sup>, N. Horikoshi<sup>3</sup>, A. Osakabe<sup>3</sup>, H. Tachiwana<sup>3</sup>, T. Hori<sup>1</sup>, H. Kurumizaka<sup>3</sup>, T. Fukagawa<sup>1</sup>; <sup>1</sup>National Institute of Genetics, Mishima, Japan, <sup>2</sup>Kyushu University, Fukuoka, Japan, <sup>3</sup>Waseda University, Shinjuku-ku, Japan*

The centromere is the genomic locus where the kinetochore is assembled to facilitate faithful chromosome segregation during mitosis through formation of a dynamic interface with microtubules from the mitotic spindle. Centromeres are specified by sequence-independent epigenetic mechanisms in most eukaryotes and centromere-specific histone H3 variant CENP-A serves an important epigenetic marker for the centromere specification. However, centromeric chromatin is much complicated and there should be additional features, which are involved in the centromere specification and kinetochore assembly. We recently identified the CENP-T-W-S-X complex, which forms a unique nucleosome-like structure with the histone-fold. Whereas we demonstrated that tetramer formation of CENP-T-W-S-X is essential for kinetochore assembly in both in vivo and in vitro, it is still unclear how the CENP-T-W-S-X tetramer contacts to DNA and the nucleosome-like structure is established.

Here, we examined how the CENP-T-W-S-X complex contacts DNA. The CENP-T-W-S-X complex efficiently binds to ~100 bp DNA. Remarkably, we found that the CENP-T-W-S-X complex introduces positive supercoils into plasmid DNA, whereas the canonical histones-containing regular nucleosome induces negative DNA supercoils. We like to discuss about biological significance of this unique structure.

1122

**Epigenetic Regulation of Rsf-1, a Subunit of Remodeling and Spacing Factor Complex in Mitosis.**

*H-S. Lee<sup>1,2</sup>, S. Chae<sup>1</sup>, H. Cho<sup>1</sup>; <sup>1</sup>Department of Biochemistry, Ajou university, suwon, Korea, <sup>2</sup>Department of Molecular Science and Technology, Ajou university, suwon, Korea*

The RSF complex has been identified as an ATP-dependent nucleosome remodeling and spacing factor that facilitates the transcription on the DNA template packaged into chromatin. The RSF complex is composed of two subunits, SNF2h ATPase and Rsf-1. Notably, Rsf-1 is found to be overexpressed in a variety of cancers, in which high Rsf-1 level is often correlated with aggressiveness of cancers and poor prognosis. However, how the chromatin remodeling activity is related to cancer development remains largely unknown. Here, we showed that in early mitosis Rsf-1 localizes throughout the mitotic chromosomes but changes its localization through progression into late mitosis. Depletion of Rsf-1 by siRNA induces a severe defect in chromosomal congression as well as in the timing of cohesion resolution. We found that knockdown of Rsf-1 causes a severe imbalance in histone modifications in mitosis. An extensive immunofluorescence study also indicates that Rsf-1 is required for proper localization and movement of histone deacetylases and HAT during mitotic progression. Together, we suggest Rsf-1 as a novel epigenetic regulator in mitosis.

1123

**Segregation of extra-chromosomal DNA in fission yeast.**H. Yu<sup>1</sup>, Y. Barral<sup>1</sup>; <sup>1</sup>Institute of Biochemistry, ETH Zurich, Zurich, Switzerland

Extrachromosomal DNA (ecDNA) is prevalent in various eukaryotic organisms. It has been shown that the asymmetric retention of ecDNA is a crucial mechanism of cellular rejuvenation during asymmetric mitosis of budding yeast *Saccharomyces cerevisiae*. Nothing is known about the fate of ecDNA in symmetric dividing cells. Here we establish the fission yeast *Schizosaccharomyces pombe* as a model system for studying ecDNA behaviour in symmetric mitosis. We show that in *S. pombe*, ecDNA particles are localized predominantly at nuclear periphery, probably through the LEM domain proteins Lem2 and Man1. During mitosis, ecDNA particles exhibit condensin-dependent dynamic clustering, and are segregated asymmetrically in the two apparently equivalent daughter cells. Non-random asymmetry is abolished in mutants of Lem2, Man1, condensin as well as genes involved in transcription and silencing. Our data suggest that *S. pombe* regulate ecDNA segregation and dynamics through a combination of mechanisms that involve nuclear structure and dynamics, chromatin condensation, transcription and heterochromatin assembly.

1124

**Dissecting the role of non-coding RNAs in pericentric heterochromatin formation in human cells.**W. L. Johnson<sup>1</sup>, W. T. Yewdell<sup>1</sup>, A. F. Straight<sup>1</sup>; <sup>1</sup>Biochemistry, Stanford University, Stanford, CA

During mitosis, pairs of replicated chromosomes must remain linked until anaphase to ensure proper attachment to the mitotic spindle and equal segregation of the genome. The primary sites for cohesion between sister chromatids are the heterochromatic outer regions of the centromere, called pericentric heterochromatin. Disruption of pericentric heterochromatin leads to defects in cohesion, chromosome segregation errors and aneuploidy. In fission yeast and plants, the assembly of pericentric heterochromatin requires transcription of repetitive sequences flanking centromeres. Recent evidence suggests that pericentric transcription also contributes to centromere function in vertebrates, but how pericentric RNAs interact with the proteins that initiate and maintain heterochromatin and how these interactions contribute to cohesion and chromosome segregation is poorly understood. Using *in vivo* RNA labeling techniques, we have found that RNA is bound to the pericentric regions of human mitotic chromosomes. This RNA is encoded by pericentric DNA repeat sequences, is single-stranded and colocalizes with heterochromatin protein 1 alpha (HP1 $\alpha$ ). We show that HP1 $\alpha$  binds to pericentric transcripts *in vivo*, and that HP1 $\alpha$  and the histone 3 lysine 9 methyltransferases SUV39H1, SUV39H2 and SETDB1 directly bind RNA *in vitro*. We propose a model in which pericentric RNA transcripts directly recruit factors that initiate and maintain heterochromatin at centromeres.

1125

**An Alternative Mechanism of Action for Paclitaxel in Breast Cancer.**L. M. Zasadil<sup>1</sup>, B. A. Weaver<sup>1</sup>; <sup>1</sup>Cell and Regenerative Biology, University of Wisconsin-Madison, Madison, WI

Paclitaxel is a microtubule-stabilizing drug that binds to the  $\beta$ -tubulin subunit and accumulates within cells. As a chemotherapeutic agent, paclitaxel is used for the treatment of a variety of cancers including those of the breast. Currently, no biomarker is available to predict which

patients will benefit from paclitaxel treatment. Paclitaxel studies in cells have focused primarily on high concentrations of the drug that significantly inhibit microtubule dynamics, resulting in long-term mitotic arrest. Our preliminary measurements of paclitaxel concentrations in breast tumors indicate that the clinically relevant concentrations of paclitaxel to study in cell culture are in the low nM range, and cause more subtle effects on microtubule dynamics. Cells exposed to low concentrations of paclitaxel complete mitosis with minimal delay, but frequently contain multipolar spindles. In both chromosomally stable breast cancer cells and those that exhibit chromosomal instability (CIN), low concentrations of paclitaxel are sufficient to increase the incidence of chromosome missegregation. These data suggest that the mechanism of cell death due to low dose paclitaxel is likely to be due to abnormal mitoses that result in uneven division of genetic material, as opposed to mitotic arrest caused by high dose paclitaxel. They also predict that CIN cells may exhibit differential sensitivity than chromosomally stable cells to clinically relevant concentrations of paclitaxel. Recent studies have found that chromosomally stable cells must acquire tolerance for a nondiploid genome in addition to CIN to become viable aneuploid cells. This suggests that CIN cells are better adapted to proliferate despite chromosome missegregation, giving them increased resistance to death following paclitaxel treatment when compared to chromosomally stable cells. However, it has also been shown that low rates of chromosome missegregation are well tolerated, at least in some cell types, but high rates of missegregation lead to rapid cell death. Since CIN cells have an existing level of chromosomal missegregation, which is exacerbated by treatment with low doses of paclitaxel, these cells may be more likely than chromosomally stable cells to die after paclitaxel treatment as a result of losing both copies of a vital chromosome. We are currently testing the differences in response to low dose paclitaxel between chromosomally stable and CIN cells to determine whether chromosomal stability status can be used as a biomarker to predict which tumors are most likely to be sensitive to treatment with paclitaxel.

1126

**A single-molecule assay of ubiquitination/deubiquitination in cell extracts.***Y. Lu<sup>1</sup>, M. Kirschner<sup>1</sup>; <sup>1</sup>Harvard Medical School, Boston, MA*

Ubiquitination is the major mechanism for regulated protein degradation, and is closely associated with various diseases such as cancer and neural degenerative diseases. Kinetics of the reaction has been exploited by the cell to regulate or time physiological events such as the cell cycle where a series of substrates of the APC (a major E3 ligase) undergo sequential ubiquitination and proteasome degradation. It is unclear which mechanism sets up the reaction order, and how the order is affected by modifications to the APC. In order to study the regulatory mechanism, we designed a single molecule assay to capture transient intermediates and to measure the reaction constants in both purified reaction systems and in cell extracts. In this assay, ubiquitin, E3 ligase (APC) and substrates are fluorescently labeled respectively. The polyubiquitination and deubiquitination kinetics on substrate molecules was measured and associated with the binding of E3 ligases. Several technical improvements were made to ensure successful implementation of this assay in the presence of  $\mu\text{M}$  concentration of fluorescent-ubiquitin. Due to rapid deubiquitination and degradation, no kinetic measurements could be made before in cell extracts using conventional methods. Our single molecule assay allows the examination of the reactions mechanism and kinetics in a real cytosolic environment of cell extracts. Using this assay, we found that initial ubiquitination of substrates greatly enhances its binding with E3, thus allows further ubiquitination and degradation through a positive feedback mechanism. This mechanism allows the E3 to efficiently locate substrate molecules in crowded cellular environment, and is important for setting up the correct order of degradation. Using a modified method, we also studied how the proteasome recognizes and degrades ubiquitinated substrates in a reconstituted ubiquitin-proteasome system.

1127

**Single-cell analysis of the mitotic size control system in fission yeast.**

A. Bridges<sup>1</sup>, J. B. Moseley<sup>1</sup>; <sup>1</sup>Department of Biochemistry, Geisel School of Medicine at Dartmouth, Hanover, NH

Cell cycle progression is coupled to cell growth through a series of checkpoints that monitor size, time, and/or environmental cues. Rod-shaped fission yeast cells enter into mitosis upon reaching a critical cell size, similar to size-dependent checkpoints in other cell types. Size measurement depends on the mitotic inhibitor Pom1, which forms a gradient enriched at cell poles. Pom1 targets the mitotic inducer Cdr2, which localizes to the cell middle. Pom1 levels in the cell middle decrease as cells grow, allowing Cdr2-dependent entry into mitosis upon reaching a critical size. Here, we used single-cell analysis to resolve the role of Pom1 in cell size homeostasis. The mitotic size control system generates a reproducible cell size at division that is largely independent of cell size at birth, meaning that wild-type fission yeast cells born smaller or larger than normal will still divide at the typical size of 14  $\mu\text{m}$ . In contrast, cell size at division in *pom1* mutants was dependent on cell size at birth, indicating that Pom1 is required for dynamic cell size control. Further, our data suggest that a backup 'timer' emerges to control cell cycle progression in the absence of the Pom1 'sizer.' This Pom1-Cdr2 sizer has been linked to cell geometry due to its cellular distribution. To test this connection, we developed a fluorescent single-cell reporter that measures cell size independently of cell shape. Cell sizes at birth and division were not affected by changes in cell geometry, but rather plasticity in the Pom1-Cdr2 system maintained geometry-independent cell size control. To test the limits of this system, we engineered a strain that reversibly becomes multinucleated through repeated mitoses without intervening cytokinesis. In these cells, Pom1 and Cdr2 displayed an unexpected compartmentalization at the cell cortex, and this distribution drove synchronized mitoses in a single cell with altered size control dynamics. Our combined data identify a central role for the Pom1-Cdr2 system in the dynamic control of cell size homeostasis. This system coordinates cell cycle progression with changes in cell size and shape that occur during growth.

1128

**The Hippo Pathway targets Rae1 (an inhibitor of Cdh1-APCC) to regulate mitosis and establish organ size.**

C. M. Pfleger<sup>1</sup>, M. Jahanshahi<sup>1</sup>, K. Hsiao<sup>2</sup>, A. Jenny<sup>3</sup>; <sup>1</sup>Oncological Sciences, The Mount Sinai School of Medicine, New York, NY, <sup>2</sup>Neuroscience, The Mount Sinai School of Medicine, New York, NY, <sup>3</sup>Developmental and Molecular Biology, Genetics, Albert Einstein College of Medicine, Bronx, New York, NY

The Hippo Tumor Suppressor Pathway acts as a master regulatory pathway to coordinate proliferation, growth, and apoptosis in *Drosophila* and vertebrates. Loss of core pathway components (Serine-Threonine kinases Hippo and Warts, and also Salvador and Mats) and over-activation of the crucial pathway target Yorkie (a transcriptional regulator) promote cell division, cell growth, and cell death resistance, resulting in increased organ size. However, organ homeostasis typically engages mechanisms to ensure that variations in proliferation do not alter organ size. How the pathway integrates restricting proliferation within an "organ size checkpoint" remains a major unanswered question. Using *Drosophila* *In vitro* Expression Cloning (DIVEC), we performed a genome-wide kinase screen to identify Hippo and Warts substrates using a gel-shift assay. We identified Rae1, a reported inhibitor of the Cdh1-activated form of the Anaphase Promoting Complex/Cyclosome (APCC). We show that Rae1 acts in the Hippo Pathway to regulate both proliferation and organ size in *Drosophila*. Tissue culture studies show that Hippo signaling promotes phosphorylation and degradation of Rae1

downstream of Warts. *In vivo Drosophila* genetic interactions confirm that this negative regulation of Rae1 is important in Hippo-mediated restriction of organ size. Loss of Rae1 reduces organ size, decreases cyclin A and cyclin B levels, and impairs S-phase entry and causes mitotic arrest of those cells that do enter the cell cycle. These data suggest a role for Rae1 in both S-phase entry and mitotic progression. Exogenous Rae1 increases cell proliferation, cyclin A and cyclin B levels, and organ size. Importantly, reducing Cdh1 gene dosage suppresses the reduced organ size upon Rae1 loss or Hippo over-expression, implying that Cdh1 is important to these organ size phenotypes. We propose a model that Hippo signaling promotes Cdh1-APCC activity to restrict proliferation and organ size by relieving its Rae1-mediated inhibition. Work by others established that reducing the gene dosage of Yorkie suppresses organ overgrowth upon loss of Hippo signaling. Reducing Rae1 gene dosage also dramatically suppresses organ overgrowth. Surprisingly, we also see catastrophic tissue lethality arguing that tissue overgrowing from loss of Hippo requires a minimum threshold of Rae1 to survive. Tissue lethality upon reducing Rae1 occurs in the context of loss of Merlin, Expanded, Hippo, or Warts but not over-expressing Yorkie, highlighting a fundamental difference between loss of core components of Hippo signaling and Yorkie activation. This “synthetic lethality” is reminiscent of oncogene/non-oncogene “addiction” models and implicates Rae1 as a therapeutic target for cancers in which Hippo signaling is dysregulated.

1129

### **Dissecting the cell size monitoring system in fission yeast by quantitative analysis of the Pom1 concentration gradient.**

O. Hachet<sup>1</sup>, M. Hersch<sup>2</sup>, S. Dalessi<sup>2</sup>, S. Bergmann<sup>2</sup>, S. Martin<sup>1</sup>; <sup>1</sup>Department of fundamental microbiology, University of Lausanne, Lausanne, Switzerland, <sup>2</sup>Swiss Institute of Bioinformatics, University of Lausanne, Lausanne, Switzerland

In the rod shaped fission yeast, like in many other organisms, cell division is tightly coordinated with cell growth and allows cell division to occur at a constant cell length. This control relies in part on a geometric cell size monitoring system based on cortical concentration gradients of the DYRK kinase Pom1 that emanates from the cell tips. Pom1 modulates CDK1 (Cdc2) activity by negatively regulating the Cdr2 kinase localized at the cell middle; this inhibition is thought to be alleviated by cell elongation. However the mechanistic nature of the Pom1 gradient readout responsible for mitotic entry remains to be described.

We have shown that the establishment and maintenance of Pom1 gradients involves a cycle of dephosphorylation and autophosphorylation: Pom1 is locally dephosphorylated at cells tips by the Tea4-Dis2 (type 1 phosphatase) complex, revealing a lipid-binding domain that mediates Pom1 binding to the plasma membrane. As Pom1 diffuses along the membrane, Pom1 autophosphorylates at multiple sites to promote its release into the cytoplasm.

We have developed an Image J plugin for semi-automatic quantitative analysis of the Pom1 gradients. Using this tool our analyses revealed a correlation between cell length and the size of the central domain with low Pom1 signal and high Cdr2 signal, suggesting the size control of this medial cell zone is critical for regulating mitotic entry. We use two experimental approaches to manipulate this medial cell zone: first we make use of a chemical genetic approach based on an analogue sensitive allele of Pom1 that can be specifically inhibited. Using suboptimal doses of the inhibitor, we can manipulate the shape of the gradient and study its impact on mitotic commitment and Cdr2 localization. Second, by generating Pom1 alleles with increasing numbers of auto-phosphorylation sites mutated, we show a progressive spreading of the Pom1 gradient and a progressive increase in cell size at division according to the number of mutated sites. This indicates that the multiple autophosphorylation sites impact on the gradient shape. Together, these approaches combined with quantitative analysis provide new tools to dissect the Pom1 gradient readout responsible for mitotic entry.

1130

**Bod1 is a novel inhibitor of Protein Phosphatase 2A-B56 during mitosis.**

*I. M. Porter<sup>1</sup>, K. Schleicher<sup>1</sup>, J. R. Swedlow<sup>1</sup>; <sup>1</sup>Gene Regulation and Expression, University of Dundee, Dundee, UK*

Bod1 is a small, 22 kDa, protein that is required for resolution of syntelic attachments, proper chromosome alignment and proper phosphorylation of MCAK by Aurora B in mitosis. Here we demonstrate that Bod1 is a novel inhibitor of PP2A-B56 during mitosis. Bod1's sequence is similar to Ensa and Arpp-19, two proteins recently identified as inhibitors of PP2A-B55, which are required for proper entry into mitosis. Bod1-GFP immunoprecipitates possess phosphatase activity that is inhibited by 2 nM okadaic acid. This activity is markedly increased if the Bod1/PP2A complex is dissociated in the reaction by addition of salt and detergent. Bod1 binds specifically to the PP2A-B56 holoenzyme and not PP2A-B55. Binding of Ensa and Arpp-19 to PP2A-B55 requires a conserved Asp and phosphorylation by Gwl kinase at a neighboring Ser. Similar residues, T95 and D98, are critical for Bod1 function; expression of Bod1 T95A or D98A mutants fail to rescue Bod1 siRNA depleted cells whereas expression of a T95E mutation rescues as well as wt Bod1. Cdk1 phosphorylates Bod1 at T95 *in vitro* and the T95E mutant immunoprecipitates PP2A-B56 more strongly than either wt or T95A Bod1. Taken together, these data indicate that phosphorylation of Bod1 at T95 induces specific binding and inhibition of PP2A-B56. These data suggest that loss of Bod1 might therefore cause hyperactive PP2A-B56 and defects in mitotic progression. siRNA depletion of Bod1 from HeLa cells results in increased PP2A-B56 localisation to centromeres, causes loss of phosphorylation of MCAK and PBIP, delocalization of Plk1 and Sgo1, and defects in chromosome biorientation and cohesion. The Bod1 phenotype can, in part, be rescued by co-depletion of B56, consistent with the idea that Bod1 inhibits PP2A-B56 activity. Our results demonstrate that Bod1 is a critical modulator of PP2A-B56 activity and that together Bod1, Ensa and Arpp-19 form a new class of mitotic PP2A inhibitors.

1131

**The Inhibitory Role of Aurora A in Mitotic Entry in the Early Embryonic Cell Cycle.**

*Q. Kang<sup>1</sup>, J. Pomerening<sup>1</sup>; <sup>1</sup>Department of Biology, Indiana University-Bloomington, Bloomington, IN*

Cyclin-dependent kinase 1 (CDK1) is the master kinase that directs a wide array of mitotic events, ranging from nuclear envelope breakdown to chromosome separation. Other kinases—Aurora A and Polo-like kinase 1 (Plk1), for example—serve additional roles at mitosis. Research in the past decade has suggested that positive feedback loops underlie the activation of CDK1, Aurora A and Plk1. My current studies using *Xenopus* embryonic extracts, however, has revealed a more complicated network exists among these kinases. Through some initial data, I found that Aurora A may not only act as an activator, but also as an inhibitor to fine tune the activation of CDK1. By removing, inhibiting or overexpressing endogenous proteins, “single-cell” approaches using *Xenopus* extracts enable us to test the behavior of modified cell cycle control systems. We discovered that adding purified Aurora A protein into cycling extract caused mitosis delay in a dose-dependent manner. Newly synthesized Aurora A protein produced after the addition of *in vitro*-transcribed mRNA also delayed mitosis, excluding any potential artifacts caused by protein contaminants. Neither depleting nor inhibiting Aurora A severely affected proper mitotic timing in the first cycle, but accelerated the second and the third cycles by 10-20 minutes, suggesting that losing Aurora A activity has a cumulative effect on cell cycle progression. To narrow down through which leg(s) Aurora A exerts its inhibitory effect on CDK1 activation, Wee1 kinase was depleted to weaken its double-negative feedback loop with CDK1.

Mitosis in this extract was delayed, but to a lesser extent compared to overexpressing Aurora A without depleting Wee1. This result suggests that Aurora A may not function through activating Wee1 to inhibit CDK1, but through inhibiting the Cdc25 phosphatase pathway to prevent the timely activation of CDK1. In summary, we have identified a novel inhibitory effect of Aurora A on the mitotic onset in early embryonic extract. This work has significant potential to reveal how the connection of the M-phase-control system that ensures mitosis is regulated properly and with tremendous precision. Since all M-phase kinases are commonly overexpressed in tumors and are implicated in carcinogenesis, gaining an understanding of the systems-level rules of these signaling cascades will provide new and critical insights into how proliferative diseases arise. It may also enable the identification of proteins that could be the most efficacious targets in clinical therapies for cancer and other diseases.

**A universal correlation between protrusion direction and division axis of cells in 3D matrices.**

*L. He<sup>1</sup>, D. Wirtz<sup>1,2,3</sup>; <sup>1</sup>Institute for NanoBioTechnology, The Johns Hopkins University, Baltimore, MD, <sup>2</sup>Johns Hopkins Physical Sciences in Oncology Center, The Johns Hopkins University, Baltimore, MD, <sup>3</sup>Department of Chemical and Biomolecular Engineering, The Johns Hopkins University, Baltimore, MD*

The regulation of cell mitosis is critical for normal development of tissues and organs. Uncontrolled mitosis has been implicated in natural genetic variations, progression of cancer and human aging. Previous studies investigating the control of the cell division orientation were performed with cells cultured on 2D substrates. However, many types of cells divide in 3D matrices, in particular fibroblast and fibrosarcoma cells which are located in collagen I-rich connective tissues. Adding a third dimension to the culture by employing a three-dimensional (3D) matrix could better recapitulate the microstructure, mechanical properties and biochemical signals of the 3D extracellular matrix (ECM) for both normal and pathologic tissues. Here, we employed single live-cell imaging assay, shRNA technique and quantitative image analysis to probe the regulation of cell division in 3D collagen matrices. Our results showed that cells exhibit different modes of cell mitosis in 3D matrix compared with their counterparts on 2D substrates. Results also revealed a strong correlation between the direction of the last protrusion before cell mitosis and the orientation of cell division. Such correlation held for vastly different types of cells, including fibrosarcoma, breast cancer and human embryonic kidney cell lines. This correlation did not change as the density of collagen matrix varied. Moreover, depleting the expression of integrin receptors, inhibiting the activities of Src kinase or matrix metalloproteinase did not abolish the correlation between the directions of the last protrusion and cell division. These results suggested that there is a universal correlation between the cell protrusion direction and the division orientation of cells in 3D collagen matrices. This study provides novel insights into the mechanisms governing the control of cell mitosis in a 3D cultural environment.

**Pds5 is required for sister chromatid resolution at mitosis.**

*N. Binjumah<sup>1</sup>, R. Patel<sup>1</sup>; <sup>1</sup>Department of Biochemistry, University of Leicester, Leicester, UK*

The correct segregation of chromosomes at mitosis is vital for maintaining genome integrity in eukaryotic cells. Errors in this process can result in aneuploidy and ultimately lead to the development of cancer or birth defects. The core components of the cohesin complex include Smc1 and Smc3 (members of the structural maintenance of chromosomes family of ATPases),

scc1 (a member of the kleisin family of proteins) and scc3 (SA1 and SA2 in vertebrates). However, additional proteins such as Pds5A and Pds5B are also known to regulate sister chromatid cohesion although their role remains unclear. Using an RNAi approach, our results show that Pds5 proteins are required for the removal of cohesin both from the arms of the sister chromatids and from the centromeric region. Our data suggest that Pds5 may be important for the recruitment of proteins that trigger the removal of cohesin from the chromosomes and initiate sister chromatid disjunction.

1134

**Spatial organization of the Ran pathway in mitotic human cells.**

*D. Oh<sup>1</sup>, D. Needleman<sup>1</sup>; <sup>1</sup>Harvard University, Cambridge, MA*

During spindle assembly, microtubules are enriched around chromatin by a process which, in many systems, is driven by the GTPase Ran. The Ran pathway is thought to establish a reaction-diffusion network that generates spatial gradients in the behaviors of soluble proteins. However, the validity of this model of Ran activity is still unclear because the spatial distributions of the activities of all the relevant components in the Ran pathway have not been measured. We developed a novel form of fluorescence fluctuation spectroscopy capable of measuring the concentration, diffusion, and interactions of fluorescently labeled proteins simultaneously at hundreds of locations throughout cells. We are using this technique to study the behaviors of Ran, Importin  $\alpha$ , Importin  $\beta$ , RanGAP1, and cargo proteins by expressing them tagged with GFP in human mitotic cells. Our preliminary results show spatial gradients in protein behaviors throughout mitotic cells, and produce surprising new insights about the principles underlying the spatial organization of the Ran pathway.

1135

**Ki-67, a PP1 interacting protein and chromosome periphery organizer.**

*P. Vagnarelli<sup>1</sup>, L. Sanchez-Pulido<sup>2</sup>, C. P. Ponting<sup>2</sup>, W. C. Earnshaw<sup>3</sup>; <sup>1</sup>Biosciences, Brunel University, London, UK, <sup>2</sup>MRC Functional Genomics Unit, University of Oxford, Oxford, UK, <sup>3</sup>Wellcome Trust Centre for Cell Biology, University of Edinburgh, Edinburgh, UK*

Ki-67 is a proliferation antigen that is expressed during all cell cycle phases except the G0 phase. Staining for Ki-67 has been used very widely to identify cells that maintain the ability to proliferate amongst populations of differentiated cells. Although Ki-67 is one of the most popular proliferation markers and widely used in cancer diagnosis and prognoses, its biological function is still unknown. We have identified Ki-67 as the evolutionary ancestor of Repo-Man (a PP1 targeting subunit and substrate specifier) and we have shown that Ki-67 itself is a PP1 interacting protein.

Ki67 is a nuclear protein in interphase and re-localizes around the periphery of the mitotic chromosomes from prometaphase until telophase. It thus belongs to the so-called perichromosomal layer compartment.

Lack of Ki-67 was previously reported to prevent the localization of hKLP2 to the mitotic chromosomes. Here we have identified Ki-67 as an important factor in nucleolus disassembly during mitosis and as a key organizer of the chromosome periphery.

## G1, G1-S, and S Phase Regulation

1136

### Positional Memory of Quiescent Cells.

G. Mitchell<sup>1</sup>, G. Yao<sup>1</sup>; <sup>1</sup>Molecular and Cellular Biology, University of Arizona, Tucson, AZ

Improper entry into or exit from quiescence can lead to a variety of human diseases, including cancer. A long-standing debate has raged about whether quiescent cells occupy a distinct G0 phase outside of the proliferative cell cycle, or whether they are simply deposited along a continuous G1 phase at the point where they last encountered growth signals. Mechanistically, our previous work demonstrated that the mammalian transition from quiescence to active proliferation is determined at the restriction point (R-point) by an Rb-E2F bistable switch. Stochastic activation of this switch can account for the heterogeneity in cell cycle entry observed among a population of isogenic cells. Here, using single cell experiments, we demonstrate that quiescent embryonic fibroblasts are distributed at varying distances from the R-point, and that after this positional distribution is altered by growth stimulation, these cells can memorize their new positions for several days. In other words, our work supports a model in which quiescent (G0) cells display G1-like positional heterogeneity, and can memorize these “quiescent positions” in the absence of growth signals. This cellular memory of quiescent positions could be critical for the self-renewal of stem and progenitor cells and the development of cancers arising from cancer stem cells.

1137

### In Vivo Detection of Cell Cycle Kinetics in Mice.

J. M. Elia<sup>1</sup>, C. M. Lane<sup>1</sup>, C. T. Carson<sup>1</sup>; <sup>1</sup>BD Biosciences, San Diego, CA

BrdU (Bromodeoxyuridine) can be used to study cell cycling in living cells both in vitro and in vivo. BrdU is a thymidine analogue which replaces thymidine during DNA replication (S phase of the cell cycle) and can be detected by specific monoclonal antibodies. Combining BrdU, proliferation dyes (VPD450) and cell surface markers allows for the detection of cell cycle within specific cell populations in vivo and in vitro. We aimed to analyze the cell cycle characteristics of distinct cell populations in bone marrow, spleen and thymus. BALB/c and C57Bl/6 mice were injected with 1 mg of BrdU (IP) for 24-96 hrs. Cell preparations from each of these organs were stained with antibodies to identify T, B, and macrophage cell types. Thymus and bone marrow displayed the highest levels of BrdU incorporation, while the spleen showed the lowest. Spleen incorporated BrdU at approximately 10%, in which the main population of cycling cells were either B220+ cells or Mac-1+ macrophages. In the thymus, the CD4/CD8 double positive and double negative immature T cells showed the highest percentage of BrdU positive cells (incorporating approximately 40%). In contrast, single positive CD4, CD8, and CD3 positive mature T cells incorporated the least as would be expected. The bone marrow compartment incorporated the most BrdU (53%). This compartment is made up of B cells, macrophages, T cells and hematopoietic progenitors. The B cells macrophage and HSC progenitors accounted for the majority of the BrdU+ cells. Further dissection of the bone marrow compartment for the HSC progenitor KLS (Ckit+/Sca-1+/Lineage-) showed that this population incorporated BrdU at 35-50%. These cells were loaded with VPD450 then sorted for KLS and plated on a feeder layer for 18-30 hours to determine cell proliferation trends post sort. The cells were harvested and assayed for the loss of BrdU and VPD450 peak formation. The progenitors lost 15% of their BrdU in the first 30 hrs proving the cells were actively cycling in culture. All together, these data demonstrate that combining analysis of BrdU incorporation in conjunction with cell surface markers and cell proliferation dyes enables the dissection of cell cycle status of distinct

hematopoietic cell types in vivo and in vitro. These techniques could be adapted to other organs or cell systems comprised of heterogeneous cell types.

1138

**Kinetics of early growth response proteins in human periodontal fibroblast wound healing model.**

*I. Tamura<sup>1</sup>, A. Kamada<sup>1</sup>, S. Goda<sup>1</sup>, Y. Yoshikawa<sup>1</sup>, E. Domae<sup>1</sup>, T. Ikeo<sup>1</sup>; <sup>1</sup>Department of Biochemistry, Osaka Dental University, Hirakata, Japan*

Early growth response (EGR) is a nuclear transcription factor implicated in the regulation of cell proliferation. We previously suggested that high molecular weight EGR-1 was not present in the nuclear fraction and the expression of native EGR-1 showed a peak at 60 min with both of FGF-1 and -2 on Western blotting analyses. Wound healing in the connective tissue is a highly orchestrated process that involves inflammation, cell proliferation, reorganization of the extracellular matrix and tissue remodeling. However, there is little information on the EGR expression in human periodontal fibroblasts during wound healing. In this study, we investigated the kinetics of EGR-1 and EGR-2 in a human periodontal fibroblast wound healing model. Three periodontal culture fibroblasts derived from three different teeth were first pre-incubated for two days in serum-free Dulbecco's modified Eagle medium (DME). After scraping with a P-200 pipette chip, periodontal culture fibroblasts were incubated for one, two or three days in DME supplemented with 10% FCS. EGR-1 and EGR-2 were expressed in the cell layer near the wound, and expression was downregulated upon wounding. Strong immunoreactions for EGR-2 were observed throughout the cell layer after one day. After two days, EGR-1 was expressed around the edge of the wound, and expression of EGR-2 decreased gradually. Although EGRs in periodontal fibroblasts are generally glycosylated, this expression is not correlated with scraping treatment. These results demonstrate the inducible nature of EGR proteins in damaged human periodontal tissues, and suggest a potential important role for EGR-1 in fibroblast growth and mobility during wound healing or tissue regeneration in vivo.

**Variability of cell cycle duration is not random in MDCK cells.**

*U. Berge<sup>1</sup>, D. Bochenek<sup>1</sup>, P. Horwath<sup>2</sup>, A. Marmaras<sup>3</sup>, E. Stelzer<sup>4</sup>, F. Pampaloni<sup>4</sup>, R. Kroschewski<sup>1</sup>; <sup>1</sup>Institute of Biochemistry, ETH Zürich, Zürich, Switzerland, <sup>2</sup>Light Microscopy Center, ETH Zürich, Zürich, Switzerland, <sup>3</sup>Department of Mechanical and Process Engineering, ETH Zürich, Zürich, Switzerland, <sup>4</sup>Frankfurt Institute for Molecular Life Sciences, Goethe University Frankfurt, Frankfurt am Main, Germany*

MDCK cells, canine kidney epithelial cells, can differ phenotypically, yet are related by divisions. We analysed cell cycle duration of individual MDCK cells and their progeny to decipher if cellular differences arise. Single cells were either seeded in elastic matrix or on rigid 2-dimensional substrate, where they were transfected with either non-targeting or ninein targeting siRNAs oligos. The individual nuclei and their progeny were tracked, and lineage trees were generated.

We find that in both culture environments the cell cycle duration is highly variable within a single cellular lineage. This effect was strongest for cells grown within the elastic matrix. But, down-regulation of the mother centriolar and centriole-microtubule anchoring factor ninein strongly decreased this variance. These results suggest that the variability of cell cycle duration is not random but may depend on both external and internal cues. They might also reflect the existence of pathways dedicated to the generation of cell diversity.

Analysis of the lineages reveals the presence of a recurring pattern, whereby three out of the four progenies of a grandmother cell behave similarly, while the fourth one shows more variable cell cycle duration. However, subtrees without the pattern also exist and the daughters of such a grandmother cell can generate subtrees, where this pattern emerges de novo. Further, the capacity to generate this pattern segregates unequally between daughter cells. The frequency and magnitude of this pattern are reduced upon ninein down-regulation. Thus, our results suggest that cells influence the generation of irregularities in cell cycle duration.

Together, these results indicate that MDCK cells can divide asymmetrically segregating non-randomly some determinants of interphase duration. Furthermore, the impact of these determinants on proliferation is modulated by the nature of the environment.

### How Does the Cell Cycle Respond to Environmental Change?

Q. A. Justman<sup>1</sup>, A. W. Murray<sup>1</sup>; <sup>1</sup>Center for Systems Biology, Harvard University, Cambridge, MA

*S. cerevisiae* cells rely on environmental nutrients and internal stores for the raw materials they need to grow and build daughter cells. Because it takes longer for the cell to build a daughter than to duplicate its genome, the cell cycle must lengthen to accommodate reductions in growth rate. However, it is unclear whether specific programs exist to accomplish this in a regulated way. We hypothesized that Start, the cell cycle program that restricts S-phase entry to cells of a threshold size, is also used to lengthen the cell cycle when environmental nutrients become scarce. To test this hypothesis, we observed the growth of *S. cerevisiae* cultures by microscopy after we deprived them of essential nutrients instantaneously, noting each cell's position relative to Start. Here, we report three observations made using this approach.

1. Each *S. cerevisiae* cell contains sufficient internal reserves to grow, pass Start, and produce a viable daughter when deprived many single nutrients (e.g.  $(\text{NH}_4)_2\text{SO}_4$ , glycerol, metals, etc.). Many cells complete more than one cell cycle after withdrawal of these nutrients, then they arrest in G1, before Start.
2. Glucose is an exception to this rule: its withdrawal induces immediate growth arrest, irrespective of cell cycle position. In the arrested state, cell size remains constant for hours and cells neither bud nor divide. If glucose is re-supplied, arrested cells resume growth and progress through the cell cycle without delay or loss of viability. These results suggest while Start can accumulate cells in G1 when environmental conditions worsen generically, glucose-grown cells have an additional, dominant "emergency brake" that can halt the cell cycle at any position when glucose is withdrawn.
3. Consistent with this interpretation, we have identified mutations that remove the glucose-responsive "emergency brake." These mutants react to glucose withdrawal differently if they are in different phases of the cell cycle: newborn cells fail to pass Start; cells that have passed Start continue to grow, divide, and arrest in the next G1. Current work aims to identify molecular components and regulators of the "emergency brake" and understand the fitness costs associated with not engaging it properly during environmental transitions.

1141

**Cdk1 inhibitors rapidly diverge their phosphorylation sites but maintain phosphodegron function.**

E. Valk<sup>1</sup>, J. I. Gutierrez<sup>2</sup>, M. Loog<sup>1</sup>, L. J. Holt<sup>2</sup>; <sup>1</sup>Institute of Technology; University of Tartu, Tartu, Estonia, <sup>2</sup>UC Berkeley, Berkeley, CA

The general architecture of the cell cycle is conserved but the molecular details underpinning this network are highly divergent. For example, all cell cycles described so far involve a mutual antagonism between the Cyclin Dependent Kinase (Cdk1) and a stoichiometric inhibitor of Cdk1 (Cki), but the Cki molecule cannot be recognized across lineages by sequence homology. Upon reaching a certain threshold of cyclin accumulation, Cdk1 phosphorylates the Cki to create a phosphodegron thus creating a double negative feedback loop. In *S. cerevisiae*, the Cki phosphodegron is generated by a complex processive phosphorylation cascade. This cascade has been proposed to set the thresholds for the G1-S transition and mitotic-exit; generate switch-like behavior for Cki destruction; and filter noise from other kinase signalling pathways. However, the arrangement of Cdk1 consensus sites in the degron of the Cki has diverged extensively. We have characterized divergent degrons *in vitro* and *in vivo*. Even the most divergent degrons retain function when imported into *cerevisiae* and support viability. The kinetics of destruction of divergent degrons is strikingly similar *in vivo* despite huge differences in phosphorylation efficiency and processivity *in vitro*, indicating that this system has substantial robustness to change. However, the signal processing fidelity of divergent degrons seems to have degraded in terms of discrimination between Cdk1 input and spurious inputs from mating pathway kinases.

1142

**Prion-like behavior regulates cyclin transcript localization and cell-cycle control.**

C. Lee<sup>1</sup>, H. Zhang<sup>1</sup>, A. Baker<sup>1</sup>, P. Occhipinti<sup>1</sup>, M. Borsuk<sup>2</sup>, A. Gladfelter<sup>1</sup>; <sup>1</sup>MCB, Dartmouth College, Hanover, NH, <sup>2</sup>Thayer School of Engineering, Dartmouth College, Hanover, NH

Mechanisms for positioning mRNAs in the cytoplasm is well established in early development but are not well understood in cycling cells. We show here that a specific G1 cyclin transcript is clustered and not uniformly distributed in the cytoplasm of large multinucleate cells. This anomalous cyclin transcript localization results from prion-like behavior of an RNA-binding protein, and deletion of a poly-glutamine stretch in this protein results in random transcript localization. These multinucleate cells, like many tumor cells, are remarkable in that nuclei cycle asynchronously despite sharing a common cytoplasm. Notably randomization of cyclin transcript significantly diminishes nucleus-to-nucleus differences in the local levels of mRNAs and synchronizes cell-cycle timing. Thus, autonomous and variable nuclear cycling in a common cytoplasm arises due to prion-like behavior of an RNA-binding protein. Many RNA-binding proteins from yeast to humans exhibit polyQ expansions and areas of low structural complexity, suggesting that polyQs may be a physiological mechanism for non-random positioning of transcripts and generating variability in cell cycle timing.

1143

 **$\gamma$ -tubulin has a significant role in inactivating APC/C<sup>Cdh1</sup> at the G<sub>1</sub>/S boundary.**

H. Edgerton-Morgan<sup>1</sup>, B. R. Oakley<sup>1</sup>; <sup>1</sup>Molecular Biosciences, University of Kansas, Lawrence, KS

Our lab has found that  $\gamma$ -tubulin has a role in regulating the anaphase promoting complex/cyclosome (APC/C) in interphase. In *Aspergillus nidulans*, a cold-sensitive mutant

allele of  $\gamma$ -tubulin, *mipAD159*, causes a nuclear-autonomous failure of inactivation of the APC/C at some point between late mitosis and S phase when grown at a restrictive temperature, resulting in constitutive destruction of cyclin B and removal of nuclei from the cell cycle (Nayak *et al.*, 2010, *J. Cell Biol.*, 190, 317-330). In many organisms Cdh1 activates the APC/C in G<sub>1</sub>, targeting S-phase cyclins for destruction. This prevents the onset of S phase and APC/C<sup>Cdh1</sup> must, thus, be inactivated for S phase to be initiated. In *A. nidulans*, cyclin B is an S-phase cyclin and this raised the possibility that *mipAD159* causes a failure of inactivation of APC/C<sup>Cdh1</sup> at the G<sub>1</sub>/S transition. We identified, GFP-tagged, and deleted the *A. nidulans* homolog of *cdh1*, and we designate the gene *cdhA* and its product CdhA. CdhA-GFP localizes to the nucleoplasm and spindle pole body (SPB) in late G<sub>2</sub>, disappears shortly before mitosis, returns to both locations at the beginning of G<sub>1</sub>, and disappears from the SPB at G<sub>1</sub>/S. We found that *cdhA* is not essential, but CdhA targets cyclin B for destruction in G<sub>1</sub> and is required to prevent cyclin B from accumulating in subapical cells. CdhA is not, however, required for the localization of cyclin B to the SPB. To determine if *mipAD159* caused failure of inactivation of APC/C<sup>CdhA</sup>, we created a strain carrying *mipAD159* and the *cdhA* deletion. We found that cyclin B accumulated in all nuclei. These data reveal that  $\gamma$ -tubulin plays an important role in inactivation of APC/C<sup>CdhA</sup> at the G<sub>1</sub>/S boundary. Accumulating data suggest that localization of mitotic and cell cycle regulatory proteins to polar microtubule organizing centers such as centrosomes and SPBs is important for their activity and, consequently, their roles in mitosis and cell cycle progression. We, therefore, examined the localization of CdhA in strains carrying *mipAD159*. We found that CdhA failed to dissociate from the SPB in nuclei that failed to accumulate cyclin B and cyclin dependent kinase 1. These data suggest that *mipAD159* causes failure of dissociation of CdhA from the SPB resulting in continuous APC/C<sup>CdhA</sup> activity and failure to enter S phase. Since *mipAD159* is a recessive allele (Jung *et al.*, 2001, *Mol. Biol. Cell*, 12, 2119-2136), we hypothesize that  $\gamma$ -tubulin interacts with a protein or protein complex that is required for CdhA destruction or dislocation from the SPB. Supported by NIH grant GM031837.

### Cyclin-specific docking motifs promote phosphorylation of yeast signaling proteins by G1/S Cdk complexes.

S. Bhaduri<sup>1</sup>, P. M. Pryciak<sup>1</sup>; <sup>1</sup>Microbiology and Physiological Systems, University of Massachusetts Medical School, Worcester, MA

Cyclin-dependent kinases (Cdks) drive the eukaryotic cell cycle. In *S. cerevisiae*, a single Cdk (Cdc28) associates with nine different cyclins, which drive specific events at distinct cell cycle stages. Although Cdk activity is generally highest at later stages (S and M), some Cdk substrates are phosphorylated predominantly at the G<sub>1</sub>/S transition. These early Cdk substrates include two signaling proteins in the pheromone response pathway, Ste5 and Ste20, whose phosphorylation is driven preferentially by G<sub>1</sub>/S cyclins (Cln1 and Cln2) and not by G<sub>1</sub>, S, or M cyclins. The basis of this cyclin specificity was previously unknown.

We recently found that both Ste5 and Ste20 have recognition sequences, or “docking” sites, for the G<sub>1</sub>/S cyclins. These docking sites bind specifically to Cln1 and Cln2, but not to other cyclins (Cln3, Clb5, Clb2). They strongly promote Cln1/2-driven phosphorylation of each substrate in vivo, and function largely independent of position and distance to the Cdk sites. They are also functionally interchangeable, as the Ste20 docking site can be used to drive phosphorylation of Cdk sites in Ste5. We exploited this functional modularity to re-wire the Cdk regulatory control of pheromone signaling: i.e., by providing a docking site plus Cdk phosphorylation sites that flank a critical functional domain, we could transfer Cdk regulation from Ste5 onto Ste20. We then used this re-engineered circuit as a tool to identify functional Cln1/2 docking sites in several other Cdk substrates. The number of sites discovered suggests that docking likely facilitates substrate

recognition in many G1/S Cdk targets. Finally, we found that these docking sites enhance substrate phosphorylation in a cyclin-specific manner, and that the cyclin preference can be switched by using a different type of docking site (i.e., an "RxL" motif that binds B-type cyclins). Moreover, we find that an artificial docking interaction can allow any cyclin (i.e., G1, S, M) to drive in vivo phosphorylation of a substrate that is normally G1/S-specific.

Collectively, our results show that some Cdk substrates are intrinsically capable of being phosphorylated by several different cyclin-Cdk forms, but they are poor substrates in vivo without a cyclin-specific docking motif. These findings provide the first examples of docking motifs specific to G1/S cyclins, and they help explain how some Cdk phosphorylation events can be timed to occur early in the cell cycle rather than later.

1145

**Mechanical cell cycle checkpoints mediate control of cell proliferation in epithelial tissues.**

S. J. Streichan<sup>1</sup>, C. R. Hoerner<sup>1,2</sup>, T. Schneidt<sup>1</sup>, D. Holzer<sup>1</sup>, L. Hufnagel<sup>1</sup>; <sup>1</sup>Cell Biology and Biophysics Unit, European Molecular Biology Laboratory (EMBL), Heidelberg, Germany, <sup>2</sup>Department of Biology, Stanford University, Stanford, CA

The control of cell cycle progression in single eukaryotic cells has been well studied from yeast to humans. However, little is known about how proliferation is regulated in the context of epithelial tissues, where cells are mechanically coupled with each other and are constrained by their neighbors, e.g. during development and wound healing.

Here we study the cell cycle progression of Madin-Darby canine kidney (MDCK) cells in response to mechanical manipulations and pharmacological inhibition of the MEK-ERK signaling pathway. Using live cell imaging and advanced image analysis, we find that cell cycle duration correlates with cell size and that there is a characteristic cell size required for G1/S-transition. Moreover, the proliferation rate within a tissue is increased or reduced in a predictable manner by stretching or compressing the tissue, respectively, thereby accelerating or delaying cell cycle progression. We conclude that mechanical checkpoints during cell cycle progression are employed to control proliferation in tissues and maintain tissue integrity.

1146

**Inhibition of TGF- $\beta$  signaling promotes proliferative activity of neonatal cardiomyocytes.**

H. Hino<sup>1</sup>, P. Dai<sup>1</sup>, T. Hatakeyama<sup>1</sup>, Y. Harada<sup>1</sup>, H. Tanaka<sup>1</sup>, T. Takamatsu<sup>1</sup>; <sup>1</sup>Department of Pathology and Cell Regulation, Kyoto Prefectural University of Medicine, Kyoto, Japan

Mammalian cardiomyocytes irreversibly withdraw from the cell cycle and become terminally differentiated shortly after birth. The mechanism underlying this event remains largely unknown. It is already known that the TGF- $\beta$  family is a major cytokine in regulating cell growth, differentiation, adhesion and apoptosis in many cell types. In this study, we examined whether and how TGF- $\beta$  signaling regulates the proliferative activity of neonatal cardiomyocytes. We investigated the effects of TGF- $\beta$ 1 or SB-431542, a potent T $\beta$ RI/ALK5 inhibitor, on the proliferative activity of neonatal rat cardiomyocytes. We found that TGF- $\beta$ 1 stimulation inhibits cardiomyocyte proliferation significantly, while SB-431542 treatment promotes this activity of cardiomyocytes remarkably. To clarify the mechanisms by which TGF- $\beta$  signaling regulates cell cycle progression, we examined whether the expression or subcellular localization of cell cycle regulators, which control the G1 progression and G1/S transition, are affected on TGF- $\beta$  signaling alteration. Exposure to TGF- $\beta$ 1 in cultured cardiomyocytes induced binucleated cardiomyocytes and accumulation of p27 in nuclei. Treatment of cultured cardiomyocytes with

SB-431542 resulted in a significant decrease in nuclear localization of p27. Taken together, our findings suggest that TGF- $\beta$  signaling regulates the proliferative activity of neonatal cardiomyocytes via the cell cycle regulator p27.

1147

**The role of Origin Recognition Complex in chromatin organization.**

S. Giri<sup>1</sup>, A. Chakraborty<sup>1</sup>, Z. Shen<sup>1</sup>, A. Jain<sup>2</sup>, T. Ha<sup>2</sup>, S. G. Prasanth<sup>1</sup>; <sup>1</sup>Cell and Developmental Biology, University of Illinois, Urbana Champaign, Urbana, IL, <sup>2</sup>Biophysics, University of Illinois, Urbana Champaign, Urbana, IL

The Origin Recognition Complex (ORC) is a hetero-hexameric complex required for the initiation of DNA replication in eukaryotes. Apart from its role in replication initiation, ORC plays important roles in several other cellular processes including centrosome duplication, sister chromatid cohesion, chromosome segregation, cytokinesis and heterochromatin silencing. While a lot of progress has been made in elucidating the function of ORC in DNA replication, its role in chromatin organization remains to be clearly elucidated. Our lab has identified a novel protein, ORC-Associated (ORCA/LRWD1), that is a critical component of the pre-replicative complex. ORCA associates with different ORC subunits and with ORC2 directly. The association with ORC2 is required for the stability of ORCA. Furthermore single molecule analysis indicates that one molecule of ORCA associates with one molecule of ORC, one molecule of Cdt1 and two molecules of geminin. Association of ORCA with Cdt1 is during mitosis and G1 while the association with geminin is in post-G1 cells. Knockdown of ORCA leads to defects in ORC loading onto chromatin indicating that ORCA stabilizes ORC on chromatin. We demonstrate that ORCA is required for progression of cells from G1 to S phase of cell cycle. Our data collectively point towards a role of ORCA in regulating cell cycle possibly by modulating the association of ORC with chromatin. The role of ORCA and the different ORC subunits in chromatin organization will be discussed.

**Yeast S-phase B-type cyclin Clb6 is a substrate in late G1 for the cyclin-dependent kinases Cdc28 and Pho85.**

V. J-W. Kuan<sup>1</sup>, W. Wang<sup>1</sup>, Y-W. Tseng<sup>2</sup>, S-Y. Wu<sup>3</sup>, Y-L. Juang<sup>2,3</sup>, S. C. Schuyler<sup>1</sup>; <sup>1</sup>Department of Biomedical Sciences, Chang Gung University, Kwei-Shan, Taiwan, <sup>2</sup>Institute of Medical Sciences, Tzu Chi University, Hualien, Taiwan, <sup>3</sup>Institute Microbiology, Immunology and Biochemistry, Tzu Chi University, Hualien, Taiwan

In budding yeast *Saccharomyces cerevisiae*, the S-phase B-type cyclins Clb5 and Clb6 are transcribed in the G1-phase of the cell cycle, where they bind to the cyclin-dependent kinase (CDK) Cdc28, but the CDK activity is kept off by Sic1, a CDK inhibitor (CKI). Although Clb5 and Clb6 are homologous, the N-termini of the proteins are divergent. The N-terminus of Clb6 contains a D-box motif (R-x-x-L-x-x-x-N) and a KEN box motif, both of which may serve as signals for regulated proteolysis by the anaphase-promoting complex/cyclosome (APC/C), an E3 ubiquitin ligase. The N-terminus of Clb6 also contains three potential SP/TP phosphorylation sites that are thought to contribute to the regulation of Clb6 protein stability regulated by the SCF<sup>Cdc4</sup> ubiquitin ligase later in the cell cycle in S-phase. We have set out to study the regulation of Clb6 protein stability in late G1 by initially investigating the phosphorylation of Clb6. Wild-type Clb6 and a mutant Clb6, with the three potential N-terminal phosphorylation SP/TP sites mutated to alanine, were prepared by *in vitro* transcription/translation and labeled with <sup>35</sup>S-Methionine. Active Cdc28 and Pho85 kinases were isolated out of yeast extracts made from *cdc4-1* temperature-sensitive mutant yeast cells arrested in late G1 at 37°C. In kinase assays,

we have observed that wild-type Clb6 was a substrate for both Cdc28 and Pho85 kinases, whereas the phosphorylation site mutant Clb6 was not. The observed phosphorylation was eliminated by the addition of calf intestinal phosphatase. Initial results have revealed that the cyclin partners of Cdc28 responsible for the phosphorylation of Clb6 are both the G1-phase cyclins Cln1 and Cln2, where Cln2-Cdc28 may be the primary source of kinase activity. Clb6 phosphorylation was found not to be dependent upon S-phase cyclin-CDK activity, such as Clb5-Cdc28 or Clb6-Cdc28 complexes isolated from *cdc4-1* late G1 arrested cells. We are currently investigating which cyclin partner(s) of Pho85 can phosphorylate Clb6 in late G1. Finally, using the phosphorylated form of wild-type Clb6 protein as the target substrate, we plan to perform *in vitro* APC/C<sup>Cdh1</sup> assays to explore whether phosphorylated Clb6 is targeted by regulated proteolysis in late G1.

### Reconstitution of DNA replication licensing on the chromatin fiber.

K. Hizume<sup>1,2</sup>, M. Yagura<sup>1</sup>, H. Araki<sup>1,2</sup>; <sup>1</sup>National Institute of Genetics, Mishima, Japan, <sup>2</sup>the Graduate University for Advanced Studies (Sokendai), Mishima, Japan

Eukaryotic DNA replication initiates at multiple regions of genomic DNA, which is called replication origin. The proper determination of the sites of replication origins is important for stable maintenance of genomic information. Onto replication origins, origin recognition complex (ORC) located throughout the cell cycle in budding yeast, and MCM complex is loaded during G1 phase with the help of Cdc6 and Cdt1. The complex consisting of ORC, MCM, Cdc6, and Cdt1 is called pre-replicative complex (pre-RC), and the formation of pre-RC licenses the replication origin to initiate DNA replication during the next S phase.

Although the assembly process of these proteins on origin has been studied by genetic and biochemical researches, the architecture of ORC or pre-RC on origin has not been understood well. In addition, eukaryotic genome DNA forms chromatin fibers with histones, so that, for understanding the molecular mechanism of the licensing of DNA replication *in vivo*, it is essential to analyze ORC and subsequent pre-RC formation on chromatin fibers.

Here, we reconstituted chromatin fibers from yeast core histones and DNA fragments containing yeast origin sequence and analyzed the interaction between ORC and the chromatin fibers. We found that purified ORC binds to the origin-containing chromatin more stably than to naked DNA and forms a nucleosome-free region at origins by interacting with histones. Molecular imaging using atomic force microscopy (AFM) revealed that ORC associates with adjacent nucleosomes. Moreover, the stable chromatin binding of ORC required linker DNA. Thus, ORC establishes origin-specific interactions by binding both to nucleosome-free-origin DNA and to neighboring nucleosomes. We are also trying to form pre-RC on the reconstituted chromatin, and will discuss how the formation of chromatin fibers on origin DNA affects pre-RC formation.

## Mitotic Spindle-Structure/Organization

### How Cell Size Regulates Spindle Size.

M. C. Good<sup>1,2</sup>, M. D. Vahey<sup>2</sup>, D. A. Fletcher<sup>2</sup>, R. Heald<sup>1</sup>; <sup>1</sup>Molecular & Cellular Biology, UC Berkeley, Berkeley, CA, <sup>2</sup>Bioengineering, UC Berkeley, Berkeley, CA

A mitotic spindle can assemble and function to segregate chromosomes in cells of widely varying sizes, but the extent to which spindle size is regulated directly by cell size is unknown. During *Xenopus laevis* embryogenesis, the 1.2 millimeter diameter egg cleaves rapidly to form

smaller blastomeres, and after an initial plateau phase, spindle size changes linearly with cell size. Major challenges to uncovering physical mechanisms of spindle scaling include recapitulating the broad range of cell sizes found in the embryo, and decoupling cell size and developmental stage. To overcome these issues we developed a system for making synthetic cell-like compartments of defined sizes in vitro. By encapsulating *Xenopus* egg extracts we can create artificial cells of varying size that support spindle assembly. We find that the steady-state length and area of *X. laevis* extract spindles is dependent on the size of the compartment they are assembled in. Specifically, encapsulated spindles possess both an upper and lower size boundary and a linear scaling range. Interestingly, although *X. laevis* and *X. tropicalis* spindles have different steady-state sizes in bulk extract and large compartments, both spindle types converge on the same lower size limit in the smallest compartments. Multiple features of *Xenopus* spindle length regulation under confinement closely match embryo data demonstrating at least in part that spindle scaling can occur independent of developmental regulation. Intriguingly, spindle size tracks more closely with cell volume than with cell geometry, suggesting that spindles respond to the amount of material available in the cell. We propose a limiting substrate model to explain the linear response of spindle size to cell size during frog embryogenesis.

1151

**Fission yeast Psr2 helps establish initial spindle bipolarity and subsequent proper chromosome segregation.**

J. Costa<sup>1</sup>, P. Tran<sup>1,2</sup>; <sup>1</sup>Cell & Developmental Biology, University of Pennsylvania, Philadelphia, PA, <sup>2</sup>UMR 144 CNRS, Institut Curie, Paris, France

Proper chromosome segregation during mitosis is of paramount importance for proper genetic inheritance to daughter cells from mother cells. Fission yeast model organism has proven to be a powerful tool in which to study the mechanisms that control spindle bipolar structure and chromosome segregation. Mis-segregation of chromosomes can lead to aneuploidy and chromosome instability, which are hallmarks of cancer cells and other human diseases. Chromosome segregation is accomplished by the mitotic spindle, composed of microtubules, microtubule-associated proteins (MAPs), motors and other regulatory proteins. The spindle is a bipolar structure, with microtubules emanating from opposite poles crosslinking and overlapping at the spindle midzone in an antiparallel manner. Spindle bipolarity establishment is generally thought to be accomplished by the motor kinesin-5. However, kinesin-5 can equally generate parallel or antiparallel microtubules. What then organizes antiparallel microtubules required for spindle bipolarity? In a screen for fission yeast Spindle Assembly Defective mutants, we discovered Psr2 (Pole Separation Regulator 2). Psr2-deletion leads to transient monopolar spindle, longer spindle at metaphase-anaphase transition, and subsequent significant chromosome segregation defects.

Psr2p localizes to the spindle pole body (SPB), and its localization is dependent on the conserved Sad1p/SUN protein and Psr1p. Psr1-deletion has been shown in our lab to have transient monopolar spindle, prolonged prophase-metaphase, and chromosome segregation defects, similar to Psr2-deletion. In addition, Psr1p binds the conserved Mal3p/EB1, and presumably microtubule plus ends emanating from the opposite poles. This leads to antiparallel microtubules to initial spindle bipolarity. Psr2 and Psr1 may interact in the same pathway. Interestingly, Psr1p also requires Psr2p to localize to the SPB, but only specifically at the start of mitosis through early anaphase. Our findings give better understanding of the mechanism for prophase bipolar spindle establishment, and its importance for subsequent faithful chromosome segregation.

**Furry is a positive regulator of microtubule acetylation in mitotic spindle.**

T. Nagai<sup>1</sup>, S. Chiba<sup>1</sup>, M. Ikeda<sup>1</sup>, S-I. Kanno<sup>2</sup>, A. Yasu<sup>2</sup>, K. Ohashi<sup>1</sup>, K. Mizuno<sup>1</sup>; <sup>1</sup>Grad. Sci. Life Sci., Tohoku University, Sendai, Japan, <sup>2</sup>Inst. of Dev., Aging and Cancer., Tohoku University, Sendai, Japan

During mitosis, microtubules form the bipolar spindle that separates chromosomes into two daughter cells. Tubulin subunits of mitotic spindle are subject to several post-translational modifications, including acetylation of  $\alpha$ -tubulin at Lys-40. Tubulin acetylation is a "stable marker" of microtubule lattice and affects the function of microtubule-binding kinesin motors. Whereas several regulators of tubulin acetylation have been identified, functional significance and regulatory mechanisms of tubulin acetylation in mitotic spindle are still largely unknown. Furry (Fry) is an evolutionarily conserved protein from yeast to human. Previous studies showed that Fry is involved in polarized cell growth, morphogenesis, and cell cycle progression in yeast and invertebrates. We previously showed that mammalian Fry is required for proper formation of spindle microtubules and precise alignment of mitotic chromosomes and that Fry has the potential to directly bind to microtubules and localizes on the mitotic spindle. However, it is unclear how Fry affects the microtubule function during mitosis. In this study, we show that Fry is a positive regulator of microtubule acetylation. Knockdown of Fry reduced the level of spindle microtubule acetylation in HeLa cells. Transient expression of the N-terminal fragment of Fry induced microtubule hyperacetylation in interphase cells. These results indicate that Fry has the potential to up-regulate the level of microtubule acetylation via its N-terminal region. Moreover, we identified SIRT2 tubulin deacetylase as a novel Fry-binding protein. Fry bound to SIRT2 via its N-terminal region and this interaction was increased in mitotic cells. Fry did not bind to a catalytically inactive mutant of SIRT2, which suggests that Fry inhibits SIRT2 activity by binding to the catalytic domain of SIRT2. *In vitro* microtubule deacetylation assays revealed that Fry inhibits SIRT2 activity via its N-terminal region. Together these findings suggest that Fry is involved in the positive regulation of spindle microtubule acetylation through localization on the spindle microtubules and inhibition of the tubulin deacetylase activity of SIRT2.

1153

**Mars and Mei-38: The roles of two spindle assembly factors in *Drosophila* syncytial embryos.**

D. Hayward<sup>1</sup>, J. G. Wakefield<sup>1</sup>; <sup>1</sup>Biosciences, University of Exeter, Exeter, United Kingdom

The microtubules (MTs) that comprise the mitotic spindle are generated from multiple sites from within the cell. Condensed mitotic chromosomes themselves have long been proposed as a source of MTs, including those emanating directly from kinetochores. TPX2 and HURP are two key proteins implicated in the formation and maintenance of kinetochore MTs in vertebrates. Both have been implicated in promoting MT polymerisation and stabilisation and their presence in complex together is suggestive of co-operative function. However, their exact mechanistic roles in chromatin mediated MT formation have yet to be determined.

*Drosophila melanogaster* provides an excellent biological system for the study of mitotic spindle formation, in which biochemical and proteomic analyses can be complemented with genetic and cell biological techniques. Mars has been proposed as the *Drosophila* homologue for HURP, while our research group, and others, have proposed Mei-38 as a potential TPX2 homologue. We are investigating the comparative roles of Mei-38 and Mars with the aim of understanding their contributions to chromatin mediated MT formation.

During interphase of embryos expressing GFP-fusions, both Mei-38 and Mars are present in the nucleoplasm, like TPX2 but unlike the cytoplasmically localised HURP. Both proteins show similar localisation patterns to spindle MTs throughout mitosis, with Mei-38 additionally present at centrosomes. We show that Mei-38 is able to promote MT polymerisation and bind to and bundle MTs in vitro. Equivalent experiments with recombinant Mars demonstrate MT binding properties, but no evidence of MT polymerisation or bundling. Surprisingly, the absence of Mei-38 does not have a huge significance on spindle formation or embryonic development. Flies are viable and fertile, though spindles exhibit a delay in metaphase-anaphase progression and a decrease in spindle length. In comparison, Mars null flies are female sterile, with embryos failing at the first mitotic cycle. A hypomorphic Mars mutant reveals multiple spindle failures including frequent centrosome detachment, monopolarity and short spindles.

By employing the use of GFP to immunoprecipitate interacting MAPs, double mutants and interfering antibody injections, we aim to establish the role each protein plays in building kinetochore microtubules.

1154

**The *Arabidopsis* augmin complex contains two plant specific subunits and plays a critical role in microtubule organization during cell division.**

T. Hotta<sup>1</sup>, Z. Kong<sup>1</sup>, C-M. K. Ho<sup>1</sup>, C. T. Zeng<sup>1</sup>, T. Horio<sup>2</sup>, S. Fong<sup>1</sup>, T. Vuong<sup>1</sup>, Y-R. J. Lee<sup>1</sup>, B. Liu<sup>1</sup>; <sup>1</sup>Department of Plant Biology, University of California, Davis, Davis, CA, <sup>2</sup>Department of Molecular Biosciences, University of Kansas, Lawrence, KS

Microtubules are organized into the bipolar spindle array to ensure accurate segregation of chromosomes during cell division. It has been realized that in animal cells centrosome-independent and microtubule-dependent microtubule nucleation directly contributes to spindle assembly, in addition to those initiated from the centrosomes and chromosomes. It has been shown that the  $\gamma$ -tubulin complex is targeted to spindle microtubules via the augmin complex in order to initiate microtubule nucleation and consequently to amplify microtubules in animal spindles. In higher plant cells that lack the centrosome, we tested whether an augmin complex functioned in spindle microtubule nucleation and organization. Using AUG3 which has limited homology with the human augmin subunit HAUS3 as the bait, we successfully purified the augmin complex from the seedling of *Arabidopsis* and identified eight subunits (AUG1 to AUG8) based on mass spectrometry analysis. Among them, AUG7 and AUG8 are plant specific proteins whose homologs can only be found in the plant kingdom, while the other six subunits (AUG1 to AUG6) show weak similarity to their animal counterparts. They exhibit a localization pattern similar to that of  $\gamma$ -tubulin during mitosis. Insertional mutations of *aug1*, *aug2*, *aug3*, *aug4* and *aug5* at the corresponding loci were only inherited by heterozygous plants, suggesting these AUG subunits to be essential. We isolated a sterile *aug7* homozygous mutant in which *AUG7* was expressed at a considerably lower level than the wild-type control. This mutant exhibited phenotypes of severe growth retardation.  $\gamma$ -Tubulin was barely detected in spindles and phragmoplasts of the *aug7* cells, and concomitantly these microtubular arrays were disorganized. We conclude that plant cells deploy an evolutionarily conserved augmin-dependent mechanism to organize microtubules during the mitosis and cytokinesis.

1155

### The Three-dimensional Organization of the *Xenopus laevis* Meiotic Spindle Resolved Using Electron Tomography.

E. M. Tranfield<sup>1</sup>, I. Peristere<sup>1</sup>, J. Ellenberg<sup>1</sup>, F. Nedelec<sup>1</sup>, C. Antony<sup>1</sup>; <sup>1</sup>European Molecular Biology Laboratory, Heidelberg, Germany

Understanding the packing density, length, spacing, and polarity of the microtubules (MTs) in the vertebrate spindle is important for extending our understanding of the spindle functionality. Light microscopy studies in *Xenopus laevis* egg extract propose a dynamic tiled array of MTs that are cross-linked and focused during bipolar spindle assembly. However, the three-dimensional (3D) organization of the vertebrate spindle at the level of individual MTs is still unresolved. Using electron tomography it is now possible to image large areas and we aim to image half of the large *Xenopus laevis* meiotic spindle, as assembled in the well established cell-free egg extract, and to resolve its 3D organization. The quality and location of the spindles in a sample are assessed using light microscopy, and correlative light and electron microscopy is used to retrieve spindles of interest after sample processing. Well-formed, isolated spindles are high-pressure frozen, freeze substituted and processed into plastic for electron tomography. Spindles are serial sectioned parallel to their long axis and the sections are screened on a transmission electron microscope to verify MT orientation and chromosome integrity. For samples that fulfill these criteria, high magnification supermontage tilt series are acquired on a FEI Tecnai F30 transmission electron microscope, and reconstructed into large tomograms. Tomograms from serial sections are stacked together into a large 3D volume. MT and chromosome masses are modeled using the Filament Editor tool in Amira. To date, a partial volume of the spindle extending from pole to midzone has been acquired, and reconstructed. Modeling of the data is currently underway. We will present our current model of the spindle from which we hope to gain insight into the detailed spatial organization of microtubules in the vertebrate spindle.

1156

### The inter-relationship between spindle assembly pathways in *Drosophila* syncytial embryos.

D. Hayward<sup>1</sup>, J. G. Wakefield<sup>1</sup>; <sup>1</sup>Biosciences, University of Exeter, Exeter, United Kingdom

Mitotic spindle formation is an example of an inherently flexible and robust biological system, where at least three well-described molecular mechanisms of microtubule (MT) generation act co-operatively to ensure faithful chromosome segregation. The predominant source of MTs for the spindle are the centrosomes, electron dense organelles that recruit the MT nucleator, gamma-tubulin. Despite their predominance, it has been shown that centrosomal MTs are dispensable for spindle formation in some experimental systems. Generation of MTs also occurs in the vicinity of mitotic chromatin, both through stabilisation of MTs by the activation of spindle assembly factors (SAFs) and through nucleation from kinetochores. MTs contributing to the mitotic spindle are also generated from pre-existing spindle MTs through the action of the Augmin protein complex.

While we know much about the molecular details of these three pathways, little is known about how they interact, and the mechanisms by which they can compensate for the loss of each other. Simultaneous perturbation of multiple pathways can be used to advance our understanding of these phenomena, however not without complications; a purely genetic approach often results in lethality, making it impossible to analyse spindle formation itself, while RNAi gradually reduces protein function over a number of days, leading to pleotropic effects that are difficult to analyse. Instead, we have employed a combined approach of analysing MT

organisation during spindle formation in embryos carrying mutations in genes required for specific MT generation pathways, or in embryos injected with interfering antibodies against these proteins. Loss of centrosomal MTs, through inactivation of the core centriolar protein Spd2, results in the formation of multiple MT nucleating sites, whose MTs nonetheless coalesce to form a functional bipolar spindle. In contrast, removal of Augmin results in a significant delay in MT generation at the onset of mitosis, with astral MTs eventually connecting to kinetochores to form a bipolar spindle.

We will further discuss our results, and their implications for the formation of centrosomal, chromatin mediated and Augmin generated MTs.

1157

**A novel role for the IFT B complex in mitotic spindle assembly.**

*A. Bright<sup>1</sup>, S. Doxsey<sup>1</sup>; <sup>1</sup>Program in Molecular Medicine, University of Massachusetts Medical School, Worcester, MA*

Intraflagellar transport (IFT) is a bidirectional transport system required for ciliogenesis. IFT proteins form multimeric complexes, A and B, which transport pre-assembled ciliary components along the axoneme while riding microtubule motors. Cilia disruption causes ciliopathies, characterized by cystogenesis and misoriented cell division. Interestingly, several IFT proteins localize to mitotic spindle poles, suggesting a role for these proteins in mitosis. In fact, we previously showed that IFT B complex member, IFT88, is part of a dynein-1 driven mitotic transport complex required for spindle orientation. (Delaval, Bright et al, NCB, 2011). However, nothing is known about the remaining ciliary IFT B complex members' mitotic function. We addressed this by comparing IFT B complex size during mitosis and interphase, and found that the complex is maintained in mitosis even in the absence of cilia. Furthermore we identified mitotic interactions between several IFT B complex members and dynein-1, confirming the existence of a mitotic IFT B/dynein-1 complex. These results provided an argument for characterizing mitotic functions for additional IFT B complex proteins (eg. IFT57, IFT52, and IFT20). Like IFT88, IFT57 and IFT20 depletions caused several mitotic defects including disrupted spindle poles, non-congressed chromosomes, increased mitotic index, etc. Surprisingly, IFT52 displayed none of these phenotypes. Because these mitotic disruption phenotypes resemble dynein-1 depletion we tested whether IFT depletion affects dynein-1 function. Surprisingly, dynein-1 levels are increased specifically during mitosis when IFT88 or IFT57 is depleted, while IFT52 depletion decreases dynein-1. With this striking result we conclude that IFT proteins are not passive dynein-1 passengers, but are in fact actively regulating dynein-1 during mitosis. This work raises the important possibility that mitotic, as well as cilia defects could contribute to ciliopathies.

1158

**Spindle Length Scales with XMAP215-dependent Microtubule Growth Rates in Agreement with a Mass-Balance Model.**

*S. Reber<sup>1</sup>, J. Baumgart<sup>2</sup>, P. Widlund<sup>1</sup>, A. Pozniakovskiy<sup>1</sup>, F. Julicher<sup>2</sup>, T. Hyman<sup>1</sup>; <sup>1</sup>MPI-CBG, Dresden, Germany, <sup>2</sup>MPI-PKS, Dresden, Germany*

Although we have extensive knowledge of individual proteins that modulate microtubule dynamics, we still lack an understanding of the mechanisms by which their collective properties give rise to a spindle with a defined size and shape. Here, we describe spindle size using a mass balance model, which implies that rates of gain and loss of microtubule polymer are equal for a spindle of constant size. Microtubule mass balance depends on microtubule nucleation,

growth and lifetime. To test this model, we modulate microtubule growth independently of other kinetic parameters by using mutants of the XMAP215 microtubule polymerase in *Xenopus* spindles. We show that spindle length increases linearly with microtubule growth velocities. Taken together, the combined theory and experiment allow us to relate the molecular activity of the polymerase directly to spindle length. We conclude that spindle length is determined by microtubule mass balance in a liquid crystal drop of constant microtubule density.

1159

**Tension-dependent dynamic microtubule model for metaphase and anaphase phenomena.**

*E. J. Banigan<sup>1</sup>, M. A. Lampson<sup>2</sup>, A. J. Liu<sup>1</sup>; <sup>1</sup>Physics & Astronomy, Univ Pennsylvania, Philadelphia, PA, <sup>2</sup>Biology, Univ Pennsylvania, Philadelphia, PA*

We present a simple theoretical model that captures key phenomena of eukaryotic chromosome segregation such as metaphase chromosome oscillations, microtubule (MT) attachment error correction, and anaphase chromosome separation. During metaphase, chromosome pairs align near the center of a bipolar MT spindle and oscillate as the MTs attaching them to the cell poles polymerize and depolymerize. Simultaneously, the cell fixes misaligned chromosome pairs that are attached to only one cell pole by some tension-dependent mechanism. Finally, in anaphase, chromosome pairs separate as each chromosome in the pair is pulled by depolymerizing MTs toward its respective cell pole. Despite the ubiquity of these phenomena, their details vary from system to system. Instead of including all known components to develop a comprehensive, species-specific description, we introduce a minimal model based on fundamental properties of MT kinetics. We use the tension-dependence of the rates of single MT polymerization/depolymerization kinetics measured by Akiyoshi et al. [1] and assume that the same functional dependence holds for the compression dependence. We apply these kinetics to many MTs connected to kinetochores to form a spindle, and solve this stochastic model numerically and by a master equation approach. We find that tension dependence of the rate constants enhances the speed at which a single chromosome is pulled by MTs during anaphase- or error-correction-like behavior. Furthermore, we show that the force-velocity curve for the single chromosome attached to dynamic MTs exhibits behavior reminiscent of a phase transition: at high loads, large tension fluctuations induce the MTs to spontaneously switch from a depolymerizing state into a polymerizing state. The system is hysteretic; upon decreasing the load on a chromosome being pushed by growing MTs, the system remains in the polymerizing state for loads far smaller than those required to initially induce polymerization. This behavior leads to the chromosome oscillations we observe in the two-chromosome system. Interestingly, in the two-chromosome system, we observe breathing oscillations, which are not captured by any other existing model of chromosome oscillation. Altogether, our model reflects generic features of three phenomena in eukaryotic mitosis and leads to an understanding of their underlying mechanisms. The minimal model can also be used to understand how different components affect these phenomena via the rate constants.

1160

**Force-balance model of suppression of multipolar division in cancer cells with extra centrosomes.**

*J. Zhu<sup>1,2</sup>, M. Kwon<sup>3,4</sup>, M. Bagonis<sup>5</sup>, D. Pellman<sup>3,4,6</sup>, A. Mogilner<sup>1,2</sup>; <sup>1</sup>Mathematics, UC Davis, Davis, CA, <sup>2</sup>Neurobiology, Physiology, and Behavior, UC Davis, Davis, CA, <sup>3</sup>Pediatrics, Harvard Medical School, Boston, MA, <sup>4</sup>Dana-Farber Cancer Institute, Boston, MA, <sup>5</sup>Cell Biology, Harvard Medical School, Boston, MA, <sup>6</sup>Howard Hughes Medical Institute, Chevy Chase, MD*

Cancer cells often possess extra centrosomes which have the potential to cause cell death due to catastrophic multipolar division. Many cancer cells, however, are able to escape multipolar mitosis by clustering the extra centrosomes to form bipolar spindles. The mechanism of centrosome clustering is therefore of great interest to the development of anti-cancer drugs because the de-clustering of extra centrosomes provides an appealing way to eliminate cancer cells while keeping healthy cells intact. We present a physical model assuming 1) dynamic centrosomal microtubules interact with chromosomes by both pushing on chromosome arms and pulling along kinetochores; 2) these microtubules interact with force generators associated with actin/adhesion structures at the cell boundary; and 3) motors act on anti-parallel microtubules from different centrosomes. We find via computer simulations that chromosomes tend to aggregate near the cell center while centrosomes can be either clustered to form bipolar spindles or scattered to form multipolar spindles, depending on the strengths of relative forces, cell shape and adhesion geometry. The model predictions agree with data from cells plated on adhesive micropatterns and from biochemically or genetically perturbed cells. Furthermore, our model is able to explain various microtubule distributions in interphase cells on patterned substrates.

1161

**Establishing the copy number and centromeric architecture of the centromere-specific histone Cse4p.**

*A. P. Joglekar<sup>1</sup>; <sup>1</sup>Cell & Developmental Biology, University of Michigan Medical School, Ann Arbor, MI*

Considerable debate exists regarding the copy number of the centromere-specific histone H3 variant Cse4p and the physical conformation of the centromeric locus in budding yeast. Estimates of Cse4p copy number per kinetochore, mainly obtained using fluorescence microscopy in cells expressing Cse4-GFP fusion protein, range from exactly one Cse4p molecule per kinetochore to 6-8 molecules. Although biochemical studies point to Cse4p incorporation exclusively at the CEN locus, whether the structure containing Cse4p molecule/s is a hemisome, two hemisomes, a canonical nucleosome, or a heterotypic nucleosome remains unknown. To obtain Cse4p count in live cells, we conducted stepwise photobleaching measurements of single budding yeast kinetochores carrying Ndc80-GFP(S65T) in live cells. Objective statistical analysis of photobleaching time series allowed us to determine the molecular brightness for GFP within the yeast nucleus in mid-anaphase arrested cells. This molecular brightness is consistent with 6-7 Ndc80 molecules per kinetochore in anaphase. Comparison of Ndc80-GFP signal in metaphase and anaphase also revealed that there is little change in the molecular count for this complex over these phases of the cell cycle, as reported before. As reported before, the metaphase and anaphase ratio of Ndc80-GFP and Cse4-GFP is 3.5 and 4 respectively. Therefore, we conclude that there are 2 copies of Cse4p per yeast kinetochore in both metaphase and anaphase. We are developing related microscopy techniques including FRET to fully establish the physical conformation of the Cse4p molecules at the centromeric locus. Our goal is to establish the physical architecture of the foundation of the kinetochore-microtubule attachment.

1162

**Kif18A and Kif4A suppress the growth of different subsets of spindle microtubules to antagonistically control chromosome alignment.**

J. Stumpff<sup>1</sup>, C. Fonseca<sup>1</sup>, J. Thompson<sup>1</sup>, M. Wagenbach<sup>2</sup>, L. Wordeman<sup>2</sup>; <sup>1</sup>Molecular Physiology and Biophysics, University of Vermont, Burlington, VT, <sup>2</sup>Physiology and Biophysics, University of Washington, Seattle, WA

The alignment of chromosomes at the equator of the microtubule-based mitotic spindle is one of the most conspicuous steps of the cell division process, however, the mechanisms that control alignment are not understood. Mitotic chromosome movements are intimately coupled to the growth and shortening of bundles of microtubules, called K-fibers, which attach chromosomes to the spindle via a specialized protein structure called the kinetochore. K-fiber dynamics must be spatially controlled to align and maintain chromosomes at the spindle equator. Two kinesin-like motor proteins, Kif18A (kinesin-8) and Kif4A (kinesin-4), play critical roles in providing this control. Interestingly, these two kinesins are both plus-end directed motors that suppress microtubule growth *in vitro*, yet oppositely affect chromosome alignment. We demonstrate that Kif18A and Kif4A suppress different subsets of microtubules within the spindle and that targeting the Kif4A motor to the plus-ends of K-fibers can functionally compensate for the loss of Kif18A activity. Collectively, these data suggest that similar modifications of microtubule dynamics can have profoundly different effects when applied to different classes of spindle microtubules.

1163

**Elevated polar ejection forces stabilize kinetochore-microtubule attachments.**

S. Cane<sup>1</sup>, A. A. Ye<sup>1</sup>, S. J. Luks-Morgan<sup>2</sup>, T. J. Maresca<sup>1,2</sup>; <sup>1</sup>Molecular and Cellular Biology Graduate Program, University of Massachusetts Amherst, Amherst, MA, <sup>2</sup>Biology Department, University of Massachusetts Amherst, Amherst, MA

Chromosome biorientation promotes congression and generates elevated tension that stabilizes kinetochore-microtubule (kt-MT) interactions. Molecular motors also contribute to chromosome alignment, but it is unclear how motor forces impact kt-MT attachment stability. A critical force that acts on mitotic chromosomes is the kinesin-10-dependent polar ejection force (PEF), which has been proposed to facilitate congression by pushing chromosome arms away from spindle poles. Here we describe a live-cell PEF assay in which expression levels of the chromokinesin NOD (*D. melanogaster* kinesin-10) are experimentally controlled. Application of the assay revealed that PEFs hyper-stabilize syntelic kt-MT attachments in a dose- and motor-dependent manner. Aurora B kinase activity is unaffected by NOD overexpression indicating that elevated PEFs overwhelm Aurora B-mediated correction of syntelic attachments. We expect the PEF assay to be a valuable tool for defining how forces regulate kt-MT interactions and error correction in living cells.

## Cilia and Flagella II

### Screening a Million Mutations to Identify Novel Ciliary proteins.

T. A. Timbers<sup>1</sup>, V. L. Jensen<sup>1</sup>, S. Garland<sup>2</sup>, D. G. Moerman<sup>2</sup>, M. R. Leroux<sup>1</sup>; <sup>1</sup>Molecular Biology and Biochemistry, Simon Fraser University, Burnaby, BC, Canada, <sup>2</sup>University of British Columbia, Vancouver, BC, Canada

Cilia are primordial microtubule-based organelles found on most vertebrate cell types. Motile cilia perform well-understood roles, such as enabling sperm locomotion, and clearing debris from respiratory airways. How non-motile (primary) cilia enable sensory physiology (vision, smell, hearing) and modulate various signaling pathways (Wnt, Hedgehog, PDGF) important for development, are, in comparison, less well understood. Primary cilia are implicated in many human disorders including polycystic kidney disease and Bardet-Biedl syndrome, and disrupting their functions collectively results in retinal degeneration, kidney cyst formation, obesity, brain malformations, and various other ailments. To uncover novel proteins required for the formation and function of primary cilia, we have undertaken an innovative, high-throughput screen for cilia structure and function using a library of 2,000 mutagenized *C. elegans* strains, which altogether carry about 1 million mutations. As the genomes of these mutant strains are sequenced and annotated, we are able to rapidly identify the mutation responsible for the observed ciliary phenotype, eliminating the rate-limiting cloning step required in genetic screens. Using this approach, we have identified *C. elegans* strains with novel mutations that result in gross defects in cilia structure, which we identify with a simple, commonly used dye-filling (dyf) assay, in which worms are incubated in a lipophilic dye (e.g. Dil) that fills ciliated sensory neurons through ciliary membranes that are (normally) exposed to the environment. We are also identifying mutants with abrogated ciliary functions, identified by assaying cilia-dependent behaviors, including starvation pattern, dauer formation and CO<sub>2</sub> avoidance. Detailed molecular and cellular analysis of the most interesting candidates (genes that are novel and possess a human orthologue) from this screen in both *C. elegans* and mammalian tissue culture will provide new insights into the factors required for cilium biogenesis, structure and function, a fundamental cellular process that also has important biomedical implications.

### Characterization of BBC73, a *Tetrahymena thermophila* ortholog of the human EFHC1.

Y. Zhao<sup>1</sup>, T. Giddings<sup>1</sup>, M. Winey<sup>1</sup>; <sup>1</sup>University of Colorado Boulder, Boulder, CO

The basal body is a microtubule-based cellular structure found widely in eukaryotes. At its core the basal body contains a radial array of nine triplet microtubules. Basal bodies reside at the cell surface where they act to form motile cilia or the immotile, sensory primary cilia. Dysfunctional basal body or ciliary components have been implicated in a number of human diseases known as ciliopathies. We identified Bbc73 in a *Tetrahymena* basal body proteome (Kilburn, Pearson *et al.* 2007. *J. Cell Biol.* **178**:905 – 912). Bbc73 is highly conserved from ciliates to humans. Mutations in the human ortholog EFHC1 was been found to cause juvenile myoclonic epilepsy (Suzuki *et al.* 2004. *Nature Genetics.* **36**: 842 - 849). We have localized Bbc73 to both the basal bodies and the cilia at endogenous levels in *Tetrahymena*. Immunoelectron microscopy further revealed that Bbc73 mainly localizes to the microtubule scaffold of the basal bodies. We also demonstrated that the N terminal domain of Bbc73 is responsible for its localization by deletion mutant analysis. We have also identified a paralog of Bbc73 in *Tetrahymena* genome. This protein (Bbc60) exhibits a localization pattern similar to Bbc73. A complete genomic knockout

analysis of *BBC73* is being constructed with the expectation that the phenotypes of the null strain will contribute to understanding the function of this protein.

1166

**Investigation of a novel cilia-related gene K04F10.2/KIAA0556.**

A. Sanders<sup>1</sup>, E. Malarkey<sup>2</sup>, E. van Wijk<sup>3</sup>, J. van Dam<sup>3</sup>, S. Cevik<sup>1</sup>, R. Bowie<sup>1</sup>, K. Kida<sup>1</sup>, R. Russell<sup>4</sup>, R. Roepman<sup>3</sup>, H. Kremer<sup>3</sup>, B. Yoder<sup>2</sup>, O. Blacque<sup>1</sup>; <sup>1</sup>University College Dublin, Dublin, Ireland, <sup>2</sup>University of Alabama at Birmingham, Birmingham, AL, <sup>3</sup>Radboud University Nijmegen Medical Center, Nijmegen, Netherlands, <sup>4</sup>CellNetworks, University of Heidelberg, Heidelberg, Germany

Multiple proteomics and genomics approaches have been used to identify the molecular parts list of cilia and flagella. However, the specific cilia-related functions of many of these components remain unknown. Previously, K04F10.2 was identified as a candidate cilia-related gene in *C. elegans*, exhibiting specific expression in ciliated sensory neurons. Evolutionarily conserved, K04F10.2 encodes a protein with motifs homologous to galactose binding domains. GFP-tagged K04F10.2 is enriched at the ciliary transition zone (TZ) and at the more proximal basal body region. Although K04F10.2 null mutants possess grossly normal cilium structure and ultrastructure, overexpression of K04F10.2 results in a dye-filling abnormality (Dyf), short cilia, cilia that are misaligned, and abnormally short dendrites. Genetic analyses using double mutants revealed a synthetic interaction (SynDyf) between K04F10.2 and Joubert syndrome *Arl13b/arl-13*, but not with TZ-associated *nphp-4* and *mks-5* alleles. Consistent with the nematode data, KIAA0556/K04F10.2 knockout mice possess grossly normal cilium structure. However, these mice present with hydrocephalus, indicating possible defects in motile cilia. To further understand the molecular basis of KIAA0556/K04F10.2 function, efforts are currently underway using affinity proteomics to identify the constituents of KIAA0556-containing complexes. Together, these data implicate K04F10.2 as a novel TZ-enriched protein with functions distinct from canonical MKS and NPHP modules.

**Identifying causative mutations in *Chlamydomonas* flagellar mutants using whole genome sequencing.**

S. K. Dutcher<sup>1</sup>, H. Lin<sup>1</sup>, M. L. Miller<sup>1</sup>, Z. Zhang<sup>1</sup>; <sup>1</sup>Genetics, Washington University, St Louis, MO

Whole-genome sequencing (WGS) provides a platform for the identification of mutations that produce a mutant phenotype (Dutcher *et al.*, 2012). Given the growing number of ciliopathies in human patients, identification of mutants in a genetically tractable organism produces validation and an avenue to studying the mechanistic role of proteins. We use Illumina sequencing to identify the mutational profiles of three *Chlamydomonas* mutant strains: *fla9*, *pf7*, and *imp3*. Each lane of sequencing produces about 300M reads and about 92% of the JGI version 5.3 genome shows >25-fold coverage. Multiple mutants are loaded into a lane. On average, each mutant has 35,000 to 50,000 changes relative to the reference genome. Using a library of ~250,000 polymorphisms assembled from WGS of ten mutant and wild-type strains, we identify approximately 5,000 strain-specific changes. We focus on exonic and splice site mutations as potential causative mutations. The *fla9* temperature-sensitive flagellar assembly strain maps to 450 kb on chromosome 17. This region has three mutations with coverage ranging from 60-122 fold. We show by the isolation of an intragenic revertant and transgenic rescue that a mutation in *IFT81*, which encodes a Complex B intraflagellar transport protein, is responsible for the phenotype. The mutation causes the loss of an exon that has no effect on IFT train frequency or velocity at 21°C, but fails to assemble flagella at 33°C (Iomini *et al.*, 2001). The short flagella

mutant strain, *pf7*, maps to 400 Mb on chromosome 17. This region has five mutations with coverage ranging from 13-85 fold. We show by the isolation of intragenic revertants that a mutation in *CCDC40*, which encodes a coiled-coil domain protein, is responsible for the phenotype. The Ccdc40 protein has been implicated in the assembly of the nexin link and primary ciliary dyskinesia in humans, dogs, and zebrafish. The *imp3* mutant strain, which was identified via a role in mating (Goodenough *et al.*, 1976), shows a severe flagellar regeneration phenotype. It was mapped to chromosome 2, which contains a single change. We show by rescue that a nine base pair deletion, which encodes the terminal conserved amino acids YFL in the catalytic subunit of a protein phosphatase 2A (PP2A), is responsible for both phenotypes. WGS is a quick and inexpensive means to identify the genes responsible in the large collection of flagellar mutants in *Chlamydomonas*. This approach will facilitate the understanding of flagellar assembly and signaling.

### Post-Transcriptional Mechanisms for Cytoskeletal and Ciliary Formation.

T. Boothby<sup>1</sup>, C. M. van der Weele<sup>1</sup>, S. M. Wolniak<sup>1</sup>; <sup>1</sup>Cell Biology & Molecular Genetics, University of Maryland, College Park, MD

The desiccated microspore of *Marsilea* (fern) is a meiotic product that undergoes rapid development upon hydration to produce 32 spermatozoids. The single cell in the spore undergoes 9 successive divisions in 4.5 h to produce 39 cells, 32 of which are spermatids. Each spermatid differentiates to become a coiled gamete with an elongated nucleus, an elaborate cytoskeleton and ~140 cilia. The gametes are released 11 h after the spore is placed in water. We are interested in how these cells undergo profound morphological change. Our earlier work shows that development is controlled post-transcriptionally. The gametophyte processes stored pre-mRNA by splicing retained introns and polyadenylating the transcripts, and then translates these mRNAs at precise times during development. We used RNAseq to elucidate transcriptional mechanisms controlling development. PolyA-RNA was isolated from 'early' (1-2h), 'middle' (3-5h), and 'late' (6-8h) intervals and sequenced using Illumina technology. *De novo* transcriptome assemblies were generated for each sample using Trinity software. We obtained >234,000 transcripts from all samples. To construct unigenes and reduce potential artifacts, the longest transcript from each isoform cluster was selected. They were grouped into contigs (unigenes) for use in reference transcriptomes in downstream analysis. BLAST and Gene Ontology (GO) comparisons with known genomic databases provided similarity and homology identities with contigs in our datasets. The Tuxedo suite was used to calculate FPKM values for relative abundance. GO enrichments show an increase in the numbers of rare transcripts as development proceeds. The early transcriptome featured components participating in DNA replication, RNA processing, mitosis, and cell cycle regulation. GO enrichment analysis of the late transcriptome reveals an over-abundance of centrosomal, ciliary and microtubule components, RNA splicing, RNA localization, and mRNA transport. GO enrichment shows the middle transcripts as a rich mix of early and late transcriptomes, with fewer than expected contigs being unique to this transitional period. RNAseq combined with RNAi silencing assays reveal that the gametophyte has two pools of stored pre-mRNAs and employs a bi-phasic strategy in controlling translation. The first pool of pre-mRNAs is processed and translated rapidly for the cell division phase of development. The second pool is then processed and translated for the *de novo* formation of basal bodies, cytoskeletal formation, nuclear remodeling, cell elongation and ciliogenesis in the forming spermatozoids. Supported by NSF grant 0842525 to SMW.

**Ciliogenesis depends on the splicing of retained introns in the male gametophyte of *M. vestita*.**T. C. Boothby<sup>1</sup>, R. S. Zipper<sup>1</sup>, S. M. Wolniak<sup>1</sup>; <sup>1</sup>University of Maryland, College Park, MD

Post-transcriptional regulation of RNA is a hallmark of many rapidly developing systems. We are interested in mechanisms that mediate the storage and temporal utilization of RNA during rapid development. To address these questions, we use the transcriptionally-silent male gametophyte of *Marsilea vestita*, which starts as a single cell and produces 7 sterile cells and 32 spermatozooids in 11 h. Each spermatid undergoes *de novo* basal body assembly and produces ~140 cilia affixed to a complex cytoskeleton. We showed previously that several splicing factors are regulated in a cell type specific manner, leading us to speculate that splicing plays a regulatory role in the translation of stored RNA. We performed RNAseq and assembled transcriptomes *de novo* from early, middle, and late developmental stages of spermatogenesis. We developed a Visual Basic for Applications program that identified a subset of intron retaining transcripts (IRTs) and their fully spliced isoforms, a large portion of which are involved in spermatid specific events such as basal body formation and ciliogenesis. Analyses of potential IRTs revealed that a large proportion of 5' and 3' splice signals correspond to evolutionarily conserved U2 consensus sequences. Inhibition of splicing with Spliceostatin A (SSA) perturbed development, resulting in failed spermatid differentiation, and the absence of basal body formation, cytoskeletal organization, and ciliogenesis. SSA and  $\alpha$ -amanitin treatments confirm that the appearance of fully spliced isoforms is a spliceosome-dependent, but transcriptionally-independent event. RNAseq and isoform specific RT-PCR reveal that splicing of different IRTs occurs at different times during development. Phenocopies resulting from RNAi knockdowns of specific IRTs were seen only after splicing would normally occur. Thus, IRTs stored in the gametophyte are not translatable, but they become translatable following removal of their retained introns. The abundance of RNA encoding splicing homologs present in the precatalytic or catalytic spliceosome was examined. Surprisingly, RNA encoding splicing factors present in the precatalytic spliceosome was predominantly abundant late in development, whereas RNA encoding factors present in the catalytic spliceosome was abundant early in development. RNAi knockdowns of these splicing factors confirmed that RNA encoding components of the catalytic spliceosome are required earlier in development than RNA encoding precatalytic components. These results suggest that precatalytic splicing factors are present as stored proteins at the onset of development, and could be associated with stored RNA. The association of IRTs with spliceosomes at various stages of maturity, coupled with the translation of catalytic splicing factors prior to precatalytic splicing factors provide an elegant means by which to regulate differential timing of intron removal necessary for controlling the translation of stored RNA essential for spermatid differentiation. Supported by NSF grant 0842525 to S.M.W.

**Proteomic analysis of flagellar transition zones.**D. R. Diener<sup>1</sup>, G. B. Witman<sup>2</sup>, J. L. Rosenbaum<sup>1</sup>; <sup>1</sup>Molec. Cell. Dev. Biol., Yale University, New Haven, CT, <sup>2</sup>Cell and Dev. Biology, UMass Medical School, Worcester, MA

The transition zone (TZ) of cilia and flagella is a specialized region of the organelle that forms the boundary between the basal body and the axoneme and is part of the barrier separating the cell body and flagellar compartments. An expanding list of proteins involved in ciliopathies have been mapped to the TZ through a variety of genetic, immunofluorescence, and protein interaction techniques. In a global approach to identifying components of the TZ, we have isolated TZs from the biflagellate alga *Chlamydomonas*. Prior to mitosis, these cells resorb their

flagella, leaving behind a small vesicle of TZ membrane containing the central hub characteristic of the *Chlamydomonas* TZ. Although the flagellar microtubules depolymerize during flagellar resorption, nine projections emanate from the hub and in many cases retain attachments to the membrane, suggesting that a TZ scaffold *sans* microtubules but including membrane and membrane connectors persists. We have purified these TZs by gradient centrifugation. Electrophoretic analysis of the isolated TZs shows they are enriched in centrin, a known component of the TZ. The initial proteomic analysis of this preparation identified 115 proteins, approximately 50 of which are also in the *Chlamydomonas* flagellar proteome; however, axonemal proteins, such as dyneins and radial spokes, were not present. Nine known ciliopathy proteins were identified, including CEP290/NPHP6, NPHP1, MKS1 and a tectonic homologue. Validation of putative TZ proteins that have human orthologues is underway. Supported by NIH Grant #GM014642 to JR and a gift from the Grousbeck Family Foundation to JR and GW.

**Meckelin functions in basal body orientation and cortical unit organization in *Paramecium tetraurelia*.**

T. Picariello<sup>1</sup>, M. Valentine<sup>1</sup>, J. Yano<sup>1</sup>, J. Van Houten<sup>1</sup>; <sup>1</sup>University of Vermont, Burlington, VT

Meckelin (MKS3), a conserved transmembrane protein found at the base of the cilium, functions in ciliogenesis, centriole positioning and ciliary gating. Mutations in *MKS3* result in the ciliopathy Meckel Syndrome (MKS). Previously our lab depleted *MKS3* mRNA levels in the ciliate *Paramecium tetraurelia* using RNAi. Depletion resulted in global defects such as short and missing cilia, disruptions to the ciliary membrane and localized defects in basal body organization on the dorsal surface of the cell.

The surface of *Paramecium* consists of highly organized cortical units arranged in longitudinal rows called kineties. Each cortical unit contains one or two basal bodies, from which cilia arise, and a set of microtubule rootlets that emanate from the basal body in a fixed orientation. The post-ciliary microtubule rootlet arises from the right side of the basal body and projects towards the posterior of the cell while the transverse microtubule rootlet arises from the left side of the basal body and projects laterally toward the adjacent kinety. The cortical units are separated from each other by sets of ridges.

Our current work suggests that depletion of *MKS3* mRNA also results in disruptions of the cortical unit organization, the submembranous cytoskeleton and the basal body associated microtubules. The most prominent type of disruption is the insertion of a single unit between two cortical rows creating a cluster of cortical units. A second type of cortical cytoskeletal disruption is the insertion of a partial row of cortical units resulting in the formation of an abbreviated kinety. Disruptions of this type vary from several cortical units in length to disruptions extending for the majority of the cell's dorsal surface.

Furthermore, the orientation of the post-ciliary rootlet and transverse microtubule are changed with *MKS3* RNAi. The microtubule rootlets no longer project in their predicted orientations. The mis-oriented rootlets are seen where there are disruptions in basal body organization and the orientation of the rootlets varies between and within observed areas of disruption.

In addition to its established role in ciliogenesis and basal body positioning, our work supports the idea that Meckelin functions to establish the cortical units and to provide polarity to the basal bodies during cell division. The disruptions suggest that the link between Meckelin and the cytoskeleton serves to orient the basal bodies within the individual cortical units and in doing so, provides the proper environment for ciliogenesis.

**A novel function of the the centriolar satellite protein SSX2IP/hMsd1 in targeting BBS4 to the ciliary compartment.**

*M. Klinger<sup>1</sup>, W. Wang<sup>1</sup>, S. Kuhns<sup>2</sup>, F. Baerenz<sup>3</sup>, D. Mayilo<sup>4</sup>, D. Inoue<sup>5</sup>, J. Wittbrodt<sup>5</sup>, G. Pereira<sup>2</sup>, O. J. Gruss<sup>1</sup>; <sup>1</sup>ZMBH, DKFZ-ZMBH Alliance, Heidelberg, Germany, <sup>2</sup>DKFZ, DKFZ-ZMBH Alliance, Heidelberg, Germany, <sup>3</sup>DKFZ, Heidelberg, Germany, <sup>4</sup>FMI Basel, Basel, Switzerland, <sup>5</sup>Centre of Organismal Studies (COS), University of Heidelberg, Heidelberg, Germany*

Primary, non-motile cilia fulfil essential functions in transducing mechanical or chemical stimuli into intracellular signals in the majority of differentiated human cells. Defects in cilia assembly (ciliogenesis) lead to a wide range of human diseases, commonly termed ciliopathies, such as the Bardet-Biedl syndrome or polycystic kidney diseases. The primary cilium is organized by a microtubule based core structure, the axoneme. This unique microtubule array consists of nine parallel microtubule doublets originating from the basal body. Basal bodies derive from centrioles that migrate to the cell cortex in cells exiting the cell cycle, e.g. during differentiation. Here, we characterise the function of a previously unknown centriolar satellite protein, SSX2IP/hMsd1, in the assembly of primary cilia. Using differential proteomics in maturing *Xenopus* oocytes, we recently identified SSX2IP/hMsd1 as a maturation factor for mitotic centrosomes in cycling cells (Baerenz et al., submitted). We now show that during late phases of the cell cycle, SSX2IP/hMsd1 as well as the centriolar satellite marker PCM-1 preferentially localize to mother centrioles. This observation suggested a role of SSX2IP in basal body assembly, which are known to arise from the mother centriole that is targeted to the plasma membrane. Consistent with that, we show that SSX2IP localises to the basal body of primary cilia in human RPE-1, murine NiH3T3 cells and medaka embryos. Importantly, knockdown of SSX2IP in RPE-1 cells leads to defects in ciliogenesis resulting in cilia with significantly reduced axoneme length. We provide evidence that SSX2IP promotes efficient recruitment of the ciliopathy-associated protein Cep290, to both centrosomal satellites and the basal body. Moreover, loss of SSX2IP impairs the localization of the BBSome component BBS4. BBS4 relocalizes during ciliogenesis from centriolar satellites to the ciliary compartment. We show that loss of SSX2IP interferes with BBS4 primary cilia relocalization and limits its ciliary entry. Our experiments establish SSX2IP as a new regulator of primary cilia formation in human cells and reveal a new link between centriolar satellites and cilia assembly.

**A microRNA control of primary cilia formation.**

*J. Cao<sup>1</sup>, L. Zhu<sup>1</sup>, Y. Xu<sup>1</sup>, Y. Zhou<sup>1</sup>, X. Yan<sup>1</sup>, X. Zhu<sup>1</sup>; <sup>1</sup>Shanghai Institute of Biochemistry and Cell Biology, Shanghai, China*

Primary cilia are antenna-like organelles projecting from cell membrane. They are critical for several signaling pathways and related to many genetic diseases. MicroRNAs are reported to play important roles in multiple biological and pathological processes, such as embryo development and tumorigenesis. CP110, a protein that caps the distal side of the centrioles, is inhibitory to ciliogenesis, whereas actin dynamics has recently been shown to affect cilia formation and growth by inducing the centrosomal accumulation of ciliogenic vesicles. Whether microRNAs could contribute to primary cilia formation, however, is not known. Here we found that overexpression of a microRNA (miR-129-3p) induced robust ciliogenesis in the presence of serum and increased cilia length in the absence of serum, whereas blocking miR-129-3p with sponge inhibited the serum starvation-induced cilia formation. CP110 was predicted to have two potential target sites of miR-129-3p in its 3' UTR by TargetScan software. Repression of CP110 by miR-129-3p was confirmed by luciferase assay and Western blotting. As CP110 RNAi was much less efficient than the overexpression of miR-129-3p in both the cilia induction and

elongation, we investigated additional targets of miR-129-3p. We found that actin cytoskeleton was largely disorganized upon the overexpression of miR-129-3p. Wound healing assay indicated a repression of the branched F-actin formation. Because a microRNA can destabilize its target mRNA, we used gene chip assay and TargetScan software analyses to screen for miR-129-3p targets in actin dynamics-related cilia formation. Four actin-related genes, ARP2, TOCA1, ABLIM1 and ABLIM3 were identified. RNAi of these genes phenocopied the effects of miR-129-3p overexpression. miR-129-3p was highly expressed in mouse tissues abundant in primary cilia, including renal tubules, retina and brain. In order to explore the in vivo functions of miR-129-3p, morpholino oligonucleotides against miR-129-3p was microinjected into zebrafish embryos. Developmental abnormalities including curved body, pericardial oedema and defective left-right asymmetry were observed. Both the cilia number and length were reduced as well in the Kupffer's vesicle and the pronephros. Taken together, our results suggest that miR-129-3p controls ciliation by downregulating both CP110 and positive regulators of branched F-actin.

1174

**CEP162 is the axoneme-recognition protein promoting ciliary transition zone assembly.**  
*W.-J. Wang<sup>1</sup>, H. Tay<sup>2</sup>, G. Perumal<sup>3</sup>, S. Rajesh<sup>1</sup>, F. Macaluso<sup>3</sup>, J. Asara<sup>4,5</sup>, J. Amack<sup>2</sup>, B. Tsou<sup>1</sup>;*  
<sup>1</sup>Cell Biology, Memorial Sloan-Kettering Cancer Center, New York, NY, <sup>2</sup>Cell and Developmental Biology, SUNY Upstate Medical University, Syracuse, NY, <sup>3</sup>Analytical Imaging Facility, Albert Einstein College of Medicine of Yeshiva University, Bronx, NY, <sup>4</sup>Medicine, Harvard Medical School, Boston, MA, <sup>5</sup>Division of Signal Transduction, Beth Israel Deaconess Medical Center, Boston, MA

Assembling the transition zone (TZ) around nascent ciliary microtubules nucleated from centrioles is essential for ciliogenesis, but how microtubules are recognized to promote TZ assembly at the base of a growing cilium is unclear. By quantitatively dissecting centrosome proteomes into domain-specific subcategories, we identified a centriole-bound, microtubule-associated protein, CEP162, as the TZ-specification factor. CEP162 is associated with centriole distal ends, where it recognizes local ciliary microtubules, and interacts with the core TZ component CEP290. Loss of CEP162 disrupts TZ formation and ciliogenesis. However, abolishing centriolar tethering allows CEP162 to remain associated with axoneme tips throughout ciliogenesis, and ectopically recruit TZ components, generating extra-long cilia with exceedingly swollen tips that burst and release ciliary contents. CEP162 is thus an axoneme-recognition protein tethered at centriole distal ends to promote and restrict TZ formation specifically at the cilia base.

**Mouse Kif7, a ciliopathy protein and regulator of Sonic Hedgehog signaling, has microtubule depolymerization activity.**

M. He<sup>1</sup>, K. Anderson<sup>1</sup>; <sup>1</sup>Developmental Biology, Sloan Kettering Institute, New York, NY

In vertebrates, primary cilia are required for the Sonic Hedgehog (Shh) signaling, which plays crucial roles in embryonic development and tissue homeostasis. The Kinesin-4 family protein Kif7 acts in the center of the Shh pathway, between the Smo membrane protein and the Gli transcription factors. Here we show that Kif7 moves to the tip of primary cilia upon pathway activation, paralleling the movement of Gli and Sufu. In the absence of Kif7, Gli2 and Sufu are mislocalized within cilia. Our data suggest a Shh signaling complex, which includes Kif7-Gli-Sufu, acts at the tip of primary cilia. In addition to these roles in the Shh pathway, we find that *Kif7* mutant cilia are significantly longer than that of the wild type. The mutant cilia have microtubule structural defects and tubulin acetylation and glutamylation are decreased in the

distal part of the mutant axoneme. Coupled with the absence of these post-translational modifications, *Kif7* mutant cilia are more labile in response to cilia retraction stimuli. Analysis of genetic interactions between *Kif7* and *IFT* genes confirms the importance of Kif7 in maintaining cilia structure. We show that, like conventional kinesins, Kif7 can form homodimers and bind to microtubules. Consistent with the localization of endogenous Kif7 to the tips of primary cilia, ectopically expressed Kif7 associates with the plus-end of microtubules. Interestingly, unlike other Kinesin-4 family proteins, purified Kif7 protein promotes microtubule disassembly *in vitro*. Thus we have identified Kif7 as a microtubule depolymerizing kinesin that acts in the primary cilia to regulate the length of axonemal microtubules and couples cilia growth to tubulin modification. We propose that dual functions of Kif7 as a core component of the Shh pathway and a ciliary motor may explain the connection between mammalian Shh pathway and the primary cilia.

1176

**PF19 encodes the catalytic subunit of katanin, p60, and is required for assembly of the flagellar central apparatus in *Chlamydomonas*.**

E. F. Smith<sup>1</sup>, E. E. Dymek<sup>1</sup>; <sup>1</sup>Biological Sciences, Dartmouth College, Hanover, NH

For motile eukaryotic cilia and flagella the central apparatus plays a crucial role in generating wild-type waveforms and beat frequency. While important and significant advances have recently been made in the field of ciliogenesis, we still do not know how the central pair of microtubules and associated projections are assembled in the axoneme. The basal bodies provide a template for the assembly of the doublet microtubules, and intraflagellar transport (IFT) provides a mechanism for transport of axonemal components into the growing cilium. What is not known is how the central pair of microtubules is nucleated or how their associated polypeptides are assembled. We previously demonstrated that *Chlamydomonas* mutants with defects in the p80 subunit of katanin (*pf15*) lack the central pair of microtubules. Here we report that the *Chlamydomonas pf19* mutation results in a single amino acid change within the p60 catalytic subunit of katanin (L277S), and that this mutation ablates microtubule severing activity. L277 is highly conserved in p60 from *Chlamydomonas* to mammals and is within the AAA domain, only 28 amino acids upstream from the Walker A nucleotide binding motif. The *pf19* mutant has paralyzed flagella that lack the central apparatus. Using a combination of mutant analysis, RNAi-mediated reduction of protein expression, and *in vitro* assays, we demonstrate that the p60 catalytic subunit of the microtubule severing protein katanin is required for central apparatus assembly in *Chlamydomonas*. In addition, we show that in *Chlamydomonas* the microtubule severing activity of p60 katanin is not required for stress-induced deflagellation or cell cycle progression. The *pf15*, *pf19*, and *pf15pf19* double mutants are all viable and show no sign of cell cycle defects. In addition, all three mutant strains have no defects in flagellar autotomy. Therefore, katanin does not appear to be required for deflagellation in *Chlamydomonas*. As a first step towards defining a mechanism for katanin's role in central pair assembly, we are conducting a structural analysis of central pair assembly in wild-type cells, and localizing the p80 and p60 katanin subunits during assembly. This work was supported by NIH GM66919 to E.F.S.

1177

**C. elegans ciliary architecture depends on molecules that regulate tubulin polyglutamylation levels.**

M. Silva<sup>1</sup>, R. O'Hagan<sup>1</sup>, W. Zhang<sup>1</sup>, J. Weiss<sup>1</sup>, K. C. Nguyen<sup>2</sup>, D. H. Hall<sup>2</sup>, M. M. Barr<sup>1</sup>;

<sup>1</sup>Genetics, Rutgers University, Piscataway, NJ, <sup>2</sup>Center for C. elegans Anatomy, Albert Einstein College of Medicine, Bronx, NY

Cilia are sensory organelles found on most cell types in the human body. In humans, ciliary defects lead to pleiotropic diseases called ciliopathies. Although all cilia are built by microtubule (MT) based intraflagellar transport (IFT) and have common features, cilia also display specializations in form and function. The molecular mechanisms that modulate IFT to generate such specializations in ciliary architecture are unknown.

To study how cilia diversity is generated, we use the nematode *Caenorhabditis elegans*. The hermaphrodite possesses 60 ciliated sensory neurons (CSNs), and the male has an additional 52 sex-specific CSNs. We compared two types of morphologically and functionally distinct CSNs: amphid channel neurons and cephalic male (CEM) neurons. Using high-pressure freeze fixation, transmission electron microscopy and electron tomography, we found significant differences in MT architecture between amphid and CEM cilia. In amphid channel cilia, the middle segment contains MT doublets. However, because the B-tubules of each doublet terminate abruptly at the end of the middle segment, the distal segment of amphid channel cilia contain only A-tubule singlets. By contrast, B-tubules in CEM cilia middle segments split off from doublets such that both A- and B-tubules continue as distinct MT singlets in the distal segment. It is unknown how this difference in architecture contributes to specialized sensory functions in these distinct neuron types.

To understand how this ultrastructural difference is generated, we examined the role of tubulin posttranslational modifications (PTMs) on ciliary MT architecture and IFT motors. We used genetic analysis, immunocytochemistry, and in vivo imaging of IFT motors to characterize the *tll* family of glutamylases and the *ccpp-1* deglutamylase. We found that loss of these molecules, which regulate MT polyglutamylation levels, causes defects in CEM MT singlet numbers, MT doublet stability, and the motility of specific ciliary kinesins.

**A novel *Chlamydomonas* mutant, *tpg2*, reveals a conserved 177-kDa protein crucial for the localization of TTLL9, an enzyme that catalyzes tubulin polyglutamylation in the axoneme.**

T. Kubo<sup>1</sup>, H-A. Yanagisawa<sup>2</sup>, Z. Liu<sup>3</sup>, R. Shibuya<sup>1</sup>, M. Hirono<sup>1</sup>, R. Kamiya<sup>1,4</sup>; <sup>1</sup>Department of Biological Sciences, Graduate School of Science, The University of Tokyo, Tokyo, Japan,

<sup>2</sup>Graduate School of Medicine, Molecular Cell Biology, The University of Tokyo, Tokyo, Japan,

<sup>3</sup>Emory University, School of Medicine, Atlanta, GA, <sup>4</sup>Department of Life Science, Faculty of Science, Gakushuin University, Tokyo, Japan

Tubulin undergoes polyglutamylation on the surface of microtubules in various cellular elements such as axons, axonemes, centrioles and mitotic spindles. This modification is catalyzed by proteins belonging to the tubulin tyrosine ligase-like protein family (TTLL). We have recently found that the *Chlamydomonas* mutant *tpg1* lacks TTLL9, has a greatly reduced amount of polyglutamylated alpha tubulin in the axoneme, and is deficient in the functioning of a specific inner-arm dynein (Kubo et al. 2010, Curr. Biol. 20, 441-445, Kubo et al. 2012, Cytoskeleton, submitted). In this study, we analyzed *tpg2*, a novel mutant phenotypically similar to *tpg1*, and found that it has a mutation in a gene encoding a 177-kDa flagellar protein (p177), which is

widely conserved but of unknown function. The flagella of *tpg2* lack both p177 and TTLL9. Immunoprecipitation assays revealed that p177 is complexed with TTLL9 in both the cytoplasm and the flagella. Furthermore, experiments using *fla10*, a temperature-sensitive mutant deficient in kinesin-II, suggested that the TTLL9-p177 complex is transported in the axoneme by intraflagellar transport. These and other results indicate that p177 is essential for the localization and function of TTLL9 in the axoneme.

1179

#### **A Role for Gas8 in Motile Cilia and Left-Right Asymmetry.**

W. R. Lewis<sup>1</sup>, E. B. Malarkey<sup>1</sup>, R. C. Pasek<sup>1</sup>, N. F. Berbari<sup>1</sup>, B. K. Yoder<sup>1</sup>; <sup>1</sup>Cell, Developmental, and Integrative Biology, University of Alabama at Birmingham, Birmingham, AL

Cilia are microtubule based organelles that project from the surface of a cell. Cilia dysfunction in humans can lead to a wide variety of diseases that are collectively referred to as "ciliopathies." While our understanding of ciliopathies has progressed over the past decade, it remains far from complete, with previously uncharacterized mammalian genes constantly being shown to have ciliary roles. For example, work on the *Chlamydomonas reinhardtii* gene, PF2, revealed defects in the Nexin-Dynein Regulatory Complex (NDRC) and cilia motility. The Growth Arrest Specific 8 (*Gas8*) gene product is the mammalian homologue of PF2 and is associated with the NDRC where it is thought to play a role in cilia and flagella motility. To date, no *in vivo* mammalian studies on *Gas8* have been reported, thus its significance in mammalian systems and disease remains undetermined. To this end, we have generated a *Gas8* mutant mouse model. Analysis of cilia on ependymal cells of the lateral ventricles of the brain in *Gas8* mutants indicates a severe defect in cilia motility and hydrocephalus. Also interesting is the fact that a number of *Gas8* mutants present with *situs inversus*, implicating *Gas8* in left-right body axis patterning and nodal cilia motility or signaling. Previous *in vitro* studies indicate that *Gas8* localizes to the axoneme of the motile cilia and base of primary cilia and is implicated in sonic hedgehog signaling where it is proposed to be a positive regulator of the pathway activator smoothed. Based on our preliminary data, we hypothesize that *Gas8* is required for proper function of the NDRC and cilia motility; furthermore we hypothesize that *Gas8* is required for nodal cilia motility and/or signaling at the embryonic node.

1180

#### **Structural and biochemical properties of the Outer-Dynein-Arm Docking Complex (ODA-DC) in *Chlamydomonas* flagella.**

M. Owa<sup>1</sup>, T. Ide<sup>1</sup>, S. M. King<sup>2</sup>, R. Kamiya<sup>1,3</sup>, K. Wakabayashi<sup>1</sup>; <sup>1</sup>Department of Biological Sciences, Graduate School of Science, The University of Tokyo, Tokyo, Japan, <sup>2</sup>Department of Molecular, Microbial and Structural Biology, University of Connecticut Health Center, Farmington, CT, <sup>3</sup>Department of Life Science, Faculty of Science, Gakushuin University, Tokyo, Japan

Outer dynein arms in cilia and flagella are bound to specific loci on outer-doublet microtubules with a regular spacing of 24 nm. Their binding to the doublet microtubules is mediated by the outer dynein arm docking complex (ODA-DC) present at the base of the outer arm. In *Chlamydomonas*, the ODA-DC is composed of three subunits, DC1 (ODA3), DC2 (ODA1) and DC3 (ODA14). ODA-DC binds to specific loci on the outer-doublets of mutant axonemes that lack outer arm dynein, suggesting that it is responsible for the binding of outer arm dyneins to specific sites. To understand the basis for this crucial function of the ODA-DC, we examined the structural and biochemical properties of ODA-DC using both recombinant and native proteins. Low-angle rotary shadowing indicated that the recombinant ODA-DC has an oval shape, ~25

nm in length. Chemical crosslinking of axonemes from a mutant lacking outer arms revealed that the native ODA-DCs associate with each other on the doublet microtubules. A Hill plot for the binding of recombinant ODA-DC to *oda1* axonemes (lacking the ODA-DC) indicates that the binding is cooperative. These data suggest that the periodic and cooperative binding of ODA-DC molecules on the doublet microtubules is based on an end-to-end association of the ODA-DCs. Furthermore, thin-section EM analysis of *oda1* axonemes mixed with excess amounts of recombinant ODA-DC suggests that the recombinant ODA-DC molecules were preferentially bound to the correct sites on the doublet. Thus, there may be additional factor(s) that specify the ODA-DC binding sites on the doublet microtubules.

## Microtubule Dynamics and Its Regulation II

1181

### DCX recognizes longitudinal curvature, not the nucleotide state of the lattice, during microtubule end-tracking.

S. Bechstedt<sup>1</sup>, G. Brouhard<sup>1</sup>; <sup>1</sup>McGill, Montreal, QC, Canada

Doublecortin (DCX) is a protein that stabilizes microtubules (MTs) in developing neurons and nucleates 13-pf MTs in vitro. Using fluorescence microscopy assays, we previously showed that the binding of DCX to MTs is optimized for the lateral curvature of the 13-pf lattice. Using assays with dynamic MTs, we discovered that DCX binds to polymerization intermediates at growing MT ends. DCX shares its microtubule binding site with EB1, the canonical MT end-tracking protein, and we wondered if DCX tracks MT ends by the same mechanism as EB1, namely by recognition of the GTP state of MT ends. Unlike EB1, DCX does not bind preferentially to microtubules assembled with GTP analogs. Rather, we have found that DCX shows high affinity for regions of longitudinal curvature on MTs, while EB1 did not. This behavior could explain the high affinity of DCX for nucleation intermediates and MT tips, which have been shown to flare outward. These findings indicate the existence of two distinct features of microtubule ends, nucleotide state and longitudinal curvature, which can be sensed independently by different proteins. Our results demonstrate that DCX templates new 13-pf MTs through preferential associations with the sides of nucleation intermediates of the MT lattice.

### Acetylation of EB1 regulates chromosome dynamics in mitosis.

Z. Wang<sup>1</sup>, P. Xia<sup>1</sup>, X. Liu<sup>1,2</sup>, T. Ward<sup>2</sup>, B. Wu<sup>1</sup>, G. Gibbons<sup>3</sup>, X. Yao<sup>1</sup>; <sup>1</sup>Laboratory of Cellular Dynamics, Hefei, China, <sup>2</sup>Physiology, Morehouse School of Medicine, Atlanta, GA, <sup>3</sup>Laboratory of Cellular Dynamics, Atlanta, GA

The faithful chromosome segregation during mitosis is orchestrated by dynamic interaction between spindle microtubule plus-ends and the kinetochore. Here we show that PCAF, a kinetochore-associated acetyltransferase, acts as a negative modulator of microtubule stability through acetylation of EB1, a protein that controls the plus ends of microtubules. PCAF acetylates EB1 at its C-terminal tail and disrupts the stability of a hydrophobic cavity on the dimerized EB1 C-terminal, which was previously reported to interact with plus-end tracking proteins containing the SxIP motif. As determined with an acetylation site-specific antibody, EB1 acetylation is dramatically increased in mitosis and localized to the spindle microtubule plus-ends. Surprisingly, persistent acetylation of EB1 delays metaphase alignment, resulting in impaired checkpoint silencing. Consequently, suppression of Mad2 overrides mitotic arrest induced by persistent EB1 acetylation. Thus, our findings identify dynamic acetylation of EB1 as

a molecular mechanism to orchestrate accurate kinetochore-microtubule interactions in mitosis. These results establish a previously uncharacterized regulatory mechanism governing localization of microtubule plus-end tracking proteins and thereby the chromosome dynamics during cell division. Currently, we are delineating how EB1 acetylation regulates the temporal dynamics of specific EB1-TIP interactions at the kinetochore during chromosome movements.

1183

### **VE-cadherin Signaling Induces EB3 Phosphorylation to Suppress Microtubule Growth and Stabilize Adherens Junctions.**

*M. Geyer<sup>1</sup>, F. Huang<sup>1</sup>, N. Daneshjou<sup>1</sup>, A. Garcia<sup>1</sup>, L. Idalino<sup>1</sup>, B. Kreutz<sup>1</sup>, D. Mehta<sup>1</sup>, A. B. Malik<sup>1</sup>, Y. A. Komarova<sup>1</sup>; <sup>1</sup>Pharmacology, UIC, Chicago, IL*

The endothelium, lining the vessel wall forms a semi-permeable restrictive barrier that regulates tissue fluid homeostasis and transmigration of blood cells. Vascular Endothelial (VE)-cadherin homotypic adhesion controls endothelial barrier permeability through assembly of adherens junctions (AJs). The functions of actin and microtubule (MT) cytoskeleton are critical for the integrity of AJs; however, how VE-cadherin homotypic adhesion induces the cytoskeletal changes remains unknown. Here we addressed the question whether VE-cadherin adhesion influences MT dynamics through modulation of function of End Binding (EB) protein, the most conserved and ubiquitous family of +TIPs, and whether these changes in MT dynamics are themselves critical for AJ integrity. By using time-lapse confocal imaging and PlusTipTracker software, we showed that VE-cadherin mediated adhesion modulates steady-state MT dynamics by suppressing MT growth. Destabilization of VE-cadherin adhesion by extracellular  $Ca^{2+}$  depletion or addition of the small inhibitory peptide (RVDAE), which binds to VE-cadherin extracellular 1 module and disrupts VE-cadherin trans-interaction was accompanied by activation of Src-phospholipase C (PLC)<sub>v</sub> 2 signaling and concomitant synthesis of Ins-1,4,5-trisphosphate (IP<sub>3</sub>). In addition, destabilization of VE-cadherin adhesion induced reversible phosphorylation of serine 162 in EB3. Inhibition of both Src and PLC as well as depletion of PLC<sub>v</sub>2 inhibited EB3 dephosphorylation following loss of VE-cadherin adhesion. Consistent with increased cytosolic  $[Ca^{2+}]_i$  in endothelial cells subjected to extracellular  $Ca^{2+}$  depletion protocol, downregulation of calcineurin (CaN), the  $Ca^{2+}$ -dependent phosphatase, or pre-treatment of cells with the CaN inhibitors also prevented dephosphorylation of EB3. This S162 phospho-switch was required to destabilize the EB3 dimer and suppress MT growth. The phospho-defective S162A EB3 mutant in contrast induced MT growth in confluent endothelial monolayers and disassembled AJs. Thus, VE-cadherin outside-in signaling regulates cytosolic  $Ca^{2+}$  homeostasis and EB3 phosphorylation, which induces assembly of AJs. These results identify a novel function of VE-cadherin homotypic interaction in modulating endothelial barrier through the tuning of MT dynamics.

1184

### **Control of chromosome stability by PCAF-EB1-TIP150 axis.**

*T. L. Ward<sup>1</sup>, P. Xia<sup>2</sup>, Z. Wang<sup>2</sup>, X. Lu<sup>2</sup>, Y. Chu<sup>2</sup>, X. Wang<sup>2</sup>, G. Adams<sup>1</sup>, M. Yan<sup>2</sup>, D. Wang<sup>2</sup>, X. Yao<sup>1,2</sup>; <sup>1</sup>Morehouse School of Medicine, atlanta, GA, <sup>2</sup>University of China Science and Technology, Hefei, China*

Microtubule is a key cytoskeleton network essential for cellular plasticity and dynamics in all eukaryotes. Recent study suggests that mutation of BRCA2 can lead to chromosome instability by perturbation of PCAF activity at the centromere. Although microtubule acetylation is essential for cellular plasticity, it has remained elusive how kinetochore microtubule plus-end dynamics are regulated by PCAF acetylation. Here we demonstrate that TIP150 regulates

kinetochore-microtubule attachments by promoting spindle microtubule plus-end stability. Suppression of TIP150 by siRNA results in mitotic delay with misaligned chromosomes and perturbation in chromosome biorientation. TIP150 is a tetramer that binds an EB1 dimer through the C-terminal domains and overexpression of the C-terminal TIP150 or disruption of TIP150-EB1 interface by a membrane-permeable peptide perturbs accurate chromosome segregation. Remarkably, the EB1-TIP150 interaction is regulated by PCAF acetylation, and persistent acetylation perturbs accurate metaphase alignment and spindle checkpoint satisfaction. Consequently, suppression of BubR1 overrides mitotic arrest induced by persistent EB1 acetylation but exhibits aneuploidy. Thus, our findings identify a mechanism in which dynamic TIP150-EB1 hexamer governs kinetochore microtubule plus-end plasticity and the temporal control of TIP150-EB1 interaction by PCAF acetylation ensures chromosome stability in mitosis.

1185

### **TBCB and EB1 crosstalk in microtubule dynamics.**

*G. Carranza<sup>1</sup>, M. L. Fanarraga<sup>1</sup>, J. Villegas<sup>2</sup>, H. Soares<sup>3,4,5</sup>, J. C. Zabala<sup>1</sup>; <sup>1</sup>Biología Molecular, Universidad de Cantabria, Santander, Spain, <sup>2</sup>Anatomía y Biología Celular, Universidad de Cantabria, Santander, Spain, <sup>3</sup>Escola Superior de Tecnologia da Saude, Lisboa, Portugal, <sup>4</sup>Instituto Gulbenkian de Ciência, Oeiras, Portugal, <sup>5</sup>Centro de Química e Bioquímica da Faculdade de Ciências, Universidade de Lisboa, Lisboa, Portugal*

Tubulin folding cofactors (TBCs) are a set of different proteins discovered as key elements in the so-called "postchaperonin" tubulin folding pathway. TBCs are responsible for the achievement of the quaternary conformation of the  $\alpha\beta$ -heterodimer after tubulin monomers have reached their tertiary structure. In vivo, these proteins are implicated in microtubule dynamics through their ability to dissociate the tubulin heterodimer. TBCB and TBCE are two well-conserved  $\alpha$ -tubulin interacting proteins playing important roles in vivo as revealed by the plethora of human disorders in which they are implicated. TBCB shares with TBCE two similar domains, a CAP-Gly, and a UBL domain, but the cytoskeleton-associated protein glycine-rich (CAP-Gly) domains are localized at the C-terminal position in TBCB and at the N-terminal position in TBCE. In this work, we have used a multidisciplinary approach to study the molecular mechanism of TBCB's regulation of microtubule dynamics. We have established that the last three amino-acid residues of TBCB protein are crucial for TBCE interaction and an efficient tubulin dimer dissociation. The overexpression of the mutated form of TBCB lacking the DEI/M-COO<sup>-</sup> motif, similar to the EEY/F-COO<sup>-</sup> element in EB1 and related proteins, produces a massive microtubule destruction in vivo suggesting its role in autoinhibition. Using extensive biophysical and biochemical approaches, we unmasked the molecular mechanism by which TBCB controls microtubule depolymerization by means of EB1. In addition, we show for the first time that TBCB interacts directly with cytosolic chaperonin containing TCP-1 (CCT) during the folding process of  $\alpha$ -tubulin. All the results obtained from this work led us to propose three different models to explain the mechanism for which the C-terminal tail of TBCB protects microtubule from depolymerization, the role of TBCB in tubulin folding as a CCT cofactor, and the mechanism by which the deregulation of TBCB activity induces the microtubule catastrophe in living cells.

1186

**Evolving tip structures can explain age-dependent microtubule catastrophe.**

C. E. Coombes<sup>1</sup>, D. J. Odde<sup>2</sup>, M. K. Gardner<sup>1</sup>; <sup>1</sup>Genetics, Cell Biology, and Development, University of Minnesota, Minneapolis, MN, <sup>2</sup>Biomedical Engineering, University of Minnesota, Minneapolis, MN

Microtubules are key structural and transport elements in cells. The dynamics at microtubule ends are characterized by periods of slow growth, followed by stochastic switching events termed “catastrophes”, in which microtubules suddenly undergo rapid shortening. The mechanistic basis of catastrophe is not known. To investigate microtubule catastrophe events, we performed 3D mechanochemical simulations that account for interactions between neighboring protofilaments. We found that there are two separate factors which contribute to catastrophe events in the 3D simulation: the GTP-Tubulin cap size, which settles in to a steady-state value that depends on the free tubulin concentration during microtubule growth, and the structure of the microtubule tip. Importantly, 3D simulations predict, and *in vitro* microscopy experiments confirm, that microtubule tip structures evolve during microtubule growth. Specifically, we found that the lengths of the individual protofilaments within a microtubule become more tapered over time as the microtubule grows. Along with the evolving microtubule tip structures, catastrophe events increase in frequency as a function of microtubule age, both experimentally and in simulation. Thus, the likelihood of a simulated catastrophe event is intimately linked to the changing physical structure of the growing microtubule tip. The link between tip structure and catastrophe is supported by experimental and simulation results which demonstrate that disruption of the naturally evolving microtubule tip structure by the depolymerizing kinesin MCAK also disrupts the age-dependent catastrophe process. These results have important consequences for catastrophe regulation in cells, as microtubule-associated proteins could promote catastrophe events in part by modifying microtubule tip structures.

1187

**XMAP215 and EB1 Act in Synergy to Promote Microtubule Growth.**

M. Zanic<sup>1</sup>, P. Widlund<sup>1</sup>, A. Hyman<sup>1</sup>, J. Howard<sup>1</sup>; <sup>1</sup>Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, Germany

In cells, a complex network of microtubule-associated-proteins regulates the dynamic growth and shrinkage of microtubules that is essential for division and migration. *In vitro* approaches with purified components have helped to elucidate the mechanisms and the effects of individual microtubule plus-end-localizing proteins (+TIPs) on microtubule dynamics. Because microtubule dynamics observed *in vitro* with individual +TIPs does not account for the dynamics observed *in vivo*, it is important to study the combined effects of +TIPs. Here we show that two well-studied +TIPs — microtubule plus-end-tracking protein EB1, and the microtubule polymerase XMAP215 — act together to strongly promote microtubule growth to rates never before observed with purified proteins. Unexpectedly, we find that the combined effects of XMAP215 and EB1 are highly synergistic, with acceleration of growth well beyond the product of the individual effects of either protein. The synergy remains after EB1’s C-terminal 20 amino acids have been removed, showing that it does not rely on any of the canonical EB1 interactions. The increase in growth rates is accompanied by a strong enhancement of microtubule catastrophe, thereby rendering the fast and dynamic microtubule behavior typically observed in cells.

1188

**EB proteins sensitize microtubules to drugs by increasing catastrophes.**

R. Mohan<sup>1</sup>, E. Katrukha<sup>1</sup>, I. Grigoriev<sup>1</sup>, A. Akhmanova<sup>1</sup>; <sup>1</sup>Department of Biology, Utrecht University, Utrecht, Netherlands

End Binding (EB) proteins, master regulators of dynamics at the plus ends of microtubules, can modulate the interaction of various microtubule targeted agents (MTAs) with microtubules. In this study, we investigated the effects of stabilizing and destabilizing MTAs on the dynamics of EB-associated microtubules. We found that low nanomolar concentrations of destabilizing MTAs, both in cells and in vitro, can induce a seemingly non-dynamic state of microtubules, which we termed the “balancing point”. Microtubule-destabilizing MTAs induce the “balancing point” by promoting very short phases of microtubule growth and shortening, without changing the EB binding and turnover at the microtubule ends. In the absence of EB proteins, MTAs failed to induce the “balancing point” state, suggesting that EB proteins sensitize microtubule ends to MTAs. In cells, MTAs can induce “balancing point” even when the function of microtubule rescue factors such as CLIP-170 is inhibited. Laser photoablation experiments showed that microtubule-destabilizing MTAs affected not only microtubule growth but also depolymerization: a severed microtubule plus end was stable or showed only very limited shortening, suggesting that the microtubule structure might be altered. A microtubule stabilizer, Paclitaxel, on the other hand, did not induce “the balancing point” condition either in cells or in vitro, although it did increase the frequency of catastrophes. This was due to the fact that paclitaxel also increased the frequency of rescues. In vitro studies showed that paclitaxel introduced stabilized lattice regions that could serve as points of repeated microtubule rescue. A common mechanism for the action of MTAs on the dynamics of EB-associated microtubules is an increase in the catastrophe frequency.

1189

**A +TIPs census in mammalian genome uncovers numerous crosslinkers between microtubules and various cellular structures.**

K. Jiang<sup>1</sup>, G. Toedt<sup>2</sup>, S. Montenegro Gouveia<sup>3</sup>, N. E. Davey<sup>2</sup>, S. Hua<sup>1</sup>, B. van der Vaart<sup>3</sup>, J. Larsen<sup>4</sup>, J. Demmers<sup>5</sup>, M. O. Steinmetz<sup>6</sup>, T. J. Gibson<sup>2</sup>, A. Akhmanova<sup>1</sup>; <sup>1</sup>Cell Biology, Utrecht University, Utrecht, Netherlands, <sup>2</sup>European Molecular Biology Laboratory, Heidelberg, Germany, <sup>3</sup>Department of Cell Biology, Erasmus Medical Center, Rotterdam, Netherlands, <sup>4</sup>Department of Biology, University of Copenhagen, Copenhagen, Denmark, <sup>5</sup>Proteomics Center, Erasmus Medical Center, Rotterdam, Netherlands, <sup>6</sup>Biomolecular Research, Paul Scherrer Institut, Villigen, Switzerland

Microtubule plus end tracking protein (+TIPs) are structurally and functionally diverse factors that accumulate at the growing microtubule ends, regulate their dynamics and serve as linkers between microtubules and various cellular structures. Among a few +TIPs that can recognize growing microtubule ends autonomously, the End Binding (EB) family plays a dominant role at the microtubule plus ends by recruiting numerous other +TIPs. However, our current knowledge about the function of +TIPs is limited because we lack a complete picture of the composition of the ‘+TIPtome’. Here, we established a procedure to systematically search for EB partners by combining proteomics and bioinformatics methods. We have obtained ranked lists of potential candidates, experimentally tested a subset of these proteins for EB binding and plus end tracking and significantly extended the list of EB partners that have the capacity to accumulate at the growing microtubule ends, including membrane-, centriole- and actin-associated proteins as well as kinases and a small GTPase. These proteins should be taken into account in future when considering molecular mechanisms that govern the interplay between microtubules and other cellular structures. We found that one of the newly identified

+TIPs, a centriolar protein CEP104, interacts with the centriolar capping complex CEP97/CP110 and regulates ciliogenesis. Another newly identified +TIP, AMER2, can serve as a reporter of microtubule-plasma membrane interactions. By using this reporter, we are able to directly confirm the long standing idea that cortical actin inhibits the interaction between microtubules and the plasma membrane. In a more general context, a combination of proteomics and motif ranking approaches can be applied to other types of protein binding motifs to uncover their proteome-wide occurrence and their contribution to the global protein interaction networks.

1190

**Assembly of a millimeter-sized microtubule aster in a model cytoplasm.**

*K. Ishihara<sup>1</sup>, P. A. Nguyen<sup>1</sup>, A. C. Groen<sup>1</sup>, C. M. Field<sup>1</sup>, T. J. Mitchison<sup>1</sup>; <sup>1</sup>Department of Systems Biology, Harvard Medical School, Boston, MA*

The cytoplasm of large egg and embryonic cells are organized primarily by radial arrays of microtubules called asters. Prior to cell division, asters expand to cover the entire millimeter-sized cytoplasm in 20 minutes. Such rapid exploration of cell shape and size is thought to be crucial for positioning of centrosomes and the cleavage plane (Wuhr et al., 2010, *Curr Biol* 20, 2040-45). It is unknown how microtubules (MTs) assemble at such a large distance from their presumable nucleation centers or centrosomes. We hypothesize three distinct processes that contribute to addition of MT at the aster periphery: (1) MT polymerization at plus-ends, (2) MT transport and (3) MT-stimulated MT nucleation. We used interphase *Xenopus* egg extract with either centrosomes or beads coated with Aurora A antibody (Tsai & Zheng, 2005, *Curr Biol* 15, 2156-63) to recapitulate aster growth. Through time lapse microscopy, we quantified the distribution of growing plus ends of MTs and found it to be uniform within the expanding aster. MT transport, observed by fluorescent speckle microscopy, was minimal. We explored the consequences of noncentrosomal MT nucleation on aster growth by constructing a biophysical model of plus-end distribution. Our model suggests that MT-stimulated MT nucleation, when coupled with plus-end dynamic instability, increase the rate of aster expansion. In the depleting limits of a hypothetical MT nucleator, the model offers an explanation to how MT density is maintained at the aster periphery. Our work begins to explore the biophysical mechanisms underlying the assembly of a millimeter-sized cytoskeletal network.

1191

**Golgi outpost mediated microtubule nucleation is necessary for outgrowth and stability of *Drosophila* dendritic arborization neurons.**

*K. M. Ori-McKenney<sup>1</sup>, L. Y. Jan<sup>1</sup>, Y-N. Jan<sup>1</sup>; <sup>1</sup>University of California, San Francisco, San Francisco, CA*

Microtubule nucleation is essential for proper establishment and maintenance of axons and dendrites. The centrosome is thought to be the primary site of nucleation in most cells; however, *Drosophila* dendritic arborization (da) neurons do not contain centrosomes, and therefore provide a model system to study acentrosomal microtubule nucleation. Here we investigate the origin of microtubules within the terminal branches of Class IV da neurons, which produce an elaborate dendritic arbor. Using EB1-GFP to track the growing plus end of the microtubule in vivo, we find that microtubule organization differs dramatically in the terminal branches compared with the primary branches. EB1-GFP comets grow towards the distal tip of the terminal branches and originate from specific sites within the arbor. Intriguingly, we observe that EB1 comets often emanate from stationary Golgi outposts positioned throughout the arbor, but especially at branch points. In vitro assays also reveal that partially purified Golgi outpost vesicles can directly nucleate microtubules. We find that gamma-tubulin along with CP309, the *Drosophila* homologue of AKAP450, are necessary for this process. Together these results

provide the first evidence that individual Golgi outposts can act as acentrosomal microtubule nucleation centers throughout the dendritic arbor. Golgi outpost mediated nucleation contributes not only to the complex organization of the microtubule cytoskeleton, but also to the growth and maintenance of the entire dendritic arbor.

1192

**An inherited beta-tubulin mutation disrupts microtubule dynamics, kinesin-microtubule binding interface and causes polymicrogyria, CFEOM, and axon dysinnervation.**

A. M. Luchniak<sup>1</sup>, G. Y. Cederquist<sup>2</sup>, M. A. Tischfield<sup>2</sup>, M. Maya Peeva<sup>2</sup>, Y. Song<sup>2</sup>, E. C. Engle<sup>2</sup>, M. L. Gupta, Jr<sup>3</sup>; <sup>1</sup>Biochemistry and Molecular Biology, University of Chicago, Chicago, IL, <sup>2</sup>Department of Neurology, Boston Children's Hospital, Boston, MA, <sup>3</sup>Molecular Genetics and Cell Biology, University of Chicago, Chicago, IL

Microtubules are cytoskeletal polymers that perform a multitude of functions during development of the central nervous system. They assemble from  $\alpha\beta$ -tubulin heterodimers in a polarized fashion and form dynamic networks inside the cell. The vast majority of higher eukaryotes utilize multiple  $\alpha$ - and  $\beta$ -tubulin isoforms. However, the role of specific tubulin genes during neuronal development remains elusive. Missense mutations in *TUBB2B*, encoding  $\beta$ -tubulin isoform 2B segregate with a range of neurological phenotypes associated with impaired neuronal migration, suggesting a key role for *TUBB2B* in this process. We identified a novel inherited heterozygous mutation in *TUBB2B* that results in congenital fibrosis of the extraocular muscles (CFEOM), previously linked to mutations in *TUBB3*, and polymicrogyria. This mutation causes an E421K amino acid substitution, decreased production of TUBB2B-E421K polypeptide, and impaired folding of tubulin heterodimers *in vitro*. Using *in vitro* biochemical assays we showed that the successfully folded mutant  $\alpha\beta$ -tubulin heterodimers are incorporated into microtubule polymers. We modeled the E421K mutation in budding yeast *S. cerevisiae*, a powerful tool for studying the effects of specific tubulin mutations on microtubule function. While the tubulin heterodimers bearing the E421K substitution co-assembled into microtubules, they altered their dynamics leading to increased stability of microtubule polymers, and decreased kinesin localization due to disruption of the kinesin-tubulin binding interface. E421K- $\beta$ -tubulin incorporates into microtubules and alters their biochemical properties, thus it has unique characteristics not seen for previously identified *TUBB2B* mutations. Furthermore, the exogenous expression of Tubb2b-E421K in developing colossal projection neurons affected homotopic connectivity without perturbing neuronal production and migration. These observations reveal that the E421K substitution results in axon dysinnervation as a primary phenotype as observed in affected individuals. Our results provide mechanistic insights into why E421K and not other *TUBB2B* mutations results in axon dysinnervation, highlighting the overlapping and divergent functions of  $\beta$ -tubulin isoforms during development of the central nervous system in humans.

1193

**Microtubules Are Involved in Pneumolysin-Induced Pulmonary Endothelial Hyperpermeability.**

I. B. Alieva<sup>1</sup>, E. A. Zemskov<sup>2</sup>, S. Sridha<sup>2</sup>, T. Chakraborty<sup>3</sup>, A. D. Verin<sup>2</sup>, R. Lucas<sup>2</sup>; <sup>1</sup>Cell Morphology, A.N. Belozersky Institute, University of Moscow and People's Friendship University of Russia, Moscow, Russia, <sup>2</sup>Vascular Biology Center, Georgia Health Sciences University, Augusta, GA, <sup>3</sup>Institute of Medical Microbiology, Justus-Liebig University, Giessen, Germany

The cytoskeleton plays a crucial role in maintaining endothelial barrier function. Indeed, cytoskeletal reorganization changes the cell shape and provides the structural basis for either an enhancement or a loss of endothelial barrier function. Our previous data have demonstrated

a critical involvement of microtubule (MT) disassembly in thrombin- and nocodazole-induced EC barrier dysfunction and have indicated that MT dynamics is an early event in the circuit of the reactions leading to changes in pulmonary EC barrier permeability. Antibiotics-induced release of the pore-forming virulence factor pneumolysin (PLY) in patients with pneumococcal pneumonia results in its presence days after lungs are sterile and is a major factor responsible for the induction of permeability edema. Here we investigated the involvement of MTs into PLY-induced endothelial dysfunction and we examined whether the TNF-derived TIP peptide, which was previously shown to protect from PLY-induced hyperpermeability, could prevent PLY-induced changes in cytoskeletal organization. The endothelial MT network is heterogeneous, which is consistent with the dynamic characteristics of its constituent MT. The MT population can be divided into two subpopulations: dynamic MTs and acetylated MTs, the latter of which are more stable and more resistant to the effects of external factors than the former ones. The density of the MT network is the highest in the internal cytoplasm, but diminishes gradually in the direction of the cell margin. PLY induced a partial MT depolymerization of the dynamic and stable MT network at the cell periphery. Treatment with the TNF-derived TIP peptide increased the dynamic MT density near the cell edge, but did not influence the density of stable acetylated MTs. Quantitative analysis of MT density in the 5- $\mu$ m zone from the cell margin revealed that dynamic MTs decreased more than twice upon PLY action, but increased over basal levels upon TIP peptide pre-treatment. The TIP peptide completely rescued dynamic MTs near the cell edge and restored the density of stable acetylated MTs upon PLY treatment. As such, PLY caused de-polymerization of both dynamic and stable MTs. The TNF-derived TIP peptide can effectively rescue both dynamic and stable MTs from the pore-forming toxin's action and should therefore be further evaluated as a potential therapeutic agent for treating pulmonary permeability edema associated with severe pneumonia. Supported by NIH grants R01HL094609 (R.L.), RO1HL067307 (A.D.V.), GHSU CVDI and AHA 11SDG7670035 grants (E.A.Z.), RFBR grants 09-04-00363 and 12-04-00488 (I.B.A.).

#### **Microtubule (MT)-dependent regulation of muscle length.**

V. K. Schulman<sup>1</sup>, E. S. Folker<sup>2</sup>, M. K. Baylies<sup>1,2</sup>; <sup>1</sup>Weill Cornell Graduate School of Medical Sciences, New York, NY, <sup>2</sup>Sloan-Kettering Institute, New York, NY

Many muscle diseases are characterized by smaller, weaker myofibers, highlighting the fact that muscle size is critical for muscle function. To study the regulation of muscle size, we used the model organism, *Drosophila melanogaster*, a system that permits *in vivo* cell biological studies with an additional means to assess muscle function at later stages of development. Many aspects of morphogenesis determine overall muscle size, including nuclear number, cell volume, and myofiber length. We have focused on how muscle length is regulated because we have shown that larvae with shorter muscles exhibit significantly impaired muscle function. Through a combination of mutational analysis and RNAi-based screens, we have identified a number of factors that affect muscle length. Mutations in, or depletion of, Lis1, NudC, Rapsynoid (Raps/Pins), the minus-end directed MT motor Dynein Heavy chain (Dhc), and its regulatory light chain (Dlc), all result in muscles that are shorter than controls. Conversely, mutations in, or depletion of, the plus-end directed motor Kinesin heavy chain (Khc), its regulatory light chain (Klc), and Ensconsin (Ens), exhibit significantly longer muscles compared to controls. Finally, we have identified Sunday Driver (Syd) as a factor that coordinates Kinesin and Dynein activities as they pertain to muscle length determination. Although homozygous *syd* mutants produce muscles of the proper length, double heterozygotes of *syd* and *khc* have longer muscles than controls, and double heterozygotes of *syd* and *dhc* have shorter muscles than controls. This suggests that the adapter protein, Syd, is simultaneously regulating Dhc and Khc to influence muscle length. Collectively, these data suggest that muscle length is regulated by a

MT-dependent process mediated by motor protein complexes that are coordinated by Syd to facilitate proper extension of the muscle pole.

**Understanding the three-dimensional organization of microtubule coils in human platelets.**

R. Gibeaux<sup>1</sup>, K. Sadou<sup>2</sup>, S. Khochbin<sup>2</sup>, F. Nédélec<sup>1</sup>; <sup>1</sup>Cell Biology and Biophysics Unit, European Molecular Biology Laboratory (EMBL), Heidelberg, Germany, <sup>2</sup>Inserm U823, Institut Albert Bonniot, Grenoble, France

Blood platelets circulate through blood vessels. They have as primary function to survey the integrity of the vascular system and are activated in response to blood vessel injuries. Microtubule coils are the major structural elements responsible for platelet characteristic disc shape and the only example of a circumferential marginal band existing in mature human cells. This tight microtubule assembly is found along the long axis of discoid platelets, beneath the plasma membrane. Upon activation, platelets lose their lentiform shape and within a few seconds they become more rounded and start to project pseudopodia. This activation is crucial for their spreading, aggregation and the formation of platelet plugs. The associated shape change is correlated with the reorganization of the internal cytoskeleton including the constriction of microtubule coils into smaller rings around centrally concentrated organelles.

For a long time it has been thought that the marginal band consists of a single microtubule polymer that is wound in 8 to 12 coils, the so-called single microtubule model (reviewed in Hartwig and Italiano, 2003). Visualization of microtubule growth in living platelets recently revealed that the marginal band is a dynamic structure composed of multiple microtubules assembled in a bidirectional pattern favoring a multiple microtubule model (Patel-Hett *et al.*, 2008).

To decisively understand the three dimensional organization of the platelet marginal band at the single-microtubule resolution, we use electron tomography on plastic embedded sections from cells cryofixed by high pressure freezing. We reconstruct the complete microtubule cytoskeleton in human platelets at the resting and different activation states. Using data extracted from electron tomograms about the number, the length distribution, the polarity and the three dimensional organization of microtubules and other parameters collected from the literature, we are able to perform first principle computer simulations using Cytosim, a program developed for stochastic simulations of cytoskeletal fibers, diffusible activities and flexible objects in a confined environment. There, our goal is to understand the dynamic maintenance of the marginal band at resting state and its reorganization upon platelet activation.

1196

**Exploring microtubule dynamics in vivo and its role in tissue biogenesis.**

B. Lacroix<sup>1</sup>, S. Ihara<sup>2</sup>, K. Bourdages<sup>1</sup>, J. Dorn<sup>1</sup>, D. R. Sherwood<sup>2</sup>, P. S. Maddox<sup>1</sup>, A. S. Maddox<sup>1</sup>; <sup>1</sup>IRIC, Université de Montréal, Montréal, QC, Canada, <sup>2</sup>Duke University, Durham, NC

Cytoskeletal dynamics control vast numbers of cellular processes including cell polarity and cell division both of which are critical for tissue biogenesis. A complex developmental process, tissue biogenesis requires that the constituent cells undergo division, differentiation, movement, and reorganization of adhesions. Despite playing a central role, the dynamic properties of microtubules (MTs) in tissue biogenesis have not been studied.

We hypothesized that MT dynamics are differentially regulated throughout tissue biogenesis, and that this regulation is important for the differentiation and function of specific tissues. To test this idea, we generated a *C. elegans* strain in which GFP-tagged tubulin is expressed

specifically in cell lineages giving rise to the egg-laying apparatus (vulva), from larval stages to adult. This system allows us to measure and compare MT dynamics in cells of the same lineage at different developmental stages within the same organism. Intact living worms are immobilized and mounted for time-lapse real-time confocal imaging of MT dynamics in 3 or 4 dimensions with high spatial and temporal (1 sec) resolution. Interestingly, MTs from differentiated cells have a higher growth rate than those of precursor cells (0.1534 +/- 0.0028 vs. 0.1199 +/- 0.0033  $\mu\text{m}/\text{sec}$ ), and display long biphasic growth excursions, slowing as they near the cell periphery. Precursor cells' MTs have shorter growing phases and higher catastrophe and rescue frequencies.

To define the molecular mechanism of differentiation state-specific variations in MT dynamics, we depleted MT- and tubulin-binding proteins by RNAi and assessed vulva formation and function. By varying the timing of RNA introduction, we distinguished whether proteins are essential for tissue biogenesis (i.e. cell division, migration, etc.), the function of the fully developed tissue, or both. Our targeted RNAi screen identified two proteins with inverse phenotypes: CLS-1<sup>CLASP2</sup> is specifically required for tissue biogenesis and KLP-7<sup>MCAK</sup> is required for tissue function. Furthermore, depletion of a given protein at different developmental stages resulted in differential effects on MT dynamics and therefore terminal phenotypes.

Thus, we have developed a powerful model system to investigate the role of MT dynamics in tissue biogenesis using intact animals. We further show that MT dynamics are differentially and selectively regulated during cell differentiation and that this regulation is fundamental to development of multi-cellular organisms.

### Different casein kinase isoforms as important regulating factors of plant microtubular functioning.

P. A. Karpov<sup>1</sup>, A. I. Yemets<sup>2</sup>, A. V. Rayevsky<sup>1</sup>, Y. B. Blume<sup>3</sup>; <sup>1</sup>Laboratory of Bioinformatics and Structural Biology, Institute of Food Biotechnology and Genomics, Kiev, Ukraine, <sup>2</sup>Laboratory of Cell Biology and Nanobiotechnology, Institute of Food Biotechnology and Genomics, Kiev, Ukraine, <sup>3</sup>Department of Genomics and Molecular Biotechnology, Institute of Food Biotechnology and Genomics, Kiev, Ukraine

It was demonstrated that different members of the casein kinase (CK) I family play a basic role in regulation of plant microtubule (MT) organization and dynamics. Bioinformatic analysis revealed the presence of 18 CK1-like kinases in *Arabidopsis thaliana*. The spatial structures of catalytic domains of CK1s from *Rattus norvegicus* ( $\alpha$ ,  $\beta$ ,  $\gamma$ 1-3,  $\delta$ , and  $\epsilon$ ) and 18 homologues from *Arabidopsis* were reconstructed. Superimposition of catalytic domains of CK1 ( $\alpha$ ,  $\beta$ ,  $\gamma$ 1-3,  $\delta$ , and  $\epsilon$ ) from *R. norvegicus* and *A. thaliana* homologues confirms high structural similarity for 13 plant CK1-like kinases: KC1D, CKI1, CKL2, CKL3, CKL4, CKL5, CKL6, CKL7, CKL8, CKL9b, CKL10, CKL12 and CKL13. It was found that CK1-specific inhibitor D4476 interacts with rat CK1 $\delta$  and all 13 plant homologues in similar ATP-competitive manner. Ligand docking, molecular dynamics and chemogenomic analysis of D4476 complexes with rat CK1 $\delta$  and 13 CK plant isoforms revealed similar molecular mechanisms of ligand binding. Respectively, it was shown that regulation of plant MT dynamics by CK1 depends on its ability to bind tubulin or MT-associated proteins. D4476 had a strong effects on growth and morphology of *A. thaliana* primary roots. It was found that root growth and development was sensitive to all tested (0.1-50  $\mu\text{M}$ ) concentrations of D4476. The effects of this inhibitor on MT organization (spatial reorientation of cortical MTs) were proved with confocal laser scanning microscopy on GFP-MBD (GFP-Map4) expressing *Arabidopsis* root cells. Thus, obtained results demonstrate the plant CK1 members can regulate MT behavior through direct tubulin (isoform CKL6) and EB1 (isoforms CKL2 and CK1D) phosphorylation. We identified motifs presumably involved in MT-

binding of plant CK1D and CKL2 with EB1 and CKL6 with tubulin. These results were also confirmed by GeneVestigator data on CKL6, CKL2 and CK1D expression in *A. thaliana* roots.

1198

**Nitration of plant  $\alpha$ -tubulin tyrosines in nitric oxide cell signaling.**

A. I. Yemets<sup>1</sup>, Y. A. Krasylenko<sup>1</sup>, D. I. Lytvyn<sup>1</sup>, Y. B. Blume<sup>2</sup>; <sup>1</sup>Laboratory of Cell Biology and Nanobiotechnology, Institute of Food Biotechnology and Genomics, Kiev, Ukraine, <sup>2</sup>Department Genomics and Molecular Biotechnology, Institute of Food Biotechnology and Genomics, Kiev, Ukraine

Nitric oxide (NO) regulates numerous cellular processes in plants; however, the exact mechanisms of NO signalling are still poorly studied. Protein post-translational modifications realize direct NO action, affecting proteins' structure, function and/or protein-protein interactions. Among the candidates for NO-downstream effectors are cytoskeletal proteins because of their involvement in many processes regulated by NO. We demonstrated for the first time the occurrence of  $\alpha$ -tubulin tyrosine nitration in *Nicotiana tabacum* suspension culture BY-2 cells under physiological conditions using tubulin immunoprecipitation and Western-blot analysis (Yemets et al., 2011, Plant Sci, 181(5):545–554). The colocalization of  $\alpha$ -tubulin and 3-nitrotyrosine on preprophase bands, mitotic spindles and fragmoplasts in untreated BY-2 cells was revealed by immunofluorescent microscopy with antibodies against  $\alpha$ -tubulin and 3-nitrotyrosine. It was shown, that treatment with NO donor sodium nitroprusside decreased number of mitotic cells. Hence,  $\alpha$ -tubulin tyrosine nitration can be considered as important mechanism for the regulation of microtubular dynamics.

1199

**Plant acentriolar cortical microtubule array reorganization uncovers cellular processes governing array regulation.**

L. Vineyard<sup>1</sup>, S. L. Shaw<sup>1</sup>, J. Lucas<sup>2</sup>; <sup>1</sup>Biology, Indiana University Bloomington, Bloomington, IN, <sup>2</sup>Santa Clara University, Santa Clara, CA

The acentriolar microtubule arrays in *Arabidopsis* hypocotyl cells organize into functional patterns that are critical for cellular morphogenesis. To elucidate the mechanisms required for array patterning, we synchronously induced the formation of transverse co-aligned microtubule arrays in epidermal cells using plant hormones. We defined four general classes of cortical microtubule array pattern in the box-shaped epidermal cells prior to hormone exposure. Quantification of plus-end polymerization trajectories revealed a striking 3:1 asymmetry in the number of microtubules polymerizing out of the outward-facing (periclinal) array versus those moving into the array from the lateral (anticlinal) side faces of the cell. After induction, we identified a specific spatial and temporal sequence of microtubule array changes that lead to transverse co-alignment from all four initial array patterns. Cells appear to shift their arrays by rapidly correcting the orientation asymmetry and by introducing transverse microtubules from the lateral side faces of the cell. Transverse patterning initiated around the cell's midzone and progressed to the apical and basal ends. The longitudinally oriented polymers at the cell's apical and basal ends were the last elements of microtubule pattern to change. We conclude that transverse array organization is driven primarily by the introduction of new transverse microtubules from the lateral side faces of the cell. Application of the hormone induction assay to *Arabidopsis* CLASP and Katanin mutants indicates opposing roles in the mechanism of transverse microtubule array patterning.

**The response of the microtubule cytoskeleton to extreme deformations of the cell***E. Buchman<sup>1</sup>, O. Haddad<sup>1</sup>, D. Fudge<sup>1</sup>; <sup>1</sup>Integrative Biology, University of Guelph, Guelph, ON, Canada*

This study sought to investigate the response of the microtubule cytoskeleton to extreme deformations of the cell, on the order of 50% cell strain. Using a custom built live-cell imaging and stretching chamber, we employed epi-fluorescence microscopy and GFP conjugated proteins to illuminate either full microtubules (GFP-tubulin) or growing microtubule plus ends (GFP-EB1) in MDCK cells cultured on silicone strips. We found that the microtubule cytoskeleton is remarkably resilient to strains up to 50%, undergoing only minor changes in network organization (ie. alignment of filaments with the perturbation axis), while maintaining their characteristic dynamic instability. Following stretch, microtubule bending fluctuations were found to decrease in amplitude, though they showed a tendency to recover towards prestretch values in only fifteen minutes. Our analyses of microtubule bending fluctuations suggest that similar analyses may serve as a proxy for investigating the distribution and magnitude of forces in the cytosol by way of measuring nonequilibrium shape changes in cytoskeletal filaments. Furthermore, this study has implications for the use of cells and microtubule networks in 'smart-materials' and bioengineering applications involving high strain.

**Conformational Changes in Tubulin in GMPCPP and GDP-taxol Microtubules Observed by Cryo Electron Microscopy.***H. Yajima<sup>1</sup>, T. Ogura<sup>2</sup>, R. Nitta<sup>1</sup>, Y. Okada<sup>1</sup>, C. Sato<sup>2</sup>, N. Hirokawa<sup>1</sup>; <sup>1</sup>Department of Cell Biology and Anatomy, Graduate School of Medicine, University of Tokyo, Tokyo, Japan, <sup>2</sup>Biomedical Research Institute and Biological Information Research Center, National Institute of Advanced Industrial Science and Technology (AIST), Tsukuba, Japan*

Microtubules are dynamic polymers that stochastically switch between growing and shrinking phases. Microtubule dynamics are regulated by GTP hydrolysis by  $\beta$ -tubulin, but the mechanism of this regulation remains elusive because high-resolution microtubule structures have only been revealed for the GDP state. Here we solved the cryo-EM structure of microtubule stabilized with a GTP analogue guanylyl 5'- $\alpha,\beta$ -methylenediphosphonate (GMPCPP) at 8.8 Å resolution by developing a novel cryo-EM image reconstruction algorithm. In contrast to the crystal structures of GTP-bound tubulin relatives such as  $\gamma$ -tubulin and bacterial tubulins, significant changes were detected between GMPCPP and GDP-taxol microtubules at the contacts between tubulins both along the protofilament and between neighboring protofilaments, contributing to the stability of the microtubule. These findings are consistent with the structural plasticity or lattice model, and suggest the structural basis not only for the regulatory mechanism of microtubule dynamics, but also for the recognition of the nucleotide state of the microtubule by several microtubule-binding proteins, such as EB1 or kinesin.

1202

**Luminal localization of  $\alpha$ -tubulin K40 acetylation by cryo-EM analysis of Fab-labeled microtubules.**

V. Soppina<sup>1</sup>, J. F. Herbstman<sup>2</sup>, G. Skiniotis<sup>2</sup>, K. J. Verhey<sup>1</sup>; <sup>1</sup>Department of Cell and Developmental Biology, University of Michigan Medical School, Ann Arbor, MI, <sup>2</sup>Life Sciences Institute and Department of Biological Chemistry, University of Michigan Medical School, Ann Arbor, MI

The  $\alpha\beta$ -tubulin subunits of microtubules can undergo a variety of evolutionarily-conserved post-translational modifications (PTMs) that provide functional specialization to subsets of cellular microtubules. Acetylation of  $\alpha$ -tubulin residue Lysine 40 (K40) has been correlated with increased microtubule stability, intracellular transport, and ciliary assembly, yet a mechanistic understanding of how acetylation influences these events is lacking. Using the anti-acetylated tubulin antibody 6-11B-1 and electron cryo-microscopy, we demonstrate that the K40 acetylation site is located inside the microtubule lumen and thus cannot directly influence events on the microtubule surface, including kinesin-1 binding. Surprisingly, the monoclonal 6-11B-1 antibody recognizes both acetylated and deacetylated microtubules. These results suggest that acetylation induces structural changes in the K40-containing loop that could have important functional consequences on microtubule stability, bending, and subunit interactions. This work has important implications for acetylation and deacetylation reaction mechanisms as well as for interpreting experiments based on 6-11B-1 labeling.

1203

**A New Motion-Detection Method Reveals Key Regulatory Steps of Microtubule Dynamics in Growth Cone Motility from Only a Pair of Images.**

A. Garrison<sup>1</sup>, M. Shanmugam<sup>1</sup>, H. C. Leung<sup>1</sup>, C. Xia<sup>1</sup>, Z. Wang<sup>1</sup>, L. Ma<sup>1</sup>; <sup>1</sup>Zilkha Neurogenetic Institute, University of Southern California, Los Angeles, CA

Microtubule dynamics is critical to many morphogenetic processes, including growth cone guidance and wound healing. However, our understanding of its regulation, especially the step of the assembly cycle that might be targeted during cell shape remodeling, is limited. Here we present a new method to identify these steps and analyze their spatial and temporal regulation in live cells. Using a GFP-tagged plus-end-tracking protein EB3 as a probe, this method analyzes motion and appearance/disappearance of labeled microtubule ends at any given time, and deduces the corresponding step of microtubule assembly at each end. Specifically, plus-end labels from two sequential images are first pseudocolored with separate colors and merged to generate a microtubule assembly map. Color-coded ends in the map are then identified and segregated based on object recognition algorithms into four dynamic steps: growth, rescue, catastrophe, and pause. Furthermore, morphological analysis provides quantitative data on microtubule assembly such as growth rate and direction at growing microtubule ends. To validate the method, we have confirmed the representation of these dynamic steps by the analysis of history and fate of identified microtubule ends. In addition, we have shown that our results are comparable to the ground truth data derived from manual analysis as well as to the quantitative data obtained by the commonly used tracking approach. Thus, this new method can be used in many cellular processes involving rapid shape remodeling when traditional tracking is not feasible. To illustrate this application, we have investigated microtubule assembly in growth cones during turning and branching. From the assembly map generated at each time point, we have found that microtubule growth direction in the central domain correlates well with future growth cone orientation. Moreover, we have found that redistribution of rescue and catastrophe is associated with changes in microtubule growth direction prior to morphological polarization, suggesting key regulation sites in directed growth cone motility.

Thus, this computer vision method offers a unique and quantitative approach to visualize and analyze microtubule dynamics and can be extended to studying spatial regulation of microtubule assembly in responses to cell signaling as well as in other complex morphogenetic processes.

1204

**The structural basis of microtubule dynamics.**

*G. M. Alushin<sup>1</sup>, G. C. Lander<sup>2</sup>, E. Nogales<sup>1,2</sup>; <sup>1</sup>HHMI, Molecular and Cell Biology, UC Berkeley, Berkeley, CA, <sup>2</sup>Life Sciences Division, Lawrence Berkeley National Lab, Berkeley, CA*

Microtubules are one of the principle classes of cytoskeletal filaments and are critical for a diverse array of cellular processes, including intracellular trafficking, the generation and maintenance of cell morphology, and cell division. Microtubules exhibit the property of dynamic instability: rather than existing as static assemblies, the filaments stochastically switch between phases of growth and shrinkage through the addition and dissociation of tubulin subunits. These dynamics are capable of performing work and are critical for microtubule function. Cell division in particular is powered by the polymerization and depolymerization of microtubules, processes which are specifically targeted and disrupted by several successful anti-proliferative therapeutics. It has been known for decades that tubulin's binding and hydrolysis of GTP underlies dynamic instability, yet a molecular mechanistic explanation remains elusive, largely because the structural details of tubulin's conformation and interaction with nucleotide in the context of the microtubule lattice are unknown. Through technological improvements in cryo-electron microscopy sample preparation, instrumentation, and image processing, we have obtained reconstructions of GMPCPP (a non-hydrolyzable GTP analog) and GDP microtubules with better than 5 Å resolution in the absence of drugs and other stabilizing factors, sufficient to resolve all elements of tubulin involved in and affected by lattice contacts and to directly visualize the positions and orientations of bound nucleotides. We integrate these results into a physical model for the interrelationship between nucleotide state, tubulin lattice contacts, and microtubule stability.

1205

**Centrosome amplification causes microcephaly.**

*V. Marthiens<sup>1</sup>, P. Paul-Gilloteaux<sup>2</sup>, C. Pennetier<sup>1</sup>, R. Basto<sup>1</sup>; <sup>1</sup>UMR144, Institut Curie, Paris, France, <sup>2</sup>UMR144/PICT-IBISA, Institut Curie, Paris, France*

The presence of more than two centrosomes in a mitotic cell- commonly referred to as centrosome amplification- has been proposed to impact on the homeostasis of tissues in the context of tumour formation by triggering chromosome instability. One of the first evidence of centrosome amplification being readily tumourigenic came from an investigation at the scale of a fly organism. In the fly model, defective orientation of the division axis driven by extra centrosomes was sufficient to confer to neural stem cells, NSCs, a tumourigenic potential. To explore this possibility in a vertebrate brain tissue, we have now generated the first mouse model where embryonic NSCs carry extra centrosomes by manipulating the machinery of centrosome duplication. We show that centrosome amplification is at the origin of a microcephaly that can be explained by defects in the progression of NSCs through mitosis. We have rapidly excluded the possibility that microcephaly relies on impaired positioning of the mitotic spindle like in drosophila, or on defects in primary ciliogenesis. Instead, we provide compelling evidences that the presence of extra centrosomes at the onset of mitosis results in

cell cycle lengthening through mitotic delay, as well as in the transmission of an abnormal number of chromosomes to the progeny that is poorly tolerated as evidenced by a massive cell death. By computational modeling, we provide further evidences of the likelihood of this scenario to explain the extent of the observed microcephaly. Surprisingly, however, such defects in the NSC population are not sufficient to prevent the production of all the populations of neurons in good shape and order, but only affect the number of neurons produced. Altogether, our results support the concept that extra centrosomes can be at the origin of microcephaly by conferring growth disadvantages and survival defects to the NSC population. This scenario would have to be considered while elucidating the mechanisms responsible for brain size reduction, especially in the context of neuro-developmental disorders caused by mitotic spindle pole abnormalities.

1206

### **T-cells Mediate Substantia Nigra Neurodegeneration in Parkinson's Disease.**

J. D. Loike<sup>1</sup>, C. Cebrián<sup>2</sup>, S. Budhu<sup>1</sup>, F. A. Zucca<sup>3</sup>, P. Mauri<sup>3</sup>, J. Mandelbaum<sup>2</sup>, J. Vonsattel<sup>4</sup>, L. Zecca<sup>3</sup>; <sup>1</sup>Physiology, New York City, NY, <sup>2</sup>Neurology, Columbia University, New York City, NY, <sup>3</sup>Institute of Biomedical Technologies, National Research Council of Italy, Milano, Italy, <sup>4</sup>Neurological Institute, Columbia University, New York, NY

Parkinson's disease (PD) patients exhibit marked inflammation in the substantia nigra (SN) with extensive and selective death of their dopaminergic (DA) neurons. We find that in primary murine neuronal cultures, SN and locus coeruleus (LC) neurons can be induced to express cell surface MHC-I by the proinflammatory cytokine gamma-interferon, L-DOPA, or conditioned medium obtained from murine microglia exposed to alpha-synuclein or neuromelanin (NM). In addition, SN DA murine neurons can process the foreign protein ovalbumin to a smaller antigenic peptide that is presented by their MHC-I and trigger their own destruction by CD8+ killer T-cells that recognize the presented antigen. Studies using human pathological samples show that DA SN and norepinephrinergic locus coeruleus (LC) neurons from adult human PD patients and age-matched controls express MHC-I as detected by immunostaining using specific antibodies directed against HLA-1 and microglobulin  $\beta$ 2. Moreover, we detect the presence of CD8+ T cells in association with NM containing DA neurons in patients with PD. Based on these results, we propose three requirements for neurodegeneration in PD; 1) MHC-I presentation, 2) antigen display, and 3) the presence of an appropriate antigen-specific cytolytic T-cell population- processes that may occur most commonly in older individuals in whom the appropriate T-cells have proliferated and for whom the blood brain barrier can be compromised. The immunologically based mechanism proposed for neurodegeneration in PD is consistent with slow disease progression, the presence of inflammatory cytokines, and the association with aging observed in PD.

1207

### **Regeneration of *Drosophila* sensory neuron axons and dendrites in the PNS and CNS.**

Y. Song<sup>1</sup>, K. M. Ori-McKenney<sup>1</sup>, Y. Zheng<sup>1</sup>, C. Han<sup>1</sup>, L. Y. Jan<sup>1</sup>, Y. Jan<sup>1</sup>; <sup>1</sup>Physiology, University of California San Francisco, San Francisco, CA

Both cell-intrinsic and extrinsic pathways govern axon regeneration, but only a limited number of factors have been identified. Moreover, it is not clear whether dendrites regenerate nor to what extent axon regeneration is evolutionarily conserved. We found, like the axons of mammalian sensory neurons, the axons of certain *Drosophila* dendritic arborization (da) neurons are capable of substantial regeneration in the periphery but not in the central nervous system (CNS), and activating the Akt pathway enhanced axon regeneration in the CNS. Moreover,

those da neurons capable of axon regeneration also displayed dendrite regeneration, which is cell type specific, developmentally regulated and associated with microtubule polarity reversal. Dendrite regeneration is restrained via inhibition of the Akt pathway in da neurons by the epithelial cell derived microRNA bantam, but facilitated by cell autonomous activation of the Akt pathway. Our study begins to reveal mechanisms for dendrite regeneration, which depends on both extrinsic and intrinsic factors including the Pten-Akt pathway that is also important for axon regeneration. We have thus established an important new model system, the fly da neuron regeneration model that resembles the mammalian injury model, with which to study and gain novel insights into the regeneration machinery.

1208

### **Mechanoprotection in neurites involves a pre-stressed spectrin cytoskeleton.**

M. Krieg<sup>1</sup>, A. R. Dunn<sup>2</sup>, M. B. Goodman<sup>1</sup>; <sup>1</sup>Molecular & Cellular Physiology, Stanford University, Stanford, CA, <sup>2</sup>Chemical Engineering, Stanford University, Stanford, CA

Many somatosensory neurons have evolved specialized molecular sensors that convert mechanical stress into behavioral responses. The genetics, development and physiology of the touch receptor neurons (TRNs) in *Caenorhabditis elegans* nematodes are especially well characterized and this animal has the particular advantage that the TRNs can be studied both in living animals and dissociated in culture. Like other somatosensory neurons, the TRNs use ion channels to convert mechanical stress into electrical signals and ultimately appropriate behaviors. Whereas the protein partners that form these mechanosensitive channels have been known for some time, the mechanism by which mechanical force is propagated from the skin to the TRN and to the channel is essentially unknown.

To investigate the transmission of forces in *C. elegans* TRN neurites, we focused on the structural protein  $\beta$ -spectrin. Spectrin forms tetramers and is a major cytoskeletal component of eukaryotic membranes that integrates the lipid bilayer to the actin cytoskeleton. In red blood cells, spectrin has been shown to unfold during shear stress (Krieger, PNAS, 2011) while tetramerization is critical for cell shape elasticity (Sleep, BiophysJ, 1999). Our results show that mutations in the tetramerization domain of *C. elegans*  $\beta$ -spectrin leads to defective neuron morphology in moving worms and therefore we hypothesized that spectrin might play an important role in bearing and transmitting mechanical load within TRNs. We combined single cell force spectroscopy experiments on isolated neurons, optomechanical manipulation of TRNs, and FRET-based strain measurements (Grashoff, Nature, 2010) in living animals to characterize the role of spectrin in maintaining neurite mechanical integrity. Our data indicate that resting TRNs are understress and that spectrin is held under constitutive tension in living animals. Based on these results and behavioral data on  $\beta$ -spectrin mutants, we speculate that  $\beta$ -spectrin-dependent pre-tension is required for efficient response to external mechanical stimuli.

1209

### **G $\beta$ -Microtubule Interaction is Critical for Neuronal Differentiation and Neurodegeneration.**

J. A. Sierra-Fonseca<sup>1</sup>, J. Martinez<sup>1</sup>, J. Rivas<sup>1</sup>, R. Bach<sup>1</sup>, J. Martinez-Jurado<sup>1</sup>, S. Das<sup>1</sup>, N. S. Lamango<sup>2</sup>, S. Roychowdhury<sup>1</sup>; <sup>1</sup>Biological Sciences, University of Texas at El Paso, El Paso, TX, <sup>2</sup>College of Pharmacy and Pharmaceutical Sciences, Florida A&M University, Tallahassee, FL

Assembly and disassembly of microtubules (MTs) is critical for axon and dendrites formation, and for neurite outgrowth. During neuronal degeneration, the architecture of MTs and proteins

associated with them are severely altered. We have shown earlier that the  $\beta\gamma$  (beta-gamma) subunit of G proteins binds to tubulin stimulating MT assembly. More recently, we found that nerve growth factor (NGF)-induced neuronal differentiation of PC12 cells promotes the interactions of  $G\beta\gamma$  with microtubules. Overexpression of  $G\beta\gamma$  in PC12 cells induced neurite formation in the absence of NGF. The goal of the present study is to understand whether interference with the  $G\beta\gamma$ /MT-mediated pathway inhibits neuritogenesis and causes neurodegeneration. Since polyisoprenylation and further carboxy-terminal processing (methylation) of  $\gamma$  subunits are important for the interaction of  $G\beta\gamma$  with MTs, we used L-23 and L-28, which are both inhibitors of polyisoprenylated methylated protein methyl esterase (PMPMEase), an esterase enzyme of the polyisoprenylation pathway, to conduct the study. In addition, GRK-ct peptide (the carboxy terminus of G protein-coupled-receptor kinase) which is known to inhibit  $G\beta\gamma$ -dependent signaling by binding to and sequestering  $G\beta\gamma$  was also used to determine whether  $G\beta\gamma$  is necessary for MT organization and neurite outgrowth. PC12 cells were treated with NGF over the course of three days, followed by overnight treatment with L-28, L-23 or the prototypical molecule, PMSF. Subcellular fractionation, co-immuno-precipitation, and confocal-scanning microscopy were used to analyze the samples. We found that neurite formation was not affected significantly in the presence of PMSF or L-23 (10 $\mu$ M). On the other hand, L-28 (10 $\mu$ M) significantly reduced neurite outgrowth, MT formation, and  $G\beta\gamma$  labeling. We found that GRK-ct peptide (10 $\mu$ M, 1h), had a very dramatic effect on morphology and survival of NGF-differentiated PC12 cells, causing neurite and MT disruption, and severe degeneration. Our results show that the  $G\beta\gamma$ -MT interacting pathway is critical for neuritogenesis, and that both inhibitors of PMPMEase, and GRK-ct peptide could be used as valuable tools to study the mechanism of neurite outgrowth and neurodegeneration and for designing strategies to develop effective drugs against neurodegenerative disorders.

### Unraveling the role of neuron sub-cellular mechanical properties in Traumatic Brain Injury.

*T. Grevesse<sup>1</sup>, M. Versaevel<sup>1</sup>, S. Gabriele<sup>1</sup>; <sup>1</sup>InFluX, University of Mons, Mons, Belgium*

The cerebral cortex is estimated to contain 15-33 billion neurons, each connected by synapses to several thousand other neurons. Neurons interact with the brain extracellular matrix (ECM) and communicate with one another by means of long protoplasmic fibers called axons, which carry trains of signal pulses called action potentials. During head injuries or violent accelerations, neurons can be severely damaged and diffuse axonal injury (DAI) is one of the most common and important pathologic features of traumatic brain injury (TBI) [1]. The susceptibility of axons to mechanical injury appears to be due to their viscoelastic properties and their high organization in white matter tracts. Recently, integrin-mediated activation of Rho has been suggested as a key player of diffuse axonal injury reported in mild TBI [2]. However, due to the natural complexity of the neuronal network, cellular and molecular mechanisms of TBI as well as the propagation of forces is still not well understood. Based on the assumption that cell deformation is the initiating event of TBI [3], we investigate the role of the mechanical properties of sub-cellular components of neuronal cells.

First, we have developed a new hydrogel to control and tune independently ECM stiffness, neuron morphology, protein type and density, which are major environment factors in cellular mechanotransduction [4]. Then, we have developed a magnetic tweezers set-up to probe the mechanical behaviour of the cell body and the neurite part.

Cryogenic primary neuron cells were grown on laminin-coated lines deposited on hydrogels to obtain a robust bipolar morphology. We have characterized the viscoelastic properties of sub-cellular components of neuronal cells with creeping experiments and our results show distinct

rheological behaviours that may explain the mechanical vulnerability of axons observed in DAI. By using immunostaining experiments and specific pharmacological agents, we have determined the role of each cytoskeletal components in the mechanical behaviour of both sub-cellular parts.

### **Explant Model For The Study of Neuronal Injury Processes.**

G. Pathak<sup>1</sup>, S. Shah<sup>1,2</sup>; <sup>1</sup>University of Maryland, College Park, MD, <sup>2</sup>Departments of Orthopaedic Surgery and Bioengineering, University of California, San Diego, La Jolla, CA

Unlike the neurons of the peripheral nervous system (PNS), neurons within the central nervous system (CNS) do not regenerate spontaneously. Inhibitory cues present in the environment and intrinsic growth ability of the injured neurons determine the extent of axonal regeneration. Mechanisms involved in this process include retrograde transport of injury signals, local translation of necessary proteins, and anterograde transport of molecules. Studies of these mechanisms will be beneficial in enhancing our understanding of neuronal regeneration, and guiding regeneration in the CNS. We have developed a simple mouse neonate hippocampal explant model to study these neuronal response to injury. As for dissociated cultures, this model enables the control the cellular environment free from systemic effects. However, the preexisting in vivo interconnectivity within the hippocampus is preserved. This allows a more accurate interpretation of results from studies on neuronal injury regeneration. For explantation, the hippocampus of one day old mouse was dissected and cultured on a Matrigel coated glass surface. Tissue was nourished by neurobasal medium with B27 serum. To assess axonal regeneration, the CA1 region of the tissue was injured, and compared to the tissues without any damage. In addition, dynamics of the growth of control and injured axons were quantified for both the injured and control explants. Results suggest that pre-conditioning or injuring the explants enhances the outgrowth of axons after injury. Current studies are investigating mechanisms by which the retrograde transport of injury signals is regulated. This work has important implications for the regulation of neuronal plasticity during neuronal development and in response to neuronal injury.

### **Mutations in p53 and NTF4 Genes are not associated with Retinal Ganglion Cell (RGC) Death in Glaucomatous Beagles.**

B. S. Shastry<sup>1</sup>, K. A. Kato<sup>2</sup>, N. Sasaki<sup>2</sup>; <sup>1</sup>Biological Sciences, Oakland University, Rochester, MI, <sup>2</sup>The Laboratory of Veterinary Medicine, Tokyo, Japan

Glaucoma is a second leading cause of irreversible vision loss in the world and can affect all age groups as well as all populations. It is characterized by the elevated intraocular pressure (IOP), optic disc changes and retinal ganglion cell (RGC) death. The precise mechanism of RGC death and progressive degeneration of optic nerve in glaucoma is not understood. Although the genetic basis of the majority of cases of glaucoma in human was not known, it has been suggested that apoptosis is the common pathway that leads to the death of RGCs in glaucoma and that neurotrophin 4 (NTF4) protein plays a role in the protection of RGCs by activating tyrosine kinase receptors. Additionally, one previous study suggested that p53 codon

72 polymorphism (R72P) might have a greater susceptibility to apoptosis in some ethnic population. Glaucoma also occurs in dogs and the primary glaucoma in beagles is inherited as an autosomal recessive trait. Although recently a candidate gene has been isolated, the mechanism underlying RGC death is not understood. In order to understand whether the same p53 and NTF4 pathway mechanism is involved in an animal model of glaucoma, we have isolated NTF4 gene from dog and analyzed both p53 and NTF4 genes for mutations in glaucomatous animals. Our analyses failed to identify any disease causing mutations in both genes with the exception of two heterozygous polymorphisms in NTF4 gene (CGA to GGA in the third codon and GCG to GCA in 49th codon). One of the polymorphisms changed the third codon (exon 1) from arginine to glycine whereas the second one (exon 2) is a silent change (alanine to alanine). However, these are not pathogenic changes because they are also present in normal animals and are not segregated with the disease. These results suggest that impaired neurotrophin signaling or compromised trophic support to the retina and p53 mediated apoptosis may not be the underlying mechanism of RGCs death in a canine model of glaucoma. Our study underscores the importance of further investigations for more comprehensive understanding of the specific form of RGC death in glaucoma.

1213

**SIL1, a causative gene of Marinesco-Sjogren syndrome, plays an essential role in establishing the architecture of the developing cerebral cortex.**

*K-I. Nagata<sup>1</sup>, Y. Inaguma<sup>1</sup>, Y. Nishimura<sup>1</sup>, H. Ito<sup>1</sup>, M. Suzuki<sup>2</sup>, N. Hamada<sup>1</sup>, M. Mizuno<sup>1</sup>, I. Iwamoto<sup>1</sup>, R. Morishita<sup>1</sup>, T. Kumaga<sup>2</sup>; <sup>1</sup>Molecular Neurobiology, Institute For Developmental Research, Aichi Human Service Center, Kasugai, Japan, <sup>2</sup>Central Hospital, Aichi Human Service Center, Kasugai, Japan*

Marinesco-Sjogren syndrome (MSS) is a rare, autosomal-recessive neurodegenerative disorder that is characterized by mental retardation, cerebellar ataxia, cataracts and progressive myopathy. The SIL1 gene encodes an endoplasmic reticulum resident co-chaperone that regulates the function of the heat-shock protein family chaperone HSPA5. Recently, mutations in SIL1 were identified as a major cause of MSS. Here, we report a novel in-frame 15 bp-deletion in the SIL1 coding region that results in a 5 -amino acid deletion in the encoded protein. To understand the role that SIL1 plays in the pathophysiology of MSS, we examined the effect of altering SIL1 expression and the effect of expressing three different MSS-linked SIL1 mutants, including the newly identified deletion mutation, during brain development. Knockdown experiments using the in utero electroporation method revealed that reducing SIL1 expression leads to an inhibition of neuron migration during corticogenesis. Expressing RNAi-resistant SIL1 reversed the migration defect; however, the MSS-linked SIL1 mutants that were tested did not rescue migration. Moreover, we found that HSPA5 also plays a role in neuron migration during corticogenesis. Biochemical analyses revealed that SIL1 proteins bearing an MSS-linked mutation exhibited weaker binding affinity to HSPA5, and perturbing the protein-protein interaction between SIL1 and HSPA5 led to impaired in vivo neuron migration. Additional analyses revealed that the defective neuron migration induced by MSS-linked SIL1 mutations is due at least in part to abnormal neuron morphology. These data suggest that the MSS-linked mutations abrogate the ability of SIL1 to interact with (and therefore regulate) HSPA5 and that impaired HSPA5 function may lead to abnormal neuron migration, which may subsequently contribute to the mental retardation that is observed in MSS patients.

1214

### Centrosomal role of spastin-NA14 interaction in the pathogenesis of hereditary spastic paraplegia.

U. Goyal<sup>1</sup>, B. R. Renvoise<sup>2</sup>, J. Chang<sup>2</sup>, C. Blackstone<sup>2</sup>; <sup>1</sup>Loma Linda University, Loma Linda, CA, <sup>2</sup>CNU, NIH/NINDS, Bethesda, MD

Hereditary spastic paraplegias (HSPs) are a group of inherited neurological disorders characterized by the cardinal feature of lower-extremity weakness and spasticity due to a length-dependent axonopathy of corticospinal upper motor neurons. The most frequent form of HSP results from mutations of the SPG4 gene product, spastin. This protein is a ubiquitous member of the AAA (ATPase associated with diverse cellular activities) family that binds to and severs microtubules. While spastin participates in crucial cellular processes, its mechanistic role in HSPs remains unclear. Spastin interacts with NA14, a major specific target for auto-antibodies in Sjögren's syndrome nuclear autoantigen 1 (SSNA1). Our analysis of endogenous spastin and NA14 proteins in HeLa cells and primary rat cortical neurons show a clear localization to centrosomes, with NA14 localizing specifically to centrioles. NA14 knock-down in stable cell lines dramatically affects cell division, in particular cytokinesis. Furthermore, overexpression of NA14 and spastin in neurons significantly increases axon outgrowth and branching, and enhances neuronal differentiation. However, the number of centrosomes is not modified. Taken together, our data suggest that NA14 acts as a small adaptor protein regulating spastin localization to centrosomes, likely leading to temporal regulation of microtubule-severing activity. Future analyses of the spastin-NA14 interaction will be crucial to understand the functional role of spastin and how its dysfunction may underlie SPG4.

1215

### The cellular prion protein mediates amyloid- $\beta$ and TNF $\alpha$ -induced cofilin-actin rod formation through NADPH oxidase.

L. S. Minamide<sup>1</sup>, K. Walsh<sup>1</sup>, A. E. Shaw<sup>1</sup>, J. Mi<sup>1</sup>, S. J. Kane<sup>1</sup>, V. Selwyn<sup>1</sup>, B. W. Bernstein<sup>1</sup>, D. R. Brown<sup>2</sup>, T. B. Kuhn<sup>3</sup>, B. Pulford<sup>4</sup>, M. D. Zabel<sup>4</sup>, M. Murphy<sup>5</sup>, J. D. Lambeth<sup>6</sup>, J. R. Bamburg<sup>1</sup>; <sup>1</sup>Biochemistry and Molecular Biology, Colorado State University, Fort Collins, CO, <sup>2</sup>Biology and Biochemistry, University of Bath, Bath, United Kingdom, <sup>3</sup>Chemistry and Biochemistry, University of Alaska, Fairbanks, AK, <sup>4</sup>Microbiology, Immunology and Pathology, Colorado State University, Fort Collins, CO, <sup>5</sup>MRC Mitochondrial Biology Unit, Medical Research Council, Cambridge, United Kingdom, <sup>6</sup>Pathology, Emory University, Atlanta, GA

In neurites of neurons undergoing hypoxia or treated with excitotoxic glutamate, soluble forms of  $\beta$ -amyloid peptide (A $\beta$ ) or the proinflammatory cytokine TNF $\alpha$ , each inducing oxidative stress, actin undergoes dynamic remodeling into rod-shaped cofilin-saturated actin filament bundles (rods) that might explain the common pathologies of familial and sporadic Alzheimer disease (AD). Rods can occlude neurites, blocking transport and disrupting synaptic function. Rods from stressed neurons contain dithiothreitol-sensitive cofilin dimers and oxidation of cysteines at positions 39 and 147 is required to form rods in vivo. Here we show that SDS-stable A $\beta$  dimer/trimer (250 pM A $\beta$ d/t) or TNF $\alpha$  (2.9 nM) induces rods in the same population (20%) of hippocampal neurons, but not in neurons lacking the cellular prion protein (PrP<sup>c</sup>). A higher percentage of PrP<sup>c</sup>-null neurons form rods after treatment with glutamate or mitochondrial inhibitors (e.g. antimycin A), suggesting these inducers generate reactive oxygen species (ROS) by a different mechanism from that of A $\beta$ d/t or TNF $\alpha$ . This finding was confirmed with MitoQ, a mitochondrial ROS scavenger, which inhibited rod formation by 50% in response to glutamate or antimycin A, but did not inhibit rods induced by A $\beta$ d/t or TNF $\alpha$ . Furthermore, TG6-44, an NADPH oxidase (NOX)-2/4 inhibitor, completely blocked neuronal rod formation in response to A $\beta$ d/t but did not block the rod response to antimycin A. PrP<sup>c</sup> is a component of detergent

resistant membrane rafts; about 50% of rods induced by A $\beta$ d/t or TNF $\alpha$  associate with enlarged (coalesced) raft domains that are visualized with a G<sub>M</sub>1-ganglioside label. We conclude that A $\beta$ d/t and TNF $\alpha$  induce rod formation via a PrP<sup>c</sup>-dependent signaling pathway involving production of ROS by NOX2/4. Because A $\beta$ -induced cognitive deficits in rodent models of AD require the presence of PrP<sup>c</sup> and brain injections of A $\beta$ d/t at the maximal rod-inducing concentration induce cognitive deficits, rods may mediate cognitive impairment. Cofilin-actin rods bridge the amyloid and cytokine hypotheses for AD.

**Expression of alternative first exon isoforms of ankyrin-G in brain regions associated with bipolar disorder.**

A. Y. Lopez<sup>1</sup>, M. Xu<sup>1</sup>, E. C. Cooper<sup>1</sup>; <sup>1</sup>Baylor College of Medicine, Houston, TX

Bipolar disorder (BD) is a mood disorder characterized by cyclic episodes of mania and depression. BD is common and can be severely disabling. Multiple independent genome-wide association studies have implicated the ANK3 gene in BD. ANK3 encodes the ankyrin-G (AnkG) protein, which mediates the attachment of integral membrane proteins to the spectrin-actin cortical cytoskeleton. AnkG has three alternative first exons (called here, nt1-3), encoding conserved N-termini for families of isoforms generated by additional variable splicing. Nt-2 and nt-3-containing AnkG isoforms are concentrated at axon initial segments (AIS) and nodes of Ranvier (NOR). Previous studies have suggested that the nt2 was forebrain specific and nt3 was cerebellum specific. Although the molecular mechanism through which variation in AnkG confers susceptibility to BD is unknown, the SNPs most highly associated with BD risk are closest to these neuronal alternative first exons. It was surprising that risk of BD might result from altered function in the cerebellum. We have therefore begun to reexamine AnkG diversity and expression patterns using new antibodies specific for the alternative first exons and immunostaining of rodent brain sections. We found evidence for widespread expression of both AnkG-nt2 and nt3 throughout the forebrain, including in regions associated with BD such as the hippocampus, amygdala, striatum, anterior cingulate cortex, thalamus and prefrontal cortex. In the hippocampus, where principal cells and interneurons are highly segregated, AnkG-nt3 isoforms appears to be absent from pyramidal cells, but highly expressed in a subpopulation of interneurons and in dentate granule cells. Ongoing experiments are aimed at identifying additional forebrain cells types in these regions of interest that express nt3 containing AnkG isoforms. Clarifying the cellular and subcellular localization of these variants may give insight into how changes ANK3 could confer susceptibility to BD.

1217

**Effect of short vs. long term stress on cytoskeletal plasticity.**

K. Sainz<sup>1</sup>, M. Bocanegra<sup>1</sup>, S. Kavuma<sup>1</sup>, D. P. Baluch<sup>1</sup>; <sup>1</sup>School of Life Sciences, Arizona State University, Tempe, AZ

Stress, which is defined as a real or interpreted threat to the physiological or psychological integrity of an individual, can result in psychological, behavioral or even physical changes. On a cellular level, stress affects neurogenesis and can cause atrophic retraction of the neuronal dendritic arbor in regions within the brain such as the medial prefrontal cortex (mPFC) and hippocampus which are responsible for executive function, learning and memory. It has been proposed that stress induced neural remodeling may contribute to psychiatric illnesses including depression, anxiety and post-traumatic stress disorder (PTSD). Previous long term stress studies have shown that cytoskeletal dendritic retraction occurs in the CA3 region of the hippocampus but in mice there are no studies that have focused on changes in neural plasticity

within the hippocampus as a result of short term stress. This study examines the effects that variable time restraint stress has on cytoskeletal plasticity in pyramidal neurons. Wild type C57BL/6 mice were placed in Plexiglas restraints for either a 30 minute, 1 or 5 hour time duration for a time span of 2, 5 or 21 days. Changes in neural plasticity were measured in the hippocampal CA3 region and mPFC (pre-limbic and cingulate) at level II-III. Verification of a stress response was evaluated using immuno-fluorescence by measuring the level of c-Fos, an intermediate early gene which is up-regulated in response to stress induced stimuli in the CNS, and BrdU to measure neurogenesis. Changes in cytoskeletal rearrangement of the pyramidal apical dendrites were measured and evaluated using Golgi stained sections. Our results indicate that changes in the cytoskeletal morphology within the pyramidal neurons begin to occur at shorter time points than have been previously reported.

1218

**Using *Xenopus laevis* to study regulatory elements of the medium neurofilament gene *in vivo*.**

C. Wang<sup>1</sup>, B. G. Szaro<sup>1</sup>; <sup>1</sup>Biological Sciences, University at Albany, State University of New York, Albany, NY

Building an axon requires highly regulated changes in the expression of key structural genes. For example, the developmental onset of the expression of the medium neurofilament (NF-M) subunit is tightly coordinated with neuronal differentiation. This tight regulation, operating at both the transcriptional and post-transcriptional levels, is mediated through the binding of specific proteins to elements within the gene and its transcribed mRNA. The identification of these elements and the proteins that bind them requires an *in vivo* model system in which the activity of genes bearing mutated prospective control regions can be rapidly screened within the context of the developing nervous system. We modified the  $\phi$ -C31 integrase-mediated *Xenopus* transgenesis protocol to generate transgenic *Xenopus laevis* using direct plasmid injection into 2-cell stage embryos. This plasmid contained an *attB* site to facilitate its integration into the *Xenopus* genome and a *DsRed2* or *EGFP* reporter gene driven by the *NF-M* promoter. To reduce position effects, the transgene was flanked by two tandem repeats of chicken *HS4* insulator sequences. Injection of 100 pg of this plasmid into embryos yielded strong reporter protein expression in differentiated neurons at the onset of endogenous NF-M expression. Replacing the *NF-M* promoter with a neuronal  $\beta$ -tubulin (*N $\beta$ T*) one confirmed strong reporter protein expression driven by specific promoters. Using this method, we identified domains within the 3'-untranslated region of the *NF-M* gene that were required for protein expression *in vivo*. These domains have been previously shown *in vitro* to differentially bind hnRNP K, an RNA binding protein essential for both NF-M protein expression and axon outgrowth. Thus, this method provides a useful tool for the study of regulatory elements of the *NF-M* gene in the developing vertebrate nervous system. *Funded by NSF IOS 951043.*

1219

**Optimizing neuron adhesion and growth by choosing the right chamber slide surface.**

S. M. Carter<sup>1</sup>, J. Granchelli<sup>1</sup>, C. Neeley<sup>1</sup>; <sup>1</sup>Thermo Fisher Scientific, Rochester, NY

Isolated neurons from normal and diseased tissues of the mammalian Central Nervous System (CNS) are routinely cultured *in vitro* to study neurogenesis and to identify factors for drug screening that promote or inhibit neurogenesis. Culturing primary neurons *in vitro* is particularly challenging because they do not continue to proliferate after dissociation and survival of primary neurons is dependent on cell adhesion and differentiation. While many cells prefer culture surfaces with high surface energies (i.e. hydrophilic surfaces), neuronal cells require the additional presence of functional binding groups on the growth surface. Consequently, glass

and plastic surfaces must be adequately modified with specific surface chemistries. In this study, we examined the correlation between cell adhesion of PC-12 and primary neuron cells and multiple chamber slide surface modifications. The chamber slide (Thermo Scientific) surfaces, available in conventional glass, a proprietary chemically modified glass (CC<sup>2</sup>), and a cell culture treated plastic surface (Permanox), were evaluated with and without a fresh polylysine coating. We were able to demonstrate that polylysine coating on glass and plastic surfaces were sufficient in supporting the attachment and growth of the PC-12 cells and primary neurons. Interestingly, the chamber slide with CC<sup>2</sup> chemical modification functionally mimics the effect of polylysine coating without the use of the actual chemical. In contrast, glass and cell culture treated plastic surfaces alone were unable to support neuronal growth. Furthermore, the quantification of primary amines on all surfaces indicated that the CC<sup>2</sup> surface yielded sufficient amine surface density to facilitate neuronal cell adhesion and growth. In conclusion, the amount of primary amines on culture surfaces directly correlates with the attachment and survival of neuronal cells. The CC<sup>2</sup> chamber slide surface provides an optimal tool for imaging study of neuronal cell culture.

1220

### **MST3 kinase regulates neuronal cytoskeleton during development.**

*S. K. Ultanir<sup>1</sup>, N. T. Hertz<sup>1</sup>, A. Burlingame<sup>1</sup>, L. Y. Jan<sup>1</sup>, K. M. Shokat<sup>1</sup>, Y-N. Jan<sup>1</sup>; <sup>1</sup>University of California San Francisco, San Francisco, CA*

Dendrite arborization and synapse formation are essential for establishing the neural circuitry for proper brain functioning. Defects in a growing number of genes are associated with neurodevelopmental disorders such as autism. Kinases play important roles in regulating the molecular components during synapse assembly and maintenance. We use chemical genetic methods to determine kinase signaling pathways essential for brain development.

MST3 kinase is a member of the Ste20-like (Sterile 20- like) kinases in mammals. MST3 is present in the dendrites and axons of the developing rat hippocampal neurons. A splice variant of MST3, MST3b, enhances axonal growth as well as regeneration. We asked if MST3 functions in dendritic development in hippocampal neurons. Using siRNA to knock-down MST3 as well as dominant-negative (kinase-dead) MST3 expression, we found that MST3 is essential for dendrite and dendritic spine development. Loss of MST3 in the first postnatal week causes a drastic increase in dendritic filopodia number and length and impairs dendrite arborization, whereas loss of MST3 in the third postnatal week leads to loss of dendritic spines and an increase in dendritic filopodia. MST3 siRNA expression in vivo by in utero electroporation of plasmids also resulted in loss of dendritic spine and increased filopodia, implicating that it plays essential functions in the formation and maintenance of dendritic architecture in vivo as well as in cultures. Downstream effectors of MST3 are not well-known. Using chemical genetic kinase substrate identification method we identified 15 potential substrates for MST3 and their phosphorylation sites. Several of these novel substrates are known regulators of cytoskeleton regulation. Most of the phosphorylation sites we identified are highly conserved among other species, implying important conserved molecular functions. By expressing phospho-mutant and phospho-mimetic forms of a subset of the novel substrates, we tested which one of these may be downstream of MST3 in dendrite morphogenesis. We found that phospho-mutant TAO kinase TAO1 or TAO2 expression or shRNA knockdown of TAO2 alone is sufficient to cause increased dendritic filopodia, reminiscent of MST3 loss of function. TAO2 kinase is a known regulator of microtubule and actin cytoskeleton and is implicated in autism. Our data implicates MST3 in regulating neuronal development by altering neuronal cytoskeleton and limiting dendritic filopodia via phosphorylating TAO2.

1221

**Cofilin in Long Term Depression and Long Term Potentiation: a Reassessment.***B. Calabrese<sup>1</sup>, J-M. Saffin<sup>1</sup>, S. Halpain<sup>1</sup>; <sup>1</sup>Division of Biological Sciences, UCSD, La Jolla, CA*

Previous studies suggested that during LTD actin filament severing by cofilin induces spine shrinkage, and during LTP inhibition of cofilin-mediated actin severing permits spine enlargement. However, we suggest that both types of structural plasticity are associated with decreased cofilin activity, but that the means for achieving this inhibition significantly affects the outcome for spine morphology. Results presented here support a model in which constitutive cofilin-mediated actin severing is critical for spine maintenance, and a reduction -- not an increase -- in endogenous spine cofilin concentration during LTD leads to spine shrinkage. Conversely, during LTP increased LIM kinase activity increases cofilin Ser-3 phosphorylation, which in turn activates phospholipase D to stimulate actin polymerization and spine enlargement. Overall, these results implicate novel mechanisms for the role of cofilin in both growth and shrinkage of synapses during circuit plasticity.

**Down regulation of PAI-1 by valproic acids modulates astrocyte-dependent regulation of neurite outgrowth from cultured rat primary cortical neuron.***K. Cho<sup>1</sup>, H. Ko<sup>1</sup>, K. Kwon<sup>1</sup>, S. Lee<sup>1</sup>, J. Park<sup>1</sup>, S. Jeon<sup>1</sup>, K. Kim<sup>1</sup>, J. Cho<sup>2</sup>, S. Han<sup>1</sup>, C. Y. Shin<sup>1</sup>; <sup>1</sup>Konkuk University, Seoul, Korea, <sup>2</sup>Gachon University, Incheon, Korea*

Valproic acid (VPA), a histone deacetylase inhibitor that is used for the treatment of epilepsy and bipolar disorders, promotes neurite extension, neuronal growth and has neuroprotective effect in neurodegenerative diseases. One of the essential regulators of neurite extension in CNS is tissue plasminogen activator (tPA). Being a serine protease, tPA plays regulatory roles such as neurite outgrowth, synaptic plasticity and long term potentiation in CNS. Most of the cells in CNS express tPA and the activity of tPA is regulated by an endogenous inhibitor plasminogen activator inhibitor-1 (PAI-1), which is expressed mainly in astrocytes. In this study, we investigated the effects of VPA on the activity of tPA/PAI-1 system in cultured rat primary neuron and astrocytes. VPA concentration-dependently increased neurite outgrowth in co-culture of astrocyte and neuron but not in pure neuron. In pure cultured neuron VPA did not affect tPA activity, however, VPA decreased PAI-1 activity in rat primary astrocytes. The decrease in PAI-1 activity in cytosol as well as extracellular secretion of rat primary astrocytes induced up-regulation of tPA activity. An inhibitor of tPA activity, tPA STOP as well as exogenous addition of PAI-1 inhibited VPA-induced neurite outgrowth. Although astrocyte culture supernatants obtained from wild type mice induced neurite outgrowth, culture supernatants obtained from tPA knock-out mice did not induce neurite outgrowth. Alternatively, culture supernatants obtained from PAI-1 knockout mice increased neurite extension more than wild type culture supernatants. The decrease in PAI-1 activity and increased neurite extension was regulated via JNK mediated post-transcriptional pathway. Regulation of tPA/PAI-1 activity in astrocyte by VPA may affect both physiological and pathological processes governed by this neuromodulator system.

## Voltage-gated Channels and Neurotransmission

1223

### Modulation of rat Eag1 potassium channels by 14-3-3 $\theta$ .

*P-H. Hsu<sup>1,2</sup>, C-Y. Tang<sup>2</sup>, C-J. Jeng<sup>1</sup>; <sup>1</sup>Institute of Anatomy and Cell Biology, School of Medicine, National Yang-Ming University, Taipei, Taiwan, <sup>2</sup>Graduate Institute of Physiology, College of Medicine, National Taiwan University, Taipei, Taiwan*

To further understand the nature of 14-3-3 regulation of ion channels, we employed the yeast two-hybrid screening of a rat brain cDNA library and identified 14-3-3 $\theta$  as a candidate interacting protein of the brain-specific rat ether-a-go-go (rEag1) K<sup>+</sup> channel. Data from in vitro yeast two-hybrid and GST pull-down assays suggested that the interaction with 14-3-3 $\theta$  was mediated by both the N- and the C-termini of rEag1. GST pull-down assay also showed that among the six brain-expressing 14-3-3 isoforms, 14-3-3 $\theta$  was the preferred binding partner of rEag1. Co-precipitation and co-localization of the two proteins were demonstrated both in heterologous HEK293T cells and in native hippocampal neurons. Furthermore, the 14-3-3 antagonist Difopein effectively disrupted the interaction of these two proteins. Truncation analyses of rEag1 revealed that the N- and the C-terminal 14-3-3 $\theta$  interaction sites were mainly located at the PAS domain and the CNBHD region, respectively. Parallel truncation analyses of 14-3-3 $\theta$  further indicated that the C-terminal helices  $\alpha$ F,  $\alpha$ G, and  $\alpha$ H were essential in mediating the association with rEag1. Electrophysiological studies showed that co-expression with 14-3-3 $\theta$  led to a suppression of rEag1 K<sup>+</sup> currents. However, neither the total protein level nor the surface expression of rEag1 proteins was significantly altered by the over-expression of 14-3-3 $\theta$ . These data imply that 14-3-3 $\theta$  binding may render a fraction of the channel locked in a non-conducting state.

### Imaging voltage with microbial rhodopsins.

*A. E. Cohen<sup>1</sup>, J. Kralj<sup>1</sup>, D. Hochbaum<sup>1</sup>, A. Douglass<sup>1</sup>, V. Venkatachalam<sup>1</sup>, D. Maclaurin<sup>1</sup>;  
<sup>1</sup>Chemistry and Chemical Biology, Harvard University, Cambridge, MA*

In the wild, microbial rhodopsin proteins convert sunlight into a transmembrane voltage, which provides energy for their host. We engineered microbial rhodopsins to run in reverse: to convert membrane potential into a readily detectable optical signal. When expressed in a neuron or a cardiac myocyte, these voltage-indicating proteins convert electrical action potentials into visible flashes of fluorescence, allowing us to make movies of electrical activity in cells, tissues, and live animals. We developed techniques for simultaneous optical stimulation and recording of electrical activity in cells, as well as computational techniques for observing electrical propagation with microsecond time resolution. Upon expression of the voltage indicator in *E. coli*, we discovered that bacteria generate electrical spikes too. We find that electrical dynamics in cells are far more widespread than was previously thought.

**Development of optogenetic methods to study neuronal connectivity.**

*N. L. Prigozhina<sup>1,2</sup>, J. Seldeen<sup>1</sup>, F. Cerignoli<sup>1,3</sup>, J. H. Price<sup>1,3</sup>, P. M. McDonough<sup>1</sup>; <sup>1</sup>Vala Sciences, San Diego, CA, <sup>2</sup>University of San Diego, San Diego, CA, <sup>3</sup>Sanford-Burnham Medical Research Institute, La Jolla, CA*

We are interested in quantifying the effects of test compounds on neuronal transmission and the development of neuronal cell circuits utilizing optogenetic methods. This will be an important in vitro tool to screen for environmental pollutants, and for drug discovery efforts to combat “chemo-brain” condition, which is a loss of cognitive ability developing in cancer patients following chemotherapy, and other forms of memory loss and dementia, including Alzheimer’s and aging.

We successfully cultured primary, hESC and iPSC-derived neurons in a high throughput format (96 well), transduced them with lentiviruses encoding light-activated channel rhodopsin (ChR2) fused with yellow or mCherry fluorescent proteins, assayed their depolarization (activation) with fluorescent calcium indicators and analyzed the neuronal activity via automated microscopy and image analysis techniques. We showed that ChR2-expressing neurons fire in response to blue light, and that the activity of the neurons in our system can be modulated (inhibited or activated) by long or short term treatments with pharmacological drugs. We have also correlated the calcium based activity assessment with expression and colocalization of pre- and postsynaptic markers using immunolabeling.

Our preliminary results demonstrate that the optogenetic approach allows for synchronized neuronal activation in cultures grown in multi-well plates, and may facilitate characterization of neuronal connectivity relevant to “chemo-brain”, memory-loss, and dementia- related dysfunction.

**R7BP modulates GIRK channel activity by allosterically regulating RGS proteins in Hippocampal Neuron.**

*H. Zhou<sup>1</sup>, M. Chisar<sup>2</sup>, K. Raehal<sup>3</sup>, K. M. Kaltenbronn<sup>1</sup>, L. M. Bohn<sup>3</sup>, S. Mennerick<sup>2</sup>, K. J. Blumer<sup>1</sup>; <sup>1</sup>Department of Cell Biology and Physiology, Washington University School of Medicine, Saint Louis, MO, <sup>2</sup>Department of Psychiatry, Washington University School of Medicine, Saint Louis, MO, <sup>3</sup>Department of Molecular Therapeutics and Neuroscience, Scripps Research Institute, Jupiter, FL*

G protein-activated inward rectifying K<sup>+</sup> (GIRK) channels hyperpolarize neurons to inhibit synaptic transmission throughout the nervous system. By accelerating G protein deactivation kinetics, the regulators of G-protein signaling (RGS) protein family modulate the timing and magnitude of GIRK activity and function. Despite many investigations, whether RGS proteins modulate GIRK activity in neurons by mechanisms involving kinetic coupling, collision coupling, or macromolecular complex formation have remained unknown. Here we show that GIRK modulation occurs by channel assembly with R7-RGS/Gβ5 complexes under allosteric control of R7 RGS-binding protein (R7BP). R7BP is a novel palmitoylated SNARE-like protein that binds heterodimers containing any member of the R7 subfamily of RGS and the Gβ5 protein, which accelerate deactivation of Gi/o-class G proteins in vitro. However, the consequences and neuronal functions of R7BP forming complex with R7RGS/ Gβ5 in neuron were still unclear. We found that elimination of R7BP occludes the Gβ5 subunit that interacts with GIRK channels. R7BP bound R7-RGS/Gβ5 complexes and Gβγ dimers interact noncompetitively with the intracellular domain of GIRK channels to facilitate rapid activation and deactivation of GIRK currents. By disrupting this allosterically-regulated assembly mechanism, R7BP ablation

augments GIRK activity. This enhanced GIRK activity increases the drug effects of agonists acting at G protein-coupled receptors that signal via GIRK channels, as indicated by greater antinociceptive effects of GABA(B) or mu-opioid receptor agonists. These findings show that GIRK current modulation in vivo requires channel assembly with allosterically regulated RGS protein complexes, which provide a novel target for modulating GIRK activity in neurological disorders in which these channels have crucial roles, including pain, epilepsy, Parkinson's disease and Down's syndrome.

1227

**Role of voltage-gated sodium channels in axon initial segment maintenance.**

*F. Castets<sup>1</sup>, C. Leterrier<sup>1</sup>, N. Clerc<sup>1</sup>, A. Montersino<sup>1</sup>, F. Rueda<sup>1</sup>, B. Dargent<sup>1</sup>; <sup>1</sup>CRN2M UMR7286, Aix Marseille Université, CNRS, Marseille, France*

In central neurons, the axon initial segment (AIS) is enriched with multiple types of ion channels, including Na<sup>+</sup>, K<sup>+</sup> and Ca<sup>2+</sup> channels in association with scaffolding protein and cytoskeletal components. In particular, the high density of voltage-gated sodium channels (Nav) drives the initiation of action potentials at the AIS. The AIS also forms a boundary between the axonal and somatodendritic compartments that has an essential role in maintaining neuronal polarity. Many studies have established the crucial role of the scaffolding protein ankyrin G (ankG) in ion channel clustering and polarity maintenance. Using cultured rat hippocampal neurons in culture and cortical organotypic slices, we observed that the knockdown of Nav by shRNA in mature neurons led to a decrease in ankG concentration in the AIS. As expected, the segregation of other ankG-interacting proteins (such as Neurofascin-186) was also disrupted in the AIS. These results suggest that, in addition to well-known role in the generation of action potentials, Nav channels may act in the maintenance of AIS structural integrity.

1228

**KCNQ2 targeting to the axon initial segment is disrupted in a transgenic mouse model of severe neonatal-onset epileptic encephalopathy.**

*B. Tran<sup>1</sup>, E. C. Cooper<sup>1</sup>; <sup>1</sup>Baylor College of Medicine, Houston, TX*

KCNQ2 and KCNQ3 are homologous voltage-gated potassium channel subunits that form neuronal "M-channels". M-channels activate slowly in the voltage range between rest and action potential threshold, thereby integrating synaptic inputs and modulating neuronal excitability. Certain KCNQ2 and KCNQ3 mutations cause dominantly inherited forms of epilepsy and myokymia; by contrast, other, de novo, KCNQ2 mutations have been found in a severe syndrome of epileptic encephalopathy. KCNQ2 and KCNQ3 are conspicuously enriched at the axonal initial segment (AIS) of many central neurons, but the time course of their arrival at the AIS has been little studied. We have performed immunofluorescence labeling and immunoblotting for these subunits in tissue samples and hippocampal neuronal cultures during development. Labeling of mouse hippocampal sections shows that in pyramidal cells, KCNQ2 is detectable at P4 and is highly concentrated within the distal portion of AISs by P15. KCNQ3 arrival at the AIS appears slightly delayed, suggesting the existence of two distinct populations of channels rather than only KCNQ2/3 heteromers. Within neocortical pyramidal neurons, KCNQ2 and KCNQ3 are expressed in the distal two-thirds of the AIS, and most concentrated at the distal tip, the location at which action potentials are initiated. Additionally, in KCNQ2 mutant mice which are a model of KCNQ2 encephalopathy (Peters et al., Nat Neurosci. 2005; Millichap and Cooper, Epil. Curr., 2012) KCNQ2 was completely undetectable at the AIS, and was found instead in perinuclear and dendritic aggregates suggestive of ER retention. KCNQ3 was redistributed to the KCNQ2-labelled aggregates, but was detected at low levels within the AIS.

These results indicate that certain KCNQ2 mutations may act as dominant-negative trafficking traps, preventing functional surface expression of subunits co-expressed from wild-type alleles and thereby leading to severe, encephalopathic phenotypes.

**The Anaphase Promoting Complex Regulates GABAergic Synaptic Transmission at the *C. elegans* Neuromuscular Junction.**

J. R. Kowalski<sup>1</sup>, H. Dube<sup>1</sup>, D. Touroutine<sup>2</sup>, P. R. Goodwin<sup>3</sup>, M. M. Francis<sup>2</sup>, P. Juo<sup>3</sup>; <sup>1</sup>Biological Sciences, Butler University, Indianapolis, IN, <sup>2</sup>Neurobiology, University of Massachusetts Medical School, Worcester, MA, <sup>3</sup>Molecular Physiology and Pharmacology, Tufts University School of Medicine, Boston, MA

Neuronal communication is critical for information processing, storage, and transmission within the nervous system. This communication, which occurs at specialized cellular junctions called synapses, is tightly regulated, and misregulation of this synaptic transmission is linked to neurological and neurodegenerative diseases. The ubiquitin enzyme system is a vital regulator of synaptic transmission. It controls the abundance of many synaptic proteins, and its dysfunction is observed in many neurological disorders. Previously, the Anaphase Promoting Complex (APC), a well characterized ubiquitin ligase and cell cycle regulator, was identified as a modulator of synapse development and synaptic transmission at glutamatergic synapses through its ability to control synaptic protein abundance. However, the mechanisms of APC action and its potential for impacting signaling at other synapse types are unknown. Here, we show that the APC regulates GABA transmission at the *C. elegans* neuromuscular junction (NMJ), a specialized synapse where a balance of excitatory cholinergic and inhibitory GABAergic signaling from presynaptic motor neurons controls postsynaptic muscle activity. In behavioral assays assessing NMJ signaling, loss-of-function mutants in several APC subunits exhibit increased muscle contraction, as indicated by hypersensitivity to the acetylcholinesterase inhibitor aldicarb. This defect can be rescued by expressing a functional copy of the defective APC gene in GABA neurons using a cell type-specific promoter. Increased muscle excitation also occurs following GABA neuron-specific APC inhibition by ectopic expression of the APC inhibitor hEmi1. In addition, APC mutants exhibit convulsions in the presence of the GABA antagonist, pentylentetrazole, which induces this behavior only in GABA signaling defective worms. Quantitative fluorescence imaging further revealed an increase in synaptobrevin-GFP at presynaptic sites in GABAergic but not cholinergic neurons of APC mutants, as well as an increase in the postsynaptic GABA<sub>A</sub> receptor UNC-49. Preliminary electrophysiological analyses of endogenous NMJ currents indicate that APC mutants exhibit normal EPSC but decreased IPSC frequencies, supporting a presynaptic role for the APC in regulating GABA signaling. Finally, fluorescence colocalization studies indicate that these effects may be due to APC activity at presynaptic sites, as we observed strong colocalization between a GFP-tagged APC subunit and synaptobrevin-RFP in GABAergic motor neurons. Taken together, these data suggest a model in which the APC acts at GABAergic motor neuron presynapses to promote GABA release. Current studies are aimed at identifying relevant substrates of the APC that mediate its effects at the NMJ.

**Investigation of the relationship between FSHR-1 and the Anaphase Promoting Complex in regulating synaptic transmission at the *C. elegans* neuromuscular junction.**

A. Wasilk<sup>1</sup>, E. Damler<sup>1</sup>, J. R. Kowalski<sup>1</sup>; <sup>1</sup>Biological Sciences, Butler University, Indianapolis, IN

Neuronal communication occurs at cellular junctions called synapses. The signaling at each synapse is tightly regulated, and misregulation of this synaptic transmission occurs in neurological diseases. The ubiquitin enzyme system controls synaptic transmission by regulating synaptic protein activity and abundance. We previously identified the Anaphase Promoting Complex (APC), an ubiquitin ligase, as a critical regulator of synaptic transmission at the neuromuscular junction (NMJ) in *C. elegans*. At the *C. elegans* NMJ, a tight balance of excitatory (cholinergic) and inhibitory (GABAergic) signaling controls muscle contraction; however, the mechanisms by which the APC regulates this transmission are unknown. Here, we identified FSHR-1 as a potential APC substrate at the NMJ. FSHR-1 is a G protein-coupled receptor homologous to the follicle stimulating hormone, luteinizing hormone, and thyroid stimulating hormone receptors in mammals. In *C. elegans*, FSHR-1 is highly expressed in neurons and the intestine and, along with roles in germline differentiation and pathogen susceptibility, is required for synaptic transmission at the NMJ. However, the specific functions and regulators of FSHR-1 in neurons are unknown. Previous research has shown *fshr-1* loss of function mutants have decreased muscle contraction, as indicated by their resistance to paralysis induced by the acetylcholinesterase inhibitor aldicarb, suggesting that FSHR-1 promotes signaling for muscle contraction. Given that this *fshr-1* mutant phenotype is opposite to that seen in animals lacking APC function, and since the FSHR-1 protein contains an APC recognition motif, we tested whether FSHR-1 and the APC function in the same genetic pathway at the NMJ. We found that double mutants lacking both the APC and *fshr-1* exhibit aldicarb resistance, similar to *fshr-1* single mutants. Thus, FSHR-1 may function downstream of the APC in regulating muscle contraction. Neuronal expression of FSHR-1 in *fshr-1* mutants restores aldicarb sensitivity to at least wild type levels, and neuronal over-expression of FSHR-1 in wild type animals induces aldicarb hypersensitivity. These results suggest that FSHR-1 function in neurons is sufficient to promote signaling for muscle excitation. Current co-localization experiments using transcriptional fusions are aimed at determining if FSHR-1 is expressed in the same NMJ cell type where the APC functions. Preparation for biochemical analyses is also underway to test if FSHR-1 is a direct APC substrate at the NMJ. Given the high conservation of neuronal protein structure and function between worms and vertebrates, by better understanding the proteins that control *C. elegans* neuronal communication, we can begin to address human neurological diseases.

1231

**Synaptotagmin 12 is necessary for homeostatic synaptic plasticity at the *Drosophila* neuromuscular junction.**

C. J. Locke<sup>1</sup>, D. K. Dickman<sup>2</sup>, G. W. Davis<sup>1</sup>; <sup>1</sup>Department of Physiology, University of California, San Francisco, San Francisco, CA, <sup>2</sup>Department of Biology, University of Southern California, Los Angeles, CA

At the neuromuscular junction (NMJ), decreased postsynaptic neurotransmitter receptor sensitivity initiates a homeostatic increase in neurotransmitter release from presynaptic motoneurons. This increase in presynaptic release precisely offsets the defect in neurotransmitter receptor sensitivity and restores normal postsynaptic excitation in the continued presence of the perturbation. This form of homeostatic plasticity is evolutionarily conserved and has been observed in organisms ranging from *Drosophila* to mouse and human.

Currently, little is known about the underlying molecular mechanisms that achieve this robust and accurate form of homeostatic plasticity. We are taking advantage of the forward genetic tools in *Drosophila* to identify genes that, when mutated, block the induction or expression of homeostatic plasticity. As part of an ongoing screen, we have discovered that mutations in the *Synaptotagmin 12* (*Syt12*) gene disrupt synaptic homeostasis at the *Drosophila* NMJ. Syt12 is an evolutionarily conserved member of the synaptotagmin family. While Synaptotagmin 1 functions as a calcium sensor for neurotransmitter release, there is evidence indicating that Syt12 does not bind calcium ions. Currently, the functions of Syt12 and other calcium-insensitive synaptotagmins remain largely unknown. We will present a genetic analysis of *Drosophila* *Syt12*, providing evidence that Syt12 is necessary for normal basal synaptic transmission and homeostatic synaptic plasticity. We demonstrate that loss of Syt12 causes a minor defect in presynaptic neurotransmitter release and completely blocks the rapid induction and sustained expression of synaptic homeostasis. Use of cell type-specific RNAi and genetic rescue demonstrates that Syt12 function is necessary in motoneurons for normal basal synaptic transmission and synaptic homeostasis. An analysis of synapse morphology demonstrates that synaptic growth, assayed by the number of synaptic boutons at the NMJ, is normal in *Syt12* mutants. Thus, we have identified a novel function for a calcium-insensitive member of the synaptotagmin family and extended our understanding of how homeostatic synaptic plasticity is executed at a model glutamatergic synapse.

## Signaling Networks Governing Cell Migration II

### Digitalis-derived compound exhibits anti-proliferative activity on hepatocarcinoma cells by down-regulating the expression of farnesoid x receptor.

*T. Fujino*<sup>1</sup>, *J. Satoh*<sup>1</sup>, *M. Kuroda*<sup>1</sup>, *A. Yokosuka*<sup>1</sup>, *Y. Mimaki*<sup>1</sup>, *M. Hayakawa*<sup>1</sup>; <sup>1</sup>Tokyo university of pharmacy and life sciences, Hachioji, Japan

Farnesoid X receptor (FXR), bile acid-activated nuclear receptor, is a pivotal factor maintaining bile acid homeostasis. We have previously shown that FXR plays a crucial role in the proliferation of human hepatocellular carcinoma cell line, HepG2, Huh7, HLE: FXR stimulates cell proliferation by suppressing the p16/INK4a expression whereas downregulation of the FXR stimulates the p16/INK4a expression, resulting in the suppressed cell proliferation. Moreover, in contrast to hepatocellular carcinoma cells, downregulation of the FXR in primary hepatocytes causes decrease of p16/INK4a expression, resulting in the stimulated cell proliferation. Thus, it is expected that we can establish the cancer therapy by suppressing the FXR expression in liver. Glucodigifucoside is a compound extracted from digitalis. We have recently shown that the compound suppresses cell proliferation of human leukemia cell line HL-60. In the present study, we investigate whether or not the compound affects cell proliferation of human hepatocellular carcinoma cell line, HepG2.

1.0x10<sup>5</sup> cells of HepG2 seeded on 60-mm dish were treated with 0.0079- 0.79 uM glucodigifucoside for 72 h, and cell number was counted. Indeed, cell proliferation was dramatically inhibited by glucodigifucoside (IC<sub>50</sub>=0.59uM). Moreover, FXR level of glucodigifucoside- treated cells was significantly lower than that of control cells, while p16/INK4a level was increased by glucodigifucoside treatment.

In conclusion, digitalis-derived compound glucodigifucoside exhibits anti-proliferative activity on hepatocarcinoma cells in FXR and p16/INK4a-dependent manner.

1232

### Role of Rho GTPases in Regulation of Cell Migration and Polarization in Human Corneal Epithelial Cells.

A. Hou<sup>1</sup>, E. Manser<sup>2</sup>, K. Gan<sup>1</sup>, K. R. Lee<sup>1</sup>, L. Tong<sup>1,3,4,5</sup>; <sup>1</sup>Singapore Eye Research Institute, Singapore, Singapore, <sup>2</sup>Institute of Medical Biology, Singapore, Singapore, <sup>3</sup>Singapore National Eye Center, Singapore, Singapore, <sup>4</sup>Duke-NUS Graduate Medical School, Singapore, Singapore, <sup>5</sup>Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore

**Objective.** Rho GTPases are conserved proteins in eukaryotic known to mediate the signaling from cell surface adhesion complexes to molecular motors and cytoskeletal structures in the cells, and hence determine cell motility. Epithelial cell migration is defective in many ocular surface diseases. Even though Rho GTPases have been linked to cell migration, their roles in the ocular surface remain unknown. This study aimed to determine the role of various Rho GTPases in human corneal epithelial directional cell migration and polarization.

**Methods.** Dominant-negative Rho GTPase or siRNA targeting Rho GTPase were transfected into cultured human corneal epithelial large T antigen (HCET) cells, and wound closure rate were evaluated by scratch wounding assay and non-traumatic cell migration assay. Cell polarization was observed by immunofluorescence staining for Golgi body.

**Results.** Out of the Rho GTPases (RhoD, Rac1, Cdc42, RhoJ, TC10 and Chp) tested, Cdc42 and RhoJ had distinctive effects on cell migration. Cells transfected with dominant-negative plasmids or siRNAs targeting Cdc42 or RhoJ have slower migration rates (in each assay) compared to control cells. In confluent HCET which commenced migration for 1 hour, the ratio of polarized cells to total cells was significantly reduced in cells with siRNA targeting Cdc42 and to a lesser extent for RhoJ, compared to scrambled siRNA, despite similar amounts of silencing on western blots.

**Conclusion.** Cdc42 and RhoJ have a facilitative role in 2-D cell migration in-vitro in HCET cells. Cdc42 and RhoJ are important for cell polarization in the early phase of in-vitro cell migration, but Cdc42 probably plays a relatively more important role. There may be distinctive downstream targets that specifically link these two Rho GTPases to cellular machinery for motility. These findings may have application in therapy of ocular surface disease with aberrant or deficient cell migration.

1233

### A novel PDGF-mediated RhoG pathway in vascular smooth muscle cells.

A. Valdivia<sup>1</sup>, S. Goicoechea<sup>1</sup>, K. Trogden<sup>2</sup>, R. Garcia-Mata<sup>1</sup>; <sup>1</sup>Biological Sciences, University of Toledo, Toledo, OH, <sup>2</sup>Cell Biology and Physiology, University of North Carolina at Chapel Hill, Chapel Hill, NC

Remodeling of the vascular smooth muscle cytoskeleton is essential for cell motility involved in the development of diseases such as atherosclerosis and restenosis. It is well known that platelet-derived growth factor (PDGF) is a major stimulus for the abnormal migration and proliferation of vascular smooth muscle cells (VSMCs) and contributes critically to vascular disease. Our results show that PDGF promotes the rapid activation of RhoG in rat vascular smooth muscle cells (A7r5). RhoG is one of the small GTPases of the Rho family and its function has been correlated previously with many of the cellular processes regulated by PDGF, including proliferation, survival and migration and Rac1 activation. Our hypothesis is that PDGF-induced changes in the morphology and behavior of VSMCs are mediated by RhoG. Here we

describe the initial characterization of a novel signaling pathway that activates RhoG downstream of PDGF. This PDGF-mediated RhoG activation is dependent of Src and PI3K activity. Both RhoG and Rac1 are activated by PDGF independently. Our results also show that one of the early phenotypic responses to PDGF, the formation of actin-rich dorsal ruffles, is modulated by RhoG activity. In addition, RhoG activation downstream of PDGF modulates cell migration in a process that involves the guanine-nucleotide exchange exchange factor (GEF) Trio.

1234

#### **Characterization of PLD2 GEF activity.**

*M. Mahankali<sup>1</sup>, K. M. Henkels<sup>1</sup>, J. G. Cambrono<sup>1</sup>; <sup>1</sup>Biochemistry and Molecular biology, Wright State University, Dayton, OH*

We have demonstrated phospholipase D2 (PLD2) is a guanine nucleotide exchange factor (GEF) for Rac2 and determined the PLD2 domains and amino acid site(s) responsible for its GEF activity. Experiments using GST fusion proteins or GST-free counterparts, purified proteins, revealed that the PX domain is sufficient to exert GEF activity similar to full length PLD2. The PLD2-GEF catalytic site is comprised of hydrophobic pocket of residues namely F107, F129, L166, and L173, all of which are in the PX domain. A nearby R172 is also important in the overall activity. PX mutants comprising any of those 5 amino acids fail to have GEF activity, but still bind to Rac2 and their lipase activity was mostly unaffected. In addition to the PX domain, a region in the PH domain (I306-A310) aids in the PX-mediated GEF activity by providing a docking site to hold Rac2 in place during catalysis. The physiological relevance of this novel GEF in cell biology is demonstrated here in chemotaxis and phagocytosis of leukocytes, as the specific PX and PH mutants abolished cell function. Hence PLD2 is a unique GEF with the PX being the major catalytic domain for its GEF activity, whereas the PH domain assists in the PX-mediated activity. Not only is PLD2 unique in terms of activity but also in terms of regulation. PLD2 is an enzyme that bears two activities: a Guanine-nucleotide Exchange Factor (GEF) and a lipase that reside in the N-terminus (PX/PH domains) and the C-terminus (HKD domains), respectively. PLD2's GEF activity yields Rac-GTP (from Rac2-GDP) and the lipase activity yields phosphatidic acid (PA) (from phosphatidylcholine). PA at low concentrations and early times (3-5 min) promotes GTP binding to Rac2, while Rac-GTP upregulates PLD2's lipase activity. This positive feedback by the two reaction products on their alternate activities serves to mount a rapid and early cellular response. However, as PA accumulates at later times (>30 min), this scenario does change. At high concentrations, PA binds to PLD2 at an allosteric site, specifically the PX/PH tandem, which is required for GEF activity and impedes efficient binding and interaction with its substrate, Rac2-GDP. This leads to a termination of PLD2's GEF activity. In addition to this inter-regulation, tyrosine kinase Janus Kinase 3 (JAK3) plays a key role in switching PLD2 from a GEF to a lipase.

Thus, this study reveals for the first time the catalytic site that forms the basis for the mechanism behind the GEF activity of PLD2. Also, this is the first report of a temporal inter-regulation of a dual enzymatic activity that resides in the same molecule with profound biological consequences in cell growth and cell migration.

1235

**Neuronal Thy-1 induces astrocyte migration via a signaling pathway that includes FAK, PI3K, Tiam-1 and Rac1.**M. Kong<sup>1</sup>, A. Alvarez<sup>1</sup>, A. Cárdenas<sup>1</sup>, N. Muñoz<sup>1</sup>, A. Valdivia<sup>2</sup>, A. F. Quest<sup>1</sup>, L. Leyton<sup>1</sup>;<sup>1</sup>Molecular and Cellular Biology, Facultad de Medicina-Universidad de Chile, Santiago, Chile,<sup>2</sup>Cell and Developmental Biology, University of North Carolina at Chapel Hill, Chapel Hill, NC

Astrocytes in the normal brain are immobile quiescent cells. However, upon brain injury, they become reactive, retract their processes, polarize and acquire front-to-rear asymmetry typical of migratory cells. Effects of the extracellular matrix (ECM) on migration have been well characterized in vitro, but how neurons modulate the ability of reactive astrocytes to migrate remains unknown. Thy-1 is an abundant neuronal glycoprotein that interacts with  $\alpha\beta 3$  integrin and syndecan-4 in astrocytes to promote strong astrocyte adhesion to the ECM through signaling events that involve FAK, PKC $\alpha$  and RhoA activation. Cell migration is a highly regulated process that requires adhesion and is controlled by RhoA, Cdc42 and Rac1 GTPases, which in turn are regulated by guanine nucleotide exchange factors (GEFs) that promote the exchange of GDP for GTP. Thus, the aim of our study was to determine whether prolonged astrocyte stimulation with Thy-1 augmented migration after initially promoting adhesion and to shed light on the molecular mechanisms involved. Immunofluorescence analysis was used to evaluate cell polarization, whereas migration was tested in wound-healing assays. Here, we demonstrate that prolonged, rather than short-term Thy-1 exposure induces astrocyte polarization and migration. Then, to identify the signaling pathways involved in Thy-1-induced migration, pharmacological and genetic inhibitors were employed. PI3K activation downstream of FAK was evaluated by Western blotting. Tiam1 and Rac1 involvement were assessed by affinity-precipitation assays. Phosphorylation of Akt, a downstream effector of PI3K, increased significantly after incubation with Thy-1. This effect was not observed in the presence of a FAK inhibitor indicating that FAK activation is upstream of PI3K. In addition Tiam1 was activated and Rac1 activity increased after 30 min. Moreover, pre-incubation with PI3K or Rac1 inhibitors, as well as overexpression of a dominant negative form of Rac1, decreased directional cell migration to basal levels. In summary, our data indicate that Thy-1 induces astrocyte polarization and migration by activating signaling pathways that involve FAK, PI3K, Tiam1 and Rac1. These observations are likely to be relevant to wound healing and regeneration in the central nervous system.

**Rap1 localization is dynamically controlled during immune cell transmigration in *Drosophila*.**D. Siekhaus<sup>1,2</sup>, O. Moffitt<sup>2</sup>, M. Haesemeyer<sup>2</sup>, R. Lehmann<sup>2</sup>; <sup>1</sup>IST Austria, Klosterneuburg, Austria, <sup>2</sup>NYU School of Medicine, New York, NY

Both metastatic cancer cells and immune cells pursuing infections must penetrate the endothelial barrier presented by the blood vessel wall to reach tissues. This transmigration requires the Rap1 GTPase to modulate Integrin affinity. We have defined a new model system in *Drosophila* to dissect the genetic pathways that control this process. Using live imaging and genetics, we have discovered that *Drosophila melanogaster* immune cells penetrate an epithelial, DE-Cadherin-based tissue barrier during their embryonic developmental movements into the tail. A mutant in RhoL, a GTPase homolog that is only expressed in *Drosophila* macrophages at this stage, specifically blocks this invasive step but not other aspects of guided

migration. The invasion defect in rhoL mutants can be rescued by lowering embryonic DE-Cadherin levels, arguing that RhoL is required to allow hemocytes to penetrate adherens junctions. We also show that RhoL is localized to the cell surface and mediates Integrin adhesion in hemocytes. We observe that RhoL mutants fail to transport the Integrin activator Rap1 from a cytoplasmic membrane containing concentration to the leading edge during invasion. We have identified 4 mutants in secretory pathway components with defects in this invasive migration, one of which has been linked to metastasis in mice. These genes are expressed specifically during the invasive phase and turn off thereafter. Rap1 localization is found to be dynamically cycling to the cell surface at this time. However after this, Rap1 is found mostly in an intracellular concentration even in wild type. We have thus identified RhoL as a new regulator of invasion, adhesion and Rap1 localization. We propose that RhoL is part of a regulated intracellular trafficking pathway required to shuttle the Rap1 Integrin activator to and from the cytoplasmic edge, permitting the dynamic shifts in adhesion required for hemocytes to invade between adherens junctions. This capacity for invasion and Rap1 relocalization appears to be developmentally regulated. Intriguingly, vertebrate Rap1 also relocalizes to the cell surface to increase integrin affinity. Our work establishes the utility of *Drosophila* for identifying novel components of transmigration and for understanding the *in vivo* interplay of cells with the barriers they penetrate.

1237

**Cadherin 6 is necessary for Rho dependent apical detachment during neural crest cell epithelial to mesenchymal transition.**

M. R. Clay<sup>1</sup>, M. C. Halloran<sup>1</sup>; <sup>1</sup>Department of Zoology, Department of Neuroscience, Cellular & Molecular Biology Training Program, University of Wisconsin-Madison, Madison, WI

Epithelial to mesenchymal transitions (EMTs) are critical events during embryonic development, but also drive several pathologies, most notably carcinoma metastasis. Neural crest cells (NCCs) undergo EMT to become migratory as a part of their normal development and zebrafish NCCs are an ideal model to study EMT *in vivo*. We defined a series of cell behaviors that drive motility during zebrafish NCC EMT, and are analyzing how specific molecules control these behaviors in the intact embryo. Cadherin 6B (Cad6B) is important for chick NCC EMT, however conflicting reports have come from studies of its function, leaving its precise roles in EMT unclear. We investigated the function of Cad6 (the zebrafish ortholog of Cad6B) during NCC EMT *in vivo*. We found *cad6* mRNA is expressed in NCCs and in the neuroepithelium during EMT. Morpholino knockdown of Cad6 resulted in accumulation of cranial NCCs in the neuroepithelium as well as disruption of craniofacial structures, suggesting Cad6 is required for EMT. Live imaging after Cad6 knockdown showed that NCCs fail to detach from the apical midline, a critical early event in EMT. Detachment is normally preceded by the accumulation of F-actin, suggesting that actomyosin may be involved. To investigate this hypothesis, we examined the function of Rho GTPase, a regulator of actomyosin whose role in EMT has also been controversial. We used live biosensor imaging of active Rho *in vivo*, and manipulation of Rho signaling to show that apical detachment is driven by Rho mediated actomyosin contraction. To test whether Cad6 affects Rho activation during detachment we imaged active Rho following Cad6 knockdown. While the level of Rho activation in the NCC apical tail is unchanged following Cad6 knockdown, Rho appears to be activated in a broader area and apical detachment does not occur. This suggests that Rho signaling must be tightly spatiotemporally controlled for proper NCC EMT and suggests that Cad6 functions to direct focal activation of Rho and actomyosin contractility in NCC EMT. This pathway may function in parallel to a recently described role for Cad6B in which it combines with non-canonical BMP signaling to activate LIMK to promote EMT.

**A Novel Arf6—ERK Pathway is Required for Migration of Metastatic Breast Cancer Cells.***J. Freed<sup>\*1</sup>, C. V. Shaffer<sup>\*1</sup>, C. C. Moore<sup>1</sup>; <sup>1</sup>Department of Pharmacology, University of the Sciences, Philadelphia, PA*

\* = co-first authors. The research presented here supports a model whereby Arf6 is critical to the mechanism of CXCR4 dysregulation in metastatic breast cancer cells. CXCR4 is a chemokine receptor essential for select neuronal, cardiovascular, and hematopoietic cell migration towards SDF (CXCL12), and is now recognized to promote cancer metastasis. Dysregulation of the SDF-CXCR4 axis in nonmotile primary tumor cells confers an aberrant migratory capacity and promotes metastatic homing of tumor cells to distal SDF-expressing organs. Metastasis is the major cause of mortality in cancer patients, therefore these findings have led to vigorous attempts to identify molecular factors that contribute to CXCR4 dysregulation in cancer. Previously we identified Arf6 as a novel regulator of the SDF-CXCR4 axis, whereby it enhances both CXCR4 cell surface levels and CXCR4 signaling to membrane-delineated ERK. Here we identified a novel Arf6—ERK pathway required for migration of metastatic breast cancer cells. Specifically, we determined the steepness and duration of SDF gradient that is associated with robust CXCR4 signaling to cortactin, an actin-binding protein with known involvement in cancer cell migration and invasion. Utilizing this defined gradient, we assessed the effects of mutational or GEF-mediated Arf6 activation, siRNA-mediated Arf6 knockdown, and MEK inhibition on CXCR4-mediated migration in response to co-stimulation with SDF and collagen, as measured by transwell cell motility assays. Our results demonstrate that in noninvasive MDA-MB-361 and MDA-MB-468 cells, Arf6 activation unmask a migratory phenotype which is blocked by MEK inhibition with PD98059 and U0126. Additionally, in highly invasive MDA-MB-231 and BT-549 cells, siRNA-mediated knockdown of endogenous Arf6 and MEK inhibition with PD98059 and U0126 significantly reduce the migratory phenotype. These responses are specific to CXCR4-mediated migration as suggested by blockade with a CXCR4 antagonist or neutralizing antibody, AMD3100 and 12G5 respectively, and no change of cell adhesion or FBS-mediated migration. These results provide insight into the role of a novel Arf6—ERK pathway in regulating CXCR4-mediated migration, and support the model that Arf6 is critical to the mechanism of CXCR4 dysregulation in metastatic cancer cells. These studies were supported by NIH grant GM-097718, AFPE sponsored AACP New Investigator grant, and start-up funds from USP.

**ARF6 and Shp2 phosphatase regulate CXCR4 phosphorylation and signaling to ERK.***A. Jancina<sup>1</sup>, C. C. Moore<sup>1</sup>; <sup>1</sup>Department of Pharmacology, University of the Sciences, Philadelphia, PA*

CXCR4, a chemokine G protein-coupled receptor, is essential for select neuronal, cardiovascular, and hematopoietic cell migration towards its ligand SDF. It has also been determined to be a major co-receptor for HIV-1 entry, and CXCR4 gene mutations lead to WHIM syndrome, an immunological disease. More recently, CXCR4 has been implicated in cancer and is now recognized to play a critical role during metastasis. Primary non-motile tumor cells with dysregulated SDF-CXCR4 axis adopt migratory phenotype and metastasize to distal SDF-expressing organs. Metastasis is the major cause of mortality in cancer patients, therefore it is important to identify the machinery that regulates CXCR4 in tumor cells. Normally, following SDF stimulation, CXCR4 is rapidly phosphorylated by G protein-coupled receptor kinases (GRKs) or protein kinase C (PKC). CXCR4 phosphorylation initiates adaptor recruitment, promoting receptor uncoupling from G proteins leading to receptor desensitization, and promoting receptor trafficking to sites of endocytosis leading to receptor downregulation.

Previously we identified ARF6 as a novel regulator of SDF-CXCR4 axis, whereby it inhibits removal of CXCR4 from cell surface following agonist stimulation, and potentiates CXCR4 signaling to membrane-delineated ERK. Here we addressed mechanism by which ARF6 regulates CXCR4 trafficking. Specifically, we assessed effects of time, SDF dose, deglycosylation, serine/threonine/tyrosine phosphatase inhibitors on CXCR4 phosphorylation, and the ability of ARF6 to modulate CXCR4 phosphorylation. Here, we demonstrated that ARF6 inhibits CXCR4 phosphorylation in a dose- and time-dependent manner, and upon CXCR4 deglycosylation. ARF6 inhibition of CXCR4 phosphorylation is unaltered in presence of phosphatase inhibitors OA and PHS1. We also assessed the effects of PHS1, and siRNA-mediated ARF6 and Shp2 knockdown on ERK signaling, upon gradient SDF sensing. We identified a novel gradient SDF→CXCR4→Shp2→sustained ERK pathway, and demonstrated that Shp2 is differentially regulated upon SDF gradient sensing. These data provide further insight into the mechanism by which CXCR4 is regulated, and support a working model that ARF6 and Shp2 modulate CXCR4 phosphorylation and signaling in metastatic cancer cells, leading to dysregulated termination of CXCR4 signaling and trafficking of CXCR4 to endocytic sites.

#### **Coupling of excitable signaling and cytoskeletal systems mediates cell migration.**

C-H. Huang<sup>1</sup>, M. Tang<sup>1</sup>, C. Shi<sup>2</sup>, P. A. Iglesias<sup>2</sup>, P. N. Devreotes<sup>1</sup>; <sup>1</sup>Cell Biology, Johns Hopkins University, Baltimore, MD, <sup>2</sup>Electrical & Computer Engineering, Johns Hopkins University, Baltimore, MD

Many cells migrate by stochastically extending protrusions such as pseudopodia or lamellipodia. These protrusions are associated with activations of signaling responses as well as the actin based cytoskeleton. It is not clear what triggers the signaling and cytoskeletal activities in the absence of stimuli or how each contributes to the cellular projections. Here we show that the signaling and cytoskeletal events are in slow and fast excitable systems, respectively, which can act independently. During migration the active phase of signaling coincides with the formation of large projections, but whose leading edges expand in a series of steps corresponding to short bursts of cytoskeletal activity. Blocking the signaling system inhibits large extensions and impairs migration although the cytoskeleton system continues to oscillate rapidly and the cell periphery undulates. These observations suggest that engagement of the "idling" motor force of the cytoskeleton by the intermittent, more prolonged activity of the signaling system acts as the pacemaker for cell migration.

#### **EGFR and Integrin $\alpha 2\beta 1$ Dependent Invasiveness of Lung Adenocarcinoma Cells that Survived 10 Gy Ionizing Radiation.**

X. Li<sup>1</sup>, S. Ishihara<sup>1</sup>, M. Yasuda<sup>2</sup>, T. Mizutani<sup>1</sup>, K. Kawabata<sup>1</sup>, T. Nishioka<sup>3</sup>, H. Haga<sup>1</sup>; <sup>1</sup>Transd. Life Sci., Grad. Sch. of Life Sci., Hokkaido Univ., Sapporo, Japan, <sup>2</sup>Dept. of Oral Pathobiology, Grad. Sch. of Dent. Med., Hokkaido Univ., Sapporo, Japan, <sup>3</sup>Dept. of Radiology, Grad. Sch. of Med., Hokkaido Univ., Sapporo, Japan

Ionizing radiation (IR) enhanced tumor invasiveness is emerging as one mechanism responsible for the limited benefit of radiotherapy. However, the mechanism is unclear yet. In our previous study, we showed that subcloned lung adenocarcinoma cells (A549-P cells; abbreviated as P cells) that survived 10 Gy IR (A549-IR cells; abbreviated as IR cells) acquired high invasiveness *in vitro*. Here, we tried to identify the mechanism by which IR cells gain the increased invasiveness by examining altered gene expression and signaling pathway in IR cells compared

to P cells. To simulate the microenvironment *in vivo*, cells for analysis were embedded in 3-dimensional (3D) collagen type I matrices. Given that integrins play crucial roles for tumor cells by directly binding components of extracellular matrix and providing the traction necessary for cell motility and invasion, several integrins expression patterns in IR cells were compared with those in P cells. RT-PCR and immunoblotting results demonstrated that integrin  $\alpha 2$  and  $\beta 1$  expressions were elevated in IR cells. Knock-downs of their expressions by siRNA separately, or function blocking of integrin  $\alpha 2\beta 1$  resulted in round morphology and abrogation of IR cells invasion. Additionally, immunofluorescence staining by antibody that specific to activated integrin  $\alpha 2\beta 1$  indicated its activation only in collagen matrices, but not on glass substrate. Therefore, integrin  $\alpha 2\beta 1$  was supposed to be an essential receptor that mediated cell spreading and invasion in 3D collagen. The epidermal growth factor receptor (EGFR) represents the main target for non-small cell lung cancer (NSCLC) therapy, as its overexpression or constitutive activation contributes to malignancy and correlates with poor prognosis. Indeed, in IR cells, activity of EGFR was significantly enhanced. Treatment of IR cells with selective EGFR tyrosine kinase inhibitor PD168393 showed that cell invasion, EGFR activation, extracellular signal-regulated kinase (ERK1/2) activation and integrin  $\beta 1$  expression were inhibited in a dose-dependent manner. Taken together, our results suggest that overexpression of integrin  $\alpha 2\beta 1$  and activation of EGFR cooperatively promoted higher invasiveness of IR resistant lung cancer cells, which could be the alternative targets to combine with radiotherapy.

1242

#### **Examining the Role of mTOR in T Cell Proliferation and Migration Under Immunosuppression by Rapamycin.**

M. J. Gregg<sup>1</sup>, M. J. Billard<sup>2</sup>, T. K. Terrant<sup>3</sup>, Y. J. Miyamoto<sup>1</sup>; <sup>1</sup>Elon University, Elon, NC, <sup>2</sup>Thurston Arthritis Center, University of North Carolina at Chapel Hill, Chapel Hill, NC, <sup>3</sup>Department of Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC

mTOR (mammalian target of rapamycin) is a serine/threonine protein kinase that has a role in cell growth and metabolism. mTOR is also the core of two functionally distinct complexes, mTORC1 and mTORC2. mTORC1 has a prominent role in cell growth and proliferation while mTORC2 has been shown to affect cell proliferation and cytoskeletal organization. However, the role of mTOR signaling in T cell migration is not fully understood. Studies were conducted to determine the effects of rapamycin, an immunosuppressant that targets mTOR, on Jurkat T cell proliferation and migration. Rapamycin treatment of Jurkat cells was expected to inhibit cell proliferation and cell migration due to its inhibition of normal mTOR signaling. Jurkat T cells were stimulated with PMA (50 ng/ml) and PHA (10ug/ml) in the presence or absence of rapamycin (5, 10, 20, 50 nM; 12, 24, and 48 hours). Cell counts at 12, 24, and 48 hours showed a concentration-dependent inhibition of cell proliferation by rapamycin; no significant effects were seen beyond 20 nM of rapamycin. Phosphorylated ERK expression was decreased in activated T cells treated with rapamycin as determined by Western blot analysis. Rapamycin also inhibited Jurkat T cell migration toward CXCL12. Results show that even in combination with activating agents, rapamycin inhibits T cell proliferation and migration, suggesting that mTOR signaling may also have an effect on ERK signaling and T cell chemotaxis.

1243

**FXR regulates the cell proliferation of human kidney-derived cell line HK-2.**

*N. Sakamoto<sup>1</sup>, Y. Furusato<sup>1</sup>, T. Fujino<sup>1</sup>, M. Hayakawa<sup>1</sup>; <sup>1</sup>Tokyo University of Pharmacy and Life Sciences, Hachioji, Japan*

Farnesoid X receptor (FXR) is a pivotal factor maintaining bile acid homeostasis and highly expressed in the liver, kidney, intestine, and adrenal gland. We have previously revealed that FXR controls the proliferation of hepatocellular carcinoma cells: FXR stimulates cell proliferation by suppressing the p16/INK4a expression whereas downregulation of the FXR stimulates the p16/INK4a expression, resulting in the suppressed cell proliferation. In the present study, we investigate whether or not FXR also plays a crucial role in the proliferation of human kidney-derived cell line, HK-2.

The treatment of HK-2 with FXR siRNA reduces the level of p16/INK4a expression resulting in the stimulation of cell proliferation. HGF treatment down-regulates the FXR expression resulting in the stimulation of cell proliferation, however, p16/INK4a expression level is elevated by HGF. In conclusion, FXR negatively regulates cell proliferation of kidney cells. HGF positively regulates kidney cell proliferation by downregulating the FXR expression in p16/INK4a-independent manner.

**Role of Inositol 1,4,5-triphosphate Receptors in Dendritic Cell migration and Antigen Presentation.**

*P. Solanes<sup>1</sup>, M. Heuzé<sup>1</sup>, G. Visentin<sup>1</sup>, A. M. Lennon-Duménil<sup>1</sup>; <sup>1</sup>Inserm U932, Institut Curie, Paris, France*

Immature dendritic cells (DCs) reside in peripheral tissues where they sample their environment for the presence of antigens (Ags) by coupling locomotion to endocytosis. Upon encounter with infectious agents, they switch to a mature state and initiate the adaptive immune response by activating T cells in lymph nodes. Whereas mature dendritic cell migration to draining lymph nodes is driven by various chemokine receptors and adhesion molecules, the factors that drive the migration of immature DCs in peripheral tissues remains to be understand.

In migrating cells, calcium has a multifunctional role in directional sensing, polarization, cytoskeleton reorganization, traction force generation and relocation of focal adhesions. The main organelle that controls calcium-related cell functions is the endoplasmic reticulum (ER), which is a major calcium store. ER calcium is released upon binding of the second messenger, Inositol 1,4,5-triphosphate (IP3) to its receptors IPR1,2,3, which correspond to calcium channels located at the ER membrane. In this study, we address the role of the ER and IP3R in cell migration and antigen presentation by DCs.

We have found that Xestospongine C, an IP3R inhibitor, impairs the migration of immature DCs suggesting that ER calcium stores play a role in the sampling function of DCs. Using lentivirus-encoded shRNA, we silenced each type of IP3R (IP3R type 1,2 and 3) and analyzed their role in DC migration and polarization, cytoskeleton redistribution (actin, myosin IIA) and in antigen presentation. Interestingly, our results suggest that IP3R3 plays an important role in the function of immature DCs.

1245

**Cellular pathways involved in epithelial-to-mesenchymal transitions in neural crest cells.**

S. Li<sup>1</sup>, C. Ketchum<sup>2</sup>, A. Upadhyaya<sup>3</sup>, C. Keefer<sup>1</sup>, L. Taneyhill<sup>1</sup>; <sup>1</sup>Department of Animal and Avian Sciences, University of Maryland, college park, MD, <sup>2</sup>Biophysics Program, University of Maryland, college park, MD, <sup>3</sup>Department of Physics, University of Maryland, college park, MD

Neural crest cells are a population of multi-potent progenitor cells in the developing vertebrate embryo that undergo an epithelial-to-mesenchymal transition (EMT) from the dorsal neural tube and migrate extensively to generate diverse derivatives. Abnormal development of neural crest cells (NCC) can lead to neurocristopathies or even cancers. Both internal biochemical signals and external mechanical factors play essential roles in facilitating neural crest cell EMT. How cells modulate their adhesion machinery and dynamically reorganize their actin cytoskeleton to respond to the mechanical features of their external environment during EMT is not well understood. To evaluate the role of the actomyosin cytoskeleton during neural crest cell EMT and migration, midbrain neural folds that contain premigratory neural crest cells were dissected out from chick embryos, explanted into chamber slides, and incubated to allow for the formation of migratory neural crest cells. Time-lapse imaging revealed that midbrain neural crest cells spread out from the center of these explants with a velocity around 0.4  $\mu\text{m}/\text{min}$  and form a layer of cells with lamellipodial structures. To elucidate cellular pathways controlling EMT and migration, chemical inhibitors (blebbistatin, Y-27632, latrunculin, nocodazole) that perturb molecular cascades regulating cellular structures were employed. Effects of these perturbations on neural crest cell EMT and migration were quantified in terms of the spreading rate of the explants, velocity distributions of individual cells and vorticity of collectively moving cell groups. We observed that blebbistatin treatment reduces the overall velocity of moving neural crest cells to negligible levels. Moreover, migratory neural cells developed rounder cell bodies, and lamellipodia were transformed into filopodia at the periphery of the extract. These results potentially implicate a role for non-muscle myosin II, the target of blebbistatin, in chick midbrain neural crest cell EMT and migration. Experiments on non-muscle myosin II loss-of-function will further validate this finding. Actin crosslinkers such as  $\alpha$ -actinin also participate in pathways affected by these cytoskeletal inhibitors through their regulation of focal adhesion formation and cytoskeletal organization, thereby modulating cell stiffness and migration. We have documented the changes in the distribution of the actin-crosslinking protein  $\alpha$ -actinin in migratory neural crest cells after the treatment of explants with these inhibitors. Collectively, our studies give insight into specific cellular pathways regulating neural crest cell EMT and migration and the impact on various biophysical parameters upon perturbation of these pathways.

1246

**Reversible host cell transformation by *Theileria annulata* uncovers crosstalk between inflammatory cytokine signalling and actin cytoskeleton dynamics.**

M. Ma<sup>1,2</sup>, C. Muheim<sup>2</sup>, M. Baumgartner<sup>1,2</sup>; <sup>1</sup>Neuro-Oncology, Experimental Infectious Diseases and Cancer Research, University Children's Hospital Zürich, Zürich, Switzerland, <sup>2</sup>Molecular Pathobiology, University of Bern, Bern, Switzerland

Oncogenic transformation of mammalian cells is mostly irreversible and leads to aberrant cell regulation including enhanced cytoskeleton dynamics, cell motility and invasiveness. In contrast, oncogenic host cell transformation by the intracellular protozoan parasite *Theileria annulata* and the acquisition of metastatic properties by the host cell can be attenuated by drug-mediated elimination of the parasite. We are using this reversible model of cancer to study transformation-dependent actin cytoskeleton dynamics and cell motility.

Mitogen-activated protein kinase kinase kinase kinase 4 (MAP4K4), alternatively named HGK or NIK, is a Ste20 family germinal centre serine/threonine kinase. MAP4K4 regulates cytoskeleton

dynamics and cell motility on one hand, and TNF $\alpha$ -regulated glucose metabolism on the other hand. Cells transformed by *Theileria* produce a cocktail of cytokines including TNF $\alpha$  and display morphological alterations and aberrant motility *in vitro* and actively disseminate *in vivo*. Here we show that host MAP4K4 is recruited to the parasite surface and accumulates in actin-rich host cell lamellipodia in a parasite-dependent manner. Elimination of the parasite leads to decreased MAP4K4 protein expression and kinase activity, whereas silencing of MAP4K4 in infected cells by siRNA impairs lamellipodia formation and cell motility. MAP4K4 expression in infected cells increases in the presence of conditioned medium or when non-conditioned medium is substituted with recombinant TNF $\alpha$ . TNF $\alpha$ -induced MAP4K4 expression is mediated through JNK, while silencing MAP4K4 can block JNK activation. Thus, parasite-induced TNF $\alpha$  secretion stimulates MAP4K4 expression and JNK pathway activation through a positive feedback. Interestingly, unlike MAP4K4 protein, mRNA expression levels of MAP4K4 increased after parasite elimination. We explain this conundrum by two mechanisms: First, intracellular *T. annulata* sequestered host cell p53, which after parasite elimination is released to the nucleus to induce MAP4K4 expression. Second, elimination of parasite enhances miRNA targeting of MAP4K4-3'UTR sequence, suggesting parasite regulation MAP4K4 through transcriptional and post-transcriptional mechanisms.

Thus, using a reversible cancer model system we revealed a novel, tightly controlled crosstalk between inflammatory cytokine signalling and actin cytoskeleton dynamics, which is likely involved in human inflammatory and motility disorders.

1247

#### **Electrospun Poly-L-Lactic acid substrate alters migration and signaling pathway regulation in astrocytes.**

K. Van Vlasselaer<sup>1</sup>, J. Zuidema<sup>1</sup>, N. Schaub<sup>1</sup>, R. Gilbert<sup>1</sup>, G. Plopper<sup>1</sup>; <sup>1</sup>Biology, Rensselaer Polytechnic Institute, Troy, NY

The body cannot naturally recover completely from traumatic spinal cord injury due to the rapid formation and prolonged presence of the glial scar resulting in patient paralysis. Although the glial scar supports the damaged barrier between cerebrospinal fluid and circulatory blood it also creates a barrier to neuronal repair through reactive astrogliosis and astrocyte expression of chemorepellants such as neurocan. Prior work indicates that astrocytes grown on electrospun Poly-L-Lactic acid (PLLA) fibers produce less neurocan and thus PLLA fiber substrates create a chemically permissive environment for neuronal repair and formation of functional connections. Here we used a novel cloning cylinder based assay to measure migration on both random and aligned spun PLLA fibers. Changes in migratory behavior are determined through measurement of the samples feret's diameter (major and minor axis) as well as total sample entropy. To simulate migratory stimulation and inhibition, non-hydrolyzable GTP analogues and phosphatidyl-inositol-3-kinase inhibitors are utilized as respective on and off switches for migration. Migratory signaling pathways differ on random and aligned fibers through application of stimulatory and inhibitory treatments as evidenced by altered migratory parameters. Differences in cellular response on random and aligned fibers indicate that the PLLA substrate type is the determining factor in regulation of migratory behavior as well as alteration of signaling pathways.

1248

**RACK1 and vimentin complex to regulate FAK during endothelial invasion.**

*J. M. Dave<sup>1</sup>, S. A. Maxwell<sup>1</sup>, K. J. Bayless<sup>1</sup>; <sup>1</sup>Molecular and Cellular Medicine, Texas A&M Health Science Center, College Station, TX*

Angiogenesis is defined as formation of new blood vessels from preexisting ones and is critical for many physiological and pathological processes including, but not limited to, wound healing and tumor growth. To identify molecules relevant to angiogenesis, we performed a proteomic screen comparing invading versus non-invading endothelial cells (ECs) using angiogenic growth factors (GFs) and sphingosine 1-phosphate (S1P) in three-dimensional collagen matrices. We found up-regulated levels of Receptor for Activated C Kinase 1 (RACK1) and the major intermediate filament protein, vimentin that correlated with increased EC invasion. Because both RACK1 and vimentin have been linked to focal adhesion kinase (FAK), we investigated whether this pathway played a role in EC invasion. RACK1 depletion reduced invasion responses in ECs, which was associated with attenuated activation of FAK. Knockdown of vimentin blocked invasion responses and significantly decreased levels of phosphorylated and total FAK. Treatment of ECs with pharmacological inhibitor of FAK dose-dependently reduced invasion indicating a crucial role for FAK activity during EC invasion. Because RACK1 and vimentin were both up-regulated with S1P treatment, required for EC invasion, and regulated FAK, we tested whether they complexed together in ECs. RACK1 complexed with vimentin, and GFs enhanced this interaction. To further understand the interplay between RACK1, vimentin, and FAK, we tested whether RACK1 and vimentin associated with FAK during three-dimensional endothelial invasion. We observed that RACK1, vimentin and FAK complexed together in invading endothelial cultures. Moreover, depletion of RACK1 decreased association between vimentin and FAK, suggesting that RACK1 was required for stabilizing vimentin-FAK interaction during EC sprouting. Taken together, these results demonstrate that pro-angiogenic signals (S1P and GFs) converge to enhance expression and association of vimentin and RACK1 which act upstream to regulate FAK, resulting in successful endothelial sprout formation in three-dimensional collagen matrices.

1249

**Investigating the role of methylation in neural crest migration.**

*K. Vermillion<sup>1</sup>, L. S. Gammill<sup>1</sup>; <sup>1</sup>Genetics, Cell Biology and Development, University of Minnesota, Minneapolis, MN*

Neural crest cells are multipotent cells that migrate extensively to give rise to diverse structures throughout vertebrate embryos. Research has shown that a network of transcription factors specifies neural crest precursors at the borders of the neural plate, and that histone methylation regulates expression of these transcription factors. Our objective was to determine whether protein methylation also regulates neural crest migration. Indeed, knock down of an essential methylation cycle enzyme, S-adenosyl homocysteine hydrolase (SAHH), by morpholino electroporation into chick embryos impedes neural crest migration. Moreover, pharmacological inhibition of SAHH in chick neural tube cultures causes a vast reduction in the number and polarity of migratory neural crest cells, suggesting that methylation is essential for neural crest migration. In embryos, newly emerging and actively migrating cranial neural crest cells exhibit elevated levels of lysine-methylated proteins by immunofluorescence. Further analysis of individual migratory neural crest cells shows methyl-lysine immunoreactivity in the cytoplasm, suggesting a role for non-histone protein methylation in migratory neural crest cells. Proteomic profiling of cytoplasmic proteins with mono- and di-methylated lysines in premigratory and migratory neural crest cells has identified 188 putatively methylated proteins. A large subgroup of these proteins regulate the cytoskeleton, and post-translational methylation of these proteins

may be involved in regulating their function to control neural crest cell motility. Several of the proteins identified were found only in the migratory population, raising the possibility that changes in methylation status may be able to dynamically regulate neural crest migration. We have characterized the localization of three of these proteins, actin depolymerizing factor, myosin 9 and tropomyosin-1-alpha, in neural crest cells and are working to identify the methylated residue within each of these proteins. Functional analysis of these proteins is also underway to determine the importance of their methylation for neural crest migration.

**Deletion of LRP5 prevents intraretinal angiogenesis caused by VLDLR mutations.**

C-H. Xia<sup>1</sup>, X. Gong<sup>1</sup>; <sup>1</sup>*School of Optometry, University of California, Berkeley, Berkeley, CA*

This study aims to understand the underlying mechanisms for the opposite retinal vasculature phenotypes in the loss-of-function mutant mice of low-density lipoprotein receptor-related protein 5 (LRP5) and very low-density lipoprotein receptor (VLDLR), and to characterize the retinal vasculature defect in mice lacking both LRP5 and VLDLR. Fundus examination, fluorescein angiography, immunostaining, and 3-dimensional retinal vasculature reconstruction are performed to evaluate the molecular and cellular alterations of retinal vasculature in mutant animals. Our recent studies indicate that VLDLR and LRP5, members of the LDL receptor family, play opposite roles during intraretinal angiogenesis. A loss of LRP5 in mice leads to an undergrowth of the intraretinal vasculature, associated with the formation of clusters of endothelial cells (ECs) in the nerve fiber layer, and a failure of ECs to migrate into deeper retinal layers. In contrast, VLDLR knockout mice show retinal ECs penetrate through the photoreceptor cell layer to cause an overgrowth of the intraretinal vasculature and subretinal neovascularization. However, the genetic hierarchy of pro-angiogenic signals mediated by LRP5 versus anti-angiogenic signals mediated by VLDLR during retinal angiogenesis remains unclear. We have tested whether LRP5 is crucial or dispensable for the neovascularization caused by VLDLR gene mutations by generating and characterizing the LRP5/VLDLR double knockout (DKO) mice. Our results reveal that retinal vessels fail to penetrate into the photoreceptor layer in DKO mice, and an enormous number of ECs clusters appear in the nerve fiber cell layer. Thus, the presence of LRP5 is a prerequisite for the overgrowth of retinal vasculature in VLDLR knockout mice. More importantly, a functional loss of LRP5 is sufficient to prevent neovascularization caused by the VLDLR knockout mutation. LRP5 may be an effective target for inhibiting intraretinal neovascularization.

**Analysis of signaling pathways mediating in vitro reendothelialization.**

W-R. Lie<sup>1</sup>, J. Hwang<sup>1</sup>, R. Wiese<sup>1</sup>, C. Scott<sup>2</sup>, P. Sydlowski<sup>2</sup>, R. Amara<sup>2</sup>, K. Huryn-Selvar<sup>3</sup>, J. Ma<sup>3</sup>, H. Liu<sup>3</sup>, L. C. Armstrong<sup>3</sup>; <sup>1</sup>*Bioscience R&D, EMD Millipore, St. Charles, MO*, <sup>2</sup>*Bioscience R&D, EMD Millipore, Danvers, MA*, <sup>3</sup>*Bioscience R&D, EMD Millipore, Temecula, CA*

The molecular mechanisms mediating the process of large vessel reendothelialization have clinical relevance to recovery from balloon denudation and stent implantation. However, the details of the pathways underlying reendothelialization are incompletely understood, in part because of the lack of an *in vitro* model of reendothelialization that permits biochemical analysis. To fulfill the need for such a model of reendothelialization and other wound healing processes, we developed a simple method to apply a reproducible high density of linear scratch wounds to cell monolayers. This method leaves a high proportion of cells at wound edges to initiate migration and thus permits sensitive detection of biochemical changes selectively occurring in this migrating cell population. The key component of the method is a comb-like

device that, when applied to a cell monolayer in a rectangular tissue culture plate, leaves 1.5 mm wide strips of cells separated by 1 mm gaps, with minimal abrasion of the underlying culture surface. We employed this method to perform detailed biochemical characterization of the response of human umbilical vein endothelial cells (HUVECs) to wounding. Intracellular signaling pathways were analyzed using multiplexed bead-based immunoassays and Western blotting at several time points following scratch wounding. Among the MAPK signaling pathways, selective engagement of the Erk1/2 pathways was observed, with elevated pErk1/2 and pMEK1 within 30 min of wounding, followed by a gradual decline in signal. Increased phosphorylation was also observed for components of the Akt signaling pathway, including Akt, p70S6K, and GSK3 $\alpha/\beta$ , with similar kinetics as for pErk1/2. Secretion of cytokines by wounded or intact HUVEC monolayers was also analyzed using multiplexed, bead-based immunoassays. Increased secretion of the pro-inflammatory cytokines GRO $\alpha$ , IL-8 and MCP-1 was detected at 30 and 90 min after wounding, but levels of those cytokines normalized after 4 h. In contrast, secretion of angiopoietin-2 and endothelin-1 was decreased at 30 and 90 min after wounding. The results demonstrate that upon wounding, endothelial monolayers respond with a burst of signals that favor growth and migration, promote immune cell recruitment, and reduce vasoconstriction. Thus, this high density cell scratch method provides an *in vitro* model of reendothelialization that enables biochemical characterization of the key signaling nodes determining a pathological or favorable wound healing response.

1252

#### **Bicarbonate-mediated nematode sperm maturation involves soluble adenylyl cyclase (sAC) activity.**

Y. Zhao<sup>1</sup>, W. Sun<sup>1</sup>, T. Lin<sup>1</sup>, L. Miao<sup>1</sup>; <sup>1</sup>*Institute of Biophysics, Chinese Academy of Sciences, Beijing, China*

The sperm must undergo a maturation process called sperm capacitation in mammals and sperm activation in nematodes, which consists of morphological, biochemical and physiological changes in sperm necessary to acquire fertilizing potential. It has demonstrated that bicarbonate is essential for mammalian sperm capacitation. Different from flagellated sperm, nematode sperm are crawling cells and their motility is driven by the cytoskeleton composed of major sperm protein (MSP). Bicarbonate is required for *Ascaris* sperm activation; however, its role remains unknown. Our studies showed that sperm in bicarbonate-free buffer could not extend the normal lamellipodium. In addition, the increase of the bicarbonate concentration could promote the MSP cytoskeleton assembly in the absence of sperm activator, These data suggest the bicarbonate is required for the MSP cytoskeleton assembly. Subsequently, we found the Anion Exchanger (AE) and CFTR were involved in nematode sperm activation because the inhibitors of AE and CFTR blocked the sperm activation, indicating that bicarbonate entry into sperm cells is mediated by AE and CFTR channels. Furthermore, the cAMP level increase was observed during sperm activation and the increase of bicarbonate concentration significantly raised the intracellular cAMP level, indicating that bicarbonate might directly stimulate soluble adenylyl cyclase (sAC) activity and generate the cAMP, as observed during flagellated sperm capacitation. While pre-treatment of sperm with inhibitor of phosphodiesterase, which degrades cAMP into 5'-AMP, tremendously increased the intracellular cAMP level and in turn inhibited the sperm activation. These data suggested the microdomain organization of cAMP signaling is important for nematode sperm activation. Taken together, our data demonstrated that bicarbonate might function in nematode sperm to stimulate an evolutionarily conserved soluble adenylyl cyclase generating cAMP as second messenger for signal transduction during sperm activation, though the morphology of nematode sperm and their molecular machinery for motility are unlike that in flagellated sperm.

1253

**Repression and Habituation In Diatom Light-stimulated Motility Responses.**S. A. Cohn<sup>1</sup>, T. S. Kordes<sup>1</sup>, A. L. Wolske<sup>1</sup>; <sup>1</sup>Biological Sciences, DePaul University, Chicago, IL

Most pennate diatoms move using a form of gliding motility with the ability to change their direction of movement based on the local light irradiance detected at the tips of the cells (Diat. Res. 14:193; 19:167). Light exposure at the ends of cells can cause cells to either reverse direction and move out of the light, or move into the light, depending on the wavelength and intensity of the light exposure. Our work has confirmed that this light-stimulated effect is characteristic for each species with regards to both wavelength and irradiance sensitivity. In order to test for lingering effects of the light exposures (i.e. if initial exposures enhance or repress the responses of subsequent exposures) we measured the direction change response times for leading-end irradiations after the cells were previously irradiated at the leading or trailing ends. We found that high-energy irradiation at the trailing tip of *Craticula cuspidata* cells causes a rapid but quickly diminishing repression of direction change. For example, compared to a control leading-end response time of  $14 \pm 2$  sec for blue light (145nm), an exposure to the trailing end 5 sec prior to the leading end exposure increases the response time to  $147 \pm 57$  sec. Exposure with red light (165nm) 5 sec prior to the leading end exposure also generates a repression ( $97 \pm 36$  sec, compared to  $25 \pm 5$  sec for control cells). This repression by prior trailing end exposures is almost completely gone within 30 sec. A prior exposure of *Craticula* cells on the leading end causes about a 1.5-fold repression of a second leading end exposure that peaks 20-60 sec after exposure and lasts for about 75 sec. *Pinnularia viridis* cells show similar types of responses, with blue trailing end exposures increasing subsequent response times to  $187 \pm 30$  sec, compared to control response times of  $14 \pm 2$  sec; the repression by prior front end exposures are 2-2.5 fold and peak about 15 sec after exposure. *Stauroneis phoenicenteron* cells also show rear-end repression, increasing response times from  $41 \pm 6$  sec to  $166 \pm 40$  sec. The peak of the trailing end repression varies between the three species we tested, with the repression in *Craticula* cells peaking at 5 sec after light exposure, compared with 10-15sec for *Pinnularia* cells, and 20 sec for *Stauroneis* cells. The repression effect generated by front end exposure can also be habituated by multiple exposures. For, example, initial blue front end exposures in *Craticula* repress response time from  $18 \pm 1$  sec to  $31 \pm 4$  sec, but exposing cells to sequential irradiations reduces subsequent response times back to control levels ( $20 \pm 1$  sec) after 10-12 consecutive exposures. This work was supported by the DePaul College of Science and Health, and equipment purchased through NSF Grant IBN-9982897.

**Inversin is required for fibroblast polarity and directional cell migration.**

I. R. Veland<sup>1</sup>, R. Montjean<sup>2</sup>, L. Eley<sup>3</sup>, L. B. Pedersen<sup>1</sup>, A. Schwab<sup>4</sup>, J. Goodship<sup>3</sup>, K. Kristiansen<sup>1</sup>, S. F. Pedersen<sup>1</sup>, S. Saunier<sup>2</sup>, S. T. Christensen<sup>1</sup>; <sup>1</sup>Department of Biology, University of Copenhagen, Copenhagen, Denmark, <sup>2</sup>Inserm U983, Hôpital Necker, Paris, France, <sup>3</sup>Institute of human Genetics, Newcastle University, Newcastle, United Kingdom, <sup>4</sup>Institute of Physiology II, University of Muenster, Münster, Germany

Inversin is an enigmatic protein with various interacting partners and functions, some of which are associated with the primary cilium, a microtubule-based, sensory organelle controlling a number of signaling pathways during development and in tissue homeostasis. Inversin regulates Wnt signaling by targeting Dishevelled (Dvl) for degradation and critically regulates developmental processes in vertebrates (Lienkamp et al., 2012). However, little is known on the

roles of Inversin in cytoskeletal reorganization and regulation of key proteins in cell polarity processes during directional cell migration.

Here we investigated the role of Inversin in these processes using cultures of mouse embryonic fibroblasts (MEFs) derived from *inv*<sup>-/-</sup> and *inv*<sup>+/+</sup> animals. Initially, we confirmed that both *inv*<sup>-/-</sup> and *inv*<sup>+/+</sup> MEFs form primary cilia, and that Inversin localizes to the primary cilium in *inv*<sup>+/+</sup> MEFs as evidenced by IFM analysis with anti-Inversin antibodies and by transfection with GFP-Inversin. Further, *inv*<sup>-/-</sup> MEFs displayed severely compromised migratory abilities and cytoskeletal rearrangements in wound healing assays, including distorted lamellipodia formation and cilia orientation. Transcriptomic analysis on differentially expressed genes in co-regulated gene networks revealed that several pathways are affected in *inv*<sup>-/-</sup> MEFs, including Wnt signaling and regulating actin organization and focal adhesions, as compared to *inv*<sup>+/+</sup> MEFs. Further, Dvl-1 and Dvl-3 localized to MEF primary cilia, and  $\beta$ -catenin/Wnt signaling was elevated in *inv*<sup>-/-</sup> MEFs, which also showed reduced ciliary localization of Dvl-3. Furthermore, *inv*<sup>-/-</sup> MEFs display dramatically altered activity and/or localization of RhoA, Rac1, and Cdc42 GTPases in addition to aberrant expression and targeting of the Na<sup>+</sup>/H<sup>+</sup> exchanger NHE1 and of ERM proteins to the edge of cells facing the wound. Many of these defects were rescued by re-expression of GFP-Inversin in *inv*<sup>-/-</sup> MEFs, supporting the conclusion that Inversin plays a critical role in controlling the migratory behavior of fibroblasts, at least in part through transcriptional regulation of genes involved in Wnt/PCP signaling and pathways controlling cytoskeletal organization.

**Two Hox Genes Coordinate the Expression of a Transmembrane Protein MIG-13 that Specifies Anteroposterior Polarity in Cell Migration.**

G. Ou<sup>1</sup>; <sup>1</sup>Institute of Biophysics, Chinese Academy of Sciences, Beijing, China

Directed cell migration is fundamental for metazoan development. In *C. elegans*, two homobox genes, *lin-39* and *mab-5*, respectively control anterior migration of Q neuroblast on the right side and posterior migration of Q neuroblast on the left side of the animal. However, their targets and underlying cellular mechanism remain elusive. Here, we found that MIG-13, an evolutionarily conserved transmembrane protein, functions cell-autonomously in specifying anteroposterior cell polarity, and MIG-13 is a novel target of LIN-39 and MAB-5. In QR descendants, anterior cell polarity is reduced in *mig-13* or *lin-39* mutant; LIN-39 binds to 5' UTR of *mig-13* and the binding is essential for *mig-13* expression and anterior migration. In QL lineage, MAB-5 inhibits *mig-13* expression, and ectopic expression of *mig-13* disrupts posterior cell polarity and reduces posterior migration. Our data thus revealed that LIN-39 and MAB-5 coordinate the expression of MIG-13 in migrating cells to specify anteroposterior polarity.

**Functional role of let-7 microRNA family during alcoholic liver injury.**

G. Alpini<sup>1</sup>, Y. Han<sup>1</sup>, K. McDaniel<sup>1</sup>, C-G. Liu<sup>2</sup>, H. Tsukamoto<sup>3</sup>, F. Meng<sup>1</sup>; <sup>1</sup>Scott & White Digestive Diseases Research Center, Research, Medicine, Scott & White, Central Texas Veterans Health Care System and Texas A&M HSC College of Medicine, Temple, TX, United States., Temple, TX, <sup>2</sup>Experimental Therapeutics, The University of Texas-MD Anderson Cancer Center, Houston, TX, United States., Houston, TX, <sup>3</sup>Southern California Research Center for ALPD and Cirrhosis, Keck School of Medicine, University of Southern California, Los Angeles, CA, United States., Los Angeles, CA

Background: microRNAs are endogenous molecules which constitute a new class of negative regulators of gene expression. Ethanol is an etiologic agent in hepatic disease and new

evidence implicated that ethanol-sensitive microRNAs (miRNAs) are indeed regulatory masterswitches during liver injuries. The current study was aimed to characterize the functional role of specific miRNAs during hepatic injury in intragastric overfeeding mice *in vivo* and LPS treated human hepatic stellate cells (HSCs) and normal hepatocytes (N-Heps) *in vitro*. Methods: miRNA expression in 4 weeks chronic alcohol feeding mouse liver specimen and control liver tissue, as well as in LPS treated hepatic HSCs and N-Heps was assessed using a hybridization based microarray. Expression of selected mature miRNAs was evaluated by real-time PCR. The effect of selected miRNA on cell migration was assessed in hepatic stellate cells using miRNA precursor to increase cellular expression. Tissue remodeling potentials were further measured by matrix metalloproteinase activity using real-time PCR and zymogen gel assay. Results: Along with the enhanced hepatocellular apoptosis after 4 weeks ethanol feeding, we identified significantly up-regulated 0.8% and down-regulated 0.9% of known miRNA compared to controls. The down-regulated miRNAs, including let-7 family members, were further verified by Taqman real-time PCR assay. Treatment of hepatic stellate cells and N-Heps with LPS (20 ug/ml) for 48 hours induced a significant decrease of let-7b, as well as a moderate down-regulation of let-7a. Over-expression of let-7b and let-7a blocked LPS-induced cell migration in both HSCs and N-Heps tested. Bioinformatics and dual-luciferase reporter assays identified toll-like receptor 4 (TLR4) as a direct target of let-7 miRNAs in both HSCs and N-Hep cells. While TLR4 expression in HSCs and N-Hep cells was significantly increased after LPS treatment, inhibition of let-7b and let-7a also resulted in an increase of TLR4 level, and enhanced HSC and N-Hep cell motility. Additionally, modulation of let-7b and let-7a also altered expression of matrix metalloproteases 2 and 9, mediators involved in tissue remodeling during alcoholic liver injury. Furthermore, the expressions of TLR4, MMP-2 and MMP-9 were significantly altered in chronic ethanol feeding mouse liver specimens compared to controls. Conclusion: Our results show that miRNAs are critical regulators of hepatic cell migration and remodeling during alcoholic liver injury. The findings provide new insight into the function of specific miRNAs and the mechanisms of alcohol induced liver injury and tissue repair.

## Cytoskeletal Membrane Interactions

### Molecular basis for CARMIL function in lamellipodia.

A. Zwolak<sup>1</sup>, R. Dominguez<sup>1</sup>; <sup>1</sup>Physiology, University of Pennsylvania, Philadelphia, PA

Coordinated intracellular rearrangement of the actin cytoskeleton in response to extracellular cues is an important theme in cell motility. CARMIL is emerging as a crucial regulator of lamellipodia-based motility, linking GTPase signaling to actin filament dynamics at the leading edge. CARMIL's role in regulating lamellipodium formation and maintenance makes it an important player in tumor metastasis, neuronal development, and cell motility. However, the molecular basis for CARMIL's role in these cellular processes is unclear. The objective of this study is to determine the molecular mechanism by which CARMIL affects lamellipodia formation. We primarily used the methods of x-ray crystallography and small-angle x-ray scattering (SAXS), as well as biochemical and biophysical approaches for this objective. The main results of this study are: (1) we demonstrate for the first time that CARMIL can bind specific types of lipids *in vitro*. (2) Using site-directed mutagenesis, we identify several residues involved in membrane interaction. (3) Maximum lipid-binding activity requires a dimerization domain, which does not directly contribute to membrane binding. (4) X-ray crystallographic studies of CARMIL address the structural basis for membrane binding by CARMIL. Our main conclusions are that CARMIL is capable of directly binding the plasma membrane, leading to

co-localization at the lamellipodium leading edge with its known binding partners Capping Protein (CP) and Myosin I to regulate actin dynamics. CARMIL's lipid-binding specificity provides a possible mechanism for further spatiotemporal regulation of lamellipodia. CARMIL dimerization may play a role in signal transduction by CARMIL from the membrane to the actin cytoskeleton, in addition to enhancing membrane interaction. Our results addressing CARMIL's mechanism of action in lamellipodial dynamics will likely also be relevant to its role in neuronal development and tumor metastasis.

1258

**Structural and functional bases for auto-inhibition of IRSp53 and activation by Cdc42.**

*D. J. Kast<sup>1</sup>, Y. Madasu<sup>1</sup>, C. Yang<sup>2</sup>, M. Boczkowska<sup>1</sup>, T. Svitkina<sup>2</sup>, R. Dominguez<sup>1</sup>; <sup>1</sup>Physiology, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, <sup>2</sup>Biology, University of Pennsylvania, Philadelphia, PA*

Cell migration is a key step in tumor invasion and metastasis, involving dynamic reorganization of the actin cytoskeleton and membranes. BAR domain proteins play important roles in such processes by linking membrane and actin cytoskeleton dynamics to signaling pathways controlling actin cytoskeleton reorganization. IRSp53 is a BAR domain protein that has received significant attention because of its critical involvement in lamellipodia- and filopodia-based cell motility under the control of Rho-family GTPases, making it a key player in tumor metastasis. However, little is known about the mechanisms of regulation of BAR domain-containing proteins in general and IRSp53 in particular. IRSp53 is a multi-domain protein, containing an N-terminal inverted BAR (I-BAR) domain that senses and/or induces negative membrane curvature and a C-terminal SH3 domain that binds proline-rich regions in a wide range of actin cytoskeleton proteins. The flexible linker joining the I-BAR and the SH3 domains is rich in proline residues and contains a semi-CRIB motif that has been implicated in Rho-family GTPase binding. Here, we reveal the structural and functional bases for IRSp53 regulation, including autoinhibitory interactions and activation by Cdc42. Using a combination of structural and biochemical methods, we show that the CRIB motif of IRSp53 is unique in that it provides a binding platform for both the SH3 domain of IRSp53 (autoinhibition) and GTP-Cdc42 (activation). As a consequence, we now refer to this motif as the "CRIB-Pro motif". Using a FRET assay, we further show that full-length IRSp53 undergoes a large conformational change upon binding of GTP-Cdc42, consistent with the release of autoinhibitory interactions. A crystal structure of a complex between GTP-Cdc42 and the CRIB-Pro motif shows that the proline-rich region of the motif interacts with Cdc42 through a surface different from that of canonical CRIB domains. Mutagenesis studies in vitro and in vivo corroborate the importance of these interactions, indicating that the CRIB-Pro motif is uniquely adapted to serve as Cdc42-dependent switch to relieve SH3-mediated autoinhibitory interactions in IRSp53.

**Actin turnover in lamellipodial fragments.**

*J. Allard<sup>1</sup>, N. Ofer<sup>2</sup>, E. Abu Shah<sup>2</sup>, K. Keren<sup>2</sup>, A. Mogilner<sup>1</sup>; <sup>1</sup>Mathematics, University of California Davis, Davis, CA, <sup>2</sup>Technion - Israel Institute of Technology, Haifa, Israel*

Actin treadmilling is the central mechanism driving cell motility. While its biochemical components are largely known and their properties studied extensively in vitro, quantitative details of actin dynamics in vivo are not completely understood. The actin treadmill in its purest form exists in lamellipodia, and its biophysics is well studied in fish epithelial keratocytes. We focus on lamellipodial fragments from keratocytes, which lack a cell body but retain the ability to crawl with the speed and persistence of whole cells. We measured spatial distributions of F-

actin, G-actin and uncapped barbed ends of actin filaments and found that the F-actin density decreases away from the leading edge, G-actin density increases away from the leading edge, and that the uncapped barbed ends, though most dense at the leading edge, are distributed across the whole lamellipodium. We compared these data with a simple mathematical model describing F-actin rearward flow, G-actin diffusion and distributed actin assembly and disassembly. Model predictions quantitatively agree with data and, interestingly, predict that most actin monomers at the leading edge must be unavailable for polymerization in order to account for the observed motility speed. A more elaborate model incorporating (i) sequestration of monomers by  $\beta$ -thymosin, (ii) ADP-ATP exchange and (iii) oligomers, which diffuse and disassemble into monomers, can quantitatively match observed distributions and speeds. Our results provide a quantitative understanding of lamellipodial actin turnover and make predictions for pathways of actin disassembly and concentrations of actin accessory proteins. Most importantly, the model predicts that actin turnover in the lamellipodium is local, in contrast to the widely-assumed global transport of G-actin across the whole cell.

**Amoeboid motility is dependent on the extent of cell confinement and regulated by intracellular pressure.**

A. Yip<sup>1</sup>, K-H. Chiam<sup>2,3</sup>, P. Matsudaira<sup>1,2</sup>; <sup>1</sup>National University of Singapore, Singapore, Singapore, <sup>2</sup>Mechanobiology Institute, Singapore, Singapore, Singapore, <sup>3</sup>Institute of High Performance Computing, Singapore, Singapore

Mesenchymal cell motility, driven by actin polymerization and focal adhesion assembly, had been widely implicated in biological cell migration. However, some cells such as leukocytes and tumor cells were found to migrate with bleb-like protrusions initially devoid of F-actin, and independent of cell-substrate adhesion. The mechanism underlying this amoeboid-like motility remains vague.

In this study, neutrophil-like differentiated HL60 cells were confined between two polyacrylamide substrates embedded with fluorescent beads. Cells were found to exhibit two distinct modes of motility depending on the availability of cell-substrate adhesions: lamellipodia-driven (mesenchymal) motility in the presence of fibronectin-coated substrates; and bleb-driven (amoeboid) motility in the absence of fibronectin-coated substrates. Three-dimensional forces involved during cell migration were also calculated from bead displacements.

We also found that mesenchymal migration speed is dependent on substrate rigidity, with largest cell speed at intermediate substrate rigidity. Conversely, amoeboid migration speed is dependent on the gap size between substrates, with maximal cell speed occurring at intermediate gap size. Amoeboid cell migration was modelled computationally and results suggest amoeboid motility is regulated by intracellular pressure and the strength of cell-membrane to actin-cortex adhesion. Collectively, our results provide insights into mechanistic differences in mesenchymal and amoeboid motility which could potentially aid in developing therapies to prevent cancer metastasis.

1261

**The balance between cytoskeletal dynamics and membrane tension determine the number of leading edges in keratocytes.**

S. S. Lou<sup>1</sup>, J. A. Theriot<sup>2</sup>; <sup>1</sup>Department of Chemical and Systems Biology, Stanford University, Stanford, CA, <sup>2</sup>Department of Biochemistry and Howard Hughes Medical Institute, Stanford University, Stanford, CA

Rapidly motile cells such as neutrophils and keratocytes polarize to generate a single front and rear in order to sustain productive forward movement. However, other less persistent cell types, such as fibroblasts and many types of epithelial cells, frequently have multiple, apparently independent, protrusive fronts. The mechanisms that limit polarization to a single front and rear for rapidly motile cells are largely unknown. Here we use embryonic zebrafish keratocytes to investigate how a purely lamellipodial cytoskeleton self-organizes to regulate protrusion number and overall cell polarity. We have observed that keratocytes derived from 4 days post fertilization (dpf) embryos often form multiple protrusions, suggesting that the motility machinery in these cells polarizes differently from “single front” keratocytes such as those found at 2dpf. Preliminary experiments with the “multiple front” 4dpf keratocytes indicate that they can be induced to form a single leading edge upon increasing membrane tension with hypoosmotic shock. Furthermore, F-actin density is decreased in 4dpf cells as compared with 2dpf keratocytes. These results suggest that the dynamics of the actin cytoskeleton can exist in at least two different regimes, depending on whether membrane tension or the intrinsic turnover of the actin cytoskeleton limits polymerization. Using RNA sequencing, we have measured gene expression levels in 2dpf and 4dpf keratocytes and found several cytoskeleton-related genes that are differentially expressed. Future studies will attempt to identify the molecular basis for how keratocytes regulate their polarization.

1262

**Local shape control by myosin II guides endothelial cell morphology and migration in 3D environments.**

H. L. Elliott<sup>1</sup>, R. Fischer<sup>2</sup>, C. Waterman<sup>2</sup>, G. Danuser<sup>1</sup>; <sup>1</sup>Cell Biology, Harvard Medical School, Boston, MA, <sup>2</sup>National Heart, Lung and Blood Institute, National Institutes of Health, Bethesda, MD

Cell shape is fundamental to myriad cellular functions, from neuronal connectivity to erythrocyte gas exchange. In angiogenesis, vascular endothelial tip cells adopt a highly extended ‘arboreal’ morphology while migrating through three dimensional extracellular matrices, displaying numerous dynamic pseudopodial branches that explore the environment and guide their movement. To gain insight into the function and regulation of endothelial cell morphology during migration, we developed a novel image analysis method for quantifying cell shape and subcellular protein localization over a range of length and time scales. At the cell scale this revealed a cyclical relationship between cell branching and cell migration efficiency, whereby phases of exploratory branch extension and cell body translocation are temporally separated. Perturbations of myosin II function or regulation break this cycle, altering branch number, directionality and structure, and hindering migration by preventing the transition between the exploratory and migratory phases. Quantitative analysis of the cell morphologies displayed during migration, and in the presence of myosin II perturbations, implied a local mechanism of cell shape regulation by actomyosin contractility. We investigated this mechanism at the sub-cellular scale by quantifying both subcellular fluorescence localization and local membrane geometry. This revealed a relationship between myosin II accumulation and membrane curvature, further supporting a local mechanism of cell shape control. Our analysis thus shows that regulation of actomyosin contractility contributes to complex cell morphologies both locally

and globally, helping to guide endothelial cell pathfinding during angiogenesis. This provides a link between nanometer-scale cytoskeletal organization and cell-scale geometry, helping to bridge the length-scale gap between small spatiotemporal length scale molecular mechanisms and the final, larger length-scale output of cytoskeletal function, namely cell morphology and migration.

1263

**Interplay between cytoskeletal forces, membrane tension, hydrostatic pressure, and shape in rapidly migrating cells.**

C. Gabella<sup>1</sup>, E. Bertseva<sup>1</sup>, C. Bottier<sup>1</sup>, I. F. Sbalzarini<sup>2</sup>, A. B. Verkhovsky<sup>1</sup>; <sup>1</sup>Lab. of Cell Biophysics, EPFL, Lausanne, Switzerland, <sup>2</sup>Dept. of Computer Science, ETH, Zurich, Switzerland

In motile cells, membrane tension and shape are believed to emerge from the interplay of cytoskeletal forces and the hydrostatic pressure difference across the membrane. In particular, it is believed that actin polymerization pressure drives the formation of thin cell protrusions such as the lamellipodia and filopodia, while the hydrostatic pressure difference promotes the emergence of rounded blebs, but does not contribute to lamellipodia. To get insight into the balance of forces at the membrane interface, we measured membrane tension (with tether assay), protrusion velocity, and the 3D shape (by fluorescence displacement method) of migrating fish epidermal keratocytes subjected to volume perturbations and cytoskeletal drugs. Hypoosmotic treatment (medium dilution) induced cell swelling, slight increase in membrane tension and significant increase in protrusion velocity, while hyperosmotic treatment (addition of sucrose to the culture medium) induced cell shrinkage, transient decrease of membrane tension, and sustained decrease in protrusion velocity. The increase of protrusion velocity upon hypoosmotic treatment was not due to regulation of protrusive machinery by ion concentration, because treatment with the diluted medium supplemented with sucrose (to compensate for osmotic pressure difference) had no such effect. Inhibiting myosin-dependent contractility with blebbistatin induced cell flattening and fragmentation, reduced protrusion velocity and resulted in the appearance of cell populations with membrane tension both higher and lower than the control values. Remarkably, hypoosmotic treatment normalized blebbistatin-treated cells by restoring their tension, protrusion velocity, and shape. Across these differently treated groups of cells, as well as within each group, no clear positive or negative correlation between protrusion velocity and membrane tension was observed, but instead high protrusion velocity seemed to coincide with increased cell volume and/or elevated vertical profile. We propose that hydrostatic pressure together with myosin-dependent contractility maintain elevated cell profile, thus facilitating diffusion of actin subunits and increasing the lamellipodia protrusion velocity. Supported by Swiss National Science Foundation and Swiss SystemsX.

**Revisiting lamella hypothesis and myosin II-induced actin disassembly using a high-resolution single-molecule speckle microscopy with a new actin probe polymerizable to formin-assembled actin filaments.**

S. Yamashiro<sup>1</sup>, H. Mizuno<sup>1</sup>, M. B. Smith<sup>2</sup>, G. L. Ryan<sup>2</sup>, D. Vavylonis<sup>2</sup>, N. Watanabe<sup>1</sup>; <sup>1</sup>Life Sciences, Tohoku University, Sendai, Miyagi, Japan, <sup>2</sup>Department of Physics, Lehigh University, Bethlehem, PA

Single-molecule speckle (SiMS) microscopy has been a powerful method to analyze actin dynamics *in vivo* by tracking single-molecules (speckles) of EGFP-actin. However, there have been warnings that EGFP-actin might influence actin dynamics and interfere with processive actin polymerization by formins. To overcome the problems, we developed improved methods of

SiMS microscopy using an actin probe labeled with a fluorescent DyLight dye on lysine side chains. By using an *in vitro* microscopic assay, we verified that DyLight (DL)-actin retains the ability to collaborate with formin and profilin. To deliver DL-actin into cells, we developed a method that enables incorporation of DL-actin in the cytoplasm at a very low density with a high success rate. In cells, DL-actin labeled cellular actin networks with improved photostability and brightness. These favorable properties of DL-actin in combination with the Speckle TrackerJ software extends the application of speckle analysis to *in vivo* nanometer-scale displacement analysis. We reevaluated whether two F-actin populations with distinct retrograde flow velocities coexist in lamellipodia, as postulated in the lamella hypothesis (Ponti et al, *Science*, 2004), including short-lived speckles (lifetime <10 sec) that moved within a few hundred nanometers. Our data show that F-actin undergoes uniform retrograde movement with a monotonous flow speed regardless of their lifetimes. We also addressed the role of actin-myosin contraction on actin turnover in lamellipodia and lamella with a myosin II ATPase inhibitor blebbistatin. Our new method extends SiMS analysis to monitoring actin dynamics with nanometer-scale and order-of-a-second resolution, which is useful for reevaluating remaining issues in previous studies.

**Arp2/3 Inhibition induces amoeboid-like protrusions in MCF10A epithelial cells by reduced cytoskeletal membrane coupling and focal adhesion assembly.**

Y. M. Beckham<sup>1</sup>, R. J. Vasquez<sup>2</sup>, J. Stricker<sup>3,4</sup>, K. Sayegh<sup>3,4</sup>, C. Campillo<sup>5</sup>, M. L. Gardel<sup>1,3</sup>;

<sup>1</sup>Institute for Biophysical Dynamics, University of Chicago, Chicago, IL, <sup>2</sup>Section of Hematology, Oncology and Stem Cell Transplantation, Department of Pediatrics, University of Chicago, Chicago, IL, <sup>3</sup>James Franck Institute, University of Chicago, Chicago, IL, <sup>4</sup>Department of Physics, University of Chicago, Chicago, IL, <sup>5</sup>Centre de Recherche, Institut Curie, Paris, France

Here we demonstrate that Arp2/3 regulates a transition between mesenchymal and amoeboid protrusions in MCF10A epithelial cells. Using genetic and pharmacological means, we first show Arp2/3 inhibition impairs directed cell migration. Arp2/3 inhibition results in a dramatically impaired cell adhesion, causing deficient cell attachment and spreading to ECM as well as an 8-fold decrease in nascent adhesion assembly at the leading edge. While Arp2/3 does not play a significant role in myosin-dependent adhesion elongation, mature focal adhesions undergo large scale movements against the ECM suggesting a reduced ECM coupling. Cell edge protrusions occur at similar rates when Arp2/3 is inhibited but their morphology is dramatically altered. Persistent lamellipodia are abrogated and we observe a markedly increased incidence of blebbing and unstable pseudopods. Micropipette-aspiration assays indicate that Arp2/3-inhibited cells have a weak coupling between the cell cortex and the plasma membrane, and suggest a potential mechanism for increased pseudopod and bleb formation. Pseudopods are not sensitive to inhibition of formin or myosin II activity. Collectively, these results indicate that Arp2/3 is not necessary for rapid protrusion of the cell edge but plays a crucial role in assembling focal adhesions required for its stabilization.

1266

**Examining the Roles of Myosin II and Dynein Motors in Nucleokinesis of Migrating Neurons Using Small Molecule Inhibitors.**

J. S. Ramahi<sup>1</sup>, D. J. Solecki<sup>1</sup>; <sup>1</sup>Developmental Neurobiology, St. Jude Children's Research Hospital, Memphis, TN

Migration of neurons from their germinal zone to final location is an essential process in the developing brain. Following polarization of a developing neuron, nucleokinesis occurs in a two-stroke process. Nucleokinesis can be temporally defined by centrosome movement into the dilation of a leading neurite followed by nuclear translocation. The roles the actin and

microtubule network play in this process, and which generates force on the cell, are currently debated. We are examining the cytoskeleton elements and motors involved in neuronal migration through *ex vivo* time-lapse imaging using migrating cerebellar granule neurons as a model, conditionally controlling motors using small molecule inhibitors. Previous work from our lab shows pharmacological inhibition of the myosin II motor using blebbistatin severely retards movement of the centrosome. Using HPI-4 (hedgehog pathway inhibitor 4, Ciliobrevin A) to inhibit dynein, dynamics of the centrosome, neurite dilation, and nuclear movement were compared to inhibition of myosin II. In addition to stopping centrosome movement, blebbistatin treatment stops movement of the neurite dilation. Inhibition of both myosin II and dynein show different effects on stopping movement of the mother versus daughter centriole.

In addition to tracking centrosome and nuclear movement, we are examining potential modes of crosstalk between the actin and microtubule cytoskeleton and associated motors in nucleokinesis. We have imaged venus-dynein and myosin II-venus dynamics under conditional drug inhibition of the motor protein of the opposite cytoskeleton network, and under cytoskeletal perturbation using jasplankinolide, taxol, and nocodazole. Live imaging shows venus-dynein flows towards the dilation in the leading process of migrating neurons, and accumulates behind the nucleus after somal translocation. This shows a contrast to myosin, which is shown to stay enriched in the leading process of neurons during nuclear migration.

1267

#### **Dynamics of cancer-cell filopodia on substrates of different stiffness.**

*Y-R. Liou<sup>1</sup>, Y-C. Kao<sup>1</sup>, W. Tornø<sup>2</sup>, P-L. Kuo<sup>1,2</sup>; <sup>1</sup>Graduate institute of biomedical electronics and bioinformatics, National Taiwan University, Taipei, Taiwan, <sup>2</sup>Department of electrical engineering, National Taiwan University, Taipei, Taiwan*

Cell motility is highly modulated by substrate stiffness. While filopodia plays a crucial role in cell migration, the effects of environmental stiffness on filopodial dynamics remain unclear. In this work, we present the filopodial dynamics on substrates of different stiffness using a novel platform. The platform consists of an optical system called structured illumination nano-profilometry, which has a lateral resolution of 140 nm and allows filopodia observation in living cells without labeling. Human lung adenocarcinoma cells CL1-5 were cultured on substrates primarily composed of polyvinyl chloride. The substrate stiffness was tuned by addition of a plastic softener to yield Young's modulus ranging from 20 to 60 kPa. MTT assay shows that the viability of cells cultured on our substrates was similar to those cultured on commonly used elastomers such as polydimethylsiloxane. Time lapsed live cell images were acquired and for each cell the filopodial density, defined as the total number of filopodia divided by the perimeter of the cell, and the length of individual filopodia were calculated. We found that after cultured on softer substrates for 24 hours, cancer cells exhibited a significantly larger density and longer length of filopodia compared with those cultured on stiffer surface. Analyzing the temporal change of individual filopodial length reveals that a softer surface promotes cancer cells to consistently protrude filopodia. The effects of stiffer substrates on the filopodial dynamics were inhibited by treating the cells with blebbistatin. These results suggest that filopodial dynamics are closely modulated by the adhesion strength of cells. Our data quantitatively relate filopodial dynamics with environmental stiffness and should shed light in the understanding and treatment of cancer metastasis.

### Primary Zebrafish Keratocyte Explant Cultures: A Model for EMT and Epithelial Wound Healing.

K. J. Leyva<sup>1</sup>, C. K. Uppalapati<sup>1</sup>, K. E. Cooper<sup>2</sup>, E. E. Hull<sup>2</sup>; <sup>1</sup>Microbiology & Immunology, Arizona College of Osteopathic Medicine, Glendale, AZ, <sup>2</sup>Biomedical Sciences Program, Midwestern University, Glendale, AZ

The control of collective cell migration of keratocyte sheets in explant culture is of interest in epithelial wound healing and is dependent on the gene expression profile of keratocyte explant cultures over time. In a zebrafish genome array, ~17.5% of the probe sets were differentially expressed greater than 2-fold (at significant levels) between 1 and 7 days in explant culture. Among the differentially expressed genes were many of the biomarkers for epithelial-mesenchymal transition (EMT), including keratin to vimentin, E-cadherin to N-cadherin, and loss of junctional protein expression. Supporting evidence for EMT is seen in the morphological change and rearrangement of the actin cytoskeleton during explant culture with a visible disassembly of the cell sheet. Additionally, immunofluorescent assays reveal that E-cadherin function and expression appears to decrease over time with a corresponding, although weaker, increase in N-cadherin expression by 7 days. Consistent with these morphological changes, a variety of wound healing-related genes and actin regulatory proteins were also found to be differentially expressed. To validate the microarray data, quantitative PCR (qPCR) on several genes from the array was performed. In addition, qPCR analysis of differential mRNA expression of TGF $\beta$  and TNF $\alpha$  at various time points between 0 and 7 days of explant culture indicates that the peak of differential expression of both cytokines occurred at 3 days and, therefore, was not detectable in the microarray data. Collectively, our data establish that an EMT process is occurring during zebrafish keratocyte explant culture and support the use of this system as a wound healing model.

### Orientation of actin filaments and microtubules in teleost retinal pigment epithelial cells, and effect of the lectin, concanavalin A, on melanosome motility.

C. King-Smith<sup>1</sup>, N. E. Fischer<sup>1</sup>, P. Gannon<sup>1</sup>, M. Gunnam<sup>1</sup>, R. J. Vagnozzi<sup>1</sup>; <sup>1</sup>Department of Biology, Saint Joseph's University, Philadelphia, PA

Retinal pigment epithelial cells of teleosts contain numerous melanosomes (pigment granules) that exhibit light-dependent motility. In light, melanosomes disperse out of the RPE cell body into long apical projections that interdigitate with rod photoreceptors, thus shielding the photoreceptors from bleaching. In darkness, melanosomes aggregate through the apical projections back into the cell body. Previous research has demonstrated that melanosome motility in the RPE cell body requires microtubules, but in the RPE apical projections, actin filaments are necessary and sufficient for motility. Here we characterize the distribution of actin filaments and microtubules in isolated fish RPE cells. Both cytoskeletal polymers are found in the cell body and throughout the length of apical projections. Myosin S1 labeling and platinum replica shadowing of dissociated RPE cells revealed that actin filaments present in bundles within RPE apical projections are uniformly oriented with barbed ends towards the distal tips. Treatment with the tetravalent lectin, concanavalin A, which has been shown to suppress cortical actin flow by crosslinking cell-surface proteins, inhibited melanosome aggregation and stimulated ectopic actin polymerization, but did not block melanosome dispersion. These results suggest that dispersion of melanosomes from the cell body into apical projections could be accomplished by a barbed-end directed myosin motor. Inhibition of aggregation but not

dispersion by ConA crosslinking is consistent with the idea that melanosome aggregation could occur via passive attachment of melanosomes to actin filaments undergoing retrograde flow.

**Thrombomodulin is an ezrin-interacting protein that controls epithelial morphology and promotes collective cell migration.**

G-Y. Shi<sup>1</sup>, Y-Y. Shu<sup>1</sup>, H-L. Wu<sup>1</sup>; <sup>1</sup>Department of Biochemistry and Molecular Biology, College of Medicine, National Cheng Kung University, Tainan, Taiwan

Objective: Thrombomodulin (TM) is an integral membrane protein involved in cell-cell adhesion through its extracellular lectin-like domain; here, we investigate how TM is connected to the cytoskeleton and its biological functions in epithelial cells.

Methods: A magnetic bead-assisted protein isolation kit was used to identify the interacting proteins of the TM cytoplasmic domain. The cytosolic proteins that bound to green fluorescent protein (GFP)-tagged TM were isolated and analyzed by mass spectrometry. This preliminary experiment suggested that ezrin might associate with TM cytoplasmic domain. By using in vitro binding assays, we analyzed the interaction of the TM cytoplasmic domain with ezrin and mapped the ezrin-binding site on the TM cytoplasmic domain. We examined the association of TM with ezrin and actin filaments in epithelial cells and further analyzed the effects of TM knockdown on cell morphology and migration. In addition, we explored the potential role of TM-ezrin interaction in collective cell migration during wound healing.

Results: The in vitro binding assays showed that the TM cytoplasmic domain bound directly to the N-terminal domain of ezrin. Mutational analysis of the TM cytoplasmic domain identified 522RKK524 as important ezrin-binding residues. Immunoprecipitation experiments showed that TM interacted with ezrin in HaCaT and A431 epithelial cells. Confocal microscopy analysis of A431 cells revealed that TM colocalized with ezrin at cell-cell adhesion sites, where actin filaments densely associated with the plasma membrane. Knockdown of endogenous TM expression by RNA interference induced morphological changes and accelerated cell migration in A431 cells. Moreover, epidermal growth factor, upstream of ezrin activation, stimulated the interaction between ezrin and TM. In mouse skin wound repair, TM and ezrin were highly expressed in neo-epidermis, implying that both proteins are key molecules in re-epithelialization that requires collective cell migration of epithelial cells. Finally, exogenous expression of TM in TM-deficient A2058 melanoma cells promoted collective cell migration, but ezrin knockdown abrogated this phenotype.

Conclusion: TM, which associates with ezrin and the actin cytoskeleton, maintains epithelial morphology and promotes collective cell migration.

**Profilin-1 downregulation promotes mammary tumor growth and dissemination but not metastatic colonization.**

Z. Ding<sup>1</sup>, M. Joy<sup>1</sup>, R. Bhargava<sup>2,3</sup>, M. Gunsaulus<sup>1</sup>, N. Lakshman<sup>4</sup>, S. Pal<sup>1</sup>, M. Miron-Mendoza<sup>4</sup>, S. Maiti<sup>1</sup>, M. Petroll<sup>4</sup>, A. Wells<sup>1,2,5</sup>, P. Roy<sup>1,2,5</sup>; <sup>1</sup>Department of Bioengineering, University of Pittsburgh, Pittsburgh, PA, <sup>2</sup>Department of Pathology, University of Pittsburgh, Pittsburgh, PA, <sup>3</sup>Magee Women's Hospital, Pittsburgh, PA, <sup>4</sup>Department of Ophthalmology, University of Texas Southwestern Medical Center, Dallas, TX, <sup>5</sup>McGowan Institute of Regenerative Medicine, University of Pittsburgh, Pittsburgh, PA

Profilin1 (Pfn1), a ubiquitously expressed actin-binding protein, plays indispensable role in migration and proliferation of normal cells. Seemingly contrary to these essential cellular functions of Pfn1, its expression is downregulated in breast cancer, the significance of which is unclear. This study for the first time examines the functional consequences of Pfn1

downregulation in breast cancer cells in vivo. Expression profiling of Pfn1 in human breast cancer specimens of various histopathological stages correlate lower Pfn1 expression levels with propensity to metastasize. In xenograft models of human breast cancer cells, we find that both mammary tumor growth and metastasis are enhanced upon loss of Pfn1 expression. Our data suggest that Pfn1 depletion promotes breast cancer metastasis mainly through facilitating emigration of tumor cells from the primary tumor site. Consistent with this implication, we further show that upon Pfn1 depletion, breast cancer cells acquire a hyper-invasive signature (marked by MMP9 upregulation, faster invasion through collagen matrix). In Pfn1-deficient cells, hyperinvasiveness involves a PI3K-PI(3,4)P2 signaling axis. Finally, in striking contrast to its action of promoting primary tumor growth, loss of Pfn1 strongly inhibits metastatic outgrowth of disseminated cells. These data not only demonstrate that Pfn1 plays an essential role in metastatic colonization process, but may also suggest that tumor microenvironment influences how loss of Pfn1 dictates cellular phenotype.

### **Coupling cell function with cell migration: the example of dendritic cells.**

*M. Chabaud<sup>1</sup>, M. Heuzé<sup>1</sup>, P. Solanes<sup>1</sup>, E. Terriac<sup>2</sup>, R. Adelstein<sup>3</sup>, Y. Zhang<sup>3</sup>, J. Jacobelli<sup>4</sup>, M. Piel<sup>2</sup>, A-M. Lennon-Duménil<sup>1</sup>; <sup>1</sup>U932, Institut Curie, Paris, France, <sup>2</sup>UMR144, Institut Curie, Paris, France, <sup>3</sup>NIH, Bethesda, MD, <sup>4</sup>NJH, Denver, CO*

Dendritic Cells (DCs) patrol peripheral tissues in search for pathogenic antigens (Ag) to capture, by integrating macropinocytosis and cell motility. We used micro-fabricated channels to unravel the mechanisms that allow the spatiotemporal regulation of these two biological processes. We found that DCs display a discontinuous migration mode that includes high motility phases, during which macropinosomes form at the cell front, and low motility phases during which they are resorbed and their content transported to endolysosomes. We further show that low motility phases result from the association of the actin-based motor protein Myosin II with the MHCII-associated Invariant Chain (Ii), a key regulator of Ag processing and presentation. Ii transiently diverts Myosin II from the cell rear to the cell front, resulting in decreased motility but enhanced macropinocytosis and Ag transport to endolysosomes. Accordingly, while Ii-deficient DCs migrated faster but displayed decreased ability to capture external Ag, DCs over-expressing Ii exhibited the opposite phenotype. Remarkably, artificial decrease of DC motility strongly enhanced their Ag capture capacity, whereas macropinocytosis inhibition resulted in increased DC velocity, indicating that these two processes are tightly coupled. Thus, the displacement of Myosin II from migration to endocytosis enables immature DCs to coordinate these two functions in time and space, most likely optimizing their ability to scan peripheral tissues. Because Myosin II controls the motility of many cell types, we foresee that diversion of this motor protein by cell-specific components might be an evolutionarily conserved mechanism that enables cells to couple their function to their migratory capacity.

## **Intermediate Filaments**

1273

### **The structure of vimentin linker 1-2 as determined by SDSL-EPR and identification of the vimentin central rod domain elementary structure.**

*J. F. Hess<sup>1</sup>, M. Budamagunta<sup>2</sup>, A. Aziz<sup>1</sup>, J. Voss<sup>2</sup>, P. G. FitzGerald<sup>1</sup>; <sup>1</sup>Cell Biology and Human Anatomy, UC Davis, Davis, CA, <sup>2</sup>Biochemistry and Molecular Medicine, UC Davis, Davis, CA*

Intermediate filaments (IFs) are a diverse group of cytoskeletal proteins located in both the nucleus and cytoplasm. The dominant structural feature of all IFs is the alpha helical central rod

domain. In this report, we present spectroscopic data to show that linker 1-2 of vimentin, a type III IF, adopts an alpha helical parallel helices structure and thus links and continues the structures identified for the end of rod 1B and former rod 2A. Using both room temperature and low temperature methods we have identified coiled-coil structure within rod 1B and the shift from coiled-coil to parallel helices at the end of rod 1B. We have similarly characterized the parallel helices structure of rod 2A. With these data in hand, we find that the structure of linker 1-2 is consistent with a parallel helices structure. Additional spectroscopic techniques to measure the distance between spin labels placed at each end of linker 1-2 support an extended not globular structure, consistent with parallel helices structure. The identification of linker 1-2 as parallel helices completes the molecular characterization of the vimentin central rod domain. The data strongly suggest that within the vimentin dimer, the fundamental building block of vimentin IFs, the central rod domain is assembled into a symmetric, tripartite structure composed of amino coiled-coil domain, central parallel helices domain and carboxy coiled-coil domain. Based on existing nomenclature, we suggest the domains be labeled rod 1, parallel helices domain (PHD) and rod 2.

1274

**Crosstalk between plectin-modulated vimentin network architecture and signaling pathways controlling focal adhesion dynamics and migration.**

*M. Gregor<sup>1,2</sup>, S. Osmanagic-Myers<sup>2</sup>, G. Burgstaller<sup>2</sup>, G. Walko<sup>2</sup>, I. Fischer<sup>2</sup>, G. Resch<sup>3</sup>, G. Wiche<sup>2</sup>; <sup>1</sup>Department of Transgenic Models of Diseases, Institute of Molecular Genetics of the ASCR, v.v.i., Prague, Czech Republic, <sup>2</sup>Department of Biochemistry and Cell Biology, Max F. Perutz Laboratories, University of Vienna, Vienna, Austria, <sup>3</sup>Institute of Molecular Biotechnology, Vienna, Austria*

Plectin is a highly versatile cytolinker protein that stabilizes cells and tissues mechanically, regulates cytoskeletal filament dynamics, and serves as a scaffolding platform in signaling. Besides cross-linking of vimentin filaments to each other and to other filament systems we have recently shown that plectin plays a crucial role in anchoring vimentin filaments to focal adhesion contacts (FACs). Here we investigated how plectin affects vimentin network architecture in fibroblasts and whether network alterations are connected to signaling pathways involved in cell migration. Using electron microscopy we show in plectin-null cells that individual vimentin filaments have increased diameter and that the whole vimentin network organization is altered in these cells including extension of filaments to the very perimeter of cells, increased filament tangling, and loosening of network compactness. Networks of this type were more susceptible to heat stress-induced disruption and okadaic acid-induced retraction from the cell periphery. Altered cytoarchitecture of plectin-deficient fibroblasts, particularly the absence of vimentin filament anchorage at FACs, led to reduced adhesion of cells on various substrates in comparison to their wild-type counterparts. Consequently, we observed integrin dependent reduction in focal adhesion kinase (FAK) and Src kinase activities, and up-regulation of the small GTPase RhoA in plectin-deficient cells. Impaired signaling was paralleled by compromised focal adhesion dynamics, decreased PDGF-dependent migration potential and directionality as assessed in collective and single-cell migration assays. Thus, by modulating vimentin anchorage to FACs, plectin reinforces integrin dependent cell adhesion, positively affecting FAK and Src kinase activities and thereby exerting a negative feed-back loop on the small GTPase RhoA. These signals are further translated into an increase in focal adhesion turn-over and migration.

1275

**Vimentin serves as a signaling scaffold at focal adhesion sites to regulate cell adhesion.***L. S. Havel<sup>1</sup>, A. Marcus<sup>1</sup>; <sup>1</sup>Hematology and Medical Oncology, Emory University, Atlanta, GA*

Vimentin is a dynamic type III intermediate filament that is overexpressed in various cancers including non-small cell lung cancer (NSCLC). It is a classic biomarker for highly invasive tumors including those of NSCLC and is associated with a higher likelihood of metastasis and lower survival rate, suggesting a possible role in cancer metastasis. Vimentin exists in 3 forms: particles, squiggles and mature filaments. A population of vimentin filaments localize to focal adhesions, where they assemble and disassemble to allow cell migration. Focal adhesions attach to the extracellular matrix and are composed of a complex of proteins including focal adhesion kinase (FAK) and Src. Since our preliminary work shows that vimentin depletion reduces cell adhesion and other evidence shows that both FAK and vimentin localize to the focal adhesions, we hypothesize that vimentin acts through FAK to regulate cell adhesion and metastasis. We verified this finding by immunocytochemistry, which shows that vimentin filaments directly enter the pFAK and pSrc positive focal adhesion sites. We also show that upon vimentin depletion, pFAK, pSrc and total FAK levels decrease indicating that vimentin regulates FAK expression and activation. To explore the mechanism by which vimentin regulates FAK, we performed a screen for molecules whose phosphorylation status is altered upon vimentin depletion. One of the identified proteins was a guanine nucleotide exchange factor (GEF). We hypothesize that this GEF may be linked to vimentin and FAK mediated cell adhesion. This work provides insight into the mechanism by which vimentin affects cell adhesion and potentially metastasis of NSCLC tumors.

1276

**Vimentin movement in vivo is driven by acto-myosin activity.***A. J. Ehrlicher<sup>1</sup>, M. Guo<sup>1</sup>, D. Weitz<sup>1</sup>; <sup>1</sup>SEAS, Harvard University, Cambridge, MA*

The mechanics of the cytoskeleton in vivo are incredibly complex, making it difficult to determine the activity and roles of its components. While actin is a common biopolymer in virtually all cells, intermediate filaments are believed to contribute biochemically and mechanically. Nevertheless, many fundamental aspects of their function are unclear; how do intermediate filaments associate with the rest of the cytoskeleton, how are they transported, and how rapidly do they turn-over? Here using confocal microscopy and Dendra2 tagged vimentin, Fluorescence Recovery After Photobleaching (FRAP), and simultaneous Fluorescence Loss After photoConversion (FLAC), we measure both the time for individual filaments to move within the cell, and the turnover time of these filaments. By selectively inhibiting actin polymerization and myosin contraction, we find that vimentin movement is not driven by its polymerization, but by actin flows. Fluorescence data also demonstrate that vimentin polymerization/depolymerization is orders of magnitude slower than that of actin filaments. These data taken together demonstrate that vimentin provides mechanical strength, yet does not treadmill. Thus vimentin does not have the high ATP consumption of actin filaments, making it an efficient mechanical element of the composite cytoskeleton.

1277

**Intermediate filament, vimentin, strengthens actin networks.***E. Morris<sup>1</sup>; <sup>1</sup>Harvard University, Cambridge, MA*

The mechanics of the cytoskeleton in vivo are incredibly complex. Purified and reconstituted proteins have taught us a great deal about the mechanical properties of isolated cytoskeletal

components. Typically, however, these reconstituted systems may be composed of a single biopolymer, and while highly specific, fail to recreate the complex interactions in a composite material. Previous work in our lab has shown that when actin and microtubules (Brangwynne, 2008) or actin and myosin (Gardel, 2006, Koenderink, 2009) are combined that new and unexpected features emerge. Here we combine the intermediate filament vimentin with actin, and study their composite rheology using novel fiber tracking algorithms. By tracking individual actin filaments as opposed to beads, we visualize the actual network strain field under a given magnetic tweezing stress. When mixed with even small amounts of vimentin, we find that the deformation of the actin network is altered, suggesting that *in vivo* a small amount of vimentin can strengthen the actin network, without ATP costs of treadmilling or motor activity. Thus the two biopolymers are highly mechanically interconnected and form a composite network, indicating the structural importance of vimentin in cytoskeletal networks.

1278

#### **Elastic behavior of bundled vimentin networks.**

*H. Wu<sup>1</sup>, D. A. Weitz<sup>1</sup>; <sup>1</sup>Harvard University, Cambridge, MA*

A cell's response to mechanical stress is closely linked to the structure and elasticity of its cytoskeleton, which is comprised primarily of actin, microtubule, and intermediate filament (IF) networks. Vimentin is an IF found in mesenchymal cells that plays a role in anchoring organelles and contributes to overall cellular elasticity. Previous research has shown that vimentin networks behave like softly crosslinked gels in the presence of divalent cations. The linear elastic modulus, a measure of stiffness and resistance to elastic deformation, of the network is related to the degree of crosslinking, which is itself controlled by the cation concentration. Increasing the concentration of the divalent cations further results in the formation of bundles within the network, but this bundling behavior is not well understood. Here we investigate the response of *in vitro* reconstituted vimentin networks to applied shear in the presence of several divalent species to obtain a better description of how they work together (or in competition) as they would in a living cell.

1279

#### **Recombinant synemin-L caps growing and severs mature intermediate filaments of the desmin- and vimentin-type.**

*P. Zugschwerdt<sup>1</sup>, N. Mücke<sup>2</sup>, U. Aebi<sup>3</sup>, H. Herrmann<sup>1</sup>; <sup>1</sup>Functional Architecture of the Cell, DKFZ, Heidelberg, Germany, <sup>2</sup>Physics of Macromolecules, DKFZ, Heidelberg, Germany, <sup>3</sup>Biozentrum, University of Basel, Basel, Switzerland*

Synemin is supposed to co-assemble with the intermediate filament (IF) proteins desmin and vimentin, as it colocalizes with them at the Z-discs of skeletal muscle of vertebrates. Correspondingly, synemin is found together with desmin in sarcoplasmic aggregates of myocytes from patients with desmin-related myopathy. Therefore, we wanted to characterize how synemin interacts with desmin and vimentin.

In particular, we wanted to reveal the co-assembly mechanism and the *in vitro* assembly kinetics of desmin and vimentin in the presence of synemin. For this investigation, we have produced and purified recombinant desmin, vimentin and the smallest splice form of synemin, i.e. synemin-L. We renatured the proteins, either alone or in pairs, by dialyses from 8 M urea to 5 mM Tris-HCl, pH 8.4 ("tetramer buffer"). The resulting complexes were analyzed by analytical ultracentrifugation experiments. As revealed by velocity centrifugation runs, synemin-L sedimented with an *s*-value of 3.0 S, independent of the presence of desmin or vimentin during

renaturation. This behavior strongly indicates that it does not form a hetero-coiled coil with desmin and vimentin. Also, when synemin-L was renatured individually and then with desmin and vimentin mixed in “tetramer buffer”, no interaction occurred. Moreover, by sedimentation equilibrium centrifugation it was determined that synemin-L forms a monomer in “tetramer buffer”. When we then subjected synemin-L to “standard” assembly conditions, i.e. 50 mM NaCl, 22.5 mM Tris-HCl, pH 7.5 (“assembly buffer”), it formed small, uniform and round aggregates of about 35 nm diameter.

In a next step, we investigated how synemin-L influences the assembly process of vimentin and desmin. Notably, when synemin-L was present during the initiation of assembly with vimentin, it inhibited filament formation of vimentin completely, yielding short round, unit-length filament size aggregates similar to those seen with synemin-L alone. In contrast, desmin was able to “escape” the negative effect of synemin-L to some extent, but formed - even after extended assembly periods - short filaments only that were, however, terminated by round ends as revealed by electron microscopy. This result apparently reflects the fact that desmin assembles 5 times faster than vimentin, however, synemin-L eventually causes a “dead-end” situation for desmin assembly too. Very much to our surprise, the same globular structures at the filament ends were observed, when synemin-L was added to mature vimentin and desmin IFs, indicating it “cuts” IFs.

Together, these data suggest that synemin-L acts as a capping and severing factor of IFs *in vitro*. Overexpression experiments with synemin-L in authentic myoblasts are under way.

1280

#### **Cell stiffness correlates with cell volume.**

M. Guo<sup>1</sup>, E. Zhou<sup>2</sup>, F. Mackintosh<sup>3</sup>, J. Fredberg<sup>2</sup>, J. Lippincott-Schwartz<sup>4</sup>, D. Weitz<sup>1</sup>; <sup>1</sup>SEAS, Harvard University, Cambridge, MA, <sup>2</sup>Medical School, Harvard University, Cambridge, MA, <sup>3</sup>Physics, Vrije Universiteit, Amsterdam, Netherlands, <sup>4</sup>Cell Biology and Metabolism, National Institutes of Health, Bethesda, MD

Cells usually have a certain size, and their size has been shown to be correlated to gene expression across species. There are careful studies about standard cell sizes of different species, as well as cell size changes during stages of the cell cycle. Furthermore, people have shown that cells change their spreading area, stiffness, gene expression and even stem cell fate when grown on substrates of varying stiffness. However, whether cell size changes for the same cell type under varying micromechanical environments, and whether this is related to the observed phenomenological changes is not known. Here we show that height and volume of single adherent cells decrease when grown on a stiffer 2D substrate, while spreading area increases. When cell spreading area is confined by micropatterning on stiff substrate, we find cell volume is dependent inversely on their spreading area. We further measure cell stiffness with optical magnetic twisting cytometry. By controlling their volume in three different ways – varying substrate stiffness, cell spreading areas, and osmotic pressure in the medium – we find that cell stiffness correlates with cell volume but not substrate stiffness. Cells can be soft on a stiff substrate by changing only the spreading area; they can be stiff on a soft substrate by increasing osmotic pressure. Furthermore, we show that vimentin may be involved in cellular volume regulation.

**Geometric Control of Cytoskeletal Elements: Impact on Vimentin Intermediate Filaments (IF).***M. M. Cleland<sup>1</sup>, S. H. Shabbir<sup>1</sup>, M. Mrksich<sup>1</sup>, R. D. Goldman<sup>1</sup>; <sup>1</sup>Cell and Molecular Biology, Northwestern University Feinberg School of Medicine, Chicago, IL*

Significant efforts have been directed to study the role of vimentin IF in cell motility, cell shape, adhesion and its connections to other cytoskeletal elements like microfilaments and microtubules. By using micropatterning we show how these cytoskeletal elements are dependent on each other. By confining mouse fibroblasts in 8 different types of micropatterns of a constant size, we find that unlike microfilaments, vimentin IF are globally controlled. For example, both square and circle-shaped cells have a similar vimentin IF distribution while microfilament distribution in these two shapes is quite different. Furthermore, in asymmetric and polarized shaped cells vimentin IF avoid the sharp edges where microfilaments are highly localized. We have carried out a comparative study between wild-type and vimentin null mouse embryonic fibroblasts (MEF's) using 2 polarized patterns. The results show that in vimentin null MEF's microtubules are less dense and slightly disorganized at the curved edge of the shape. This indicates that the absence of vimentin IF affects the microtubules organization in the cells. Next, we analyzed cell polarity in teardrop shaped cells, both in wild-type and vimentin null MEF's and found that the absence of vimentin IF interferes with cell polarity in the teardrop shaped cell, which has been used as a model of a migrating cell. This phenotype can be reversed by over expression of wild-type vimentin IF whereas a non-filamentous mutant form of vimentin IF cannot rescue this phenotype, thus indicating filamentous vimentin IF is essential for microtubule organization. Supported by NIH/NHLBI training grant T32HL076139, NIGMS Intermediate Filament Program Project Grant 5P01GM096971-02 and by the Chicago Biomedical Consortium with support from the Searle Funds at The Chicago Community Trust.

**Vimentin organization is mediated by its active transport along microtubules and its binding to actin microfilaments.***C. Hookway<sup>1</sup>, L. Ding<sup>2</sup>, A. Robert<sup>1</sup>, M. Lakonishok<sup>1</sup>, G. Danuser<sup>2</sup>, V. I. Gelfand<sup>1</sup>; <sup>1</sup>Department of Cell and Molecular Biology, Feinberg School of Medicine, Northwestern University, Chicago, IL, <sup>2</sup>Department of Cell Biology, Harvard Medical School, Boston, MA*

Vimentin is organized in cells by microtubules and actin microfilaments, but the molecular mechanisms that mediate vimentin distribution by these systems is largely unknown. Here, we use live-cell imaging of photoactivatable forms of vimentin intermediate filaments (VIFs) and their unit-length filament (ULF) precursors to study the role of microtubules and actin filaments in VIF dynamics. We demonstrate that both VIF and ULF are rapidly transported in cells in anterograde and retrograde directions. We show that this motility is dependent on microtubules, as it is prevented by microtubule depolymerization, and strongly affected by actin microfilaments, as fast motility is dramatically increased by actin depolymerization with latrunculin B. We also see that ULF heavily decorate actin stress fibers and focal adhesions. Further, we demonstrate that vimentin transport does not occur passively with actin retrograde flow, nor is it mediated by microtubule dynamics. Therefore, we have investigated how VIF and ULF transport depends on active mechanisms by exploring the dependence of transport on motor proteins. We find that RNAi-mediated knockdown of microtubule motors results in VIF redistribution, and we show the effect of microtubule and actin microfilament motor knockdown or inhibition on transport. Thus, VIF organization in cells is established by its active transport along microtubules and by binding to actin filaments. Supported by NIGMS grant P01GM096971 to V.I.G. and G.D.

1283

**Vimentin IFs are involved in regulation of mitochondria potential.**

A. A. Minin<sup>1</sup>, I. S. Chernouvanenko<sup>1,2</sup>, E. A. Matveeva<sup>1</sup>; <sup>1</sup>Group of Cell Motility, Institute of Protein Research, Moscow, Russia, <sup>2</sup>Koltsov Institute of Developmental Biology, Moscow, Russia

Almost all functions of mitochondria that determine multiple cellular processes depend on their membrane potential. So the maintenance of potential level is very important for cell physiology. Our recent data demonstrate that vimentin intermediate filaments (vimIFs) control mitochondria motility and membrane potential. The effects of vimIFs on mitochondria are mediated by the mitochondria binding site of vimentin molecule located between 45 and 70 amino acid residues. This site contains several serine residues that are the phosphorylation sites of known protein kinases and could be potential spots where mitochondria-IF interactions are regulated. One of the sites is Ser55 which is phosphorylated by p-21 activating kinase-1 (PAK-1) an effector of the small GTPase Rac1. We performed the experiments to investigate the possible role of Rac1 protein in regulation of mitochondria membrane potential and their interaction with vimIFs. Using constitutively active mutant of Rac1 we verified that this regulatory protein really increases mitochondria motility and attenuates their membrane potential. Then we have found that protein kinase PAK-1 is indeed a downstream effector of Rac1 that is responsible for the effect on mitochondria. Our data demonstrate that activation of Rac1 does not affect mitochondria in the presence of dominant negative mutant of PAK-1 or when the point mutation S55A is introduced in vimentin. So we conclude that interaction of mitochondria with vimIFs is controlled by small GTPase Rac1 through its effector PAK-1 that modifies the putative mitochondria binding site in vimentin N-terminus.

**Ablation of keratin 8 ser74 phosphorylation predisposes to colon injury in transgenic mice.**

Y. Lim<sup>1</sup>, N-O. Ku<sup>1</sup>; <sup>1</sup>Department of Biomedical Science, Yonsei University, Seoul, Korea

Enterocytes express cytoskeletal keratin 8 (K8) as a major intermediate filament protein. A significant physiological function of K8 is to protect intestinal epithelia from colitis as shown in study of K8-null mice that develop chronic spontaneous colitis. K8 ser74 phosphorylation occurs under various stresses and represents a physiological stress marker for simple epithelia. We study the role of K8 ser74 phosphorylation in intestinal epithelia by using the mouse colitis model of dextran sulfate sodium (DSS). Human K8 ser74-to-Ala mutant (hK8 S74A) overexpressing mice are compared with hK8 WT mice after DSS administration. K8 S74A mice are significantly more susceptible to DSS-induced colon injury as compared with K18WT mice (94% and 17% lethality;  $p < 0.0001$ ). It is comparable sensitivity of K8-null mice vs nontransgenic FVB/n mice (83% and 15% lethality;  $p < 0.0001$ ). However, hK8 G62C mutant, partially blocked K8 S74 phosphorylation, overexpressing mice show similar sensitivity to DSS-induced colon injury as compared with control mice (6% and 17% lethality;  $p > 0.38$ ). The mortality data are confirmed by histopathological analysis that reveals more severe denudation of epithelial layer and mucodepletion of glands in S74A colon as compared with K8 WT and G62C colons. Notably, activation of p44/42 MAPK, related to cell proliferation, is upregulated, whereas expression of hsp70, well-established to play a cytoprotective role, is severely downregulated in S74A colon after DSS administration. In addition, 11% (4/37) of S74A mice develop anorectal prolapse at the age about 1 year but none of K8 WT and G62C mice suffer from the intestinal disorder. Therefore, K8 S74 phosphorylation plays a critical role in protection from intestinal injury.

**Predisposition to apoptosis in keratin 8-null liver is related to inactivation of NF- $\kappa$ B and SAPKs but not decreased c-Flip.***J. Lee<sup>1</sup>, K-H. Jang<sup>1</sup>, H. Kim<sup>1</sup>, Y. Lim<sup>1</sup>, S. Kim<sup>1</sup>, H-N. Yoon<sup>1</sup>, I. Chung<sup>1</sup>, J. Roth<sup>1</sup>, N-O. Ku<sup>1</sup>;**<sup>1</sup>Yonsei University, Seoul, Korea*

Keratin 8 and 18 (K8/K18) are major intermediate filament proteins of liver hepatocytes. They provide mechanical stability, thereby protecting cells from stress. Hence, K8-null mice are highly sensitive to Fas-mediated liver cell apoptosis. However, the role of c-Flip protein in K8-null related susceptibility to liver injury is controversial. Here we analyzed c-Flip protein expression in various K8 or K18 null/mutant transgenic livers and show that they are similar in all analyzed transgenic livers and that previously reported c-Flip protein changes are due to antibody cross-reaction with mouse K18. Furthermore, analysis of various apoptosis- or cell survival-related proteins demonstrated that inhibition of phosphorylation of NF- $\kappa$ B and of various protein kinases such as p38 MAPK, p44/42 MAPK and JNK1/2 is related to the higher sensitivity of K8-null mice hepatocytes to Fas-mediated apoptosis. Notably, we found that NF- $\kappa$ B and the studied protein kinases are associated with the K8/K18 complex and are released upon phosphorylation. Therefore, interaction of keratins with cell survival-related protein kinases and transcription factors is important for hepatocyte survival.

**Computational analysis of keratin network dynamics.***M. Moch<sup>1</sup>, G. Herberich<sup>2</sup>, T. Aach<sup>2</sup>, R. Windoffer<sup>1</sup>, R. Leube<sup>1</sup>; <sup>1</sup>Institute of Molecular and Cellular Anatomy, RWTH Aachen University, Aachen, Germany, <sup>2</sup>Institute of Imaging and Computer Vision, RWTH Aachen University, Aachen, Germany*

Keratin intermediate filaments are major components of the epithelial cytoskeleton, which protects epithelial cells against different forms of stress. The keratin network is therefore quite adaptable and may either be rather static or highly dynamic to meet the challenges at hand. At present, however, it is difficult to describe keratin dynamics in quantitative terms.

We therefore developed a workflow to measure the movement and turnover rate of fluorescently tagged keratin filaments in living cells. We used A431 vulva carcinoma cells stably transfected with green fluorescent protein-tagged keratin 13. Time-lapse fluorescence images were recorded of single cells using standardized conditions. Based on a maximum-a-posteriori motion estimation algorithm motion vector fields were generated from the image data. Taking the fluorescence intensity into account we also calculated keratin flow fields to measure keratin assembly and disassembly in different situations and subcellular topologies. For comparison, fluorescence recovery after photobleaching (FRAP) experiments were performed to determine keratin filament turnover in a different way in independent experiments. Finally, the results were transformed into a unit cell model to account for cell shape changes.

Using these methods we were able to show that increased time after splitting inversely correlates with keratin motility and turnover and that, on the other hand, treatment with epidermal growth factor (EGF) increases keratin motility and turnover. Taken together, the data further support the model of a continuous keratin turnover cycle that is under regulatory control.

1287

**Caspase cleavage-resistant keratin 18 mutation protects liver from apoptosis in transgenic mice.***H-N. Yoon<sup>1</sup>, N-O. Ku<sup>1</sup>; <sup>1</sup>Yonsei University, Seoul, Korea*

Cytoskeletal keratin 8 and 18 (K8/K18) proteins provide the structural integrity of simple epithelial cells including liver hepatocytes. Caspase cleavage of K18, but not K8, occurs during apoptosis and triggers the dramatic filament disassembly. We study the significance of K18 caspase cleavage by generating transgenic mice that overexpress human (h) K18 caspase cleavage-resistant mutant, K18 D238/397E. hK18 overexpression is comparable in hK18 WT and hK18 D238/397E mice, and caspase cleavage-resistance of hK18 is confirmed biochemically in D238/397E mouse tissues. There is no effect on viability, organ histology or keratin filament organization under basal conditions in D238/397E mice. We compare them to liver injury with hK18 WT overexpressing mice or nontransgenic mice. The D238/397E mice show similar sensitivity to Fas-induced liver injury as compared with nontransgenic or WT mice [44%, 42% and 53% (nontransgenic, WT and D238/397E) mice lethality;  $p>0.58$ ]. This result may be due to intact endogenous mouse (m) K18 in hK18 overexpressing mice that has caspase cleavage site. We then generate K18 WT and K18 D238/397E mice without mouse K18 by breeding with K18-null mice, and compare them to Fas-mediated injury. Absent mK18 is confirmed biochemically in hK18WT;mK18-null or hK18D238/397E;mK18-null mouse tissues. hK18D238/397E;mK18-null mice are significantly more resistant to Fas-induced injury as compared with hK18WT;mK18-null mice (23% and 57% lethality, respectively;  $p<0.001$ ). The mortality data are supported by less haemorrhage and apoptosis in hK18D238/397E;mK18-null livers. The alleviated apoptosis in hK18D238/397E;mK18-null livers involves in the sustained phosphorylation/activation of cell-survival related protein kinases (such as Akt, p38 MAPK, p44/42 MAPK, JNK1/2 and pRSK90) and transcription factor (NF- $\kappa$ B) up to 4–6 hrs after Fas administration. However, the phosphorylation/activation of the kinases and transcription factor in hK18WT;mK18-null livers is detected up to 4 hrs, but hardly detected 6 hrs after Fas injection with accompanying less amount of the protein levels, likely due to enhanced apoptosis. Hence, caspase cleavage-resistant keratin 18 mutation protects transgenic liver from apoptosis.

1288

**Assembly perturbations in mutant desmin filaments bound to nebulin in desminopathy.***D. A. Hernandez<sup>1</sup>, M. A. Caragea<sup>1</sup>, J. M. Hord<sup>1</sup>, H. Herrmann<sup>2</sup>, G. M. Conover<sup>1</sup>; <sup>1</sup>Department of Veterinary Pathobiology, College of Veterinary Medicine, Texas A&M University, College Station, TX, <sup>2</sup>Division of Molecular Genetics German Cancer Research Center, Heidelberg, Germany*

Desminopathy is a genetic human disease caused by mutations in desmin, an abundantly expressed intermediate filament muscle protein. Its symptoms are heterogeneous; although most cases present respiratory insufficiency, cardiomyopathy and painful skeletal muscle weakness. Intermediate filaments are flexible apolar polymers that provide cells with a dynamic cytoskeleton and nucleoskeleton. Their assembly proceeds in vitro from soluble mixtures of dimer and tetramers to long mature filaments under high ionic strength. To gain insight into the molecular mechanisms responsible for desminopathy, our study aims to understand structurally how desmin incorporates mutant desmin into the filament, and if its assembly is influenced by association to thin filament actin-binding muscle protein nebulin. The effect of nebulin binding on desmin length distribution was evaluated early during assembly using atomic force microscopy. Our length measurements show that a statistically significant shorter mutant desmin forms when associated to nebulin. Viscometry experiments evaluated the bulk behavior of the sheet of desmin filaments upon nebulin binding. Our results showed that homozygous mutant desmin

dramatically increases bulk sheet viscosity, while a 3-fold lower viscosity was found for either WT or heterozygous protein. Remarkably, we found that nebulin binding to heterozygous desmin dramatically decreased bulk sheet viscosity, while little changes were detected when nebulin bound to WT desmin. By total internal fluorescent reflection microscopy, single molecule experiments evaluated in real-time how fluorescently labeled WT desmin bound to mutant desmin during late stages of filament elongation. The co-assembly of WT desmin and mutant desmin primarily assembled via intercalary subunit exchange forming heteropolymers. Ongoing cell fractionation and immunofluorescence studies in myocytes are probing the role of phosphorylation in the organization of desmin filaments and their association to nebulin. Our combined biochemical and biophysical approach offers a powerful strategy to kinetically track how complex cellular cytoskeletal networks respond to normal or abnormal interactions that occur in desminopathy. Our working model is that desmin provides multiple attachment sites for Z-disc protein assemblies to stabilize the actin thin filaments and that nebulin plays a central role in opening the heterozygous intermediate filament mesh surrounding the sarcomere Z-discs.

### **Role of the pre-coil domain of desmin and its partnership with muscle proteins.**

*M. A. Caragea<sup>1</sup>, D. A. Hernandez<sup>1</sup>, L. V. Dunina-Barkovskaya<sup>1</sup>, N. Mucke<sup>2</sup>, H. Herrmann<sup>3</sup>, G. M. Conover<sup>1</sup>; <sup>1</sup>Veterinary Pathobiology, Texas A&M University, College Station, TX, <sup>2</sup>Division of Biophysics and Macromolecules, German Cancer Research Center, Heidelberg, Germany, <sup>3</sup>Molecular Genetics, German Cancer Research Center, Heidelberg, Germany*

The intermediate filament (IF) family of cytoskeletal proteins shares a tripartite structure: a non-alpha-helical flexible head, and tail end domains flanked by a conserved central alpha-helical coiled-coil rod domain. Previous work showed that removal of the vimentin head domain yields soluble molecules that failed to associate laterally into stable tetramers. To further understand the function of a 20-residue segment (87-108) preceding the rod domain, termed pre-coil domain (PCD), which is unique to vimentin-like type-III IF proteins, we produced a desmin delta PCD (108-470) truncated protein and characterized its biophysical and biochemical properties. Desmin, a type-III IF protein is abundant in striated muscle, assembles in vitro from soluble tetramers to make long mature filaments by lateral association of unit-length filaments that elongate making  $\approx 11$  nm average width filaments. Desmin delta PCD protein failed to make elongated filaments as observed by electron microscopy. After 10 min of assembly, we measured filament length in atomic force micrographs and found that delta PCD proteins made very short filaments ( $\approx 0.06 \mu\text{m}$ ), while headless desmin made ( $\approx 0.2 \mu\text{m}$ ) and WT desmin made ( $\approx 0.5 \mu\text{m}$ ) average length filaments. Consistent with these results, PCD failed to precipitate and remained in the soluble fraction while most of the WT desmin formed filaments and was recovered from the pellet fraction after high-speed co-sedimentation assays. Analytical sedimentation velocity analysis comparing headless and delta pre-coil desmin proteins yielded s-values (4.1 to 4.0) under low salt, while both proteins had undistinguishable s-values of 4.5 under conditions that favored filament assembly. Subtle changes in sedimentation profiles were detected in presence of nebulin. Delta PCD bound with a  $\approx 2$ -fold higher binding affinity to actin-binding muscle protein nebulin as compared to WT desmin as determined by ELISA. Expression studies in cardiomyocytes showed that GFP-head is unable to integrate efficiently at the Z-discs. All together, our data suggest that headless and PCD are soluble proteins that arrest assembly as tetramers of similar size. We present a model by which accessibility for binding partners to the central coiled-coil region of desmin is increased when head and PCD domains are absent, indicating that these domains participate in desmin filament-partner protein interactions by regulating their contact.

### **Gigaxonin Regulates the Degradation of Intermediate Filament Proteins: Insights into Giant Axonal Neuropathy.**

S. Mahammad<sup>1</sup>, P. S. Murthy<sup>1</sup>, A. Didonna<sup>2</sup>, B. Grin<sup>1</sup>, R. Perrot<sup>3</sup>, P. Bomont<sup>4</sup>, J-P. Julien<sup>3</sup>, P. Opa<sup>2</sup>, E. Kuczmarski<sup>1</sup>, R. D. Goldman<sup>1</sup>; <sup>1</sup>Department of Cell and Molecular Biology, Northwestern University Feinberg School of Medicine, Chicago, IL, <sup>2</sup>Davee Department of Neurology, Northwestern University Feinberg School of Medicine, Chicago, IL, <sup>3</sup>CHUL Research Centre and Department of Anatomy and Physiology, Université Laval, Quebec, Canada, <sup>4</sup>Inserm, Marseille, France

Giant Axonal Neuropathy (GAN) is a rare neurological disorder caused by mutations in GAN, the gene that encodes for gigaxonin. Patients experience progressive muscle weakness and impaired sensation, develop brain and spinal cord lesions, and eventually suffer mental retardation, dysmetria, seizures and death by 20-30 years. The patient's nerve cells are characterized by large axonal swellings that are filled with neuronal intermediate filaments (IF); interestingly their skin fibroblasts also contain large aggregates of vimentin IF. Based on sequence homology, gigaxonin is predicted to be an adaptor for Cullin-3 ubiquitin ligase and thus may be involved in protein degradation. To begin to understand its cellular function, Wt-gigaxonin was over-expressed in fibroblasts from GAN patients, normal controls and GAN-/- mice. In all cases, over-expression of Wt-gigaxonin leads to the disappearance or clearance of vimentin IF from cells, as determined both biochemically and immunocytochemically. Similarly, over-expression of gigaxonin in neuronal cells resulted in the clearance of neuronal IF (both peripherin and neurofilament light-chain). In all cases, the microtubule and actin filament systems were unaltered. Immunoprecipitation studies revealed an interaction between gigaxonin and vimentin, and truncation mutations suggested that binding was via vimentin's central rod domain. Addition of the proteasomal inhibitor MG-132 reversed the clearance of IF caused by gigaxonin over-expression, suggesting that the proteasomal pathway is involved. Gigaxonin is the first factor identified to play a specific role in the degradation of IF proteins and these findings provide insight into the mechanisms responsible for the turnover of a major class of cellular proteins which comprise the most stable cytoskeletal system in cells. These discoveries may shed light on the causes of more common neurodegenerative diseases that are also characterized by large accumulations of IF proteins, including Alzheimer's disease, Parkinson's disease, dementia with Lewy bodies, Charcot-Marie-Tooth disease (CMT), neuronal intermediate filament inclusion disease (NIFID) and diabetic neuropathy.

### **Epidermolysis Bullosa Simplex (EBS): Effect of shear stress level on EBS keratinocyte morphology and necrosis.**

O. Haddad<sup>1</sup>, C. Simmons<sup>2</sup>, D. Fudge<sup>1</sup>; <sup>1</sup>Integrative Biology, University of Guelph, Guelph, ON, Canada, <sup>2</sup>Mechanical & Industrial Engineering, University of Toronto, Toronto, ON, Canada

Epidermolysis bullosa simplex (EBS) is a genetic disorder characterized by recurrent skin blister formation from cytolysis of basal epidermal keratinocytes in response to minor injury or friction. Most cases of EBS are associated with mutations in the genes encoding keratin proteins K5 and K14 that form a filamentous cytoskeletal network in basal keratinocytes. In spite of the tight correlation between EBS phenotypes and mutations in keratin (and keratin associated) genes, the exact mechanisms by which these mutations lead to cell fragility in EBS patients are unknown. We recently showed that cells expressing a mutant EBS K14 protein are not more fragile than WT cells when subjected to extreme uniaxial stretches. Here we tested the hypothesis that EBS cells are more fragile when exposed to shear stress than WT cells. We

subjected a wild type keratinocyte line (NEB-1), a mutant K14-R125P EBS cell line (KEB-7), and a K14-null keratinocyte cell line (KEB-11) to shear stresses within microfluidic devices and found that mutants displayed more shear-induced cell necrosis than WT. Moreover, the preliminary cell morphology analysis showed that mutant cells deform less than WT cells when subjected to high shear stress. We also subjected NEB-1, KEB-7 and KEB-11 cell lines to large scale stretching and found that NEB-1 and KEB-7 cells exhibited almost no fragility, whereas KEB-11 cells displayed significant amounts of necrosis. This is the first study to demonstrate the fragility of EBS cell monolayers in culture and also the first to demonstrate that EBS cells are particularly fragile when loaded in shear.

### **Intrinsically disordered proteins aggregate at fungal cell-to-cell channels and regulate intercellular connectivity.**

*J. Lai<sup>1,2</sup>, C. Koh<sup>3,4</sup>, M. Tjota<sup>1,2</sup>, L. Pieuchot<sup>1,2</sup>, V. Raman<sup>1,2</sup>, K. B. Chandrababu<sup>2</sup>, D. Yang<sup>2</sup>, L. Wong<sup>3</sup>, G. Jedd<sup>1,2</sup>; <sup>1</sup>Temasek Life Sciences Laboratory, Singapore, Singapore, <sup>2</sup>Department of Biological Sciences, National University of Singapore, Singapore, Singapore, <sup>3</sup>School of Computing, National University of Singapore, Singapore, Singapore, <sup>4</sup>NUS School for Integrative Sciences and Engineering, National University of Singapore, Singapore, Singapore*

Multicellular fungi, like plants and animals, possess cell-to-cell channels known as septal pores. However, not much is known about the fungal septal pores. Electron micrographs show an electron dense proteinaceous structure at the septal pore, but the identity of these proteins is not known. Several septal pore associated organelles have been described in filamentous fungi, like the peroxisome-derived Woronin body in the Pezizomycotina that plugs septal pores in injured hyphae to minimize cytoplasmic bleeding. Here, using a combination of mass spectrometry of Woronin body associated proteins and a bioinformatics approach that identifies related proteins based on composition and character, we identify 17 septal pore associated (SPA) proteins that localize to the septal pore in rings and in a pore-centered foci. SPA proteins are not homologous at the sequence level, but share similar physical characteristics with intrinsically disordered proteins. Some SPA proteins form aggregates at the septal pore and in vitro assembly assays of these purified proteins suggest a non-amyloid aggregation mechanism driven by alpha-helical and disordered structures. Some SPA proteins appear to be involved in membrane resealing process and compartmentalized cell death. However deletions in all but three SPA proteins and multiple deletions do not show obvious phenotype, which suggests functional redundancy of some SPA proteins. Three SPA deletions show different phenotypes, which include excessive septation, degeneration of septal pores, and uncontrolled Woronin body activation. Taken together, we have identified the septal pore as a complex subcellular compartment and focal point for the assembly of intrinsically disordered proteins that control diverse aspects of intercellular connectivity.

1293

### **Is the $\beta_2$ subunit of the Na<sup>+</sup>pump a self-adhesion molecule?**

*M. Roldán<sup>1,2</sup>, G. Rojas<sup>2</sup>, J. Cancino Díaz<sup>1</sup>, L. Shoshani<sup>2</sup>; <sup>1</sup>Microbiology, ENCB-IPN, Mexico city, Mexico, <sup>2</sup>Physiology, Cinvestav-IPN, Mexico city, Mexico*

The membrane enzyme Na<sup>+</sup>,K<sup>+</sup>-ATPase is distributed in a polarized manner in epithelial cells. We have previously shown that Na<sup>+</sup>,K<sup>+</sup>-ATPase polarity depends on the  $\beta$  subunits of Na<sup>+</sup>,K<sup>+</sup>-

ATPases located on neighboring cells (Shoshani et al. 2005). Then we demonstrated by protein-protein interaction methods (FRET, co-immunoprecipitation and pull down) that the extra-cellular domain of  $\beta_1$  subunit associates in a specific and direct manner with another  $\beta_1$  subunit localized on adjacent cell (Padilla-Benavides et al. 2010). Now we wonder if the  $\beta_2$  isoform, known as the adhesion molecule on glia (AMOG) is able to associate with itself or with the  $\beta_1$  subunit? To answer this question we expressed the human  $\beta_2$  subunit fused to YFP in MDCK and CHO cells. In both stable cell lines, as observed by fluorescence microscopy, the recombinant protein is localized to the plasma membrane and concentrates in cell-cell contacts. When MDCK  $\beta_2$ -YFP cells are co-cultured with NRK cells (epithelial from rat kidney) the  $\beta_2$ -YFP is expressed both in homotypic and heterotypic borders suggesting probable interaction with the  $\beta_1$  subunit localized on adjacent NRK cell. Therefore we first analyzed  $\beta_2/\beta_1$  interaction by pull-down and Co-immunoprecipitation assays. We detect positive interactions when using dog  $\beta_1$  subunit as bait and human  $\beta_2$ -YFP as prey in pull down experiments. Also, when we IP the  $\beta_2$  isoform from rat brain the endogenous brain  $\beta_1$  subunit is co-precipitated. These findings are indicating a probable interaction *in vitro* and *in vivo* between the two isoforms.

We then looked for  $\beta_2/\beta_2$  interaction in aggregation assay analyzed by FACS. We found that CHO  $\beta_2$ -YFP cells make significantly more cell aggregates than CHO wt, indicating that the expression of the  $\beta_2$  isoform confers to the CHO fibroblasts adhesiveness, that could be explained by  $\beta_2/\beta_2$  interactions. Therefore, we assayed for this possible interaction using endogenous  $\beta_2$  from rat brain and from human RPE cell line (ARPE-19). Pull down experiments, using  $\beta_2$ -YFP as bait and rat brain or human RPE extracts as prey did not reveal any  $\beta_2/\beta_2$  interaction suggesting that at least under these experimental conditions, they do not associate. Overall, our preliminary results suggest that  $\beta_2$  isoform participates in heterotypic but not homotypic interactions.

1294

### **Cx45 can functionally replace Cx43 in activation of TGF- $\beta$ to support mural cell differentiation from mesenchymal precursors.**

J. S. Fang<sup>1</sup>, C. Dař<sup>2</sup>, D. T. Kurjiaka<sup>3</sup>, J. M. Burt<sup>4</sup>, K. K. Hirschi<sup>1</sup>; <sup>1</sup>Cardiology, Yale University, New Haven, CT, <sup>2</sup>Pediatrics, MD Anderson Cancer Centre, Houston, TX, <sup>3</sup>Biomedical Science, Grand Valley State University, Allendale, MI, <sup>4</sup>Physiology, University of Arizona, Tucson, AZ

During blood vessel formation, smooth muscle development involves signaling from endothelial cells (EC) that mediates the recruitment of mesenchymal cell (MC) precursors and promotes their differentiation toward a mural cell fate. Previously, we demonstrated that gap junction channel formation between EC and MC is required for EC-induced TGF- $\beta$  activation and mural cell differentiation. Furthermore, Cx43-comprised gap junctions mediate these processes. However, Cx43<sup>-/-</sup> embryos survive to birth with relatively normal vascular smooth muscle development suggesting involvement of another connexin in this process during embryogenesis. Developmental studies suggest that Cx45 is required for mural cell development, although its exact role was not delineated. We show herein that Cx43<sup>-/-</sup> MC transfected to stably express Cx45 in the absence of Cx43 form functional heterocellular gap junctions when co-cultured with EC. Furthermore, heterocellular Cx45-containing channels (like Cx43 channels) enabled TGF- $\beta$  activation, which then promoted the upregulation of mural cell-specific proteins in the mesenchymal precursors. Thus, these studies reveal a critical role for Cx45 in the regulation of EC-induced mural cell differentiation. Our findings are consistent with the phenotype of Cx45-deficient embryos, which exhibit dysregulated TGF- $\beta$  and lack mural cell development.

1295

**Identification of intracellular toxic signals required for bystander killing through gap junctions from HIV infected astrocytes to uninfected astrocytes.**

*E. A. Eugenin<sup>1</sup>, J. W. Berman<sup>2</sup>; <sup>1</sup>Microbiology and Molecular Genetics, PHRI/UMDNJ, Newark, NJ, <sup>2</sup>Pathology, The Albert Einstein College of Medicine, Bronx, NY*

HIV entry into the central nervous system (CNS) is an early event after infection, resulting in neurological dysfunction in a significant number of individuals. As people with AIDS live longer, the prevalence of cognitive impairment is increasing, despite antiretroviral therapy. The mechanisms that mediate CNS dysfunction are still not well understood, but are postulated to be a combination of inflammation, and viral infection and/or replication. In addition to those mechanisms, we recently demonstrated that HIV infection of astrocytes mediated survival of HIV infected cells and bystander killing of surrounding uninfected cells by a mechanism that is gap junction dependent. We now characterize the mechanisms of HIV mediated protection of infected astrocytes with an emphasis on mitochondrial dysregulation and identification of the intracellular factors that mediate bystander killing of uninfected cells. Our findings describe a novel mechanism by which HIV maintains survival of HIV infected astrocytes and we identify IP<sub>3</sub>, calcium and Cytochrome C as key signals involved in bystander killing of uninfected cells in contact with HIV infected astrocytes by a gap junction dependent mechanism. Thus, our data provide novel mechanisms of HIV survival and toxicity in the current NeuroAIDS era, where viral replication is not a major component due to effective antiretroviral treatments. Our findings identify new potential therapeutic targets to reduce the devastating consequences of NeuroAIDS.

1296

**Structure and functional studies of Cx43 mutants linked to human diseases- Oculodentodigital Dysplasia (ODDD).**

*Q. C. Shao<sup>1</sup>, R. Lorentz<sup>1</sup>, X-Q. Gong<sup>2</sup>, D. Ba<sup>2</sup>, G. S. Shaw<sup>3</sup>, D. W. Laird<sup>1</sup>; <sup>1</sup>Anatomy & Cell Biology, The University of Western, London, ON, Canada, <sup>2</sup>Department of Physiology & Pharmacology, The University of Western, London, ON, Canada, <sup>3</sup>Department of Biochemistry, The University of Western, London, ON, Canada*

Connexins are gap junction proteins which form intercellular channels between the vast majorities of cell types in the human body. A wide variety of diseases ranging from developmental disorders to cancer occur when the genes encoding the 21 member connexin family become mutated or dysregulated. Oculodentodigital dysplasia (ODDD) is a developmental disorder caused by predominantly autosomal dominant mutations that occur in the GJA1 gene that encodes Cx43. Patients that harbor these mutations suffer from developmental defects in the hands, feet, eyes, teeth and occasionally in a plethora of other organs. Collectively, we and others have classified the over two dozen characterized mutants to: a) be gap junction functionally dead; b) have residual gap junction channel function; or c) exhibit gain-of-hemichannel function. Furthermore, most, but not all, of the mutants tested are dominant to co-expressed Cx43. In the current study, we focus on the structure and functional changes linked to missense mutations in the N-terminus of Cx43. We found that all missense mutants formed non-functional gap junction-like plaques and exhibited dominant-negative effects on co-expressed endogenous Cx43. NMR protein structure determination of the N-terminal 23 amino acid polypeptides of wild-type and G2V mutant of Cx43 revealed that both polypeptides folded into kinked  $\alpha$ -helical structures. These findings predicted that the tryptophan (W) at the 4th position may be critically important in intra- and inter- molecular interactions. Thus we engineered and characterized a W4A mutant and found that this mutant formed a

regular, non-kinked  $\alpha$ -helix but did not form functional gap junctions. As predicted from NMR studies, the G2S mutant stabilized the N-terminal helix and form functional gap junctions. Collectively, these studies suggest that elongated  $\alpha$ -helical structure at the N-terminus of Cx43 is likely essential for Cx43 channel formation and function similar to Cx26. Furthermore, the nature of the mutation conveys loss-of-Cx43 function by distinctly different mechanisms that are rooted in the structure of the N-terminal region. Funded by the CIHR to DWL, DB and GSS.

**Mammary gland defects as revealed by genetically-modified mice harboring an oculodentodigital dysplasia-linked Cx43 mutant.**

M. K. Stewart<sup>1</sup>, X-Q. Gong<sup>1</sup>, K. J. Barr<sup>1</sup>, D. Bai<sup>1</sup>, G. I. Fishman<sup>2</sup>, D. W. Laird<sup>1</sup>; <sup>1</sup>Western University, London, ON, Canada, <sup>2</sup>New York University School of Medicine, New York, NY

Genetically-modified mice mimicking oculodentodigital dysplasia (ODDD), a disease characterized by reduced Cx43-mediated gap junctional intercellular communication, represent an *in vivo* model to assess the role of Cx43 in mammary gland development and function. We previously reported that severely compromised-Cx43 function delayed mammary gland development and impaired milk ejection in mice that harboured a G60S Cx43 mutant. Surprisingly, there are no definitive reports of lactation defects in ODDD patients. To address this further, we obtained a second mouse model of ODDD expressing an I130T Cx43 mutant to assess if a Cx43 mutant with residual gap junction channel activity would rescue mammary gland development and function. Our findings show that virgin Cx43<sup>I130T/+</sup> mice, distinct from Cx43<sup>G60S/+</sup> mice, develop with similar body weights compared to control, despite having a reduction in the highly phosphorylated species of Cx43 and reduced Cx43 gap junctional plaques. In addition, virgin Cx43<sup>I130T/+</sup> mice exhibit a delay in ductal elongation at four weeks that is not observed by seven weeks. Cx43<sup>I130T/+</sup> mice develop smaller mammary glands at parturition due to reduced proliferation despite similar overall gland architecture. Distinct from Cx43<sup>G60S/+</sup> mice, Cx43<sup>I130T/+</sup> mice adequately produce and deliver milk to pups suggesting milk ejection is unaffected. Thus, these studies suggest that loss-of-function mutants of Cx43 with residual gap junction channel activity can rescue functional defects in the mammary gland and helps to explain the lack of lactation defects associated with ODDD patients. Supported by the Canadian Breast Cancer Foundation.

1298

**Autosomal Recessive Cx43 Gene Mutations Cause Oculodentodigital Dysplasia by Distinct Mechanisms.**

T. Huang<sup>1</sup>, Q. Shao<sup>1</sup>, A. MacDonald<sup>2</sup>, L. Xin<sup>3</sup>, L. Robert<sup>4</sup>, D. Bai<sup>3</sup>, D. Laird<sup>1</sup>; <sup>1</sup>Anatomy and Cell Biology, Western University, London, ON, Canada, <sup>2</sup>School of Dentistry, Western University, London, ON, Canada, <sup>3</sup>Physiology and Pharmacology, Western University, London, ON, Canada, <sup>4</sup>The Hospital for Sick Children, University of Toronto, Toronto, ON, Canada

Oculodentodigital dysplasia (ODDD) is mainly an autosomal dominant human disease caused by mutations in the GJA1 gene encoding the gap junction protein connexin43 (Cx43). Surprisingly, there have been two autosomal recessive mutations reported that cause ODDD; a single amino acid substitution (R76H) and a premature truncation mutation (R33X) that results in only 32 amino acids of Cx43 being encoded. Intriguingly, patients with the R33X mutation are essentially equivalent to a Cx43 knockout, but unlike mice, patients do survive at birth, albeit with severe ODDD. In the present study, we characterized the effect of these mutants on Cx43 channel formation and their potential ability to effect co-expressed members of the connexin family. When expressed in either gap junctional intercellular communication (GJIC)-deficient HeLa cells or Cx43-expressing NRK cells, the R76H mutant trafficked to the cell membrane to

form gap junction-like plaques while the R33X mutant remained diffusely localized to the cytosol and nucleus. As expected, the R33X failed to form functional channels. Dye transfer studies in HeLa cells revealed that the R76H mutant could form functional channels that passed Alex350 dye more readily than Lucifer yellow and electrical conductance analysis in GJIC-deficient N2A cells revealed that both the macroscopic conductance and single channel conductance were smaller than those of wild-type Cx43. To evaluate if either the R76H or R33X mutants could act as trans-dominant on other members of the connexin family, we co-expressed the mutants in HeLa cells that transiently expressed Cx40 or stably expressed Cx37, Cx26 or Cx32. Alex350 dye transfer studies revealed that the R76H mutant had no detectable negative effect on the function of any of the other connexins tested while the R33X mutant exhibited significant trans-dominant effects on Cx40 and Cx37, but not Cx26 or Cx32. Taken together, our results suggest that trans-dominant effect of R33X together with its complete inability to form a functional channel may explain why patients harboring this autosomal recessive R33X mutant exhibit greater disease burden than patients harboring the R76H mutant.

### **Connexin30 mutants may cause skin disease through the induction of cell death pathways.**

A. C. Berger<sup>1</sup>, Q. Shao<sup>2</sup>, D. W. Laird<sup>2</sup>; <sup>1</sup>Physiology and Pharmacology, Western University, London, ON, Canada, <sup>2</sup>Anatomy and Cell Biology, Western University, London, ON, Canada

Gap junctional intercellular communication occurs when connexin protein complexes connect adjacent cells to mediate the passage of ions and various small hydrophilic cellular metabolites and secondary messengers. Connexin30 (Cx30) is a member of the large gap junction protein family, and autosomal dominant mutations in the gene that encodes this connexin, GJB6, are linked to non-syndromic deafness and various skin diseases. The mechanisms responsible for Cx30 mutants exhibiting distinct pathologies is not clear but our previous studies have suggested that the Clouston Syndrome-linked V37E and A88V mutants induce cell death, while the T5M mutant linked to non-syndromic deafness does not. More recently, patients harboring a newly discovered G59R mutant present with symptoms similar to those of Vohwinkel's and Bart-Pumphrey Syndromes. In our study, when HeLa cells were engineered to express wild-type Cx30 or the various mutants, only Cx30 and the T5M mutant were able to pass Alexa 350 suggesting that all mutants, except T5M, are loss of gap junction function mutants. Next, when we expressed the Cx30 mutants in rat epidermal keratinocytes (REKs), TUNEL assays performed 24 hours later revealed that the V37E and A88V mutants induced cell apoptosis. Confocal microscopy revealed that wild-type Cx30 and the T5M mutant readily assembled into gap junction-like plaques while all skin disease-linked mutants were primarily found within intracellular compartments, where they frequently co-localized with resident molecules of the endoplasmic reticulum (ER). Interestingly, a population of the A88V mutant was detected in gap junction-like plaques at 12 hours after transfection prior to the onset of cell death. Currently we are investigating the hypothesis that select Cx30 mutants are retained primarily in the ER, resulting in ER stress, which subsequently triggers the unfolded protein response and premature apoptotic cell death. Collectively, these findings are beginning to provide insight into the mechanisms of how select mutants may cause only non-syndromic deafness while others are syndromic in nature resulting in severe skin diseases. ### Mefloquine inhibits connexin26 hemichannel mutants linked to keratitis-ichthyosis-deafness syndrome.

N. A. Levit<sup>1,2</sup>, T. W. White<sup>3</sup>; <sup>1</sup>Graduate program in genetics, Stony Brook University, Stony Brook, NY, <sup>2</sup>Medical Scientist Training Program, Stony Brook University, Stony Brook, NY, <sup>3</sup>Physiology and Biophysics, Stony Brook University, Stony Brook, NY

Connexin (Cx) proteins form intercellular gap junction channels to facilitate the exchange of ions and small molecules between adjacent cells. Mutations in connexins cause several human diseases by interrupting normal cell-to-cell communication and coupling. Connexins also form functional hemichannels in nonjunctional membranes that have an unclear role in normal physiology but have altered activity in certain pathological states. Mutations in *GJB2*, the gene encoding connexin26 (Cx26), are linked to sensorineural hearing loss as well as syndromic deafness associated with skin disorders. In contrast to Cx26 mutations causing nonsyndromic deafness, those that also cause skin disease are exclusively gain-of-function single amino acid changes with autosomal dominant inheritance patterns. At least 9 missense mutations near the N-terminus and first extracellular loop of Cx26 have been linked to keratitis-ichthyosis-deafness (KID) syndrome, which can consist of life threatening skin phenotypes. Functional changes related to hemichannel open probability and permselectivity have been shown for 7 of the 9 KID-causing Cx26 mutations but the specific pathophysiologic mechanism leading to skin disease is presently unknown. We hypothesize that hemichannel dysregulation, downstream of a causative Cx26 mutation, interferes with keratinocyte proliferation and differentiation in the epidermis. To further enable evaluation of the deleterious consequences of aberrant Cx26 hemichannel activity, we have identified and characterized a series of quinine-family small molecule inhibitors. A *Xenopus laevis* oocyte expression assay combined with single-cell voltage clamp electrophysiology was used to measure mutant Cx26 hemichannel current in the presence and absence of blocking candidates. Our data show that distinct Cx26 mutant variants respond to pharmacologic agents differently, highlighting the specificity of inhibition. The highest efficacy for Cx26 blockade was achieved by mefloquine, an FDA-approved drug with minimal untoward effects reported in the skin. Mefloquine was tested at 10, 30, and 100 $\mu$ M and showed a dose response for G45E, D50N, A40V, D50A, and G12R mutants with average maximal hemichannel current suppression of 89.6%, 75.4%, 69.8%, 60.1%, and 78.8% respectively. The A88V and N14K mutants did not significantly respond to mefloquine at these concentrations. This work will pave the way for *in vivo* studies with a transgenic mouse model of KID syndrome by tissue-specific and inducible expression of Cx26-G45E, having the potential to establish a basis for pharmacologic prevention or intervention strategies.

### Mast cell degranulation induced by amyloid $\beta$ peptide is mediated by pannexin 1 hemichannels.

P. A. Harcha<sup>1</sup>, A. A. Vargas<sup>1</sup>, J. C. Sáez<sup>1,2</sup>; <sup>1</sup>Fisiología, Pontificia Universidad Católica de Chile, Santiago, Chile, <sup>2</sup>Instituto Milenio, Centro Interdisciplinario de Neurociencias de Valparaíso, Valparaíso, Chile

Mast cells are resident immune cells of vascularized tissues. In granules they store an array of pro-inflammatory mediators, which are rapidly released to the extracellular milieu upon activation.

**Objective:** Since prolonged exposure to the amyloid A $\beta_{25-35}$  peptide *in vitro* leads to neurotoxicity mediated by activation of a hemichannel-dependent cascade of glial cells and promotes mast

cell degranulation, we evaluated if acute treatment with A $\beta$ <sub>25-35</sub> peptide promotes mast cell degranulation via pannexin hemichannel activation.

**Methods:** Primary naïve mast cells were derived from bone marrow precursors of wild type (WT) and Panx1 K.O. (Panx1<sup>-/-</sup>) mice using WEHI3 cells conditioned medium. Panxs 1, 2 and 3 mRNAs were evaluated by RT-PCR analyses. Bone marrow derived mast cells were stimulated with A $\beta$ <sub>25-35</sub> peptide. The hemichannel activity was assessed by 4',6-diamidino-2-phenylindole (DAPI) uptake assays and membrane currents were evaluated by whole cell patch clamp, while degranulation was evaluated by quantification of extracellular histamine and release of toluidine blue (TB) from TB preloaded mast cells.

**Results:** Only Panx1 mRNA was detected in bone marrow derived WT mast cells. Stimulation with A $\beta$ <sub>35-42</sub>, but not A $\beta$ <sub>42-35</sub> peptide, induced histamine and TB release and also enhanced DAPI uptake and total membrane currents in WT mast cells. These responses were drastically reduced in WT mast cells pretreated with 10  $\mu$ M carbenoxolone, which blocks Panx hemichannels, and was absent in mast cells derived from Panx1<sup>-/-</sup> animals.

**Conclusion:** Bone marrow derived mast cells express functional Panx1 hemichannels, which are essential for the degranulation response induced by A $\beta$ <sub>35-42</sub> peptide. Thus, inhibition of Panx1 hemichannels might avoid the spread of inflammatory responses coordinated by mast cells in Alzheimer's disease.

#### The channel protein Pannexin1 regulates early events in skin development.

S. Penuela<sup>1</sup>, J. M. Churko<sup>1</sup>, K. Barr<sup>2</sup>, A. C. Berger<sup>2</sup>, D. W. Laird<sup>1</sup>; <sup>1</sup>Anatomy and Cell Biology, University of Western Ontario, London, ON, Canada, <sup>2</sup>Physiology, University of Western Ontario, London, ON, Canada

Pannexins are a family of channel-forming glycoproteins found at the cell surface of many mammalian cells. Panx1 and Panx3 channels have been reported as conduits for ATP release, and play an important cellular role in the differentiation of keratinocytes, chondrocytes and osteoblasts. We previously reported the expression of Panx1 and Panx3 in mouse dorsal skin as early as embryonic day 13.5. We also found that ectopic expression of Panx1 in organotypically grown keratinocyte cultures resulted in disrupted architecture of the epidermis. Using a Panx1 knockout mouse model we set out to evaluate the role of Panx1 in skin differentiation and development. Although there were no overt skin abnormalities in Panx1 null mice, histological staining of newborn skin sections revealed a significant reduction in skin thickness compared to controls. Also, in Panx1 null mice, as early as four days after birth, there was an apparent increase in hypodermal adipose tissue that persisted into adulthood. To more thoroughly characterize the cellular constituents of the epidermis and dermis, we isolated primary keratinocytes and dermal fibroblasts from both knockout and control neonatal mice. Both primary cell types from control mice expressed high levels of Panx1 and were capable of sulforhodamine B dye uptake after mechanical drip stimulation, while dye uptake in Panx1 null keratinocytes and fibroblasts was significantly less. Scratch wound experiments and proliferation assays revealed that Panx1 null primary keratinocytes were more proliferative and migratory while Panx1 null dermal fibroblasts were more proliferative than controls. Western blots of differentiating primary keratinocytes from control mice in the presence of calcium revealed a progressive decrease in the levels of Panx1 as the markers of keratinocyte differentiation increased. Thus far we can conclude that Panx1 is present at early stages of murine skin development and appears to regulate the cellular properties of resident keratinocyte, fibroblast and adipocytes of the skin. We are beginning to assess the response of

the Panx1 null mouse skin to wounding and UV irradiation to determine if the lack of Panx1 also affects normal skin function after injury. Supported by the Canadian Institutes of Health Research.

**Denervation induces functional expression of connexin hemichannels followed by an inflammatory state in fast skeletal muscles.**

L. A. Cea<sup>1</sup>, B. A. Cisterna<sup>1</sup>, C. Puebla<sup>1,2</sup>, J. C. Sáez<sup>1,2</sup>; <sup>1</sup>Departamento de Fisiología, Facultad de Ciencias Biológicas, Pontificia Universidad Católica de Chile, Santiago, Chile, <sup>2</sup>Centro Interdisciplinario de Neurociencia de Valparaíso, Santiago, Chile

Denervation of skeletal muscles induces several responses, between them are included reduction of the resting membrane potential and increase of total intracellular Ca<sup>2+</sup> levels. However, the molecular mechanism that leads to these changes remain poorly understood. In addition, it occurs reexpression of proteins that were present during muscular ontogeny, such as embryonary acetylcholine receptor. Connexins (Cxs) 39, 43 and 45 are proteins expressed during muscular development but not during adulthood. In this work, we studied if Cxs 39, 43 and 45 and functional hemichannels formed by these Cxs (Cx HCs) are reexpressed in denervated fast skeletal muscles. In denervated EDL and FDB muscles of Sprague-Dawley rats, levels of Cxs and activity of Cx HCs increased *in vivo* (Evans blue dye uptake) and *in vitro* (ethidium uptake). Both responses were inhibited by Cx HC and P2X<sub>7</sub> receptor blockers. In addition, denervated muscles did not show rhodamine-dextran (10 kDa) uptake *in vivo*, indicating that the cell membranes were permeabilized to Evans blue dye but not irreversibly damaged. Also, denervated myofibers showed activation of nuclear factor-kappaB (Phosphorylated-NFκB), and increased levels of IL-6 and IL-1β mRNA. In addition, the expression of P2X<sub>7</sub> and the TRPV2 receptors was increased. It is proposed that Cx HCs together with P2X<sub>7</sub> and TRPV2 receptors, all permeable to ions, including Ca<sup>2+</sup>, not expressed in normal muscles, might explain the reduction in resting membrane potential and increase of total intracellular Ca<sup>2+</sup> levels observed in denervated skeletal muscles.

**Dexamethasone induces inflammation through expression of functional connexin hemichannels in skeletal muscle fibers.**

L. A. Cea<sup>1</sup>, C. Puebla<sup>1,2</sup>, A. A. Vargas<sup>1</sup>, M. A. Benvenuto<sup>1</sup>, M. Frank<sup>3</sup>, K. Willecke<sup>3</sup>, J. C. Sáez<sup>1,2</sup>; <sup>1</sup>Departamento de Fisiología, Facultad de Ciencias Biológicas, Pontificia Universidad Católica de Chile, Santiago, Chile, <sup>2</sup>Centro Interdisciplinario de Neurociencia de Valparaíso, Santiago, Chile, <sup>3</sup>L.I.M.E.S. Institute, University of Bonn, Bonn, Germany

Glucocorticoids are used in clinic as anti-inflammatory agents. However, prolonged exposure to synthetic glucocorticoids leads to skeletal muscular atrophy, among others undesired changes. We studied whether dexamethasone affects the expression of connexin hemichannels (Cx HCs), which are absent in adult skeletal muscles. Wild type and specific skeletal muscle K.O. for Cx43/Cx45 (Cx43<sup>fl/fl</sup>Cx45<sup>fl/fl</sup>:Myo-Cre) mice were acutely treated with dexamethasone (300 nM, i.p.). After 5 h treatment, myofibers were dissociated from flexor digitorum brevis (FDB) muscles, where the Cx HC activity (ethidium uptake) was tested. Cxs 39, 43 and 45 were detected in muscles of wild type mice treated with dexamethasone but not in control animals. The Cx HC activity increased ~3.5-fold and was blocked by La<sup>3+</sup>, a Cx HC inhibitor. This response was absent in myofibers from skeletal muscle Cx43/Cx45 K.O. mice. Furthermore, the

resting membrane potential of myofibers decreased from -78 mV (control) to -64 mV (dexamethasone). This response was absent in myofibers from skeletal muscle Cx43/Cx45 K.O. mice. Additionally, muscles of wild type mice treated with dexamethasone showed numerous positive nuclei for phosphorylated NF- $\kappa$ B (P-NF $\kappa$ B) (absent in control animals), and elevated mRNA levels of IL-6 and IL-1 $\beta$  (RT-PCR). Therefore, we propose that atrophy induced by dexamethasone is, in part, due to early Cx HC expression that are permeable to ions including Ca<sup>2+</sup> and thus, can mediate activation of the inflammasome.

**Molecular mechanisms underlying the Connexin43-dependent amplification of Fibroblast Growth Factor-2 signaling in MC3T3 osteoblasts.**

*C. Niger<sup>1</sup>, M. A. Lucioti<sup>1</sup>, A. M. Buo<sup>1</sup>, C. Hebert<sup>1</sup>, V. Ma<sup>1</sup>, J. P. Stains<sup>1</sup>; <sup>1</sup>Orthopaedics, University of Maryland School of Medicine, Baltimore, MD*

The gap junction protein connexin43 (Cx43) plays a fundamental role in osteoblasts/osteocytes function and bone formation. In addition, fibroblast growth factor-2 (FGF2), an important modulator of skeletal tissue, activates several signaling cascades, including phospholipase C $\gamma$ 1 (PLC $\gamma$ 1), to affect osteoblast function. We have previously shown in MC3T3 osteoblasts that overexpression of Cx43 potentiated the FGF2-induced transcriptional activity of Runx2, a key regulator of osteoblast differentiation, in an ERK and PKC $\delta$ -dependent manner. The current study aimed to define the molecular mediators of this Cx43-dependent potentiation of osteoblast signaling and transcription, thus identifying second messengers generated downstream of PLC $\gamma$ 1 that may be communicated by Cx43 to affect osteoblast gene expression. Modulation of transcriptional activities was assessed by luciferase assays using the p6xOSE2-Luc construct, which contains six repeats of a Runx2 binding cognate upstream of a minimal promoter, in MC3T3 cells transiently overexpressing Cx43. Additionally, pharmacological inhibitors or siRNA directed against various mediators of the PLC $\gamma$ /inositol polyphosphates cascade were tested. Following the knockdown of expression and/or inhibition of function of PLC $\gamma$ 1, the Cx43-mediated potentiation of the FGF2 response was abrogated, indicating that PLC $\gamma$ 1 is needed for the Cx43-dependent amplification of FGF2 stimulation of Runx2. Surprisingly, diacylglycerol lipase or inositol triphosphate receptor inhibitors failed to affect the Cx43/FGF2 synergistic effect on Runx2. Accordingly, we examined other inositol phosphate mediators. Knockdown and/or inhibition of inositol polyphosphate multikinase (IPMK), and inositol hexakisphosphate kinase 1 (IP6K1), which generates inositol poly and pyrophosphates respectively, prevented the ability of Cx43 to potentiate FGF2-induced signaling through Runx2. Disruption of the IP6K pathway blocked the nuclear accumulation of PKC $\delta$  and the FGF2-dependent interaction of PKC $\delta$  and Runx2, reducing Runx2 transcriptional activity. In total, our data show that activation of the PLC $\gamma$ 1/IPMK/IP6K1/PKC $\delta$  signaling cascade is required for the potentiation of FGF2-induced Runx2 transcriptional activity by Cx43. Also, our findings implicate the water-soluble inositol polyphosphates as mediators of the Cx43-dependent amplification of the osteoblast response to FGF2, and suggest that these low molecular weight second messengers may be biologically relevant mediators of osteoblast function that are communicated by Cx43-gap junctions.

1306

**Utilizing hTERT-immortalized primary mouse osteoblasts to assess the role of Cx43 in osteoblast signaling pathways.***A. M. Buo<sup>1</sup>, J. P. Stains<sup>1</sup>; <sup>1</sup>Orthopaedics, University of Maryland School of Medicine, Baltimore, MD*

The coupling of bone-forming osteoblasts by connexin43 (Cx43)-comprised gap junctions is critical for osteoblast differentiation and optimal bone formation. We have begun to define the molecular details that enable Cx43 to regulate osteoblast differentiation and osteoblast function. Previously, using an MC3T3-E1 osteoblast-like cell line, we identified several signaling cascades that are affected by overexpression or knockdown of Cx43. Further, alterations of these signaling cascades modulate the activity of the essential osteogenic transcription factors Runx2 and Osterix. In this preliminary study, we used a recently reported human telomerase reverse transcriptase (hTERT)-immortalized primary mouse osteoblast cell line isolated from Cx43-null mice (MOB-Cx43KO) and a paired wild type control cell line (MOB-WT) (M. Thi et al., *Am J Phys Cell Phys.* 2010) to determine if the effects observed in MC3T3-E1 cells translated into this more sophisticated cell system. We examined the hypothesis that the osteogenic defects characterized in Cx43-deficient cells are due to reduced signaling resulting in impaired Runx2 and Osterix activation. Confluent cultures of MOB-Cx43KO and MOB-WT cells were examined by western blotting for levels of Cx43, Runx2, Osterix, and key signaling molecules. To test the effects of growth factor signaling, cells were serum starved overnight and then treated with FGF2 for 0, 5, or 30 minutes and analyzed for phospho-extracellular signal-regulated kinase (pERK) and phospho-protein kinase C delta (pPKC $\delta$ ) levels. Under standard culture conditions, we found that MOB-Cx43KO cells had reduced pERK and pPKC $\delta$  levels compared to MOB-WT cells. Runx2 abundance was unaffected by loss of Cx43. Conversely, Osterix expression was diminished in MOB-Cx43KO compared to MOB-WT cells. Additionally, MOB-Cx43KO cells displayed reduced pERK and pPKC $\delta$  levels relative to MOB-WT cells when treated with FGF2. These findings are consistent with our results in mouse MC3T3-E1 osteoblasts that implicate ERK and PKC $\delta$  as downstream mediators of the Cx43-dependent effects on Runx2 and Osterix activity. Future studies will examine Runx2 and Osterix recruitment to target osteoblast promoters by chromatin immunoprecipitation assays. In summary, our data support the hypothesis that the presence of Cx43 is needed for efficient basal and growth factor induced activation of ERK and PKC $\delta$  and highlight that this model (MOB-Cx43KO cells) is appropriate for more detailed mechanistic studies of Cx43 function in osteoblasts.

1307

**The Role of the Connexin43 C-Terminal Tail in the Potentiation of FGF2 Signaling in Osteoblast-like Cells.***C. Hebert<sup>1</sup>, J. P. Stains<sup>1</sup>; <sup>1</sup>Orthopaedics, University of Maryland School of Medicine, Baltimore, MD*

Gap junctions play an important role in the differentiation and function of bone forming osteoblasts, yet little is known about the molecular mechanisms by which they affect bone cell function. Connexin43 (Cx43) is the most abundant gap junction protein expressed in these cells. In this study, we examine the structure-function relationship of Cx43 with signaling in osteoblasts. The cytoplasmic, C-terminal tail of Cx43 interacts with numerous signaling complexes. We hypothesize that signal complex docking to the Cx43 C-terminal tail (CT) is required to propagate the molecules being shared by gap junctions. We have previously shown in osteoblasts that Cx43 impacts the responsiveness to FGF2 in a PKC $\delta$ - and ERK-dependent manner. In this study, we mapped the interaction domain of Cx43 and PKC $\delta$  to amino acids

243-302 of the Cx43 CT by GST pulldown assay. Using luciferase reporter assays, a Cx43 $\Delta$ CT construct lacking amino acids 244 to 382 failed to support the Cx43-dependent potentiation of transcription following FGF2 treatment in MC3T3 osteoblast-like cells. Overexpression of just the CT of Cx43 (amino acids 236 to 382) was unable to substitute for the ability of full-length Cx43 expression to potentiate transcription following FGF2 treatment, indicating that the potentiation of signaling and transcription by Cx43 is not independent of gap junction function. Notably, in the presence of full-length Cx43, overexpression of the Cx43 CT dose-dependently inhibited the potentiation of the transcriptional response to FGF2 and blocked FGF2 activated signaling via PKC $\delta$  and ERK. Conversely, this inhibition did not occur in an osteoblastic cell line (UMR-106) that lacks endogenous Cx43, suggesting that overexpression of the Cx43 CT blocks endogenous Cx43 function through direct or indirect modulation of the full length Cx43 function. In summary, the data support a model in which an intact Cx43 is required for both signal propagation/permeability and local recruitment of signaling complexes to the CT in order to mediate its cellular effects.

**Cx30 and Cx43 exhibit distinct partitioning and dynamics when co-expressed in the same cell.**

*J. J. Kelly<sup>1,2</sup>, Q. Shao<sup>1</sup>, D. J. Jagger<sup>2</sup>, D. W. Laird<sup>1</sup>; <sup>1</sup>Anatomy and Cell Biology, University of Western Ontario, London, ON, Canada, <sup>2</sup>Ear Institute, University College London, London, United Kingdom*

Connexins oligomerize into pore forming hexamers called connexons. Typically, two compatible connexons dock to form a gap junction channel that allows for the direct intercellular exchange of small molecules. Channels, in turn, proceed to cluster into aggregates known as gap junction plaques. In keratinocytes, any number of 9 connexins may be co-expressed and mutations in connexins such as Cx43 and Cx30 cause severe skin disease. In the present study we investigate how cells co-expressing Cx43 and Cx30 assemble these connexins and whether these two connexins have similar turnover kinetics. To further investigate a previously reported suggestion that Cx30 traffics via a Golgi-independent pathway, HeLa cells stably expressing Cx43 or Cx30 were treated with the ER-Golgi transport inhibitor Brefeldin A (BFA) for 8 hours before patch-clamping and assessing neurobiotin transfer. While Cx43 expressing cells exhibited a 60% decrease in neurobiotin spread, Cx30 expressing cells exhibited no change in comparison to controls. However, fluorescence recovery after photobleaching analysis of Cx30-GFP containing gap junction plaques in the presence and absence of BFA revealed that BFA delayed the recovery of the fluorescent plaque, suggesting that new delivery of Cx30 to the cell surface via ER-Golgi transport was necessary to renew the gap junction. Furthermore, when keratinocytes and NRK cells expressing both Cx30 and Cx43 were treated with BFA for 8-18 hours, Cx30 gap junctions were largely retained at the cell surface while Cx43 gap junctions were generally lost. However, in an aggressive mammary tumor cell line where the half-life of Cx43 is particularly short (1.5 hours), both Cx43 and Cx30 cleared from the cell surface in the presence of BFA within 4 hours. Finally, co-expression of Cx43-RFP and Cx30-GFP revealed that, while these connexins were found in the same gap junctions, they segregated into distinct domains suggesting their assembly was governed by different mechanisms. Collectively our data supports the notion that Cx30 traffics through the cell in a Golgi-dependent pathway, but segregates from Cx43 in the same plaque and acquires a more stable state at the cell surface in some cell types. The differential kinetics and assembly of these connexins may be of critical importance in understanding the skin pathology of patients that harbor mutations in either of the genes encoding these connexins. Supported by the CIHR to DWL, Royal Society to DJJ and DRUK to JJK.

**Analysis of Annular Gap Junction Vesicle Fission.**

*T. I. Shakespeare<sup>1</sup>, B. M. Nickel<sup>2</sup>, S. J. O'Neil<sup>2</sup>, J. Harper<sup>1</sup>, S. A. Murray<sup>2</sup>; <sup>1</sup>Biology, Fort Valley State University, Fort Valley, GA, <sup>2</sup>Cell Biology, University of Pittsburgh, Pittsburgh, PA*

Gap junction plaque disassembly involves an internalization process which results in the formation of annular gap junction vesicles. These annular gap junction vesicles undergo fissions, however, the molecular machinery or the benefit of such a process remains to be elucidated. Dynamin, a large mechanoenzyme, has been previously demonstrated to play a pivotal role in gap junction plaque internalization. Specifically, dynamin scissors the invaginated gap junction membrane from the cell surface. To investigate the role of dynamin in annular gap junction vesicle fissions, dynamin was inhibited in a SW-13 adrenocortical human cell population, either by siRNA knockdown or treatment with a dynamin GTPase inhibitor, dynasore. Immunocytochemical localization of connexin and dynamin protein antigen, time-lapse photography, transmission electron microscopy, and computer-assisted imaging with the tracking component of the Imaris software program were used to analyze annular gap junction vesicle fissions. Dynamin co-localized with annular gap junction vesicles as well as with gap junction plaques. With 3D-rotation the accumulation of the dynamin at or near the equatorial region of the annular gap junction vesicle was demonstrated. In addition, the number of annular gap junction vesicle fissions per hour was reduced in dynamin inhibited populations compared to the number of fission events in controls. Fewer annular gap junction vesicles were observed to form in the dynamin inhibited populations and those that formed were larger than in control populations. This corresponded to an increase in the number and size (area) of gap junction "buds" suspended from the gap junction plaques in dynamin inhibited populations. In control populations such buds, were frequently observed to be released from the parent membrane to form annular gap junction vesicles. We believe this to be the first report describing the details of annular gap junction vesicle fissions and demonstrating a role of dynamin in not only annular gap junction formation but in the fission process. This information is critical to understanding gap junction protein trafficking and turnover. This research was supported by NSF grants # MCB-1023144 and NIH 5T36GM008622.

**The cataract related mutation of human Connexin46 D3Y and N188T affect the voltage sensitivity and the formation of gap junction channels.**

*B. Schlingmann<sup>1,2</sup>, P. SchadzeK<sup>2</sup>, A. Ngezahayo<sup>1,2</sup>; <sup>1</sup>Center for Systems Neuroscience, School of Veterinary Medicine Hannover, Hannover, Germany, <sup>2</sup>Institute of Biophysics, Leibniz University Hannover, Hannover, Germany*

Xenopus oocytes and HeLa cells were used as expression systems to analyze how the cataract related mutations in connexin46 affect gap junctional intercellular communication. In Xenopus oocytes, we observed that hCx46N188T formed voltage gated hemichannels similar to the wild type. The channels were activated at a depolarization voltage above -50 mV. In contrast, hCx46D3Y was not able to form voltage gated hemichannels. In HeLa cells, we found that 38%, 37% and 12% of cells expressing hCx46wt, hCx46D3Y and hCx46N188T respectively formed gap junction plaques. Lucifer Yellow transfer experiments showed that 35%, 62% and 15% of the cell pairs expressing hCx46wt, hCx46D3Y and hCx46N188T formed dye coupled gap junctions. It is noteworthy that in non-transfected HeLa cells, 4.7% of the cell pairs were dye coupled. Since the D3Y mutation replaced a negative charged residue by a neutral residue, and the N188T replaced a residue with an amide group by a residue with a hydroxyl group, we generated a D3E mutation which does not change the charge at the third position and hCx46N188Q which contains also an amide group. The reintroduction of a negative charge at

the third position (hCx46D3E) could restore the formation of voltage gated hemichannels in the *Xenopus* oocytes but the reintroduction of an amide group at the position 188 failed to restore the capacity to form gap junction plaques and dye coupled gap junction channels when expressed in HeLa cells. The results indicate that the voltage sensitivity might be related to the presence of a negatively charged residue at the third position. The role of the asparagine residue at position 188 in formation of gap junction channels seems to be related to this specific residue and cannot be overtaken by a structurally similar amino acid residue.

1311

**Oligomeric structure and functional characterization of *C. elegans* innexin-6 gap junction channels.**

A. Oshima<sup>1</sup>, T. Matsuzawa<sup>2</sup>, K. Nishikawa<sup>1</sup>, Y. Fujiyoshi<sup>1</sup>; <sup>1</sup>Cellular and Structural Physiology Institute, Nagoya University, Nagoya, Japan, <sup>2</sup>Department of Biophysics, Graduate School of Science, Kyoto University, Kyoto, Japan

Invertebrates possess gap junction channels composed of innexins that evolved independently from vertebrate connexins. The important role of innexins in electrical activity in neurons and muscles has been confirmed in *Drosophila* and *Caenorhabditis elegans* (*C. elegans*), but only limited information is available on the innexin channel structure. Here we successfully expressed and purified *C. elegans* innexin-6 (INX-6, 45 kDa) gap junction channels, and characterized the structural properties and channel permeability using electron microscopy and microinjection of fluorescent dye tracers, respectively. The *C. elegans* INX-6 channels formed gap junction plaques with a loosely packed hexagonal lattice. Channel distance of INX-6, based on the reflection spots of gap junction plaques, was longer than those of connexin-26 (Cx26, 26 kDa) and connexin-43-GFP (Cx43-GFP, 70 kDa). Thin-section electron microscopy revealed that the INX-6 junction was thicker than the Cx26 and Cx43-GFP junctions. The purified INX-6 channels in dodecylmaltoside solution generally ran slower than Cx26 channels and exhibited the elution peak at ~400 kDa in gel filtration analysis, suggesting that the purified INX-6 channels were mostly hemichannels, which was supported by electron microscopy and native gel electrophoresis. Dye transfer experiments showed that 3-kDa dextran-Texas red and 10-kDa dextran-Texas red passed through INX-6-GFP-His channels at rates of approximately 50% and 10%, respectively, while no significant amounts passed through Cx43-GFP channels. These results indicate the larger dimensions of overall structure and pore diameter of INX-6 channels compared with those of most connexin channels.

1312

**The role of connexins in melanoma tumorigenesis as revealed in 2D and 3D microenvironments.**

M. J. Ableser<sup>1</sup>, Q. Shao<sup>1</sup>, D. W. Laird<sup>1</sup>; <sup>1</sup>Anatomy and Cell Biology, Western University, London, ON, Canada

Gap junctions formed from connexins (Cx) have been reported to regulate cell proliferation, differentiation and apoptosis through the formation of intercellular channels between apposing cells. Interestingly, Cxs have been identified as tumor suppressors and enhancers, a distinction that appears to be dependent on the type of tumor and stage of disease. In melanomas, however, the role of Cxs and their status during cancer onset and progression remains poorly understood. In the current study, we hypothesize that the exogenous expression of Cx26 and/or Cx43 in BL6 mouse melanomas will decrease their tumorigenic properties when grown in homocellular cultures and/or within the 3D milieu of organotypic epidermis. Western blots, immunofluorescence and Alexa350 dye coupling studies revealed that mouse melanoma BL6

cells express very low levels of Cx26 and Cx43 and are poorly coupled. When cells were engineered to express GFP-tagged Cx26 or Cx43, dye transfer studies revealed that both Cx26- and Cx43-expressing cells were highly coupled, similar to keratinocyte controls. Interestingly, when these connexin-rich melanomas were co-cultured in 2D with Cx43-rich keratinocytes, preliminary dye transfer studies revealed that the melanoma microtumors that formed remained functionally isolated and failed to couple to surrounding keratinocytes suggesting a lack of heterocellular gap junctional intercellular communication. To assess the tumorigenic properties of the newly generated melanoma cell lines, wild type, empty vector and connexin-expressing cells were subjected to proliferation, migration and anchorage-independent growth assays. Growth curve studies performed over 6 days revealed that exogenous Cx43, but not Cx26, significantly reduced total cell numbers by approximately 2.5-fold while cell migration was statistically unaltered by the expression of either connexin. Furthermore, preliminary studies suggest that Cx43 significantly reduces anchorage-independent growth by approximately 4-fold compared to controls. Overall, our results to date would suggest that Cx43, but not Cx26, affects several in vitro melanoma tumorigenic properties despite the fact that both connexins greatly enhance homocellular gap junctional intercellular communication. Currently we are assessing the growth of melanoma microtumors in the context of keratinocyte organotypic cultures to determine the influence of the microenvironment on the progression of tumors rich in connexin content. Supported by the Canadian Institute of Health Research to DWL.

## Cadherins and Cell-Cell Interactions

### Making a link between polar cell growth and speciation: a molecular and cellular perspective to understand the barrier to cross-pollination between maize and teosinte.

Y. Lu<sup>1</sup>, M. M. Evans<sup>1</sup>; <sup>1</sup>Plant Biology, Carnegie Institute for Science, Stanford, CA

Even with the increasingly available genomic, genetic, cellular and molecular tools, mechanisms of how a crossing barrier forms between two populations that were previously interbreeding is still elusive. This study aims to understand the crossing barrier between maize and some strains of teosinte, which is governed by a single locus *tcb1* (*teosinte cross barrier1*). The *Tcb1-s* haplotype present in these strains encodes a female factor that blocks maize pollen (haplotype *tcb1*) and a male factor that overcomes that block. *In vivo* assays showed that maize pollen tubes are arrested in *Tcb1-s* silks. Out of a mapping population of 16,451 chromosomes, the male factor, *Tcb1-m*, and female factor, *Tcb1-f*, have been separated by three recombination events. *Tcb1-m* is located within an interval flanked by markers that are 43,691 base pairs apart in the B73 reference genome. Only one protein-coding gene and a portion of the promoter of a second gene are in this region in the maize B73 reference genome. Gene expression analysis showed that the second gene is highly expressed in mature pollen grains and expression level in *Tcb1-s* is significantly higher, which makes it a promising candidate. This gene has been cloned and is being transformed into maize to test its *Tcb1-m* function by pollinating *Tcb1-s* females. By screening for loss-of-function mutant of *Tcb1-s*, one line with loss-of-function of *Tcb1-f* while retaining function of *Tcb1-m* has been obtained; an additional seven putative *Tcb1-f* loss-of-function mutants are being retested. To determine whether or not there are novel genes absent from the maize reference genome but present in the *Tcb1-s* haplotype that encode *Tcb1-s* function, we have constructed a BAC library from plants of a *Tcb1-s* containing maize line. BACs that cover this region were fished out and sequenced. Candidate genes are to be cloned and transformed into maize to confirm their function. Identification of the male and female genes that produce a reproductive barrier will provide novel insights into the processes

of speciation, polar cell growth and cell-cell communication. More broadly, this understanding may lead to novel applications for the control of cross-pollination and the restriction of gene flow.

### **A Genome-Wide RNAi Screen and Analysis of the Cadherin-Mediated Cell-Cell Adhesion Pathway.**

C. P. Toret<sup>1</sup>, M. D'Ambrosio<sup>2</sup>, R. D. Vale<sup>2</sup>, M. A. Simon<sup>1</sup>, W. J. Nelson<sup>1</sup>; <sup>1</sup>Biology, Stanford University, Stanford University, CA, <sup>2</sup>Department of Cellular and Molecular Pharmacology, UCSF, San Francisco, CA

The adherens junction plays critical roles in cell-cell recognition, initiation of cell-cell adhesion and directing structural and functional polarization of cells in tissues. Defects in adherens junctions are linked to many diseases and cancers. A few proteins are known to function at adherens junctions, but a comprehensive analysis of protein function at cell-cell adhesion remains to be established. We completed a genome-wide (~14000 gene) RNAi screen based on short term, Ca<sup>++</sup>-dependent formation of large cell aggregates by DE-cadherin *Drosophila* S2 cells in suspension culture, which eliminated Ca<sup>++</sup>-independent cell-cell adhesion, integrin-ECM based adhesion and cell spreading, and cell migration. Stringent screen and validation strategies were used: 1). Screen DE-cadherin S2 cells against the genome-wide RNAi collection (~1200 hits), and filter/ rescreen those that inhibited cell aggregation against new RNAis (~400 hits); 2). Analyze the 100 strongest hits for DE-cadherin/catenin levels by western blotting; 3). Perform cell-cell adhesion assays with siRNA-treated MDCK cells in suspension culture, and analyze E-cadherin-catenin levels by western blotting and immunofluorescence microscopy; and, 4). Target germ-line RNAi in *Drosophila* using TRiP vectors and score for defects in DE-cadherin-dependent oocyte positioning in the *Drosophila* germarium. These hits highlight several integral pathways (actin cytoskeleton organization, protein trafficking and turnover, signaling, gene transcription) that function to co-ordinate cadherin-mediated cell-cell adhesion. RNAi of several of these mutants had defects in oocyte positioning in *Drosophila* oogenesis and mammalian MDCK cell hanging drop assays suggesting they have conserved roles in cell-cell adhesion.

### **Alpha-catenin's role in cell-cell adhesion of DLD1 cells.**

Y. V. Yu<sup>1</sup>, W. Thomas<sup>1</sup>; <sup>1</sup>Natural Science, Colby-Sawyer College, New London, NH

Alpha-catenin is an actin-binding protein that we hypothesize to function as part of a cadherin-actin linkage in the protein complex at the adherent junction of adhesion-competent cells. To test this assumption we need a catenin positive and a catenin negative cell lines. The latter are commercially available. To obtain the former, we first subjected the heterogeneous DLD1 parental cell line to an aggregation assay, collecting the aggregation competent clusters. Those cells were dissociated, cultured to near confluence, and subjected to the same assay a second time. The doubly-selected population was then subcloned by limiting dilution. From the resulting colonies a few were selected that formed isolated islands of tightly adherent cells. We tested the colonies meeting those criteria by dot blot analysis using anti-alpha-catenin antibody (Ab 6299, ABCam) to select putative alpha-catenin positive clones. The presence of a catenin was verified by the appearance of a 102K mw band in Western blots of 10% SDS gels developed using the same antibody. To permit estimation of a catenin expression levels in the various clones, gels were loaded at constant total protein per lane (Lowry protein assays) verified by anti-tubulin staining (Thermo scientific). Trizol extracted RNA from a-catenin positive and

negative cells was verified by nanodrop and screened using a human genomic chip (details) for genes displaying up- or down-regulation coincident with states of  $\alpha$ -catenin expression. Thanks to the Dartmouth genomics lab's help with the genetic work. This work was supported by NH-INBRE and Colby-Sawyer College.

**The involvement of talin in cadherin-mediated cell-cell adhesions.**

*W. Morgan<sup>1</sup>, A. Kashina<sup>2</sup>, F. Zhang<sup>1</sup>; <sup>1</sup>Molecular & Cellular Pharmacology, University of Miami, Miami, FL, <sup>2</sup>Animal Biology, University of Pennsylvania, Philadelphia, PA*

Talin is an essential cytoskeletal protein that is known to act as a scaffold for integrin-mediated cell-matrix adhesions. Until our recent publication, little was known about the role of talin in cadherin-mediated cell-cell adhesions, which underlie the formation of multicellular organisms. We found that through calpain-2 proteolysis and posttranslational arginylation, a C-terminal fragment of talin contains vinculin- and actin- binding domains and a dimerizing domain (therefore referred to as the VAD fragment) that is recruited to cadherin-mediated adhesion sites and involved in promoting the polymerization of actin near cadherin. Here we found that the generation of the VAD fragment and its recruitment to the cadherin adhesions sites are highly dynamic processes mediated by multiple factors. Our data also suggest that the generation of the VAD fragment is likely associated with the force-induced conformational change of the talin molecule, and likely a direct result of the competition between the integrin- and cadherin-mediated adhesions in the cells.

1317

**Myosin 1c regulates the morphogenesis of E-cadherin-based cell-cell contacts in polarized epithelial cells.**

*H. Tokuo<sup>1</sup>, L. Coluccio<sup>1</sup>; <sup>1</sup>Boston Biomedical Research Institute, Watertown, MA*

Cooperation between cadherins and the actin cytoskeleton controls the formation of cell-cell adhesions during morphogenesis of polarized epithelia. We find that epithelial cells in which myosin 1c (myo1c) expression is knocked down (KD) are spread out and flatter with more stress fibers than control cells; moreover, E-cadherin localization is disorganized and rather than being vertical, lateral membranes have convoluted edges. After developing polarized monolayers, myo1c KD cells are more sensitive than control cells to reduced calcium concentrations, which cause cell-cell detachment. Myo1c sediments in the same fractions as E-cadherin following fractionation of plasma membranes on iodixanol gradients, and myo1c KD causes a significant reduction in E-cadherin recovery in one of the peak fractions. Using Myo1c point mutants or mutants in which specific domains are deleted, we find that the tail domain, especially the PIP<sub>2</sub> binding sites, are necessary for its localization to cell-cell adhesion sites. FRAP assays with GFP-myosin 1c mutants reveal that motor function is also important for myo1c dynamics at cell-cell adhesions. Actin recovery at cell-cell junctions is unaffected by myo1c KD, and jasplakinolide treatment has no effect on GFP-myosin 1c mobility. Furthermore, only the expression of wild-type GFP-myosin 1c (but not motor-dead or PIP<sub>2</sub> mutants) restores the epithelial phenotype in myo1c KD cells. We conclude that myo1c is critical for the formation and maintenance of adherens junctions in polarized epithelial cells.

1318

**Evidence for monomeric  $\alpha$ -catenin as a physical linker between cadherin and the actin cytoskeleton.**

*U. Tepass<sup>1</sup>, R. Patel<sup>1</sup>, R. Sarpa<sup>1</sup>, M. Pellikka<sup>1</sup>, N. Ishiyama<sup>1,2</sup>, M. Ikura<sup>1,2</sup>; <sup>1</sup>University of Toronto, Toronto, ON, Canada, <sup>2</sup>Ontario Cancer Institute, Toronto, ON, Canada*

The linkage of adherens junctions (AJs) to the actin cytoskeleton is essential for effective cell adhesion. How the cadherin-catenin complex contributes to the AJ-actin interaction remains a subject of intense investigation that centers on the function of  $\alpha$ -catenin, which binds to cadherin via  $\beta$ -catenin and can bind either directly or indirectly to F-actin. We have delineated a number of regions within *Drosophila*  $\alpha$ -Catenin ( $\alpha$ -Cat) that are important for AJ performance in static epithelia and dynamic morphogenetic processes. Moreover, we address two prevailing questions concerning the mechanism of  $\alpha$ -catenin function in order to distinguish between a physical linkage model and an allosteric regulation model of  $\alpha$ -catenin function. First, is persistent  $\alpha$ -catenin-mediated physical linkage between cadherin and F-actin crucial for cell adhesion? Second, what functions do  $\alpha$ -catenin monomers and dimers have at AJs? Our data support the view that monomeric  $\alpha$ -catenin acts as an essential physical linker between the cadherin- $\beta$ -catenin complex and the actin cytoskeleton whereas  $\alpha$ -catenin dimers are cytoplasmic and form an equilibrium with monomeric junctional  $\alpha$ -catenin.

1319

**Flotillins are new cadherins' partners that control cadherin stabilization at cell-cell contacts through interaction with the actin cytoskeleton.**

*C. Gauthier-Rouviere<sup>1</sup>, S. Bodin<sup>1</sup>, E. Guillaume<sup>1</sup>, F. Comunale<sup>1</sup>; <sup>1</sup>CRBM - CNRS, Montpellier, France*

Cadherins assemble into large macromolecular complexes at the cell-cell contact sites and form adherens junctions. These major adhesive structures are involved in many fundamental processes during development and adult life. Moreover, adherens junction assembly and function is perturbed in many diseases. Thus, identification of new regulators of cadherin complexes assembly is a very important issue.

Here we identify flotillin 1 and 2 as new partners of many cadherins (N, E, M, P, R and 11) that are recruited at cell-cell contacts in a cadherin-dependent manner and required for their stabilization at the cell-cell contacts. Flotillin 1 (Flot 1 ou reggie-2) and flotillin 2 (Flot 2 ou reggie-1) are ubiquitous and highly conserved proteins, located at the cytoplasmic face of the plasma membrane (PM), involved in the scaffolding of large complexes that signal across the PM thanks to their ability to form hetero-oligomeric complexes. Knockdown of flotillins dramatically affected N- and E-cadherin recruitment at cell-cell contacts in both mesenchymal and epithelial cell types. Mechanistically, we show that, although flotillins and cadherins are constitutively associated at the PM, flotillins stabilize cadherins exclusively at cell-cell contacts. Super-resolution structured illumination microscopy revealed that cadherins/flotillins complexes at cell-cell contacts are associated with actin stress fibers. Finally, we demonstrate that flotillin interaction with the F-actin cytoskeleton is required for cadherin stabilization at cell-cell contacts. In conclusion, we report here for the first time, that flotillins are major regulators of cadherin assembly and stabilization at cell-cell contacts and are thus essential for the formation of adherens junctions.

1320

**Nectin and cadherin junctions are independent but coordinated by actin cytoskeleton.***I. Indra<sup>1</sup>, R. Troyanovsky<sup>1</sup>, S. Hong<sup>1</sup>, S. M. Troyanovsky<sup>1</sup>; <sup>1</sup>Dermatology, Northwestern University, Chicago, IL*

Two transmembrane adhesive receptors, nectin and cadherin, establish two interrelated cell-cell adhesion systems. How the function and assembly of these two adhesive systems are coordinated is not completely understood. We show here that both systems can be assembled independently. Assembly of both systems requires the integrity of the actin cytoskeleton. Upon co-expression, nectin and cadherin are co-recruited into the same adherens junctions. However, their intrajunctional distributions are different. Furthermore, their relative amounts in any one junction can significantly fluctuate over the time. Taken together, our data suggest that cadherin clustering results in local remodeling of actin filaments that, in turn, become a scaffold for nectin recruitment.

1321

**N-cadherin limits the recruitment and dynamics of microtubules at cell-cell contact during stable cell-cell contact formation.***R-M. Mege<sup>1</sup>, P-O. Strale<sup>1</sup>, C. Plestant<sup>1</sup>; <sup>1</sup>Inserm U839, Institut du Fer à Moulin, Paris, France*

Engagement of cadherin at cell-cell contacts either drive the re-enforcement of these contacts leading to the formation of stable intercellular junctions or maintain cell contact instability during cell-cell intercalation and cell migration. The mechanisms leading to these opposite cell responses are not fully understood but involve coordination between plasma membrane adhesion to the surrounding environment and cytoskeleton remodeling. Well-known actors of this process are cadherins and catenins that are part of a multi-molecular complex linking the cell membrane to the underlying microfilaments. Another element of this plasticity may be the microtubule networks (MTs) working in functional interaction with cadherins and actin. However, the relationship between cadherins and MTs is still unclear and subject to controversy. We investigate here the relationship between N-cadherin and MTs during stable cell-cell contact formation. We use spreading of myogenic C2C12 cells on recombinant N-cadherin to analyze the effect of cadherin engagement on MTs distribution and dynamics. Newly formed MTs were redirected toward adhesion sites by their +TIPs shortly after cell contact initiation. However, these MTs neither aligned nor colocalized with cadherin adhesions. A quantification analysis revealed a dramatic inhibition of the MT penetration in cadherin adhesions compared to fibronectin (FN) adhesions, an inhibition that was alleviated by the expression of a dominant negative form of N-cadherin. This inhibition paralleled a significant reduction of MT +ends forward movement. In addition we observed that N-cadherin engagement induced a two-fold stimulation of actin tread milling, suggesting that forward actin movements may relay the inhibition of MT penetration and dynamics elicited by N-cadherin engagement. We thus investigated the implication of actin filaments in the response of MTs to N-cadherin engagement. Treatment with cytochalasin D increased the speed of MT +ends forward movement. In contrast, inhibition of myosin II activity with blebbistatin, which blocks the actin tread-milling, induced an increased inhibition of MT +TIPs mean velocity, suggesting that the two processes are not directly linked. Interestingly, most of the MTs of cells spread on N-cadherin turned tangentially and did not pass through the acto-myosin belt present at the rear of the adhesion zone. In accordance, the destabilization of the actin network by cytochalasins or blebbistatin triggered an increased penetration of MTs in cadherin adhesion areas, likely unraveling an obstructive effect of tangential actin bundles on MTs penetration independently of MT dynamics. In turn, we observed that N-cadherin mediated contacts form independently of MTs but that the blockade of MT dynamics by taxol induced a strengthening of cadherin

adhesions. Altogether, these results establish a complex functional cross-talk between N-cadherin adhesion and MTs organization during cell-cell contact reinforcement.

1322

**The Regulation of  $\beta$ -catenin and N-cadherin by CD82.**

*K. D. Marjon<sup>1</sup>, K. E. Sanders<sup>1</sup>, C. M. Termini<sup>1</sup>, J. M. Gillette<sup>1</sup>; <sup>1</sup>Pathology, University of New Mexico School of Medicine, Albuquerque, NM*

Tetraspanins are regulatory membrane proteins that are integral for cell-cell and cell-matrix interactions. CD82 is a member of the tetraspanin family and has been demonstrated to regulate multiple cellular processes including cellular adhesion, signal transduction, cancer progression, and exosome trafficking. CD82 has the unique ability to interact with multiple cell surface molecules and cytosolic signaling components, which results in the various described cellular functions. Our previous work has implicated a role for CD82 in cellular communication between stem cells and their niche, more specifically in the processes of homing, engraftment and adhesion. A major signaling component in stem cells and in cell-cell interactions is the  $\beta$ -catenin signal transduction pathway. In this study we investigate the potential regulatory role of CD82 in these processes. We have found that the knock down of endogenous levels of CD82 with shRNA led to a significant loss of  $\beta$ -catenin compared to wild type Kg1a cells (CD34+ hematopoietic progenitor-like cell line). The decrease of  $\beta$ -catenin is not at the mRNA level but at the protein level observed by western blot analysis and immunofluorescence. Blocking the proteasome with MG115 in the CD82 KD cells led to the recovery of  $\beta$ -catenin back to wild type protein levels. While the cellular localization of  $\beta$ -catenin in Kg1a cells is membrane associated, it does not have the same cellular distribution as CD82 suggesting the involvement of another component. Since  $\beta$ -catenin and CD82 have been implicated in cadherin regulation, we sought out to determine whether cadherins were affected. We found that N-cadherin has similar distribution patterns to  $\beta$ -catenin in Kg1a cells. Interestingly, upon knock down of CD82, we observe that N-cadherin expression is markedly decreased and qRT-PCR data indicate a loss of message. As such, our data suggest a role for CD82 in regulating and stabilizing  $\beta$ -catenin intracellular pools and N-cadherin expression. We also observe that the main regulatory component of  $\beta$ -catenin, glycogen synthase kinase 3  $\beta$ , is found in the phosphorylated state which correlates with our observed changes in cellular metabolism. The CD82-mediated perturbations in metabolism and down stream signaling will be discussed. In combination these data suggest that CD82 has an intricate role in maintaining cell-cell interactions and therefore may serve as a potential therapeutic target for improving stem cell transplantation.

1323

**Regulation of mammary epithelial dissemination.**

*E. R. Shamir<sup>1</sup>, P. T. Tran<sup>2</sup>, A. J. Ewald<sup>1</sup>; <sup>1</sup>Cell Biology and Oncology, Johns Hopkins School of Medicine, Baltimore, MD, <sup>2</sup>Radiation Oncology & Molecular Radiation Sciences, Johns Hopkins School of Medicine, Baltimore, MD*

Epithelia are fundamental tissues composed of polarized cells connected by numerous cell-cell junctions. Most solid tumors originate from epithelial cells, and their metastasis represents the major cause of death among cancer patients. Thus, a fundamental question in cancer biology is: how might cells escape from an epithelial-derived tumor?

A major paradigm in our current understanding of metastasis is loss of the adherens junction protein E-cadherin. However, most studies have tested the effect of downregulating E-cad in

cells already containing multiple genetic perturbations. The specific consequences of E-cad loss in otherwise normal cells and its sufficiency for metastasis remain unclear.

Mature mammary epithelium forms a bilayered tube separated from the surrounding ECM by basement membrane. We aimed to elucidate how an epithelial cell within such a highly organized tissue could acquire the ability to detach and individually migrate. With primary mammary tissue as a starting point, we sought to define the molecular perturbations sufficient for dissemination.

We developed methods for gene deletion and inducible gene expression, with coupling to fluorescent reporters that allow real-time observation of the cell behavioral consequences of genetic manipulations. We have demonstrated that deletion of *E-cadherin* inhibits branching morphogenesis and causes cells to lose polarity and invade locally beyond basement membrane. However, E-cad null cells surprisingly remain non-protrusive, adhere to one another, and rarely disseminate. *E-cadherin* deletion was not sufficient for dissemination in 3D culture or in vivo. We therefore hypothesized that dissemination requires additional changes to the fundamental characteristics of epithelial cells. We looked for insight in the epithelial-mesenchymal transition (EMT), a developmental transcriptional program thought to be co-opted by metastasizing cancer cells.

We next chose to test the effect of directly overexpressing the bHLH transcription factor Twist1, an EMT activator often overexpressed in invasive breast cancer. When we induced *Twist1* overexpression in all mammary epithelial cells, we observed not only inhibition of normal branching but also rapid migration of cells away from the tissue. Twist1's major recognized effect is E-cad repression, but our results suggest that a model for metastasis driven chiefly by E-cad loss is incomplete. We are now using *Twist1* overexpression as a platform for isolating the minimum molecular requirements for dissemination through (1) structure-function analysis of Twist1 mutants and (2) deep sequencing of early Twist1-induced transcriptional changes.

1324

**Tetraspanin18 is a FoxD3-repressed antagonist of neural crest epithelial to mesenchymal transition that stabilizes Cadherin6B.**

C. L. Fairchild<sup>1</sup>, L. S. Gammill<sup>1</sup>; <sup>1</sup>Genetics, Cell Biology, and Development, University of Minnesota, Minneapolis, MN

Unlike typical neuroepithelial cells in the developing central nervous system, neural crest cells undergo an epithelial to mesenchymal transition (EMT), detach from the neural tube, and migrate to give rise to diverse structures, such as the peripheral nervous system and craniofacial skeleton. Despite the fundamental importance of the neural crest to the developing embryo, and the crucial role of EMT in diverse biological processes, the mechanisms that regulate neural crest EMT remain incompletely understood. Tetraspanin18 (Tspan18) is a member of the tetraspanin family of transmembrane proteins that have been implicated in cell signaling, motility and adhesion. Our objective was to determine whether Tspan18, which is expressed in chick premigratory neural crest cells and downregulated prior to migration, negatively regulates neural crest EMT. Strikingly, when chick neural crest precursors are electroporated with a Tspan18 expression construct to sustain its expression, migration is inhibited. Furthermore, neural crest cells that fail to migrate maintain epithelial Cadherin6B (Cad6B) protein despite temporally normal downregulation of Cad6B mRNA, suggesting Tspan18 antagonizes EMT by stabilizing Cad6B protein and promoting cell adhesion. In support of this, electroporation of a Tspan18 morpholino leads to premature loss of Cad6B protein from

the neural folds. Nevertheless, neural crest migration occurs on time in the majority of embryos, at least in part because basement membrane breakdown and mesenchymal marker expression, which are later steps in EMT, are normal. Curiously, Tspan18 knockdown also represses Cad6B transcription in some cases. This effect on Cad6B mRNA is independent of the Cad6B repressor Snail2, but correlates with increased nuclear  $\beta$ -catenin, perhaps as a consequence of its release from Cad6B-dependent adherens junctions. Finally, consistent with the fact that the neural crest transcription factor FoxD3 regulates neural crest cell adhesion and promotes migration, FoxD3 negatively regulates Tspan18 expression: FoxD3 overexpression represses Tspan18 mRNA expression, while FoxD3 knockdown leads to sustained Tspan18 mRNA expression and inhibits neural crest migration. Taken together, our data show that Tspan18 stabilizes adherens junctions to post-translationally antagonize neural crest EMT, and suggests that FoxD3 represses Tspan18 expression to promote neural crest migration. Supported by NIH F31 GM087951 and a U of MN Grant in Aid.

#### **Up-regulation of semaphorin 4A expression in retinal pigment epithelial cell by neural cells.**

*J-A. Ko<sup>1</sup>, M. Shibasaki<sup>1</sup>, T-I. Chikama<sup>1</sup>, K. Yamane<sup>1</sup>, Y. Kiuchi<sup>1</sup>; <sup>1</sup>Ophthalmology, Hiroshima University, Hiroshima, Japan*

Development of multicellular organisms requires interactions between cells and their local environment and between neighboring cells. We recently established an in vitro model based on the coculture of human corneal epithelial cells, fibroblasts, or neural cells separated by a collagen membrane.

We have now examined the role of neural cells in retinal homeostasis, and effects of neural cell to the RPE (retinal pigment epithelial cell). As a result, we showed that presence of neural cells (PC12) resulted in upregulation of neural guidance protein, semaphorin 4A in retinal pigment epithelial cells (ARPE19). This effect of neural cells was apparent at both the mRNA and protein levels, and was mimicked by exposure of ARPE19 to neuropeptides (substance P and CGRP). Furthermore, depletion of substance P and CGRP by antagonist in coculture media, largely abolished their stimulatory effect on semaphorin 4A expression in ARPE19. In multiplex-assay, the amounts of inflammatory cytokines, interleukin-6 (IL-6) was decreased by the presence of neural cells, and stimulation antagonist of substance P, or CGRP inhibited its effects.

Therefore, our findings indicated that neuropeptides, substance P and (,or) CGRP released from neural cells may play an important role in the regulation of intercellular communication between retinal pigment epithelial cells as well as in the maintenance of retina structure and function. In the future, these findings provide a useful model for understanding cell-cell interaction that occur between RPE and optic nerve cells, or photoreceptors.

1326

#### **Role of Rho1 during adherens junction remodeling.**

*H. Yashiro<sup>1</sup>, J. Skeath<sup>2</sup>, G. Longmore<sup>1</sup>; <sup>1</sup>Medicine, Cell Biology, Washington University School of Medicine, St. Louis, MO, <sup>2</sup>Genetics, Washington University School of Medicine, St. Louis, MO*

Proper maintenance of cell-cell junctions is critical for the integrity of epithelial tissues during development, adult homeostasis, and in adult pathologies such as cancer and inflammation this maintenance is disrupted. The Rho family of GTPases is appreciated as key regulators of epithelial junction formation, but their precise role in the maintenance and remodeling of formed junctions is less well understood. Previous work in our lab using mosaic analysis in *Drosophila* pupal eyes revealed that Rho1 GTPase was required for the maintenance of adherens junctions (AJs) independent of Rho1's regulation of actomyosin contraction (Warner and Longmore,

2009). Loss of Rho1 function resulted in increased Cdc42 activity that promoted E-cadherin endocytosis, thereby disrupting AJs between adjacent mutant cells but not those between a wild type and mutant cell. We conducted a candidate gene suppressor screen *in vivo* in *Drosophila* pupal eyes to determine whether other genes implicated in E-cadherin endocytosis or vesicular trafficking rescued the AJ defect between Rho1-deficient pupal epithelial cells. This screen revealed that Rho1 influenced Rab11-mediated recycling endosome formation, independent of its effects upon Cdc42 and endocytosis. Overexpression of Rab11, but not Rab8 or Rab14, restored AJs in cells lacking Rho1. An *in vivo* endocytosis assay tracking the trafficking of E-cadherin showed that in the absence of Rho1 E-cadherin arrested in Rab5- and Rab11-positive common recycling endosomes (CRE) suggesting that Rho1 activity influences the progression of E-cadherin from the CRE to recycling endosomes. This occurred as a result of a localized reduction in Rab11 staining in the AJ/apical region, without affecting total cellular protein level. These effects were independent of Rho1's downstream actin modulating effectors Rok, Dia, and Pkn and the Cdc42/aPKC/Par6 complex. Instead, Rho1 functioned through the Rab11-FIP Nuf, but not the related FIP dRip11 or the exocyst complex, to restore the distribution of E-cadherin to recycling endosomes and thus rescue AJs. These data reveal that Rho1 remodels E-cadherin AJs in epithelia by regulating Cdc42-dependent endocytosis and, independently, Nuf/Rab11 recycling endosomes.

1327

**The Rho GEF Bcr regulates cytoskeletal architecture of keratinocytes and controls epidermal differentiation via the desmosomal cadherin Desmoglein-1.**

A. D. Dubash<sup>1</sup>, J. L. Koetsier<sup>1</sup>, R. M. Harmon<sup>1</sup>, E. V. Amargo<sup>1</sup>, N. A. Najor<sup>1</sup>, K. J. Green<sup>1</sup>;  
<sup>1</sup>Northwestern University, Chicago, IL

Desmoglein 1 (Dsg1) is a desmosomal cadherin that is essential for maintaining cell-cell adhesion in the suprabasal epidermis. In addition to its important structural functions, we recently showed that Dsg1 participates in a signaling pathway required for normal epidermal differentiation and morphogenesis. Other studies have identified Rho GTPases as key players in controlling the three-dimensional architecture and stratification of keratinocytes. However, while signaling factors downstream of Rho (e.g. Rho Kinase) are known to contribute to the process of epidermal differentiation, little is known about which upstream regulatory proteins (guanine nucleotide exchange factors, GEFs; or GTPase activating proteins, GAPs) are involved in coordinating Rho signaling, or how Rho-related signaling mediates the keratinocyte differentiation program. Here we have identified the Rho GEF breakpoint cluster region (Bcr) as being a major regulator of RhoA activity in epidermal keratinocytes. Knockdown of Bcr in these cells significantly reduces RhoA activity, concomitant with a decrease in the formation of stress fibers and focal adhesions. Further, in both two and three dimensional models of human epidermal morphogenesis, loss of Bcr reduces the expression of multiple different markers of differentiation, such as Desmoglein-1 (Dsg1) and Desmocollin-1 (Dsc1), as well as Keratin-1, Keratin-10 and Loricrin. We further demonstrate that loss of Bcr, SRF, or the co-factor MAL reduces levels of Dsg1 mRNA transcript in human keratinocytes. Importantly, defects in differentiation seen upon loss of MAL/SRF signaling are rescued by ectopic expression of Dsg1, suggesting that Dsg1 expression induced by Rho/SRF signaling is important for the proper differentiation of keratinocytes. Taken together, these data identify the Rho GEF Bcr as a regulator of Rho signaling in human keratinocytes, as well as the process of differentiation by a mechanism involving the desmosomal cadherin Dsg1.

**The guanine-nucleotide exchange factor Trio regulates endothelial adherens junction formation through the activation of the small GTPase Rac1.**

*I. Timmerman<sup>1</sup>, J. van Rijssel<sup>1</sup>, M. Hoogenboezem<sup>1</sup>, J. D. Van Buul<sup>1</sup>; <sup>1</sup>Molecular Cell Biology, Sanquin Research and Landsteiner Laboratory, Amsterdam, Netherlands*

Adherens junctions serve to maintain a restrictive endothelial barrier, but are dynamically regulated during inflammation and angiogenesis. The assembly of adherens junctions can be affected by activities of Rho GTPases. Conversely, cadherins can signal in an outside-in fashion to Rho GTPases, in particular Rac1, thereby relaying information from adhesion to the organization of the actin cytoskeleton. It is still unclear which GEF functions in endothelial cells to locally activate Rac1 during formation of VE-cadherin-mediated cell-cell adhesion. We show that the Rho-GEF Trio localizes at endothelial cell-cell junctions, where it interacts with the VE-cadherin complex. Trio silencing by shRNA results in more punctate junctions, accompanied by a decrease in the resistance of the endothelial monolayer. This decrease in endothelial monolayer resistance upon Trio depletion is rescued by expression of the N-terminal GEF-D1 domain of Trio, but not by the C-terminal GEF-D2 domain, indicating that Trio-induced Rac1 or RhoG activation is involved. Expression of the N-terminal Trio domain results in a morphological conversion from punctate to more linear junctions, similar to the effect seen by expression of a constitutively active mutant of Rac1 but not RhoG. In addition, Trio localizes primarily at newly forming contacts, suggesting that Trio, like Rac1, is involved in the initiation of novel cell-cell contacts. Finally, using beads coated with the ectodomain of VE-cadherin to mimic nascent junction formation, we demonstrated that VE-cadherin-dependent cell-cell adhesion activates Rac1, but not RhoG. Interestingly, Trio silencing blocked the increase in Rac1 GTPase activity observed after VE-cadherin-dependent contact formation. Collectively, we show that Trio is important for VE-cadherin-dependent Rac1 activation upon cell-cell contact formation. Our data suggest that Trio-mediated signals that are induced upon novel cell-cell contact formation promote VE-cadherin-dependent endothelial cell-cell adhesion and hence junction stabilization.

**p120-catenin binding masks an endocytic signal conserved in classical cadherins.**

*B. A. Nanes<sup>1,2</sup>, C. Chiasson-MacKenzie<sup>1</sup>, A. M. Lowery<sup>3</sup>, N. Ishiyama<sup>4</sup>, V. Faundez<sup>1</sup>, M. Ikura<sup>4</sup>, P. A. Vincent<sup>3</sup>, A. P. Kowalczyk<sup>1,5,6</sup>; <sup>1</sup>Department of Cell Biology, Emory University, Atlanta, GA, <sup>2</sup>Graduate Program in Biochemistry, Cell, and Developmental Biology, Emory University, Atlanta, GA, <sup>3</sup>Center for Cardiovascular Sciences, Albany Medical College, Albany, NY, <sup>4</sup>Ontario Cancer Institute and Department of Medical Biophysics, University of Toronto, Toronto, Canada, <sup>5</sup>Department of Dermatology, Emory University, Atlanta, GA, <sup>6</sup>Winship Cancer Institute, Emory University, Atlanta, GA*

Classical cadherins assemble into adherens junctions and mediate adhesive interactions that are essential for tissue architecture and integrity. During development, wound healing, and other dynamic morphogenic events, cadherin-based adhesive interactions display remarkable plasticity that is thought to be essential for tissue patterning. The regulated trafficking of cadherins to and from the plasma membrane is a critical cellular mechanism that modulates cadherin cell surface levels. However, the molecular machinery that determines cadherin fate after delivery to the plasma membrane is not fully understood. p120-catenin (p120) is an armadillo family protein which binds to the cadherin juxtamembrane domain and inhibits cadherin endocytosis. In the absence of p120 binding, cadherins are rapidly internalized and degraded. Here, we demonstrate that the core p120-binding site on classical cadherins contains a previously unidentified endocytic motif and that p120 binding physically occupies this motif to prevent clathrin-mediated endocytosis of cadherins. Using a gain of function approach

in which cadherin tail sequences were fused to the IL-2 receptor extracellular domain, we found that the core p120-binding regions of VE-, E-, N- and *Drosophila* DE-cadherins mediate endocytosis. Mutagenesis of VE-cadherin revealed that a three amino-acid acidic motif (DEE) is critical for both p120 binding and cadherin endocytosis, resulting in a cadherin that was both uncoupled from p120 and, paradoxically, stable at the cell surface. Mutation of three amino-acids (GGG) directly adjacent to this endocytic motif also uncoupled p120 binding, but this mutant was internalized normally from the cell surface. The p120-uncoupled mutant cadherins both assembled into cell junctions and recruited beta-catenin and alpha-catenin, but not p120, to cell borders. Using these mutants, we examined the effects of p120 binding and cadherin endocytosis on cell migration. Expression of wild-type and GGG-mutant VE-cadherin had no effect on endothelial cell migration in response to the angiogenic growth factor VEGF. In contrast, expression of DEE-mutant VE-cadherin, which was unable to undergo normal endocytic cycling, strongly suppressed cell migration in scratch wound assays but not in single-cell migration assays. Similar results were obtained when these mutants were expressed in epithelial cell lines. Collectively, these findings demonstrate that p120 binds to a novel endocytic motif present in the juxtamembrane domain of classical cadherins to prevent clathrin-mediated endocytosis. Furthermore, cadherin endocytosis is a critical feature of intercellular junction plasticity and is essential for endothelial and epithelial migration.

#### The phospho-regulation of cadherin-based cell-cell adhesion.

A. E. McEwen<sup>1</sup>, M. T. Maher<sup>1</sup>, R. Mo<sup>1</sup>, C. J. Gottardi<sup>1</sup>; <sup>1</sup>Medicine, Northwestern University, Chicago, IL

Multi-cellular organisms require cadherin/catenin-based adhesion for cellular differentiation as well as tissue architecture and integrity. Classical cadherins, such as E-cadherin, mediate calcium-dependent homophilic interactions between cells at the adherens junction. Reduction or loss of E-cad is observed in human epithelial cancers and is considered a key rate-limiting step in tumor metastasis. The cytoplasmic domain of E-cadherin binds the dual function adhesion/transcriptional co-activator protein  $\beta$ -catenin ( $\beta$ -cat), which in turn binds the F-actin binding protein,  $\alpha$ -catenin, coupling adhesion to the actin cytoskeleton. The cytoplasmic tail of E-cad is phosphorylated in the  $\beta$ -cat binding region, and this phosphorylation increases the affinity for  $\beta$ -cat *in vitro*. However, the function and regulation of E-cad phosphorylation *in vivo* remain poorly defined.

We mapped three serines (S686, 692, and 693) in the E-cad tail responsible for <sup>32</sup>P-incorporation, and binding to and stabilization of  $\beta$ -cat. These serines are required for efficient cell-cell adhesion. A phospho-deficient E-cad (3S>A) fails to restore cell-cell adhesion to the pan-cadherin null cell line A431D in contrast to while a WT and phospho-mimic E-cad (3S<D). Additionally, 3S>A E-cad accumulates in a lysosomal compartment, is less stable than WT or S>D E-cad, and its degradation is blocked by chloroquine. Preliminary cell surface biotinylation experiments show that S>A E-cad is internalized more rapidly than WT E-cad; conversely, S>D E-cad is recycled to the plasma membrane faster than WT. These findings suggest that the kinase that regulates E-cad phosphorylation may regulate cadherin endocytosis/recycling dynamics.

Using an antibody to E-cad phosphorylation at S684/686, we show that E-cad is phosphorylated *in vivo* in simple and stratified epithelial tissues, and in cultured epithelial monolayers. Monolayers "scratched" with a pipette tip show a down-regulation of phospho-E-cad at the migrating wound edge. Moreover, phosphorylation at S684/686 is sensitive to inhibitors of GSK-

3 $\beta$  such as LiCl and constitutively active Akt. These data suggest that E-cad phosphorylation is regulatable *in vivo*. We hypothesize that S686 is phosphorylated by GSK, but because GSK phosphorylation requires C-terminal phospho-serines, it is dependent on a still unknown priming kinase. To identify the priming kinase, a dsRNA knock-down screen of all ~350 kinases in the *Drosophila* genome is underway.

Epithelial cells must regulate the amount of E-cad at the cell surface according to their morphogenic or adhesive requirements. Our data suggest that E-cad phosphorylation is an emerging mechanism for regulating adhesion in response to signaling events, such as epithelial migrations and EMTs.

**Self-contact induced membrane fusion depends on E-cadherin.**

G. Sumida<sup>1</sup>, S. Yamada<sup>1</sup>; <sup>1</sup>Biomedical Engineering, University of California, Davis, Davis, CA

Mutual, homophilic cell-cell adhesion between epithelial cells is required for proper maintenance of epithelial barrier function. While opposing membranes from neighboring cells rapidly assemble junctional complexes, self-contacting membranes do not, suggesting that cells have the ability to distinguish self from neighboring cells. Using a self-contact inducing micro-fabricated substrate, we show that self-contacts of normal epithelial cells are rapidly eliminated by membrane fusion between two opposing plasma membrane regions of a single cell. This auto-fusion is most frequently observed in E-cadherin expressing epithelial cells, but not in fibroblasts. The efficiency of auto-fusion depended on extracellular calcium concentration and E-cadherin expression, suggesting that E-cadherin, while not required, enhances auto-fusion efficiency by bringing opposing membranes into close apposition to one another. Additionally, ROCK inhibition decreased auto-fusion of epithelial cells, suggesting that auto-fusion may be mechanically regulated through the actin-myosin network. This is the first demonstration of self-contact induced membrane fusion in mammalian cells, and that membrane fusion may be a key feature of the cell self-recognition signaling pathway.

**Studying E-cadherin mediated cell-cell junction formation using supported lipid bilayers.**

K. L. Hartman<sup>1,2</sup>, K. H. Biswas<sup>2</sup>, C-H. Yu<sup>2</sup>, O. J. Harrison<sup>3,4</sup>, A. W. Smith<sup>5,6</sup>, W-C. Lin<sup>5</sup>, L. Shapiro<sup>3,7</sup>, B. Honig<sup>3,4,8</sup>, J. T. Groves<sup>1,5,6</sup>; <sup>1</sup>Department of Chemistry, University of California, Berkeley, CA, <sup>2</sup>Mechanobiology Institute, National University of Singapore, Singapore, Singapore, <sup>3</sup>Department of Biochemistry and Molecular Biophysics, Columbia University, New York, NY, <sup>4</sup>Howard Hughes Medical Institute, Columbia University, New York, NY, <sup>5</sup>Howard Hughes Medical Institute, Department of Chemistry, University of California, Berkeley, CA, <sup>6</sup>Physical Biosciences and Materials Sciences Divisions, Lawrence Berkeley National Laboratory, University of California, Berkeley, CA, <sup>7</sup>Edward S. Harkness Eye Institute, Columbia University, New York, NY, <sup>8</sup>Center for Computational Biology and Bioinformatics, Columbia University, New York, NY

E-cadherin mediated cell-cell junctions play an important role in the development and maintenance of tissue structure in multi-cellular organisms. Although the expression of E-cadherin is frequently used as a marker for epithelial to mesenchymal transition, the mechanism and dynamics of cell-cell junction assembly and disassembly is poorly understood. For a deeper understanding of cell-cell junctions, supported lipid bilayers were functionalized with the extracellular domain of E-cadherin. Fluorescence Recovery After Photobleaching (FRAP), Fluorescence Correlation Spectroscopy (FCS) and Photon Counting Histogram (PCH) analyses

were used to characterize the density, mobility, and oligomeric state of the membrane bound E-cadherin molecules. Human epithelial (MKN28) cells seeded on E-cadherin functionalized bilayers showed enrichment of E-cadherin molecules, indicating the formation of a hybrid E-cadherin-mediated junction. Interestingly, we found differences between fluid and non-fluid bilayers with respect to junction formation. These results will be discussed further.

### **Adhesion Molecules in Cell Sheet Engineering for Corneal Epithelium Regeneration.**

*F. Bardag-Gorce<sup>1</sup>, A. Wood<sup>1</sup>, J. Oliva<sup>1</sup>, H. Niihara<sup>1</sup>, A. Makalinao<sup>1</sup>, H. Sota<sup>1</sup>, Y. Niihara<sup>1</sup>;  
<sup>1</sup>Hematology, LA BioMed at Harbor UCLA, Torrance, CA*

Cell sheet engineering has been successfully used for cornea epithelium regeneration. This technology shows a great potential for other organ regeneration as it avoids the limitations of tissue reconstruction using biodegradable scaffolds or single cell suspension injection. The present study focuses on investigating the adhesive characteristics of epithelial cell sheet (ECS) engineered from isolated oral mucosal epithelial cells, cultured on UpCell® (CellSeed Inc.). E-cadherin is essential for the integrity of epithelial tissues and functions as a suppressor of cell migration. In many cell invasive diseases, E-cadherin expression is lost and is generally replaced by other cadherins such as N-cadherin, a marker for cell migration and invasion. Immunofluorescence analysis of ECS showed a positive staining of E-cadherin and a negative staining for N-cadherin. Western blot analysis of E-cadherin levels in the engineered cell sheet was found up regulated, while N-cadherin levels were down-regulated in ECS. E-cadherin positive expression is known to inhibit  $\beta$ -catenin signaling, and exerts a negative effect on phosphoinositide 3-kinase (PI3K)/Akt signaling activation, thus preventing uncontrolled cell proliferation. ECS did not show beta-catenin nuclear translocation, thus preventing de-regulated growth. E-cadherin affects the formation of tight junctions by interacting with ZO-1 through interaction with alpha-catenin. ECS stained positive for ZO-1, indicating a stabilized tight junction of ECS. ZO-1 interacts in epithelial cells tight junctions with the gap junctional protein connexin-43. It also stained positive in ECS, and showed an up regulation compared to the rabbit normal corneal epithelium. In conclusion, the levels of these adhesion molecules reflected a low level of cell migratory behavior, indicating that ECS has adhesiveness and epithelial integrity that would favor a successful transplantation to the corneal stromal bed. Supported by CellSeed Inc. and Emmaus Medical, Inc.

### **Refinement of a monolayer cell-binding assay to quantify the time-dependent strengthening of cell-cell adhesion.**

*S. Teo<sup>1</sup>, F. Wagnac<sup>1</sup>, P. Chataigne<sup>1</sup>, W. A. Thomas<sup>1</sup>; <sup>1</sup>Natural Sciences, Colby-Sawyer College, New London, NH*

Cell adhesion plays a critical role in early development (e.g., the sculpting of tissues and organs), in daily maintenance of the body (e.g., wound healing), as well as in a number of aberrant conditions (e.g., tumor metastasis). A thorough understanding of cellular adhesion is thus a theme of broad importance in biomedical research. We have developed a monolayer cell-binding assay that yields data comparable to those obtained with the dual pipette assay developed in the Dufour laboratory at Institut Curie, allowing us to study DLD1 cell adhesion at Colby-Sawyer College in a manner complementary to that done at Institut Curie. Currently, individual bound cells are counted in multiple photographic fields from the monolayer. Here we outline two approaches to improve the efficiency of the quantification. In the first, a single densitometric reading (iVision software, BioVision Technologies) summarizes the grayscale distribution of pixels across each photographic field, yielding a rapid assessment of bound

fluorescent cells. Variation across preparations is minimized by background correction. In the second, monolayers with bound cells are detergent-extracted and the clarified extracts read in a Synergy HT fluorimeter using KC4 software (BioTek, Inc.). We present data evaluating the sensitivity, linearity and reproducibility of both approaches.

This project is supported by the New Hampshire IDeA Network of Biological Research Excellence (NH-INBRE) NIH Grant Number 1P20RR030360-01 from the INBRE Program of the National Center for Research Resources.

**Single-molecule characterization of mechanical homeostasis at E-cadherin-mediated cell adhesions in live cells.**

A. H. Mekhdjian<sup>1</sup>, M. Morimatsu<sup>1</sup>, N. Borghi<sup>2</sup>, W. J. Nelson<sup>3</sup>, A. R. Dunn<sup>1</sup>;

<sup>1</sup>Chemical Engineering, Stanford University, Stanford, CA, <sup>2</sup>Cell Biology, Institut Jacques Monod Unité Mixte de Recherche 7592, Centre National de la Recherche Scientifique, and Université Paris-Diderot, Paris 75013, France, <sup>3</sup>Molecular and Cellular Physiology, Stanford University, Stanford, CA

Epithelial cells transmit mechanical forces through E-cadherin-mediated intercellular contacts, and these dynamic complexes undergo force-dependent remodeling. At present, however, fundamental aspects of how cells detect and generate mechanical forces at intercellular junctions remain poorly understood. Here, we describe a FRET-based molecular force sensor that reports the forces exerted via single E-cadherin complexes in living cells. We have created single-molecule tension sensors (SMTS) that replace the fluorescent proteins in a previously reported FRET-based force probe (Grashoff et al., *Nature* 2010) with organic fluorophores that can be observed at the single-molecule level. SMTS attach to glass coverslips, and present domains from protein A to immobilize the antibody Fc domain of a fusion protein containing the E-cadherin extracellular domain (Ecad-Fc). Madin-Darby Canine Kidney (MDCK) epithelial cells adhere to surfaces functionalized with SMTS and Ecad-Fc, but not to surfaces exposed to either SMTS or Ecad-Fc alone, showing that cell attachment occurs through the Ecad-Fc/SMTS complex. Ensemble FRET measurements reveal that the force per individual E-cadherin complex is approximately 2 pN, an order of magnitude lower than previously reported AFM measurements of E-cadherin homophilic bond rupture forces (Zhang et al., *Proc Natl Acad Sci USA* 2009). This difference may indicate that the maximal load supported by individual E-cadherins is considerably greater than what is generated at equilibrium. Consistent with this interpretation, the forces we measure agree with the single-pN tensions inferred from ensemble FRET measurements using a genetically-encoded E-cadherin force sensor (Borghi et al., *Proc Natl Acad Sci USA* 2012). SMTS allow us to image spatial and temporal variations in force generation by E-cadherin adhesions: in preliminary experiments, we find that regions of high force localize primarily near the cell periphery and around the nucleus of the cell. The ability of the SMTS described here to selectively recruit fusion proteins and antibodies via their Fc domains makes them a flexible and potentially powerful tool for studying cellular mechanotransduction.

**Traction forces exerted by multicellular clusters during stretch.**

L. Casares Garcia<sup>1,2</sup>, D. Navajas<sup>1,2,3</sup>, X. Trepas<sup>1,2,3,4</sup>; <sup>1</sup>Institute for Bioengineering of Catalonia, Barcelona, Spain, <sup>2</sup>University of Barcelona, Barcelona, Spain, <sup>3</sup>Ciber Enfermedades Respiratorias, Bunyola, Spain, <sup>4</sup>Institucio Catalana de Recerca i Estudis Avancats, Barcelona, Spain

Cells from different organs such as the heart, bladder, gut or lung are routinely subjected to stretch. In response to stretch, the cytoskeleton has been reported to reinforce and fluidize. A reinforcement response is characterized by a stiffening of the cytoskeleton and an increase in traction forces whereas a fluidization response is characterized by a decrease in cytoskeleton stiffness, a decrease in traction forces and an increase in macromolecular mobility. While these phenomena are now well established at the single cell level, their impact in collective cell dynamics remains unknown. Here we subjected micropatterned clusters of epithelial cells to pulses of stretch of different duration. Using traction force microscopy we measured forces exerted by the cells on their underlying substrate throughout the stretch-unstretch maneuver. In response to a 10% linear strain, we observed a prompt increase in tractions (+57%) followed by a relaxation toward values 19% higher than baseline. When stretch was suddenly released, traction forces dropped immediately (-29% from baseline) before recovering baseline values after a 2-3 minutes. Our data show that strain-stiffening and fluidization scale up to the multicellular level.

1337

**Mechanical response of cadherin mediated adhesions to external forces.**

M. Estevez<sup>1,2</sup>, E. Nguyen<sup>2</sup>, R. Seddiki<sup>1,3</sup>, R-M. Mège<sup>3</sup>, B. Ladoux<sup>1,2</sup>; <sup>1</sup>Laboratoire Matière et Systèmes Complexes, Université Paris 7, Paris, France, <sup>2</sup>Mechanobiology Institute, National University Singapore, Singapore, Singapore, <sup>3</sup>Neural cell adhesion and migration group, UMR-S 839 Inserm, Institut du Fer à Moulin, Pierre et Marie Curie – Paris 6, Paris, France

Cells have the ability to sense and respond to the mechanical stimuli of their microenvironment during tissue rearrangement, embryonic development and disease such as cancer. Cell-matrix and cell-cell adhesions appear as mechanosensitive structures used by the cells to transmit the forces exerted upon the cells by their environment and those exerted by cells on their neighboring cells and surrounding matrix<sup>1</sup>. There is evidence that cell-cell junctions are heterogeneous in their molecular composition, adhesive strength and dynamics. In a previous work, we observed that cadherin adhesions respond to changes in the internal tension of the cell<sup>2</sup>. Therefore, it results of great interest to study how forces are transmitted through the cell-cell junctions and the dynamics of the intercellular adhesions in response to external and local forces. To address this issue, in this work we combine microfabrication methods that allow to map forces applied to and/or developed by the cells and superresolution imaging to study the dynamics of the cell-cell junctions at a molecular level. We investigate how intercellular adhesions of epithelial cells seeded on fibronectin or E-cadherin coated elastomeric substrates respond to external mechanical forces. We also use structured illumination microscopy to study the dynamics of cadherin-cadherin contacts and other mechanosensory proteins involved in cell-cell adhesion such as vinculin.

### How do cell-cell junctions sense and transduce mechanical forces?

R. Seddiki<sup>1,2,3</sup>, B. Ladoux<sup>1,4</sup>, R. Mège<sup>2,3</sup>; <sup>1</sup>Laboratoire MSC, Université Paris Diderot & Cnrs umr 7057, Paris, France, <sup>2</sup>Université Pierre et Marie Curie-Paris 6, Paris, France, <sup>3</sup>Inserm, U 839, Institut du Fer à Moulin, Paris, France, <sup>4</sup>Mechanobiology Institute (MBI), National University of Singapore, Singapore, Singapore

How cells sense and respond to external mechanical forces is important in normal development and for the maintenance of cell and tissue homeostasis, but remains a poorly understood problem in biology. Mechano-transduction of external forces is mediated by cell-extracellular matrix adhesion and cell-cell contacts. While mechano-transduction through the cell-extracellular matrix is well-studied, signaling through cell-cell adhesion complexes in multicellular tissues is not.

We aim at understanding how cadherins, the major proteins of intercellular adhesions, transduce mechanical forces across groups of cells. I aim to develop molecular tools to investigate the role of cadherins and associated cytoskeleton-adaptor proteins, especially  $\alpha$ -catenin, in mechano-transduction, as well as to design new assays to examine the effects of mechanical forces from the single cell to the multi-cellular level.

The originality of this approach is the combination of micro-fabrication, molecular and cell biology, biochemistry, and cell biophysics to study mechano-transduction at cell-cell junctions. Using these tools and advanced optical techniques, we will investigate the effects of forces and mechanical environments on the dynamics of cell-cell junctions in an epithelium, in correlation with the activity of cadherin-associated proteins and actin cytoskeleton.

### Regulation of Coxsackie and Adenovirus Receptor (CAR) by Cytokines.

P. Kotha<sup>1</sup>, T. Brockman<sup>1</sup>, K. Excoffon<sup>1</sup>; <sup>1</sup>Wright State University, Dayton, OH

Airway epithelial cells pose a formidable barrier for the entry of pathogenic viruses. The epithelial junctional proteins, which is largely composed of tight and adherens junction proteins, maintain the barrier integrity by sealing the space between the cells. Adenovirus, which commonly causes acute respiratory infections, uses CAR as its primary receptor for entry into the host cell. CAR, an adherens junction protein, is primarily expressed on the basolateral surface of polarized epithelial cells and thus is sequestered away from pathogen-exposed (apical) surface. However, despite the inaccessibility of CAR to invading adenoviruses, adenovirus infection is common. It is commonly believed that the mechanism of entry into airway epithelia is through a structural break in the epithelial barrier that exposes the basolaterally expressed CAR to the invading pathogen. However, we have recently shown that an eight exon splice form of CAR (CAR<sup>Ex8</sup>) can localize at the apical surface of epithelial cells

and serve as adenoviral receptor (Excoffon et al., 2010). Interleukin-8 (IL-8) is a proinflammatory cytokine released by the epithelial cells and resident macrophages in the lung, during infection. We hypothesize that exposure of airway epithelial cells to the IL-8 increases apical adenoviral infection through increased expression and apical localization of CAR<sup>Ex8</sup>. To test this hypothesis, the apical surface of polarized Calu-3 cells was treated with IL-8 for 4h and analyzed for CAR<sup>Ex8</sup> expression and localization using Western blot analysis and apical surface biotinylation. Apical transduction with adenovirus carrying the  $\beta$ -galactosidase reporter gene was also evaluated. Our data indicate that exposure of airway epithelial cells to IL-8 increased both the expression and apical localization CAR<sup>Ex8</sup>, as well as adenoviral infection. In summary, these results suggest that susceptibility to adenovirus infection in the lung might be modulated by IL-8.

**The Coxsackievirus and Adenovirus Receptor in cardiac remodeling.**

F. Freiberg<sup>1</sup>, N. Bergmann<sup>1</sup>, C. Tschöpe<sup>2</sup>, M. Gotthardt<sup>1</sup>; <sup>1</sup>Neuromuscular and Cardiovascular Cell Biology, Max Delbrück Center for molecular medicine, Berlin, Germany, <sup>2</sup>Department of Cardiology, Charité, Berlin, Germany

The Coxsackievirus and Adenovirus Receptor (CAR) is a type I transmembrane protein with critical functions in cell adhesion and virus uptake. Its extracellular IG-domains can form homodimers or mediate interaction with other transmembrane or extracellular matrix proteins. The cytoplasmic tail contains a motif that interacts with PDZ-domain proteins related to signal transduction and endocytosis. CAR is predominantly expressed in the developing heart and brain when cells divide and form new cell contacts. In human dilated cardiomyopathy and animal models of myocardial infarction CAR is re- induced. This suggests a role for CAR in the formation of a functional myocardium and cardiac remodelling.

We have generated a conventional CAR knockout (KO) that cannot form continuous myofilaments between adjacent cardiomyocytes. Interestingly the adult inducible knockout does not show this phenotype. Thus, we studied the differential maturation of cell-contacts and their role in cardiac remodelling on the subcellular level.

To visualize myofilament assembly and transition between cells we crossed our CAR KO animals with animals expressing fluorescently labelled myofilaments. ES cell derived cardiomyocytes and embryonic cardiomyocytes do not form continuous filaments between cells in the absence of CAR. In co-culture experiments we show proper attachment to WT cells independent on the CAR genotype. The unexpected connection between KO and WT cells implies a role for a CAR heterodimer rather than a homodimer in transitioning myofilaments between cells.

Here we provide molecular insights into the role of CAR in cardiac development and remodelling and describe a system to study cell grafting into the myocardium *in vivo*. Ultimately our approach might help improve cell-based therapy of myocardial infarction with proper mechanical and electrical coupling to the existing myocardium.

### **Coordinated Remodeling of Cell-Matrix and Cell-Cell Adhesions in Developing and Diseased Cardiac Muscle.**

*M. L. McCain<sup>1</sup>, H. Lee<sup>1</sup>, Y. Aratyn-Schaus<sup>1</sup>, A. G. Kleber<sup>2</sup>, K. K. Parker<sup>1</sup>; <sup>1</sup>Wyss Institute for Biologically Inspired Engineering, School of Engineering and Applied Sciences, Harvard University, Cambridge, MA, <sup>2</sup>Department of Pathology, Beth Israel Deaconess Medical Center, Boston, MA*

Cell-cell coupling between cardiac myocytes is essential for the heart to rapidly propagate electrical signals and contract synchronously. In the adult heart, cell-cell junctions form intercalated discs localized to longitudinal myocyte borders, while cell-matrix adhesions are segregated to transverse borders. The spatial organization of these two adhesion sites progressively evolves during tissue maturation and can become disrupted in different pathological states, forming an arrhythmogenic substrate. However, the cooperative remodeling of cell-matrix and cell-cell adhesions during development and the factors that disrupt their organization in disease are not well understood. We hypothesized that cell-matrix adhesions are important in cardiac development for guiding cell spreading and anchoring myocytes as they build their cytoskeleton and assemble intercalated discs with neighboring myocytes. As the intercalated disc matures, we reasoned that cell-matrix adhesions gradually disassemble as contractile stresses are increasingly transmitted intercellularly. Finally, we reasoned that increased microenvironmental stiffness secondary to fibrosis and disease increases force generation and excessively loads the intercalated disc, causing cell-matrix adhesions to re-assemble adjacent to the intercalated disc to stabilize the tissue. To test this, we engineered two-cell cardiac  $\mu$ tissues consisting of neonatal rat ventricular myocytes on compliant substrates with tunable elasticity and measured the structural and functional maturation of the contractile cytoskeleton and cell-matrix and cell-cell adhesions in different conditions. We found that, over time,  $\mu$ tissues increased their systolic force output while concurrently forming into an electromechanical syncytium by disassembling cell-matrix adhesions and assembling cell-cell adhesions to transmit contractile forces. When we increased substrate stiffness to mimic pathological microenvironments, force generation increased and cell-matrix adhesions formed adjacent to the cell-cell interface, potentially to reinforce the intercalated disc.  $\mu$ tissues in stiff microenvironments showed further functional evidence of maladaptive remodeling, such as lower work efficiency, longer contraction cyclic duration, and weaker relationships between tissue architecture and force generation. Our results suggest that remodeling of cell-matrix and cell-cell adhesions in cardiac muscle is a cooperative process that is guided by a functional hierarchy during development and disrupted by pathological changes to the microenvironment in disease.

1342

### **Negative Intercalated Disc Remodeling with Age Impairs Drosophila Heart Function.**

*G. Kaushik<sup>1</sup>, A. O. Sessions<sup>2</sup>, M. Nishimura<sup>3</sup>, R. Bodmer<sup>3</sup>, A. Cammarato<sup>4</sup>, A. J. Engler<sup>1,2</sup>; <sup>1</sup>Bioengineering, University of California-San Diego, La Jolla, CA, <sup>2</sup>Biomedical Sciences, University of California-San Diego, La Jolla, CA, <sup>3</sup>Sanford-Burnham Medical Research Institute, La Jolla, CA, <sup>4</sup>Division of Cardiology, The Johns Hopkins University School of Medicine, Baltimore, MD*

Cardiac performance declines with age, but our understanding of the molecular origin of this decline has been stymied by either slow aging, geometric complexity of the heart, or genetic variation of animal models. Using new microscopy methods and the genetically malleable *Drosophila* model, we studied heart mechanics, physiology, and structure in high throughput across a variety of genotypes. Though the 3 fly strains studied universally experienced a decline

in fractional shortening with age, severity varied between strains from a 6% (*white*; *w1118*;  $p < 0.05$ ) to an 18% reduction (*yellow-white*; *yw*;  $p < 10^{-3}$ ). A similar continuum existed with arrhythmic index, i.e. the variation in beat frequency, as well as with heart tube stiffness; *yw* flies experienced a 111% increase in heart tube stiffness proximal to the intercalated discs with age (1.8 to 3.9 kPa;  $p < 10^{-10}$ ). In contrast, *w1118* flies did not stiffen with age or position long the heart tube ( $p = 0.1923$ ), and also undergo mechanical separation between the ventral and cardiomyocyte layers. Quantitative PCR revealed age-dependent increased expression of adhesion and intercalated molecules in *yw*, including vinculin, alpha-catenin, and cadherin; expression remained steady or declined in *w1118*. When vinculin was overexpressed in *w1118* myocardium specifically, the aging phenotype was restored with stiffness changing and no separation occurring between muscle layers. On the other hand, heterozygous knockout of integrin-linked kinase (ILK) showed the opposite effect where a degenerative aging phenotype was avoided in *white-Canton S* flies, a strain that normally exhibits 66% midline stiffening with age. These observations and mechanistic insight from genetic perturbations indicate that age-dependent decline in cardiac performance may be due in part to negative remodeling from cell-cell and cell-matrix connections. Moreover, these junctional genes have significant human homology, lending credence to their importance in age-related human cardiac decline.

**Analysis of the angulin family consisting of LSR, ILDR1 and ILDR2: tricellulin recruitment, epithelial barrier function and implication in deafness pathogenesis.**

*T. Higashi<sup>1</sup>, S. Tokuda<sup>1</sup>, S.-I. Kitajiri<sup>2</sup>, H. Nakamura<sup>1</sup>, Y. Oda<sup>1</sup>, M. Furuse<sup>1</sup>; <sup>1</sup>Cell Biology, Kobe University Graduate School of Medicine, Kobe, Japan, <sup>2</sup>Otolaryngology - Head and Neck Surgery, Graduate School of Medicine, Kyoto University, Kyoto, Japan*

Tricellular tight junctions (tTJs) seal the extracellular space at tricellular contacts (TCs), where the corners of three epithelial cells meet. To date, the transmembrane proteins tricellulin and lipolysis-stimulated lipoprotein receptor (LSR) are known to be molecular components of tTJs. LSR recruits tricellulin to tTJs, and both proteins are required for the full barrier function of epithelial cellular sheets. Here, we show that two LSR-related proteins, immunoglobulin-like domain-containing receptor (ILDR)1 and ILDR2, are also localized at TCs and recruit tricellulin. The expressions of LSR, ILDR1 and ILDR2 were complementary in various epithelial cell types, although LSR and ILDR1 were coexpressed in some epithelia. ILDR1 is required for a strong barrier establishment in the epithelium, similar to LSR, when introduced into cultured epithelial cells, while ILDR2 provided a much weaker barrier. We further analyzed human ILDR1, whose mutations cause a familial deafness, DFNB42, and found that most DFNB42-associated ILDR1 mutant proteins were defective in recruitment of tricellulin. We also found that tricellulin mutant proteins associated with another familial deafness, DFNB49, were not recruited to TCs by ILDR1. These findings show the heterogeneity of the molecular organization of tTJs in terms of the content of LSR, ILDR1 or ILDR2, and suggest that ILDR1-mediated recruitment of tricellulin to TCs is required for hearing.

1344

**Spectrin is present at tubulobulbar complexes in the seminiferous epithelium.**

*M. Pires<sup>1</sup>, K. R. Lyon<sup>1</sup>, M. A. De Asis<sup>1</sup>, A. W. Vogl<sup>1</sup>; <sup>1</sup>Cellular and Physiological Sciences, University of British Columbia, Vancouver, BC, Canada*

Here we show that spectrin is present in apical Sertoli cell regions containing tubulobulbar complexes. Tubulobulbar complexes are elongate actin-filament-related endocytic structures that form in regions of attachment between Sertoli cells and maturing spermatids. They function

to internalize intercellular junctions as part of the sperm release mechanism. In rat, tubulobulbar complexes form in two parallel rows adjacent to each spermatid head. Each tubulobulbar complex consists of a double membrane core formed from the plasma membranes of the two attached cells and is cuffed by a dendritic network of actin filaments. The entire structure is capped by a clathrin-coated pit. Fragments of epithelium, containing mature spermatids and adjacent Sertoli cell regions containing tubulobulbar complexes, from perfusion fixed rat testes, were labeled with probes for actin, spectrin and protein EPB 4.1. The material was imaged using conventional fluorescence or confocal microscopy. The immunological probes for spectrin and EPB 4.1 were co-distributed, but surprisingly, their signals did not overlap with the actin staining; rather their staining appeared to be concentrated between adjacent complexes or to surround the actin cuffs of the complexes. The spectrin antibody reacted with a single band on immunoblots of whole testis and seminiferous epithelium. We suspect that the spectrin network may stabilize the actin cuffs or perhaps function as spacers between adjacent complexes. Our observations add another level of complexity to the cytoskeletal organization of tubulobulbar complexes. Supported by an NSERC Discovery grant to AWW.

#### **Transforming Growth Factor- $\beta$ 3-Mediated Regulation of Junctional Adhesion Molecule-B (JAM-B) in Testicular Cells.**

X. Zhang<sup>1</sup>, W-Y. Lui<sup>1</sup>; <sup>1</sup>*School of Biological Sciences, The University of Hong Kong, Hong Kong, China*

Junctional adhesion molecule-B (JAM-B) is found between Sertoli cells as well as between Sertoli and germ cells in the testis. The expression of JAM-B is highly regulated to facilitate the passage of developing germ cells across the blood-testis barrier as well as the release of mature spermatids. Transforming growth factor beta (TGF- $\beta$ ) family is implicated in the regulation of testicular cell junction dynamics during spermatogenesis. This study aims to investigate the influence of TGF- $\beta$ 3 on the expression of JAM-B as well as the underlying mechanisms. TGF- $\beta$ 3 (5 ng/ml) treatment coupled with RT-PCR and immunoblot analyses have shown that TGF- $\beta$ 3 down-regulates JAM-B expression on mRNA and protein levels in a time-dependent manner in mouse Sertoli cell line, MSC-1 cells. Cycloheximide assay further indicates that the reduction of JAM-B protein by TGF- $\beta$ 3 is mediated via post-translational modification. Moreover, the involvement of ubiquitin-proteasome pathway in TGF- $\beta$ 3-mediated JAM-B protein destabilization was demonstrated by proteasome inhibitor, MG-132, treatment and ubiquitin siRNA knockdown assays. Furthermore, co-immunoprecipitation (Co-IP) assay has further confirmed that JAM-B protein is conjugated by a chain of ubiquitin upon TGF- $\beta$ 3 stimulation in the presence of MG-132. TGF- $\beta$ 3 also speeds up the degradation of JAM-B through Smad-dependent pathway. As knockdown of Smad3 and/or Smad4 effectively abolish TGF- $\beta$ 3-mediated JAM-B degradation. Taken together, the involvement of both ubiquitin-proteasome pathway and Smad-dependent signalling are essential for TGF- $\beta$ 3-mediated JAM-B regulation in mouse Sertoli cells. [This work was supported by Hong Kong Research Grants Council (HKU772009 and HKU773710) and CRCG Seed Funding for Basic Research.]

**Glioma cells induce neural stem cells to cross the blood brain barrier.**

M. Díaz-Coránguez<sup>1</sup>, A. López-Ornelas<sup>1</sup>, N. Meráz-Cruz<sup>2</sup>, H. Puerta-Guardo<sup>3</sup>, J. Ludert<sup>3</sup>, J. Segovia<sup>1</sup>, B. Chávez-Munguía<sup>3</sup>, L. González-Mariscal<sup>1</sup>; <sup>1</sup>Physiology, Biophysics and Neuroscience, Center for Research and Advanced Studies (Cinvestav), México, D.F., Mexico, <sup>2</sup>Faculty of Medicine, National Autonomous University of México (UNAM), México, D.F., Mexico, <sup>3</sup>Infectomics and Molecular Pathogenesis, Center for Research and Advanced Studies (Cinvestav), México, D.F., Mexico

The transit of human neural stem cells, ReNcell CX, through the blood brain barrier (BBB) was evaluated in an in vitro model of BBB. The model is based on rat brain microvascular endothelial cells (RBMECs) cultured on Transwell filters with 8 µm pores, placed in a multiwell plate containing, in the basal compartment, conditioned media (CM) from astrocytes or glioma C6 cells. Glioma CM induced a significant transmigration of ReNcells in comparison to astrocyte CM. When we analyzed the role of metalloproteinases (MMPs) and soluble factors secreted by glioma cells, we found that: 1) the same amount of pro-MMP 9 and 2 is present in astrocyte and glioma CM and 2) the addition of neutralizing antibodies against hepatocyte growth factor (HGF) and vascular endothelial growth factor (VEGF) to glioma CM, inhibits ReNcells transmigration. These results indicate that HGF and VEGF promote ReNcells transmigration. The quantitative analysis of cytokines and growth factors present in glioma and astrocyte CM revealed that 1) INF-α, TNF-α, IL-12p70, IL-1β, IL-6, IL-8 and IL-10 are present in equal amounts in both CM; 2) VEGF is abundant in glioma CM and is absent from astrocyte CM; 3) glioma CM contain 20% less prostaglandin E2 (PGE2) than astrocyte CM and 4) epidermal growth factor (EGF) is 2.6 times more abundant in astrocyte CM than in glioma CM. Addition of HGF or EGF to DMEM increases the transendothelial electrical resistance (TEER), and in accordance, the addition of neutralizing antibodies against EGF to astrocyte CM, decreases TEER. In contrast, the addition of neutralizing antibodies against VEGF, of the metalloproteinase inhibitor GM6001, or the Cox-2 inhibitor NS398, revert the deleterious effect of glioma CM on TEER. The detrimental effect of PGE2 on TEER is known to be counteracted by the tight junction (TJ) sealing effect of EGF. Therefore in astrocyte CM, the abundance of EGF presumably neutralizes the effect of PGE2 on TEER, whereas in glioma CM the scarce presence of EGF allows PGE2 to decrease TEER. Taken together, these results indicate that in glioma CM, the high concentration of HGF and VEGF, together with the presence of PGE2, favors ReNcells transmigration across the BBB. To cross the BBB, the transmigrating cells need to express adhesion molecules capable of establishing cell-cell contacts with their counterparts in endothelial cells. We observe that ReNcells express the TJ proteins occludin and claudins 1, 3 and 4, and the cell adhesion molecule CRTAM, while RBMECs express occludin, claudins 1 and 5 and CRTAM. Therefore, we propose that the transmigration of ReNcells across RBMECs monolayers involves contacts between CRTAM, occludin and claudins 1, 3 and 4 present in ReNcells, with the corresponding CRTAM, occludin and claudin 5 present on RBMECs. Finally, we observe that the addition of soluble CRTAM to the apical Transwell compartment containing the ReNcells placed on top of the monolayer of RBMECs, produces a significant decrease in ReNcells transmigration, thus indicating that cell-cell adhesion mediated by CRTAM plays an important role in ReNcells transmigration across the BBB.

**Gap junction coupling of vascular cells is a target for dipyridamole: the role of the cAMP/PKA dependent pathway.**

D. Begandt<sup>1</sup>, A. Bader<sup>1</sup>, L. Dreyer<sup>1</sup>, L. Gerhard<sup>1</sup>, A. Ngezahayo<sup>1,2</sup>; <sup>1</sup>Institute of Biophysics, Leibniz University Hannover, Hannover, Germany, <sup>2</sup>Center for Systems Neuroscience, School of Veterinary Medicine Hannover, Hannover, Germany

Gap junction dependent cell to cell communication has been proposed as a target for the treatment of cardiovascular impairments. We applied scrape loading/dye transfer technique on vascular endothelial and smooth muscle cells to investigate the effect of the antithrombotic drug dipyridamole. At concentrations between 5 and 50  $\mu$ M, the drug increased the gap junction coupling of vascular cells in a time and concentration dependent manner. The increase could be inhibited by application of PKA inhibitors such as H-89 or Rp-cAMPS. The application of forskolin or 8-Bromo-cAMP mimicked the dipyridamole induced effect, thus indicating that dipyridamole affected gap junction coupling by activation of the cAMP/PKA dependent pathway. This pathway is similar to that used to explain the inhibitory effect of dipyridamole on platelet aggregation, namely the inhibition of nucleoside transporters that increases external concentration of nucleosides such as adenosine, which leads to intracellular elevation of cAMP via activation of adenosine receptors and adenylyl cyclase. As a drug which prevents arterial thrombosis and leads to vasodilatation, dipyridamole is used in treatment of cardiovascular infarction and stroke as well as in secondary prevention of vascular occlusions. Our results show that dipyridamole could develop an additional benefit effect by its action on the vascular cell system, especially on the gap junction dependent cell to cell communication.

**Rap1 GTPase activation and barrier enhancement in RPE inhibits choroidal neovascularization *in vivo*.**

E. S. Wittchen<sup>1</sup>, E. Nishimura<sup>2</sup>, M. McCloskey<sup>2</sup>, H. Wang<sup>2</sup>, L. Quilliam<sup>3</sup>, M. Chrzanowska-Wodnicka<sup>4</sup>, M. Hartnett<sup>2</sup>; <sup>1</sup>University of North Carolina, Chapel Hill, NC, <sup>2</sup>University of Utah, Salt Lake City, UT, <sup>3</sup>Indiana University, Indianapolis, IN, <sup>4</sup>Blood Research Institute, Milwaukee, WI

Inappropriate regulation or loss of barrier integrity precedes the development of many pathological situations such as tumor metastasis, inflammatory disorders, and blood-retinal-barrier breakdown characteristic of neovascular age-related macular degeneration (AMD), a leading cause of blindness worldwide. Rap1 GTPase is involved in regulating both endothelial and epithelial cell junctions; the role of Rap1A vs. Rap1B isoforms is less clear. Compromise of retinal pigment epithelium (RPE) barrier function is a contributing factor to the development of AMD. We used shRNA of Rap1 isoforms in cultured human RPE cells, and knockout mouse models to test the role of Rap1A and Rap1B on RPE barrier properties, with emphasis on the dynamic junctional regulation that is triggered when RPE cell-cell adhesion is challenged. Silencing of Rap1A *in vitro* reduced barrier integrity under steady state conditions, whereas loss of Rap1B enhanced EGTA-induced junctional breakdown, and caused a delay in reassembly. We also tested the role of Rap1 isoforms in resisting laser-induced CNV in a mouse model of AMD. Rap1b<sup>-/-</sup> mice exhibited larger CNV volumes compared to wild-type or Rap1a<sup>-/-</sup>; lesion width was increased in both Rap1a<sup>-/-</sup> and Rap1b<sup>-/-</sup> compared to wild-type. Rap1 activation in RPE of mice by intravitreal injection of a cAMP analog (8CPT-2'-O-Me-cAMP) reduced laser-induced CNV size. Rap1 activation increased recruitment of junctional proteins and F-actin to cell-cell contacts, increasing the linearity of junctions *in vitro* and in cells surrounding laser-induced lesions *in vivo*. We conclude that both Rap1 isoforms are important in resisting CNV size and for RPE barrier integrity - Rap1A in steady-state barrier integrity and Rap1B in reassembly following junction disruption. Furthermore, our data suggest that *in vivo* treatment

with 8CPT-2'-O-Me-cAMP may be a viable pharmacological means to strengthen the RPE barrier against the pathological choroidal endothelial cell invasion that occurs in AMD.

**The role of Estrogen Receptors on microvasculature in mouse skin.**

*M. Markiewicz<sup>1</sup>, A. Bradley<sup>1</sup>, G. Gilkeson<sup>1</sup>; <sup>1</sup>MUSC, Charleston, SC*

**Objective:** The goal of this study was to investigate the role of ER alpha and/or ER beta on microvasculature in the skin using unique genetic models: knockout ER alpha (ER alpha <sup>-/-</sup>) and ERbeta (ER beta <sup>-/-</sup>) female mice.

**Methods:** We first visualized and analyzed microvasculature in the skin of ER alpha <sup>-/-</sup>, ER beta <sup>-/-</sup> and control mice by injecting FITC-dextran into the heart of mice. Next, the microvessels were visualized by immunostaining with pericyte specific antibodies such as alpha-smooth muscle actin and desmin. To determine whether vessel stabilization is impaired in the knockout mice and leakage take place we performed in vivo permeability assay. Furthermore, we isolated mouse microvascular endothelial cell from ER alpha <sup>-/-</sup>, ER beta <sup>-/-</sup> mice followed by determination of genes important in stabilization of neovessels.

**Results:** In both ER alpha and ER beta knockout mice the vascular network was disorganized and the diameter of blood vessels was irregular as compared to the wild type animals. The expression levels of alpha-SMA and desmin were significantly decreased in the skin vessels of ER alpha <sup>-/-</sup> and to a lesser degree in ER beta <sup>-/-</sup> mice as compared to WT mice. To confirm that vascular leakage take place in these mice we performed in vivo permeability assay. The extraction of Evan's blue was significantly increased in the skin of ER alpha <sup>-/-</sup>, ER beta <sup>-/-</sup> mice as compared to WT animals. Interestingly, the extraction of Evans blue was also increased in the lung, heart and brain of these mice. Furthermore, we performed an array analysis of the skin taken from WT, ER beta <sup>-/-</sup>, ER alpha <sup>-/-</sup> mice. Several genes such as desmin, JAM-B, C, connexin 40, VE-cadherin, PDGFB were diminished in the tissue of knockout mice as compared to WT animals. Since the vascular changes were observed in dermal microvessels of ER alpha and ER beta knockout mice we determined the genes important in stabilization of neovessels in cultured endothelial cells isolated from ER beta <sup>-/-</sup>, ER alpha <sup>-/-</sup> and control mice. To examine mRNA levels of PDGFB, VE-cadherin and N-cadherin qPCR analysis was performed. Expression level of the following genes was downregulated: PDGFB (~15 folds), VE-cadherin (~28 folds), N-cadherin (~1.6 folds). This data may suggest that vessel stabilization is impaired in the skin of ER beta <sup>-/-</sup> mice. Similar results were obtained in cultured endothelial cells isolated from ER alpha <sup>-/-</sup> mice.

**Conclusions:** Our data indicate that ER alpha and ER beta play an important role in the process of neovascularization. Specifically, our results suggest that both receptors regulate the genes implicated in the vessel stabilization.

**Abl-related gene (Arg) is a novel mediator of endothelial barrier dysfunction.**

*J. Aman<sup>1</sup>, J. van Bezu<sup>1</sup>, K. van Hooren<sup>2</sup>, J. Voorberg<sup>2</sup>, V. W. van Hinsbergh<sup>1</sup>, G. P. van Nieuw Amerongen<sup>1</sup>; <sup>1</sup>Physiology, VU university medical center, Amsterdam, Netherlands, <sup>2</sup>Sanquin-AMC Landsteiner Laboratory, Amsterdam, Netherlands*

**Introduction**

Recently, we demonstrated that the tyrosine kinase inhibitor imatinib protected against inflammatory endothelial barrier dysfunction and vascular hyper-permeability. We identified the tyrosine kinase Abl-Related Gene (Arg / Abl2) as the target of imatinib. Here, we aimed to elucidate the role of Arg in the regulation of endothelial cell-cell and cell-matrix interactions.

### Methods & Results

The barrier-disruptive agents thrombin [1U/mL], histamine [10-5M] and VEGF [10ng/mL] all transiently activated endothelial Arg as evidenced by phosphorylation of its downstream target CrkL at Tyr207. Depletion of Arg completely abrogated CrkL phosphorylation under basal and stimulated conditions. Activation of Arg involved a Src-family kinase, as the Src-inhibitor PP2 blunted Arg activity.

Genetic depletion or pharmacological inhibition of Arg attenuated thrombin-induced endothelial barrier dysfunction, as evidenced by a reduced drop in the trans-endothelial electrical resistance. Inhibition of Arg did not affect RhoA/Rho kinase activity or calcium-dependent signaling, known as main determinants of actomyosin contraction. Resolving the endothelial resistance into separate components reflecting cell-cell contact and cell-matrix interaction displayed that Arg predominantly mediated the decrease in cell-matrix interaction.

To evaluate how Arg contributes to this decrease in cell-matrix interaction, events downstream of Arg activation were analyzed. Inhibition of Arg resulted in enhanced Rap1 activity and affected cell-matrix interaction by activating beta1-integrins. Arg-depleted endothelial cells showed peripheral redistribution of beta1-integrin, yielding a broad band of beta1-integrin at the cell periphery, which colocalized with a thick cortical actin rim. To test whether this beta-1 integrin relocalization affects cell-matrix adhesion strength, cell adhesion and detachment assays were performed. Arg-depleted cells showed a more efficient cell adhesion, as evidenced by a higher number of adhering cells as well as faster cell spreading. Moreover, cell detachment by a combination of mild trypsinization and orbital shaking, revealed that Arg-depleted cells had a delay in rounding up and a reduced detachment rate.

To address the relevance of Arg signaling during endothelial barrier dysfunction in vivo, we measured vascular leakage in a murine model of sepsis (cecal ligation & puncture). Septic mice in which Arg activity was blocked by imatinib (50mg/kg, administered 6h and 18h after the induction of sepsis) showed significantly less vascular leakage in the lungs, the kidneys and the liver.

### Conclusion

These data indicate that Arg is an important mediator of endothelial barrier dysfunction by reducing cell-matrix adhesion in a CrkL/Rap1/beta1-integrin dependent manner. Inhibition of Arg activation prevents disassembly of peripheral FAs. This improves the cell-matrix interaction, stabilizes the endothelial barrier by supporting cell-cell contacts, and is an effective means to reduce vascular leakage.

1351

### **Regulation of retinal vascular leakage by insulin: Implications for patients with diabetic retinopathy.**

*M. Sugimoto<sup>1</sup>, A. Cutler<sup>1</sup>, S. Moss<sup>2</sup>, S. Iyengar<sup>3</sup>, R. Klein<sup>2</sup>, B. Anand-Apte<sup>1</sup>; <sup>1</sup>Cleveland Clinic, Cleveland, OH, <sup>2</sup>University of Wisconsin School of Medicine, Madison, WI, <sup>3</sup>Case Western Reserve University, Cleveland, OH*

Diabetes mellitus is a global disease with considerable morbidity and mortality. Leakage from the retinal vasculature contributes to the pathogenesis of diabetic macular edema (DME), an important cause of vision loss in patients with type 2-diabetes. While epidemiological studies and randomized clinical trials have suggested that glycemic control plays a major role in the development of vascular complications of diabetes, insulin therapies for control of glucose metabolism cannot prevent long-term retinal complications.

Several clinical studies have reported that intensive insulin therapy may cause a transient worsening of retinopathy. In prospective studies on non-insulin dependent (Type 2) diabetes

mellitus patients, a change in treatment from oral drugs to insulin was associated with a significant increased risk of retinopathy progression and visual impairment. In addition, it has been reported that patients who undergo total pancreatectomy for cancer, develop severe diabetes because of the complete absence of insulin, but rarely if ever develop proliferative diabetic retinopathy, even when they survive for more than 10-20 years. Re-analysis of the WESDR data determined that there was a correlation between insulin treatment and diabetic macular edema. These results suggested that insulin treatment maybe a predictor of the onset of DME in patients with diabetes. Based on these findings we modeled and evaluated the pathophysiological effects of insulin on the retinal vasculature in mice and obtained surprising results that suggest that insulin treatment of diabetic mice results in increased retinal vascular leakage.

In this study we report results that suggest that insulin treatment exacerbates retinal vascular leakage in STZ-induced diabetes in mice. We demonstrate that insulin can disrupt tight junctions in RPE cells, up-regulate ADAM10 and subsequently soluble active betacellulin (Btc). That the soluble Btc plays a role in the disruption of tight junctions, was determined by the ability of Btc and ADAM10 siRNA to prevent insulin-induced disruption of tight junctions. We also report that in STZ-induced diabetic mice, insulin-mediated increase in vascular permeability can be inhibited by EGF receptor inhibitors further confirming the potential cross talk between insulin and Btc in the regulation of retinal vascular permeability.

These studies suggest that a combination treatment of insulin and EGF inhibition might be a useful therapeutic combination to prevent macular edema.

1352

**Drebrin preserves endothelial integrity by stabilizing nectin at adherens junctions.**

*S. Linder<sup>1</sup>, K. Rehm<sup>1</sup>, V. van Vliet<sup>1</sup>, L. Panzer<sup>1</sup>, E. Genot<sup>2</sup>; <sup>1</sup>University Medical Center Eppendorf, Hamburg, Germany, <sup>2</sup>University of Bordeaux, Pessac, France*

Regulation of cell-cell contacts is essential for the integrity of the vascular endothelium. Here, a critical role of the F-actin binder drebrin in maintaining endothelial integrity is revealed under conditions mimicking vascular flow. Knockdown of drebrin leads to pronounced weakening of cell-cell contacts, characterized by loss of nectin from adherens junctions and concomitant proteasomal degradation. Immunoprecipitation, pulldown, FRAP and mitochondrial retargeting experiments show that nectin stabilization occurs through a chain of molecular interactions. These involve drebrin binding to F-actin, drebrin and afadin interacting through their polyproline and PR1-2 regions, and recruitment of nectin through afadin's PDZ region. Key elements are drebrin's modules that confer binding to afadin and F-actin. Evidence is provided by minimal constructs containing afadin's PDZ region coupled to drebrin's F-actin binding region or to Lifeact, which restore junctional nectin even under knockdown of both drebrin and afadin. Drebrin, containing binding sites for both afadin and F-actin, is thus uniquely equipped to stabilize nectin at endothelial junctions.

**Role of two Rap1 Isoforms, Rap1A and Rap1B, in regulation of vascular permeability and endothelial cell barrier.**

*M. Chrzanowska-Wodnicka<sup>1</sup>, M. Sobczak<sup>1</sup>, S. Lakshmiathan<sup>1</sup>; <sup>1</sup>Blood Research Institute, Milwaukee, WI*

Dynamic regulation of vascular permeability is critical for normal vessel function as evidenced in pathological conditions such as edema or inflammation; yet underlying mechanisms are not fully understood. Small G protein Rap1 has been implicated in promoting endothelial cell-cell (EC)

junction formation upon elevation of cellular cAMP but also in promoting angiogenic responses to VEGF.

However, what role Rap1 plays in regulation of vascular permeability in vivo is not known. The project's objective was to investigate the function of two Rap1 isoforms, Rap1A and 1B, in the formation and maintenance of adherens junctions (AJ) in ECs and in regulation of vessel permeability in vivo. To accomplish this, we used Cre-lox P method and Tie2 promoter to generate endothelial-specific knockout mice deficient in Rap1A (EC-Rap1A KO), Rap1B (EC-Rap1B KO) or partially depleted of both isoforms (EC-Rap1A KO; Rap1B<sup>+/-</sup>). We found that vessel leakage of Evans blue dye was significantly increased only in lungs from EC-Rap1A KO and EC-Rap1A KO; Rap1B<sup>+/-</sup> mice but not from EC-Rap1B KO mice suggesting that Rap1A is the main isoform promoting vessel barrier. Using bone marrow chimeras we showed that vessel barrier protection by Rap1 is EC-autonomous. In vitro, confocal microscopy revealed that Rap1A-deficiency led to altered organization of AJs in EC monolayers, with dispersed  $\beta$ -catenin distribution across AJs, in contrast to narrow distribution in control or Rap1B KO ECs, suggesting that Rap1A may regulate endothelial barrier properties by spatially organizing AJ proteins. In contrast, dissolution of AJs in response to VEGF was impaired in Rap1B-, but not in Rap1A-deficient ECs. Further, VEGF-induced permeability was reduced in Rap1B-KO EC monolayers. In vivo, VEGF-induced vascular permeability in the skin, as measured by Miles assay, appeared decreased in EC-Rap1B KO but no in EC-Rap1A KO mice.

On the other hand, deficiency of either Rap1 isoform in ECs led to a defect in de-novo AJ formation, as evidenced by slower VE-cadherin fluorescence recovery at AJs after junction disruption with EGTA and by a defect in adhesion to VE-cadherin. Overall, these results suggest that in addition to common functions, the two Rap1 isoforms play distinct roles; Rap1A is involved in vascular barrier maintenance and Rap1B – in regulation of VEGF-mediated permeability.

## Muscle Structure, Function, and Disease

### Heart Failure on a Chip: Recapitulating Maladaptive, Multi-Scale Remodeling of the Failing Heart In Vitro.

M. L. McCain<sup>1</sup>, S. P. Sheehy<sup>1</sup>, A. Grosberg<sup>1</sup>, J. A. Goss<sup>1</sup>, K. K. Parker<sup>1</sup>; <sup>1</sup>Wyss Institute for Biologically Inspired Engineering, School of Engineering and Applied Sciences, Harvard University, Cambridge, MA

Tissue-specific biomimetic in vitro microsystems engineered to recapitulate in vivo human physiological responses, known as “organs on chips,” are currently being developed to potentially replace animal testing in the pharmaceutical industry. In addition to building microscale mimics of healthy organs, there is also a need to engineer “organs on chips” with pathological phenotypes to test the efficacy and toxicity of therapeutics in patients with specific diseases, such as pathological hypertrophy. In the heart, volume overload excessively stretches the ventricle and induces dilated cardiomyopathy, which often progresses to heart failure. We hypothesized that we could exploit this response to build and validate a “heart failure on a chip” microsystem by chronically stretching engineered ventricular tissues to stimulate maladaptive genetic, structural, and functional remodeling. To these aims, we applied chronic cyclic stretch to engineered neonatal rat ventricular tissues cultured on elastomeric silicone membranes and quantified remodeling on spatial scales ranging from the gene to the tissue. Chronic cyclic stretch initiated early in tissue assembly induced myocytes to align parallel to the loading direction. Gene expression in stretched tissues was characteristic of dilated cardiomyopathy,

including decreased  $\alpha$ - to  $\beta$ -myosin heavy chain ratios. In tissues aligned with microcontact printing, transverse cyclic stretch decreased sarcomere alignment and longitudinal cyclic stretch increased cellular aspect ratio. Cyclic stretch applied in either direction extended the time to peak intracellular calcium, which has similarly been observed in failing hearts. We adapted the muscular thin film assay to our stretchable silicone membranes to perform quantitative stress measurements in our engineered tissues and found that cyclic stretch in either direction decreased systolic stress generation, which is consistent with maladaptive remodeling. Our results show that chronic cyclic stretch induces pathological genetic, structural, and functional remodeling, indicating that mechanical stretch can be used as a stimulus for engineering "heart failure on a chip" microsystems with potential applications as drug testing platforms.

### **Transglutaminase as a critical mediator of phenotypic instability in vascular smooth muscle.**

*M. Nurminskaya<sup>1</sup>, K. Beazley<sup>1</sup>, D. Nurminsky<sup>1</sup>; <sup>1</sup>Biochemistry and Molecular Biology, University of Maryland, Baltimore, MD*

Phenotypic instability of vascular smooth muscle underlies various vascular diseases including atherosclerosis and calcification of the blood vessels, myocardium and cardiac valves. The latter is a common complication associated with diabetes, chronic renal insufficiency, hypercholesterolemia, osteoporosis and ageing, and has been correlated with increased morbidity and mortality. Using in vitro analysis we demonstrate that both osteoblastic and adipogenic transformation in VSM is critically dependent on the novel signaling conduit involving activation of the canonical  $\beta$ -catenin by enzyme transglutaminase TG2. In contrast, other signaling pathways implicated in osteoblast differentiation including BMP, PKA, Notch, NF $\kappa$ B and ERK play a limited role. These data suggest that inhibition of TG2 may represent a novel therapeutic target to prevent vascular disease in vivo. This hypothesis was tested using rat model of aortic elastocalcinosis which involves osteoblastic transformation in VSM. TG2 activity is increased in calcified aortas and here we employed two inhibitors to counteract this induction, including the TG2-specific small molecule inhibitor KCC-009 and bioflavonoid quercetin, which we have characterized as a novel inhibitor of TG2. Both treatments efficiently prevented  $\beta$ -catenin activation and deposition of calcified matrix in the arterial media. Re-activation of  $\beta$ -catenin in cultured VSMC by GSK inhibitor LiCl in the presence of quercetin restored calcium accumulation, confirming that quercetin acts via inhibition of the  $\beta$ -catenin pathway. These data provide new insights into molecular control of phenotypic instability in vascular smooth muscle.

1356

### **The impact of each domain of myosin heavy chain molecule on forming thick filaments in muscle and non-muscle cells.**

*K. Ojima<sup>1</sup>, I. Nakajima<sup>1</sup>, M. Oe<sup>1</sup>, S. Muroya<sup>1</sup>, T. Nishimura<sup>2</sup>, A. Hattori<sup>2</sup>; <sup>1</sup>Animal Products Research Division, Institute of Livestock and Grassland Science, National Agriculture and Food Research Organization, Tsukuba, Japan, <sup>2</sup>Research Faculty of Agriculture, Graduate school of Agriculture, Hokkaido University, Sapporo, Japan*

In skeletal muscle cells, myofibrillar proteins are highly organized into the sarcomere, in which thick filaments are interdigitated with thin filaments to generate contractile force. Thick filaments are composed of myosin heavy chains (MHCs) and their associated molecules. Importantly, the size of each thick filament is strictly regulated, *i.e.* 1.6 micrometer in length. However, little is known about the mechanisms which control the formation of thick filaments. Here, we demonstrated how MHC molecule functions in the assembly of thick filaments. First, to examine

the role of each domain of MHC to form thick filaments, Flag-tagged myosin fragments were exogenously expressed in cultured mouse skeletal muscle cells, and then visualized by double staining with anti-Flag, antibodies against myofibrillar proteins, and/or rhodamine-labeled phalloidin. We observed that exogenously expressed full length MHCs were assembled into thick filaments in myotubes. They formed 1.6 micrometer thick filaments in sarcomeres under light microscopy. Fragments of the light meromyosin (LMM) as well as the subfragment 2 plus LMM (S2+LMM) showed an ability to be incorporated into thick filaments with low efficiency. In contrast to those, exogenously expressed the S2 fragment was distributed diffusely throughout the cytoplasm of myotubes, suggesting that the LMM domain may facilitate to form myosin filaments in myotubes. Second, we examined whether or not myosin fragments were capable of forming thick filaments in non-muscle cells, such as COS cells. Exogenously expressed full length MHCs as well as the LMMs fragments formed filaments but their sizes were not uniform. Although expressed S2 fragments did not form any filament structures, the S2+LMM produced filaments and filamentous aggregates. Taken together, the LMM domain of MHC is essential to form filaments in both skeletal muscle and COS cells. Our results also showed that 1.6 micrometer thick filaments were generated by exogenous expression of MHCs in myotubes but not in COS cells, indicating that MHC molecules by themselves are not capable of controlling the size of polymerized filaments and that muscle cytoplasmic environments including myofibrils are indispensable for proper assembly of thick filaments.

#### **Myotonia Congenita Mutation Disrupts the Biosynthesis of CLC-1 Channels.**

*T-T. Lee<sup>1</sup>, C-J. Jeng<sup>2</sup>, T-Y. Chen<sup>3</sup>, C-Y. Tang<sup>1</sup>; <sup>1</sup>College of Medicine, National Taiwan University, Taipei, Taiwan, <sup>2</sup>School of Medicine, National Yang-Ming University, Taipei, Taiwan, <sup>3</sup>Neuroscience Center, University of California, Davis, Davis, CA*

Myotonia congenita is a hereditary muscle disorder caused by mutations in the human voltage-gated Cl<sup>-</sup> channel CLC-1. We have studied a myotonia mutation that has not been functionally characterized. Despite a gating property similar to that of wild-type channels, the mutant CLC-1 channel displayed a diminished whole-cell current density and a reduction in the total protein expression level. Our biochemical analyses further demonstrated that the reduced expression of the mutant channel can be largely attributed to an enhanced proteasomal degradation as well as a defect in protein trafficking to surface membranes. Our data suggest that the molecular pathophysiology of myotonia congenita may involve a disruption of the balance between the synthesis and degradation of the CLC-1 channel protein.

#### **Differential phosphorylation of titin domains acts complementary to increase passive stiffness in failing human myocardium.**

*S. Kötter<sup>1,2</sup>, L. Gout<sup>2</sup>, M. von Frieling-Salewsky<sup>1</sup>, S. Helling<sup>3</sup>, K. Markus<sup>3</sup>, W. Linke<sup>2</sup>, M. Krüger<sup>1</sup>; <sup>1</sup>Cardiovascular Physiology, University of Düsseldorf, Düsseldorf, Germany, <sup>2</sup>Cardiovascular Physiology, University of Bochum, Bochum, Germany, <sup>3</sup>Functional Proteomics, University of Bochum, Bochum, Germany*

Aims: Titin-based passive stiffness is an important determinant of myocardial diastolic function, and is modulated by two main mechanisms: i) alterations in the relative expression levels of the cardiac titin isoforms, N2B (3.0 MDa) and N2BA (> 3.2 MDa), and ii) phosphorylation of elastic I-band domains of titin. Importantly, phosphorylation of the N2-B unique sequence (N2-Bus) by cGMP-dependent protein kinase (PKG) or cAMP-dependent protein kinase (PKA) decreases titin stiffness in human heart, whereas phosphorylation of the titin PEVK domain by PKC

increases it. Here, we analyzed whether changes in the titin phosphorylation status affect passive myocardial stiffness in human failing hearts.

**Methods and Results:** Titin isoform composition was determined by 2% SDS-PAGE, and a set of human donor and failing hearts with similar isoform composition was selected for further analyses. Total titin phosphorylation was determined using ProQ-diamond/Sypro-Ruby stain and was slightly reduced in failing hearts compared to controls. To study specific modifications of titin domains phosphosite-directed antibodies were generated against pSer4185 in the N2-Bus and pSer11878 in the PEVK region, and relative phosphorylation of the titin domains was determined using Western blot analyses. In failing hearts, relative N2-Bus phosphorylation was significantly reduced by up to 28%, and relative PEVK phosphorylation was increased by up to 23% compared to donor hearts. Passive myocardial stiffness was analyzed using skinned fiber preparations, and the length-tension relationship was increased in fibers from failing hearts compared to controls. Because titin isoform composition was unchanged in the failing heart samples the observed increase in fiber stiffness is likely caused by the altered phosphorylation status of titin. Furthermore, using mass spectrometry we identified novel PKG- and PKA-dependent phosphorylation motifs in human and rat titin N2-Bus, which may explain the reduced phosphorylation status of total titin.

**Conclusion:** We conclude from our data that differential phosphorylation of the N2B and PEVK region of titin can act complementary to increase passive tension in the myocardium, and is an important physiological mechanism to fine-tune passive myocardial stiffness, and thus diastolic function of the heart.

#### **Insulin as a modulator of cardiac titin.**

A. E. Mueller<sup>1</sup>, C. Andresen<sup>1</sup>, K. Babicz<sup>2</sup>, S. Bongardt<sup>1</sup>, W. Roell<sup>3</sup>, W. Linke<sup>2</sup>, M. Krueger<sup>1</sup>;  
<sup>1</sup>Faculty of Medicine, Cardiovascular Physiology, Duesseldorf, Germany, <sup>2</sup>Faculty of Medicine, Cardiovascular Physiology, Bochum, Germany, <sup>3</sup>Cardiac Surgery, Bonn, Germany

The sarcomeric protein titin is the largest protein known to date, and one of the main molecular components that contribute to the passive stiffness of striated muscle tissue. In mammalian heart, titin-based myofilament stiffness is an important determinant of myocardial distensibility and diastolic function. The passive mechanical properties of cardiac titin depend on the expression ratio of the isoforms N2BA (~3.2 – 3.7 MDa, compliant) and N2B (~3.0 MDa, stiffer), and can be dynamically modified by phosphorylation through PKA, PKG and PKC. Importantly, phosphorylation by PKA and PKG reduces titin-based myofilament stiffness, whereas PKC increases it.

Here we studied the influence of insulin on titin isoform composition and phosphorylation using cultured cardiomyocytes and diabetic human heart tissue. Titin isoform composition and phosphorylation was analyzed using 1.8% SDS PAGE stained with either Coomassie, or the phosphoprotein stain ProQ-Diamond in combination with SYPRO-Ruby as well as antibody based western blot analysis. In embryonic rat cardiomyocytes (CMs) insulin treatment for 7 days significantly increased the relative expression of stiff N2B-titin by >12% compared to untreated cells. Moreover, in embryonic and adult rat CMs insulin caused a major increase in the relative titin phosphorylation within 15 minutes of treatment. This effect was blocked by inhibition of the NO/cGMP- pathway or the PI3K/AKT-pathway (LY294002), suggesting insulin-mediated phosphorylation of titin by either PKG, or PKC. Western blot analyses using phospho-specific antibodies showed that insulin treatment induced phosphorylation of the PKC-sensitive site S11878 (UniProtKB Acc. #Q8WZ42) in the PEVK region of titin. In addition, we investigated the influence of altered insulin homeostasis on titin isoform ratio and titin phosphorylation using samples from right atria of diabetic and non diabetic patients that underwent cardiac surgery

due to coronary artery disease. Diabetic heart samples showed a major increase in titin N2BA expression that was most pronounced in patients with a high HbA1c (> 7.0 %). First analyses also demonstrate a hypophosphorylation of total titin from diabetic hearts, probably caused by reduced phosphorylation of the PEVK element of titin, as indicated by Western blot analyses. We conclude that insulin is a potent modulator of cardiac titin, and may therefore play an important role in modifying myocardial stiffness in human hearts.

**An R441Q mutation of the WWP1 gene causes WWP1 degradation in skeletal muscle of chicken muscular dystrophy.**

M. Imamura<sup>1</sup>, S. Takeda<sup>1</sup>; <sup>1</sup>Department of Molecular Therapy, National Institute of Neuroscience, NCNP, Tokyo, Japan

A missense mutation in a gene encoding WWP1 was identified as the cause of chicken muscular dystrophy by genetic linkage analysis. WWP1 is a HECT-type E3 ubiquitin protein ligase, composed of 922 amino acids, containing four tandem WW domains that interact with proline-rich peptide motifs of target proteins. The missense mutation changes arginine at amino acid 441 into glutamine (R441Q) located within WW domains. The R441Q mutation would influence a property of WWP1 molecule, but little is known about it. In this study, we describe the effect of a single amino acid substitution on the expression of WWP1 protein in skeletal muscle cells. Immunoblot analysis of chicken skeletal muscle homogenate using specific antibody against WWP1 detected small fragment signals, at around 90 kDa, in addition to a 120 kDa full-length WWP1. The 90-kDa protein bands relatively increased in dystrophic chicken muscle while, in contrast, the full-length WWP1 tended to decrease. We also examine the WWP1 degradation using skeletal muscle of R441Q WWP1 transgenic mice and obtained the result compatible with that from dystrophic chicken. Moreover, we performed *in vitro* expression analysis by transfection using myogenic cell line, C2C12. In overexpression of R441Q and normal WWP1 in proliferating C2C12 cells, both of them showed marked increase of 120-kDa full-length WWP1. However, in differentiation stage of the cells, full-length WWP1 was remarkably down-regulated especially in the transfectant of mutant WWP1. This down-regulation of WWP1 was prevented to some extent by addition of cell-permeable proteasome inhibitor (MG132) into culture medium. These results suggested that R441Q missense mutation induced degradation of WWP1 during muscle differentiation, which was carried out at least in part through ubiquitin-proteasome system.

1361

**Myosin dynamics in cultured skeletal muscle cells.**

Y. Yasukawa<sup>1</sup>, K. Ojima<sup>2</sup>, J-I. Wakamatsu<sup>3</sup>, A. Hattori<sup>3</sup>, T. Nishimura<sup>3</sup>; <sup>1</sup>Graduate School of Agriculture, Hokkaido University, Sapporo, Japan, <sup>2</sup>Animal Products Research Division, Institute of Livestock and Grassland Science, National Agriculture and Food Research Organization, Tsukuba, Japan, <sup>3</sup>Research Faculty of Agriculture, Hokkaido University, Sapporo, Japan

Myosin is one of the major myofibrillar components in striated muscles. More than 300 myosin molecules assemble into a bipolar thick filament in the sarcomere. However, it is still unclear how myosin molecules in thick filaments are replaced by de novo synthesized myosin molecules without affecting the structural integrity and functions of thick filaments. In this study, we investigated the dynamics of myosin molecules in living cultured skeletal muscle cells using fluorescence recovery after photobleaching (FRAP). We observed that exogenously expressed GFP-tagged myosin heavy chain 3 (GFP-Myh3) showed the striations, which were precisely located in the A-band of the sarcomeres in myotubes. After photobleaching, the fluorescence

intensity of GFP-Myh3 gradually increased and then the striations were recovered at 6-8 hours post-photobleach. To examine whether de novo synthesized myosin molecules are required for the recovery, cycloheximide (CX), an inhibitor of protein biosynthesis, was added to the medium before photobleaching. The addition of CX did not interfere with the fluorescence recovery of GFP-Myh3, suggesting that de novo synthesized myosin molecules are dispensable for GFP-Myh3 replacement in thick filaments. Next, we compared the mobility of myosin molecules in the shafts of myotubes with that at the spreading ends (growth tips), in which sarcomeres are newly synthesized and added to the existing myofibrils. In the growth tips, the relative fluorescence intensity of GFP-Myh3 was recovered to about 90% of the initial value at two hours post-photobleach, while, in the shafts, it was recovered to 30-50% of the initial value at 10 hours post-photobleach. This result suggested that the mobility of myosin was faster in the growth tips than in the shafts of myotubes. Collectively, our FRAP results demonstrated that myosin molecules in thick filaments were actively replaced and traveled within the sarcomere, and their mobility was different between the shafts and the growth tips of myotubes.

**Treatment for inherited muscular diseases by antibiotics against nonsense mutations.**

*M. Shiozuka<sup>1</sup>, A. Nishida<sup>2</sup>, Y. Takeshima<sup>2</sup>, M. Yagi<sup>2</sup>, T. Lee<sup>2</sup>, A. Wagatsuma<sup>1</sup>, M. Yoshida<sup>1</sup>, M. Date<sup>1</sup>, M. Matsuo<sup>3</sup>, Y. Nonomura<sup>1</sup>, R. Matsuda<sup>1</sup>; <sup>1</sup>The Univ. of Tokyo at Komaba, Tokyo, Japan, <sup>2</sup>Kobe Univ., Kobe, Japan, <sup>3</sup>Kobegakuin Univ., Kobe, Japan*

Translational readthrough of a premature termination codon is a promising therapeutic method in more than 2,400 distinctly inherited human diseases caused by respective single genes. In order to investigate potent readthrough inducer with fewer toxicity than known readthrough-inducing drug such as gentamicin, we screened from kanamycin-related antibiotics using the novel transgenic mouse strain, named READ (Readthrough Evaluation and Assessment by Dual reporter). In consequence, we discovered that the arbekacin induced the in vivo nonsense suppression dose-dependently in READ mice for detection of readthrough activity. We found that arbekacin promoted the accumulation of dystrophin, the reduction of serum creatine kinase activity and the improvement of contractile function in mdx mice which carried nonsense mutation in dystrophin gene. Moreover, arbekacin exhibited the restoration of dystrophin expression on human muscle cells obtained by biopsies from Duchenne muscular dystrophy (DMD) patients with nonsense mutation of dystrophin gene. These results demonstrate that arbekacin induces readthrough of the premature termination codon, resulting in the partial restoration of dystrophin protein, in the reduction of creatine kinase activity, and in restoration of isometric force in mdx mice. Furthermore, arbekacin coaxes cells from DMD patients to ignore nonsense mutations and to promote dystrophin production. Compelling evidence is now available that arbekacin can mask the genetic defect and generate full-length functional proteins. Arbekacin is a breakthrough readthrough-inducing drug for muscular dystrophy patients harboring nonsense mutations, and can be use as gOff-label use h. Now, we are preparing "investigator-initiated clinical trial" supported by the Japan Medical Association Center of Clinical Trials. It is our hope that arbekacin will contribute towards the teatment for DMD.

**Roles of ADAM8 in skeletal muscle regeneration.**

*D. Nishimura<sup>1</sup>, H. Sakai<sup>1</sup>, T. Sato<sup>1</sup>, F. Sato<sup>1</sup>, J. W. Bartsch<sup>2</sup>, A. Sehara-Fujisawa<sup>1</sup>; <sup>1</sup>Department of Growth Regulation, Institute for Frontier Medical Sciences, Kyoto University, Kyoto, Japan, <sup>2</sup>Department of Neurosurgery, Marburg University, University Hospita, Marburg, Germany*

During skeletal muscle regeneration, damaged muscle fibers are replaced by newly formed myotubes. Muscle satellite cells, muscle-specific stem cells, proliferate and fuse with each other to form these new myotubes. In addition to skeletal muscle lineage cells, inflammatory cells are required for proper muscle regeneration. Neutrophils and macrophages promote cell damage by producing super-oxide and remove cell debris by phagocytosis. Macrophages regulate myogenesis by secreting cytokine or ECM. Members of ADAM (a disintegrin and metalloprotease) family proteins encode transmembrane metalloproteases, and are involved in the ectodomain shedding of various cell adhesion molecules, transmembrane signaling molecules, and ECM proteins (Reiss and Saftig., *Semin Cell Dev Biol.*, 2009). Among the ADAMs, ADAM8 is highly expressed in leukocytes including macrophages, neutrophils or granulocytes, and its expression increases under the inflammatory conditions such as cancer, asthma or tissue injury. Whereas ADAM8<sup>-/-</sup> embryos have no obvious developmental defects (Kelly et al., *Dev Dyn.*, 2005), evidence suggests that ADAM8 regulates inflammatory reactions and/or mediates ectodomain shedding of inflammation associated proteins such as TGF alpha, TNFR1, PSGL1, and L-selectin. However, whether ADAM8 is involved in muscle regeneration and whether loss of ADAM8 would cause pathological changes in muscular dystrophy remain unknown.

Here, we investigated roles of ADAM8 in muscle regeneration. To examine loss of ADAM8 would affect muscle regeneration, we utilized two muscle regeneration models;(1) dystrophin-null mice, models for Duchenne muscular dystrophy and (2) cardiotoxin (CTX) induced skeletal muscle injury. Firstly, we generated dystrophin-null; ADAM8<sup>-/-</sup> mice, and found loss of ADAM8 exacerbated the muscle dystrophic phenotype. Histological analysis indicated enhanced mineralization and increased inflammatory cells in the Dystrophin-null;ADAM8<sup>-/-</sup> mice. Next, we examine whether muscle regeneration process was impaired in the ADAM8<sup>-/-</sup> mice by injecting cardiotoxin. We found that macrophages infiltrated into damaged muscle fibers were fewer in the ADAM8<sup>-/-</sup> mice. These results suggest that clearance of dead cells during skeletal muscle regeneration was affected in the ADAM8<sup>-/-</sup> mice. We previously showed that ADAM8 mediates the onset of blood circulation in zebrafish through triggering release of erythroblasts from the intravascular surface (Iida et al., *Curr Biol.*, 2010). ADAM8 could be required for the detachment of inflammatory cells from capillaries, the basement membrane surrounding muscle fibers, or interstitial cells in muscle regeneration. We are currently exploring mechanisms through which ADAM8 regulates behaviors of macrophages in regenerating muscles.

## Defining Therapeutic Targets and New Therapeutics I

1364

### A new method for the quantification of angiotensin converting enzyme in dried blood spots as a tool for the follow up of patients with Gaucher disease in Colombia: preliminary results.

*N. Pacheco<sup>1</sup>, A. Uribe<sup>1</sup>; <sup>1</sup>Centro de Investigaciones en Bioquímica (CIBI), Universidad de Los Andes, Bogota, Colombia*

Gaucher disease is a Lysosomal Storage Disorder (LSD) caused by the deficiency of the enzyme beta acid glucosidase which leads to the accumulation of the metabolite glucocerebrosidase in the organism. There is treatment available for the disease, but, because there are more than 300 mutations described for Gaucher, it is difficult for clinicians to generalize a dose and monitor the response of each patient to the treatment.

Biomarkers are molecules that serve as indicators for diseases. Although specific biomarkers for Gaucher disease are not known, angiotensin converting enzyme (ACE) is commonly used for the follow up of patients. ACE is also a biomarker for Fabry disease (another LSD) and hypertension, because it is directly related with the renin-angiotensin system.

The aim of the present study is to evaluate ACE using a more economic and accessible sample: the dried blood spot (DBS). In Colombia the analyses for LSDs are carried out in big cities, making the transportation difficult and expensive. As this sample doesn't require refrigeration or big quantities of blood, is ideal for the analysis and follow up of patients.

To demonstrate that DBS is as accurate as traditional serum samples, we compared serum and DBS samples from 16 healthy individuals from 19 to 55 years old and samples from 11 patients with Gaucher disease with ages between 2 and 72 years old. ACE activity was determined by a colorimetric assay both in serum and in DBS using Furylacryloyl Phenilalanine Glycylglycine (FAPGG) as a substrate in a microplate assay.

We analyzed the kinetics of the enzyme to find out at which point there was a larger difference between healthy and Gaucher individuals. At 60 minutes the activities of both groups were the most different. We haven't found significant differences between serum and DBS samples ( $p=0.5499$ ). Also we have seen that Gaucher patients are well discriminated both in serum ( $p=0.0052$ ) and DBS ( $p=0.066$ ) and the difference ratio is maintained between the two samples analyzed. The activity of ACE in patients with Gaucher disease was considerably greater compared to the control group ( $p=5.5e-05$ ).

In conclusion, DBS is a good, inexpensive sample and can be used as a tool for the follow up of patients with Gaucher disease. These results show that the quantification of biomarkers in DBS is as accurate as in serum samples, making DBS sampling reliable for laboratory analyses.

1365

### Proapoptotic role of TGF- $\beta$ 1 and VEGF in the kidney of Fabry disease mouse model

*Y-J. Jeon<sup>1</sup>, M-H. Lee<sup>1</sup>, S-C. Jung<sup>1</sup>; <sup>1</sup>Department of Biochemistry, School of Medicine, Ewha Womans University, Seoul, Korea*

Fabry disease is a lysosomal storage disorder caused by deficiency of  $\alpha$ -galactosidase A ( $\alpha$ -gal A), resulting in deposition of globotriaosylceramide (Gb3; also known as ceramide trihexoside)

in the vascular endothelium of many organs. A gradual accumulation of Gb3 leads to cardiovascular, cerebrovascular, and renal dysfunction. Endothelial cell dysfunction leads to renal complications, one of the main symptoms of Fabry disease. However, the pathological mechanisms by which endothelial dysfunction occurs in Fabry disease are poorly characterized. The purpose of this study was to investigate whether the expression of transforming growth factor- $\beta$ 1 (TGF- $\beta$ 1) and vascular endothelial growth factor (VEGF) is associated with the renal pathogenesis of Fabry disease. We found that the protein expression levels of renal thrombospondin-1 (TSP-1), TGF- $\beta$ 1, and VEGF were higher in the kidneys from Fabry mice than from wild-type mice. The expression levels of VEGF receptor 2 (VEGFR2), fibroblast growth factor-2 (FGF-2), and phospho-p38 (P-p38) were also higher in the kidneys from Fabry mice compared with wild-type mice. Activities of cysteine aspartic acid protease (caspase)-6 and caspase-9 were higher in kidneys from Fabry than from the wild type. These results suggest that overexpression of TGF- $\beta$ 1 and VEGF in the Fabry mouse kidney might contribute to Fabry disease nephropathy by inducing apoptosis. To test whether Gb3 accumulation can induce apoptosis, we incubated bovine aortic endothelial cells with Gb3 and found increased expression of TGF- $\beta$ 1, VEGFR2, VEGF, FGF-2, and P-p38. The combination of increased expression of TGF- $\beta$ 1 and VEGF caused by Gb3 accumulation may allow upregulation of FGF-2, VEGFR2, and P-p38 expression, and these changes might be associated with Fabry disease nephropathy by inducing apoptosis.

Key words: Fabry disease, mouse, globotriaosylceramide, kidney, endothelial cell, TGF- $\beta$ 1, VEGF

1366

**Species-Specific differences in Locked Nucleic Acid Antisense Oligonucleotide Uptake *in vitro* Correlates with *in vivo* Renal Damage.**

J. Qian<sup>1</sup>, D. DiMattia<sup>1</sup>, J. Jamieson<sup>2</sup>, G. Yanocho<sup>2</sup>, M. Roy<sup>1</sup>, J. Kreeger<sup>1</sup>; <sup>1</sup>Pfizer, Groton, CT, <sup>2</sup>Pfizer, La Jolla, CA

Antisense oligonucleotides (ASOs) are RNA targeting therapeutics that can be designed to modulate RNA function through a diverse set of post-binding mechanisms by either a) binding to the RNA and interfering with its function without causing RNA degradation or b) by promoting degradation via nuclease recruitment or by acting directly to degrade the target (i.e. ribozymes, DNazymes). One active area of ASO therapeutic research has been in fully phosphorothioated single stranded locked nucleic acid (LNA) 3-8-3 (LNA-DNA-LNA) gapmers. Bolus administration of LNA gapmers results in rapid accumulation in the liver and kidney, allowing for modulation of targets expressed in these tissues. An LNA ASO approach has been used to reduce glucocorticoid receptor (GR) mRNA levels in liver for the treatment of type two diabetes mellitus. Lead LNA ASOs were chosen based on enhanced glucose tolerance and acceptable tolerability in mouse studies. Exploratory toxicity studies were completed for each compound in rats at all doses (2mg/kg, 20mg/kg, 60mg/kg, 2X/week for 3 weeks) where severe renal tubular degeneration with inflammation was observed. Interestingly, this was not observed in mouse studies where animals were dosed 2X/week for two weeks with 25 mg/kg. Hepatic necrosis was observed in rats at doses above 20 mg/kg, while these effects were generally not observed in mice. *In vitro* investigations were subsequently initiated employing two LNA ASOs (PF-05203021, PF-05201595), one of which was hepatotoxic in mice whereas the other was not with the purpose of identifying and understanding mechanistic differences in toxicity between species.

To further elucidate the mechanism of the observed species-specific renal toxicity, primary epithelial cells from rat and mouse renal proximal tubules were used to evaluate LNA cytotoxicity, uptake, as well as GR mRNA knockdown. In conjunction with these efforts, immortalized renal tubular epithelial cells from rat and mouse were used to evaluate the same endpoints. Target knockdown in immortalized and primary cell lines were significant ( $p < 0.001$ ) after 24 hours of each LNA ASO, with the single exception being with LNA ASO PF-021 in rat cells where the oligo sequence contains a single base mismatch to the target. In immortalized kidney cell lines, one LNA ASO (PF-021) was cytotoxic to mouse and rat cell lines after 32 hours of exposure, while the second (PF-595) was not significantly cytotoxic. These results in mouse cells correlate well with *in vivo* studies (i.e. PF-021 caused hepatic necrosis in mice). Conversely, limited primary cell toxicity is observed, with the rat cells being least sensitive to LNA ASO toxicity. Additionally, with constant LNA exposure, ASO accumulates in all cell lines over 48 hours in a time dependent manner. Rat primary proximal tubule epithelial cells, however, were more efficient (~2-3x) in LNA uptake, regardless of sequence. It is possible from these results that the sensitivity observed in the rat toxicity study is associated with a greater accumulation of LNA in the proximal tubule epithelium. However, the mechanism of subsequent damage is unclear and thus is still a part of ongoing investigations.

1367

#### Characterization of infiltrating M1/M2 macrophages in animal models of non-alcoholic steatohepatitis.

M. Canlas<sup>1,2</sup>, T. Csak<sup>1</sup>, G. Szabo<sup>1</sup>; <sup>1</sup>Department of Medicine, University of Massachusetts Medical School, Worcester, MA, <sup>2</sup>University of Guam, Mangilao, Guam

Non-alcoholic fatty liver disease includes steatosis, steatosis with inflammation, and steatohepatitis with necroinflammation (NASH) with or without fibrosis. Macrophages, which are great contributors to the disease, are classified into M1 (pro-inflammatory) and M2 (anti-inflammatory, pro-fibrotic) macrophages. We hypothesized that the macrophage profile changes during the development and progression of NASH. To test our hypothesis, we used animal models of steatosis (4-weeks high fat diet [HFD] or ob/ob mice) and steatohepatitis (9-months HFD or methionine-choline-deficient [MCD] diet for 1,2,5 or 8 weeks). M1 (TNF- $\alpha$ , IL-1 $\beta$ , IP-10) and M2 (CD206, CD163, Arginase-1) macrophage markers were measured in the liver using qPCR and flow cytometry. M2 polarizing factors (IL-33, IL-10) and fibrosis markers (TGF- $\beta$ ,  $\alpha$ -SMA, collagen, TIMP1) were assessed by qPCR, Western blot and ELISA. As a result, M1 markers were up-regulated in HFD induced steatohepatitis but not in steatosis. Among the M2 markers, only CD206 increased in HFD induced steatohepatitis. In MCD-steatohepatitis, M1 markers were up-regulated throughout the progression of the disease. All M2 markers were increased in early MCD-steatohepatitis (week 1), and CD206 remained elevated at all time-points. IL-10 and IL-33 mRNA were up-regulated in early MCD-steatohepatitis (week 1, 2) and in HF and MCD diet-induced steatohepatitis at all weeks, respectively. Fibrosis markers were also increased during the HF and MCD diet induced steatohepatitis at mRNA level. Serum TIMP1 protein showed an increase at 8 weeks of MCD diet feeding. In summary, our data confirms the change in M1 and M2 markers resulting in the dominance of pro-inflammatory markers in NASH. The decrease of some M2-markers might suggest exhaustion of the anti-inflammatory mechanisms while the CD206+ population might contribute to fibrosis in NASH.

**Size matters to a syncytiotrophoblast: alpha-Fe<sub>2</sub>O<sub>3</sub> nanoparticles exhibit diameter-dependent effects.**

J. J. Faust<sup>1</sup>, W. Zhang<sup>2</sup>, Y. Chen<sup>3</sup>, D. G. Capco<sup>1</sup>; <sup>1</sup>Cellular and Molecular Biosciences, Arizona State University, Tempe, AZ, <sup>2</sup>Civil and Environmental Engineering, New Jersey Institute of Technology, Newark, NJ, <sup>3</sup>Civil and Environmental Engineering, Georgia Institute of Technology, Atlanta, GA

Ferric oxide nanoparticles (NPs) stand at the cornerstone of molecular imaging, water remediation, and the semiconductor industry due to their unique physico-chemical properties on the nanoscale (10<sup>-9</sup>m) compared to their bulk form. Indeed, ferric oxide nanoparticles offer a unique opportunity to exploit their capacity to target individual cells at the organismal level selectively through functionalization of the nanoparticle surface. However, increased use highlights the need to assess the potential toxic effects of these nanomaterials. Here, we report the size-dependent effects of alpha-Fe<sub>2</sub>O<sub>3</sub> nanoparticles of three different diameters (i.e. 15-, 50-, and 80nm in diameter) after exposure to an *in vitro* model of the human placenta (BeWo B30 epithelium). In contrast to the conventional notion that smaller-size NPs exhibit greater toxicity, we show that the smaller-sized particles (e.g. 15nm) resulted in less toxic effects compared to larger alpha-Fe<sub>2</sub>O<sub>3</sub> NPs after they were applied at the same mass concentration. Transepithelial electrical resistance (TEER) demonstrated a loss of epithelial integrity for 50-, and 80nm NPs, but not for 15nm NPs compared to untreated epithelia after a single 100µg/mL exposure to the nanoparticles. Live/dead analysis showed an increase in cell death in the larger-diameter particles (50-, and 80nm) from 1 to 5 days post treatment. Moreover, analysis of reactive oxygen species (ROS) indicates a marked increase in cells positive for ROS for the 50- and 80nm NPs. To assess the route of entry in BeWo cells we employed transmission electron microscopy and observed that these NPs likely entered the cells through endocytosis after 4 hours in culture as inhibiting endocytosis resulted in a dramatic decrease in the number of cells with internalized NPs. When the epithelia integrity was disrupted as measured by TEER for the large diameter NPs we show a large number of NPs localize in the extracellular space between cells at the putative level of the cellular junctions at 8 hours, but not in untreated epithelia or when small-diameter NPs (i.e. 15nm) were applied. Moreover, scanning electron microscopy demonstrated a significant (p<0.0001) disruption of the apical brush-border. Exposure to 80nm particles at a concentration of 100µg/mL results in fewer microvilli per unit area on the apical surface compared to untreated epithelia at each time point assessed. These data indicate that different diameters of alpha-Fe<sub>2</sub>O<sub>3</sub> NPs result in different effects on the epithelium, emphasizing the need to further investigate the mechanisms by which these different sizes elicit different effects on the epithelium.

1369

**Suppression of HIV-1 Tat-induced expression of ICAM-1/VCAM-1 and monocyte adhesiveness by valproic acid in human astrocytes.**

G. S. Youn<sup>1</sup>, S. M. Ju<sup>1</sup>, D-J. Kwon<sup>1</sup>, S. Y. Choi<sup>1</sup>, J. Park<sup>1</sup>; <sup>1</sup>Department of Biomedical Science, Hallym University, Chuncheon, Korea

Extracellular HIV-1 Tat plays a critical role in the expression of inflammatory genes including adhesion molecules such as ICAM-1 and VCAM-1 in the central nervous system. Previous studies suggested that valproic acid (VPA), an anti-epileptic drug, exhibits anti-inflammatory properties. This study investigated whether VPA has a regulatory effect on the HIV-1 Tat-mediated up-regulation of ICAM-1/VCAM-1 expression and monocyte adhesion in human astrocytes. VPA significantly decreased HIV-1 Tat-induced ICAM-1/VCAM-1 expression in human astrocytes. In addition, VPA treatment significantly decreased HIV-1 Tat-induced

monocyte adhesion in human astrocytes. VPA inhibited HIV-1 Tat-induced increase of NF- $\kappa$ B promoter activity without altering p65 phosphorylation and I $\kappa$ B degradation. Furthermore, VPA suppressed HIV-1 Tat-induced expression of NF- $\kappa$ B dependent pro-inflammatory genes such as CXCL10, MCP-1, but not IL-8. These data indicate that VPA can modulate the HIV-1 Tat-mediated expression of adhesion molecules and subsequent adhesiveness of monocytes in human astrocytes and might be useful for controlling HIV-1 Tat-mediated neuroinflammation.

**Exploration of the relationship between breast cancer progression and aggression, extra-cellular matrix stiffness and tissue inflammation.**

*I. Acerbi<sup>1</sup>, S. Zheng<sup>1</sup>, B. Ruffell<sup>2</sup>, A. Au<sup>3</sup>, Q. Shi<sup>4</sup>, J. Lakins<sup>1</sup>, B. Senman<sup>1</sup>, J. Liphardt<sup>4</sup>, L. M. Coussens<sup>2</sup>, Y-Y. Chen<sup>5</sup>, C. Park<sup>6</sup>, S. Hwang<sup>7</sup>, V. M. Weaver<sup>1</sup>; <sup>1</sup>Surgery, University of California San Francisco, San Francisco, CA, <sup>2</sup>Department of Cell & Developmental Biology, Oregon Health & Science University, Portland, OR, <sup>3</sup>Cancer Center, University of California San Francisco, San Francisco, CA, <sup>4</sup>Physics, University of California Berkeley, Berkeley, CA, <sup>5</sup>Pathology, University of California San Francisco, San Francisco, CA, <sup>6</sup>Radiation Oncology, University of California San Francisco, San Francisco, CA, <sup>7</sup>Surgery, Duke University Medical School, Durham, NC*

Tumor progression is influenced by the dynamic interplay between the genetically-modified epithelium and the associated microenvironment. We previously showed that the extra-cellular matrix (ECM) progressively stiffens as mammary tumors evolve, and that stiffening the ECM promotes malignant transformation while inhibiting ECM stiffening reduces tumor progression (Levental et al., 2009; reviewed in Butcher et al., 2009). Yet breast cancers also exhibit elevated influx of inflammatory cells and tissue inflammation promotes tumor progression by fostering angiogenesis and enhancing tumor cell growth and motility (Ruffell et al., 2011). Tumor-associated macrophages additionally stimulate stromal fibroblasts, implying that tissue inflammation could promote malignancy by stiffening the ECM. To address this possibility, we explored the relationship between ECM tension and macrophages in human breast cancer and during mammary tumor development in transgenic mice. Using fresh and archived tissue samples, we quantified a progressive increase in ECM remodeling and stiffening as human breast tumors and mouse mammary cancers developed. We found that the ECM associated with triple negative breast cancers was almost twice as stiff as the ECM adjacent to ER/PR+ve tumors and that ECM tension correlated significantly with increased numbers of infiltrating activated macrophages. Consistently, we established a positive correlation between tumor progression, elevated mechanosignaling, ECM stiffness and tissue inflammation in both human and mouse tissue. However surprisingly, when macrophages were depleted from the mammary glands of MMTV-PyMT tumors, ECM tension did not change. Instead we found that inhibiting lysyl oxidase activity to decrease collagen cross-linking and ECM stiffness reduced the activation state of the macrophages within the mammary glands of 14-week old mice. Consistently, in vitro studies showed that ECM tension potentiates the expression of pro-inflammatory chemokines and increases levels of phosphoStat3 and that ECM tension directly modifies macrophage polarity. These findings suggest that ECM tension may promote tumor progression and aggression either by directly regulating macrophage activity or indirectly through enhancing expression of pro-inflammatory chemokines. Further studies are now underway to explore these findings and to clarify their impact on tumor progression and response to therapy. ### The inhibition of HMG-CoA reductase pathway protects airway epithelial cells against bacterial pore-forming toxins.

C-Y. Kao<sup>1,2</sup>, L-Y. Hung<sup>1</sup>, C-Y. Chang<sup>1</sup>, J-H. Lim<sup>3</sup>, J-D. Li<sup>3</sup>, R. Wu<sup>1</sup>; <sup>1</sup>Center for Comparative Respiratory Biology and Medicine, UC Davis, Davis, CA, <sup>2</sup>Immunology Research Center, National Health Research Institutes, Miaoli, Taiwan, <sup>3</sup>Center for Inflammation, Immunity & Infection and Department of Biology, Georgia State University, Atlanta, GA

Pore-forming toxins are the single largest class of bacterial virulence factors. We have developed a novel host-directed strategy defending against some bacterial pore-forming toxins. Pneumolysin and  $\alpha$ -hemolysin are the main pore-forming toxins shown to play critical roles in bacterial pathogenesis respectively in *Streptococcus pneumoniae* and *Staphylococcus aureus*, two common causes of bacterial infections. Airway epithelia are the initial and primary sites of many bacterial contacts and their barrier and immunity functions are critical to infectious diseases. Using primary normal human bronchial epithelial (NHBE) cells and an immortalized normal bronchial epithelial cell line, HBE1, we here show that the prior exposure to statins confers significant cellular resistance to the cytotoxicity of pneumolysin and  $\alpha$ -hemolysin. We further found that the protection requires protein synthesis and is calcium dependent. With siRNA gene silencing, pharmacological inhibitors, immuno fluorescence microscopy and biochemical approaches, we have delineated the statin-mediated cellular protection mechanisms in airway epithelial cells. Our results suggest that the inhibition of HMG-CoA-reductase pathways and certain downstream lipid metabolism may increase airway epithelium resistance to pore-forming toxins. The ultimate goal of this study is to elucidate the interactions of pore-forming toxins and the host cells at the molecular level and this might be potentially developed as an adjuvant therapy in pore-forming toxin-related bacterial infections.

### Creation of a novel claudin binder by using *Clostridium perfringens* enterotoxin and baculoviral display.

A. Takahashi<sup>1</sup>, Y. Saito<sup>1</sup>, M. Kondoh<sup>1</sup>, H. Kakutani<sup>1</sup>, H. Suzuki<sup>1</sup>, K. Matsuhisa<sup>1</sup>, A. Watari<sup>1</sup>, T. Hamakubo<sup>2</sup>, K. Yagi<sup>1</sup>; <sup>1</sup>Graduate School of Pharmaceutical Sciences, Osaka University, Osaka, Japan, <sup>2</sup>Research Center for Advanced Science and Technology, The University of Tokyo, Tokyo, Japan

**Objective:** Claudins (CLs) are a family of tetra-transmembrane proteins comprising over 24 members. CLs play a crucial role in sealing intercellular spaces in epithelium and endothelium; they are frequently over-expressed in malignant tumors. CL binders are promising lead ligands for CL-targeted drug development; however, because the preparation of recombinant CL proteins is extremely difficult, CL ligands have never been fully developed.

The C-terminal fragment of *Clostridium perfringens* enterotoxin (C-CPE), which binds to CL-3 and -4, is the most characterized CL ligand. Previously, we prepared a C-CPE mutant-displaying phage library, and developed a screening system for CL ligands using this C-CPE mutant library and CL-displaying baculovirus (CL-BV). Here, we created and evaluated novel CL-1 ligand m19 as a candidate molecule for modulating the mucosal absorption of drugs.

**Methods and results:** The functional residues of C-CPE were randomly substituted with other amino acids to create a C-CPE mutant-displaying phage library. Recombinant CL-1-BV was prepared by using the Bac-to-Bac expression system. CL-1-BV-coated immunotubes were used to screen for CL-binding phages. CL binding was evaluated with ELISA by using CL-BV-coated immunoplates, and FACS analysis by using CL-expressing cells. Modulation of epithelial barrier was examined in Caco-2 monolayer cell sheets. Jejunal absorption-enhancing effects were investigated by in situ loop assay. The C-CPE mutant library was added to immunotubes coated

with CL-1-BV. CL-1-BV-bound phages were recovered and amplified. The resultant phages were again added to immunotubes and the procedure repeated. The panning procedure was repeated three times and the C-CPE mutants expressed by the CL-1-BV-bound phages were sequenced. Recombinant mutant C-CPE proteins were prepared, and their binding to CL-1-BV was investigated. We identified a CL-1-binding mutant, m19. m19 bound to CL-1-expressing cells and showed more epithelial barrier-modulating activity than C-CPE. m19 also enhanced jejunal absorption of dextran more than C-CPE did.

**Conclusion:** The C-CPE mutant library and CL-BV works as a CL-binder screening system. m19 may be a promising lead for modulating the mucosal absorption of drugs.

1373

### Pathological function of transformation of growth form of *Candida albicans* by N-acetylglucosamine.

S. A. Ishijima<sup>1</sup>, S. Abe<sup>1</sup>; <sup>1</sup>Teikyo University Institute of Medical Mycology, Tokyo, Japan

The amino sugar N-acetylglucosamine (GlcNAc) is known to induce the hyphal mode of growth of *Candida albicans*. *C. albicans* is commensal yeast in healthy mammalian intestinal tracts, but according to the environmental condition, it transforms the growth form to hyphae. This process is considered to contribute for pathogenesis of the mucosal infection of *C. albicans*. Here we investigated whether ingestion of GlcNAc has an effect on the *in vivo* growth of *C. albicans* or the pathogenesis of a *C. albicans* infection. Using a murine model of oral candidiasis, we have found that oral administration of GlcNAc, but not glucose, increased oral symptoms of candidiasis and fungal burden. There was a dose dependent relationship between GlcNAc dosage and the severity of oral symptoms. Mice given the highest dose of GlcNAc 45 mM, also showed a significant increase in fungal burden, and increased histological evidence of infection compared to a control given water alone. GlcNAc is also a commonly used nutritional supplement for the self-treatment of conditions such as arthritis. We propose that ingestion of GlcNAc, as a nutritional supplement, may have an impact on oral health in people susceptible to oral or gastrointestinal candidiasis.

1374

### Functional characterisation and gene expression analysis of trachoma conjunctival fibroblasts.

Z. Kechagia<sup>1</sup>, H. Li<sup>1</sup>, D. Ezra<sup>1,2</sup>, M. Burton<sup>3</sup>, M. Bailly<sup>1</sup>; <sup>1</sup>Institute of Ophthalmology, University College London, London, United Kingdom, <sup>2</sup>NIHR Biomedical Research Centre for Ophthalmology, Moorfields Eye Hospital and UCL Institute of Ophthalmology, London, United Kingdom, <sup>3</sup>Infectious and Tropical Diseases, London School of Hygiene and Tropical Medicine, London, United Kingdom

Trachoma is a major cause of blindness worldwide, and number one infectious cause of vision impairments. The initiation of the disease is caused by *Chlamydia trachomatis* and after an initial phase of infection and chronic inflammation (active trachoma), scarring develops and the eyelashes turn inwards (trichiasis), rubbing on the cornea and causing visual loss. Because trichiasis occurs even after eradication of the bacterial infection, we hypothesized that trachoma scarring is due to functional alterations of the conjunctival fibroblasts. We isolated conjunctival fibroblasts from patients following trichiasis surgery as well as from matching control biopsies from Tanzanian individuals. The conjunctival fibroblasts were examined for collagen contraction in control conditions and after the addition of cytokines and growth factors expressed *in vivo*; cell force measurements; matrix metalloproteinase (MMP) expression profile; myofibroblast differentiation and whole genome expression analysis. We show that trichiasis-derived fibroblasts display increased collagen gel contraction compared to healthy controls both in

serum-free medium and in the presence of serum or platelet-derived growth factor (PDGF). However, both cell and matrix force were similar, suggesting the mechanical properties of diseased cells are not affected. Differences in MMP expression during three-dimensional cultures and collagen production were also observed, demonstrating a phenotype similar to the in vivo observations. Our findings indicate that trachoma conjunctival fibroblasts exhibit altered functional and molecular characteristics that are maintained in vitro.

1375

**Urine of AKI patients promotes metanephric cell growth and recovery of renal function after ischemia-reperfusion injury in mouse.**

*Y. Kitamoto<sup>1</sup>, H. Kitamura<sup>1</sup>, H. Sugai<sup>1</sup>, Y. Taguma<sup>1</sup>, T. Imamura<sup>2</sup>, H. Yorinaka<sup>2</sup>; <sup>1</sup>Sendai Shakaihoken Hospital, Sendai, Japan, <sup>2</sup>Kumamoto Univ Graduate School of Life Sciences, Kumamoto, Japan*

Chronic kidney disease causes renal death and recovery of the lost renal function is critical to prevent it. Chronic kidney injury with fibrosis is shown to recover significantly by mesenchymal stem cell transplantation probably through paracrine mechanism in mice, which may also be shared by the recovery from acute kidney injury (AKI) in patients. When renal tubular cells are injured in AKI, various molecules produced in the lesion leak into urine. Thus, we collected urine from AKI patients and examined its activities to promote mouse metanephroi growth including mesenchymal cells and recovery from the injury.

Fresh urine samples from 5 AKI patients were collected at their recovery stage. By centrifugation using tubes with molecular sieve-membrane, the samples were separated to the high molecular weight fraction (HMWF, MW>10 kD) and the low molecular weight fraction (LMWF, MW<10 kD). Each fraction was examined for promotive activities on cell-proliferation in metanephroi by organ culture and recovery from ischemia-reperfusion AKI in mice. Each fraction from urine containing 0.1 mg creatinine was added to 1 ml of culture medium and 4 metanephroi at E.S.12 were submerged for 3 days in it followed by protein measurement of cultured tissues. The ratio of measured protein contents in the tissue cultured in HMWF containing medium vs. that cultured in LMWF containing medium was used as a mitotic activity index for metanephric cells by the HMWF. HMWF from two patients promoted metanephric cell proliferation with the index of 1.6 and 1.9, respectively. HMWF with the highest mitotic activity was administered to 5 AKI mice intra-peritoneally with 25 mg creatinine-equivalent doses at 10 min after inducing the injury. Thereafter recovery of AKI was traced 3 days by measuring blood-urea-nitrogen (BUN) levels and kidneys harvested after the 3 days were examined histologically and by immunostaining for PCNA. BUN level increased at 1 day but decreased at 2 days after inducing injury and it was lower at 2 days in HMWF administered mice ( $26.3 \pm 3.6$  mg/dL, n=5) than in control (PBS administered) mice ( $33.8 \pm 5.0$  mg/dL, n=5) ( $p \leq 0.05$ ). Histologically no difference was observed between HMWF-administered and control mice. but more PCNA-positive tubular cells were seen in the former than the latter.

In conclusion, HMWF of urine from AKI patients has promotive activities not only on metanephric cell proliferation but also on recovery from AKI in mice. These activities found in the urine may contribute to the recovery from AKI in patients.

1376

### Methylxanthine-induced Neuroprotection in Neural Stem Cells via the System Xc pathway.

S. Crockett<sup>1</sup>, S. Ejem<sup>2</sup>, S. Nigunore<sup>2</sup>, B. Sims<sup>2</sup>; <sup>1</sup>Comparative Pathology, University of California Davis, Davis, CA, <sup>2</sup>Pediatrics, University of Alabama at Birmingham, Birmingham, AL

Methylxanthines are being widely studied to understand their neuroprotective role in disease. Methylxanthines are also an attractive agent for neuroprotection in the neonatal population. Theophylline, a member of the methylxanthine family, is commonly used in neonates for the treatment of apnea of prematurity. Methylxanthines' mechanism involves inhibition of the adenosine receptor and as phosphodiesterase inhibitors. Other potential mechanisms or pathways of action for methylxanthines are still not clearly understood. The main aim of this study is to understand the methylxanthine theophylline's role in the regulation of the cystine glutamate exchanger- a known neuroprotective pathway. In this study, we use neural stem cells to examine whether the cystine glutamate exchanger is regulated by theophylline administration. Theophylline has a dose and time dependent effect on System Xc expression. Glutamate-induced apoptosis was attenuated by theophylline administration and there was a concomitant increase in System Xc expression. Cell survival also increased with theophylline administration. MAP Kinase inhibitor (PD98059) blocked the increase seen in System Xc expression in a dose-dependent manner. Adenosine did not have a significant effect on System Xc expression. In conclusion, theophylline administration regulates System Xc expression and activity leading to neuroprotection.

### Chronic Smoking Causes Decrease in Plasma Levels of Gamma-amino butyric acid (GABA) and Glutamate in the African American Population When Compared to Non-smokers.

A. Mandal<sup>1</sup>, L. D. Williams<sup>1</sup>, J. B. Solomon<sup>1</sup>, L. M. White-Sanders<sup>1</sup>, L. A. Griffin<sup>1</sup>, S. Mishra<sup>1</sup>, P. K. Mandal<sup>1</sup>; <sup>1</sup>Biology, Edward Waters College, Jacksonville, FL

Smoking is a risk factor for various types of cancers and heart diseases. The result of the study, to assess if chronic cigarette smoking alters brain concentrations of the excitatory amino acids Glutamate and the inhibitory amino acid GABA, is presented here. Nicotine is a major substance inhaled by smokers and it is known to modulate various neurotransmitters that affect neural and cardiac function. Nicotine has been recognized as an important mediator of the actions of amino acids viz., GABA and Glutamate. However to our knowledge, no studies have assessed if chronic cigarette smoking in humans affects regional concentrations of these important amino acids. Glutamate is known to play a role in stimulating the activity of other neurons. On the contrary, GABA often slows other neurons down. GABA is a major neurotransmitter in the mammalian brain and controls neuronal excitability. It has been implicated in the addictive and withdrawal process of nicotine dependence. The production of GABA is dependent on Glutamate decarboxylase, the enzyme that catalyzes the decarboxylation of Glutamate to GABA. This ultimately affects healing of tissues by impairing the release of factors that stimulate the function of the cells responsible for the healing of tissues. GABA and Glutamate are two important neurotransmitters that are responsible for inhibition and excitation, respectively, and control the vertebrate nervous system. **Methods:** Blood samples were collected from smokers and non-smokers in a population of African Americans and plasma were prepared. Levels of GABA and Glutamate were measured by using ELISA. **Result:** Plasma level of GABA is decreased in male smokers ( $81.2 \pm 2.4$  ng/ml as against  $122.2 \pm 2.8$  ng/ml) but not in female smokers ( $129.4 \pm 4.0$  ng/ml as against  $136.5 \pm 2.0$  ng/ml), while Glutamate is decreased in both males ( $10.5 \pm 5.0$  ng/ml as against  $19.4 \pm 2.9$

ng/ml) and females ( $13.7 \pm 3.3$  ng/ml as against  $19.3 \pm 3.1$  ng/ml) when compared to non-smoking volunteers. **Conclusion:** In African Americans, levels of GABA and Glutamate are modulated by smoking and this plays a major role in altering neurotransmitter control on the nervous system. These findings provide a biological foundation for alteration of neurotransmitter levels among habitual smokers in the African-American population. This study was supported by James and Esther King Biomedical Research Program of Florida Department of Health Grant HBC-01.

### **Influence of Antioxidants on Cellular Migration and Protection from Oxidative Stress.**

J. E. Juarez<sup>1</sup>, D. Lobo<sup>1</sup>; <sup>1</sup>Biology Department, Monmouth University, West Long Branch, NJ

Resveratrol is a strong antioxidant and natural phytoalexin often found in red grapes and wine. It has been seen to have positive effects on metabolism and anti-cancer activity. Currently, our lab has been studying the regulation of cadherins, important proteins for cellular adhesion, in normal fibroblasts and fibrosarcoma cells. It is also being investigated whether antioxidants, such as resveratrol and N-acetylcysteine (NAC), can influence the control of cadherins, proliferation, or migration. Dishes of HT-1080 fibrosarcoma cells were treated with 10, 25, and 50  $\mu$ M resveratrol, resulting in inhibited cellular proliferation. While  $H_2O_2$  inhibited both proliferation and cell migration, causing cells to senesce, NAC showed not to have such an inhibitory effect. NAC treatment also did not protect the cells against  $H_2O_2$ -inhibition. Currently, we are testing if treatment with resveratrol can provide protection against  $H_2O_2$ -inhibition of proliferation/migration or alter expression of cellular signaling proteins, including cadherins.

### **Growth and lipid production in the haptophyte *Chrysochromulina* sp. under salinity stress: a potential role for stress response proteins.**

S. A. Brunelle<sup>1</sup>, W. Hardin<sup>1</sup>, B. Hovde<sup>2</sup>, J. Patterson<sup>1</sup>, R. A. Cattolico<sup>1</sup>; <sup>1</sup>Biology, University of Washington, Seattle, WA, <sup>2</sup>Genome Sciences, University of Washington, Seattle, WA

Lipid bodies serve as the cellular organelle for sequestering newly synthesized neutral lipids. Though lipid body formation represents the keystone of cellular lipid production in algae, little is known concerning the biogenesis of this organelle. Until recently, lipid bodies were thought to be static, intracellular vesicles that served as inert storage sites. New research has dramatically transformed this perception. Now lipid bodies are considered to be true organelles of complex structure that play an indispensable role in the maintenance of cellular homeostasis. The haptophyte *Chrysochromulina* sp. is an excellent model for understanding lipid body biogenesis and lipid production in algae. *Chrysochromulina* sp. has a high growth rate, two lipid bodies that are easily detected within the cell, and a genome (57 MB) that has been fully sequenced. However, limited data are available for the cell and molecular biology of this organism with respect to lipid body biogenesis. To date, studies have shown that most algal species grown under various stress conditions increase the number and/or size of lipid bodies within the cell as well as the production of lipids. The current study examines cell growth, lipid body biogenesis and lipid production in *Chrysochromulina* sp. using flow cytometry, BODIPY 505/515 staining with fluorescent microscopy and GC-MS, respectively, when placed under salinity stress. High salinity growth media (32mM NaCl) appears to delay the entry of *Chrysochromulina* sp. into the exponential growth phase and causes an increase in production of lipids when compared to the

control (8mM NaCl). Additionally, a classic eukaryotic stress response appears to be present in *Chrysochromulina* sp. Upon examination of the genome, we have found multiple sequences coding for highly conserved stress response genes including heat shock proteins (HSPs) 70 and 90. The proteins encoded by these genes have also been identified in *Chrysochromulina* sp. using anti-HSP70 and HSP90 antibodies. Proteomic analysis of proteins obtained from isolated lipid bodies shows that these HSP proteins may be associated with this organelle. We are concurrently investigating how proteins involved in stress response (HSPs) are regulated as well as their potential association with the lipid bodies using antigenic techniques.

1380

***Chrysochromulina* sp. a model alga for analyzing lipid body biogenesis.**

W. Hardin<sup>1</sup>, S. Brunelle<sup>1</sup>, B. Hovde<sup>2</sup>, J. Farrow-Johnson<sup>1</sup>, J. Dong<sup>1</sup>, R. Cattolico<sup>1</sup>; <sup>1</sup>Biology, University of Washington, Seattle, WA, <sup>2</sup>Genome Sciences, University of Washington, Seattle, WA

Microscopic analysis has documented the presence of lipid inclusions in many algal species; however, lipid body inclusions have only recently been recognized as true sub-cellular organelles. Understanding the ability of algae to modulate cellular homeostasis through the regulation of lipid production is critical as these organisms are essential in sequestering global CO<sub>2</sub>, serve an ecological role as the primary producers in marine and fresh water food webs, and there is increased commercial interest in these organisms as a source of biofuel and pharmaceutical co-products. A broad investigational strategy is being implemented to probe algal lipid body biogenesis. *Chrysochromulina* sp. (Haptophyte) has been chosen as a model system for probing the life history, lipid and protein composition of this dynamic organelle in chromalveolates. This small (~4µm) unicellular, oleaginous alga is experimentally tractable for it contains a simple complement of two large lipid bodies, lacks a cell wall which aids in lipid body recovery, sequesters a uniquely wide range of neutral lipids within the lipid bodies, can be synchronized by photoperiod and has a fully sequenced genome (57MB). Flow cytometric and quantitative lipid GC/MS analysis documents a diurnal correlation between lipid body size, lipid profile and lipid amount for this model system. The association of lipid bodies with chloroplasts and mitochondria as well as the co-localization with the endoplasmic reticulum is assessed using transmission electron microscopy as well as organelle-fluorescent probes. A newly devised lipid body isolation method, has allowed both the lipidomic and proteomic complements of *Chrysochromulina* sp. lipid bodies to be assessed. LC-MS/MS revealed peptides with homology to proteins involved in lipid metabolic pathways in diatoms, including sulfolipid biosynthesis, lipoamide dehydrogenase and phospholipid scramblase. GC/MS lipid analysis of a lipid body fraction demonstrates a suite of fatty acids, ranging from C14:0 - C22:5, with elevated levels of C16:0.

1381

**Spatial regulation UBXD8 and p97/VCP: at the intersection between ER protein quality control and fat storage.**

J. A. Olzmann<sup>1</sup>, E. J. Greenblatt<sup>1</sup>, C. M. Richter<sup>1</sup>, T. A. Shaler<sup>2</sup>, R. R. Kopito<sup>1</sup>; <sup>1</sup>Department of Biology, Stanford University, Stanford, CA, <sup>2</sup>SRI International, Menlo Park, CA

Lipid droplets (LDs) are endoplasmic reticulum (ER)-derived organelles composed of a neutral lipid core surrounded by a phospholipid monolayer, which is decorated with integral and peripherally-associated proteins. How proteins are sorted and delivered from their site of synthesis in the ER to LDs and the mechanisms underlying LD formation and turnover remain mostly unknown. To address these questions we investigated the mechanism by which UBXD8,

a hairpin-anchored protein implicated in ER-associated degradation, partitions between the ER and LDs. Our results identify the rhomboid pseudoprotease UBAC2 as a UBXD8 receptor that anchors UBXD8 to the ER and links it to upstream ubiquitination machinery. UBAC2 prevents UBXD8 trafficking to LDs and dominantly represses LD-targeting signals encoded in the UBXD8 hairpin structure or induced by lipogenic stimuli. Proteomic analysis of UBXD8 complexes affinity-purified from ER or LD biochemical fractions indicate extensive interactions with ubiquitination machinery and lipid metabolism enzymes, placing UBXD8 in a central position to globally coordinate neutral lipid metabolism in both organelles. Moreover, we found that UBXD8 recruitment of the AAA ATPase p97/VCP to LDs lead to a striking increase in LD abundance by impairing the rate of LD turnover. The most direct mechanism by which UBXD8 could suppress LD turnover would be to inhibit ATGL, the lipase that catalyzes the rate-limiting step in lipolysis, and an interaction between UBXD8 and ATGL detected in our proteomics studies was confirmed by endogenous co-immunoprecipitation. Given the established role for UBXD8 in protein degradation, we were surprised that although ATGL undergoes metabolically-regulated proteasomal degradation, its steady-state level, half-life, and LD association were unaffected by overexpression of UBXD8 or UBAC2. Instead, we found that ATGL is present in mutually exclusive complexes with either UBXD8 or its endogenous activator CGI-58, and co-immunoprecipitation and bimolecular fluorescence complementation experiments revealed that UBXD8 tonically represses the allosteric activation ATGL by inhibiting the association of ATGL and CGI-58. Together, our data identify a fundamental mechanism by which the unique compositions of the ER and LD proteomes are preserved/established despite sharing a common membrane of origin, and uncover an unrecognized regulatory role for UBXD8, UBAC2, p97/VCP and ubiquitin in cellular fat metabolism.

1382

#### **Live Cell Analysis of Lipid Droplet Biogenesis Using the Hepatitis C Virus NS5A Protein.**

*M. Lovelle<sup>1</sup>, I. Nevo-Yassaf<sup>1</sup>, Y. Yaffe<sup>1</sup>, M. Kozlov<sup>2</sup>, E. Sklan<sup>3</sup>, K. Hirschberg<sup>1</sup>; <sup>1</sup>Pathology, Tel Aviv University, Tel Aviv, Israel, <sup>2</sup>Physiology and Pharmacology, Tel Aviv University, Tel Aviv, Israel, <sup>3</sup>Human Microbiology, Tel Aviv University, Tel Aviv, Israel*

Lipid droplets (LDs) are the principal organelles for the storage of neutral lipids and cholesterol esters in eukaryotes. Considered for a long time as mere inert deposits, LDs are now conceived as dynamic organelles implicated in numerous biological processes in health and disease. Several RNA viruses have been shown to use host LDs at different steps of the viral life cycle. Particularly, important discoveries indicate an essential role for lipid droplets in the Hepatitis C Virus (HCV) replication and assembly. Despite the progress in lipid-droplets research, many fundamental questions are still not resolved. The molecular mechanisms that underlie LD formation, growth and movement as well as interaction with other organelles remain for the most part unclear. The most widely accepted model for LD formation postulates the synthesis and accumulation of neutral lipids between the leaflets of the endoplasmic reticulum (ER) membrane. A nascent lipid droplet emerges that is enclosed in a monolayer originating from the cytosolic leaflet. Using the fluorescently tagged, LD-binding non-structural protein 5A (NS5A) of HCV, we visualized LD biogenesis and maturation for the first time in living intact cells. NS5A binds ER membranes and partitions to the surface of triglyceride accumulations that constitute LD precursors. The putative dynamic LD precursor elements were identified as worm-like structures moving back and forth to the cell periphery. At the ER periphery, LDs bud and subsequently move slowly towards the cell center. Nascent LDs go through recurring homotypic fusions that lead to formation of mature LDs. We are currently assessing the role of Rab1 and its GAP TBC1D20 in LD biogenesis. These proteins interact with NS5A and are part of the HCV-host interface.

1383

**Lipidated ApoB degradation and the ER-LD juncture.**

M. Suzuki<sup>1</sup>, Y. Ohsaki<sup>1</sup>, J. Cheng<sup>1</sup>, T. Fujimoto<sup>1</sup>; <sup>1</sup>Department of Anatomy and Molecular Cell biology, Nagoya University Graduate School of Medicine, Nagoya, Japan

In the hepatocyte, lipids stored in LDs are utilized preferentially to synthesize very low-density lipoproteins (VLDL). Apolipoprotein B (ApoB), the principal protein of VLDL is lipidated cotranslationally by the microsomal triglyceride transfer protein (MTP) activity in the ER. When the lipidation process is perturbed, nascent ApoB is subjected to the ER-associated degradation (ERAD). On the other hand, lipidated ApoB becomes mature VLDL by acquiring additional lipids in the secretory compartment, but it is degraded in the ER and/or post-ER compartments under certain conditions. Macroautophagy has been reported as a possible post-ER degradation mechanism, but other mechanisms are also likely to be involved.

We previously reported that ubiquitylated ApoB accumulated in lipid droplets (LDs) when proteasomes and/or autophagy were suppressed, and proposed that LDs function as a platform of ApoB degradation. A further study showed that ApoB in LDs was lipidated and that the ApoB-laden LDs and the ER cistern formed an amalgamation structure called gApoB-crescent. The result raised the possibility that the ApoB-crescent is related to ERAD of lipidated ApoB.

To elucidate the molecular mechanism of ApoB degradation around LDs, we searched for proteins that are engaged in the process and identified UBXD8, p97 and Derlin-1. In Huh7 cells, UBXD8 mainly localizes in LDs, whereas Derlin-1 is a putative dislocon in the ER. Nonetheless they bound each other in the vicinity of LDs. Knockdown of UBXD8 reduced p97 recruitment to LDs, increased ApoB-crescents, and caused accumulation of ubiquitylated ApoB in LDs. Knockdown of Derlin-1 also increased ApoB-crescents, and suppressed the interaction between ApoB and UBXD8. However, the amount of ApoB cross-linked with ADRP was increased by UBXD8 knockdown, whereas it was decreased by Derlin-1 knockdown. These results suggested that lipidated ApoB is dislocated from the ER lumen to the LD surface for proteasomal degradation and that Derlin-1 and UBXD8 are engaged in the pre- and post-dislocation step, respectively.

**A conserved ER-membrane protein complex facilitates phospholipid exchange between the ER and mitochondria.**

S. Lahiri<sup>1</sup>, J. T. Chao<sup>2</sup>, B. P. Young<sup>2</sup>, S. Tavassoli<sup>2</sup>, C. J. Loewen<sup>2</sup>, W. A. Prinz<sup>1</sup>; <sup>1</sup>LCMB, NIDDK, Bethesda, MD, <sup>2</sup>University of British Columbia, Vancouver, BC, Canada

Mitochondria are critical cellular components that are needed for energy production, lipid metabolism, and apoptosis. Mitochondrial membrane biogenesis requires the import of proteins and lipids. Most lipids are synthesized in the endoplasmic reticulum (ER) and transferred to different cellular compartments by vesicular trafficking. Interestingly lipid trafficking from the ER to mitochondria has been found to be non-vesicular as it is energy independent and does not require any cytosolic protein in vitro. It has long been thought that lipids are exchanged between the ER and mitochondria at regions of close contact between these organelles. However, the mechanism of transport and the proteins responsible for tethering the ER and mitochondria have not been determined. Here, we devised a novel genetic screen in *S. cerevisiae* to identify proteins needed for lipid exchange between the ER and mitochondria. Among the proteins we found were all six members of an evolutionarily conserved complex named ER-membrane protein complex (EMC). Deletion of multiple EMC genes resulted in a significant reduction in the transport of phosphatidylserine (PS) from the ER to mitochondria. The EMC-mutants showed growth retardation and loss of mitochondrial function, as they were unable to grow on a nonfermentable carbon source. Cells lacking EMC proteins and a protein that is a member of a

recently described complex that tethers ER and mitochondria (the ER-mitochondria encounter structure, ERMES complex) were not viable. Moreover in this strain, for the first time, we observed ER to mitochondria PS transfer to be almost completely abolished. The PS transport defect along with the growth defect could be rescued by the expression of an artificial ER-mitochondrial tethering protein. Together, these findings suggest that the EMC-proteins along with the EREMS-complex mediate ER to mitochondria PS transport by promoting membrane tethering between these two organelles. They also conclusively establish that lipid transport from the ER to mitochondria is an essential cellular process. Whether the EMC and ERMES complexes directly facilitate lipid exchange between the ER and mitochondria or simply tether these organelles remains a topic for future investigation.

**Erlins are part of an ER macromolecular assembly regulating cellular cholesterol levels.**

*M. D. Huber<sup>1</sup>, P. W. Vesely<sup>1</sup>, L. Gerace<sup>1</sup>; <sup>1</sup>Department of Cell Biology, The Scripps Research Institute, La Jolla, CA*

Cellular levels of cholesterol, a key component of biological membranes, are controlled by cholesterol sensing machinery in the ER. This involves the sterol binding protein Scap, which associates with the inactive precursor forms of sterol regulatory element binding protein transcription factors (SREBPs). Under cholesterol sufficiency, the SREBP/Scap complex is retained in the ER by binding to Insig. Below a critical ER cholesterol threshold, SREBP/Scap dissociates from Insig, allowing subsequent proteolytic activation of SREBPs in the Golgi.

Erlin-1 and -2 are heteromultimeric proteins of the ER that have been previously implicated in the proteasomal degradation of several ER proteins. These include 3-hydroxy-3-methylglutaryl-CoA reductase, the rate limiting enzyme of the sterol biosynthesis pathway. However, whether erlins directly affect cellular lipid homeostasis is not known. Here we show that erlin-1 and -2 are directly involved in cellular cholesterol regulation. We found that downregulation of erlins aberrantly activated SREBPs and their target genes in cells grown under sterol sufficiency. This was accompanied by substantial accumulation of cellular cholesterol. Using immunoprecipitation, in vivo crosslinking and colocalization studies we determined that erlins are physically associated with the SREBP machinery. Furthermore, recombinant erlins bound cholesterol selectively and with high cooperativity. FRAP analysis and sucrose gradient centrifugation showed that the diffusional mobility and size of the erlin complex are modulated by changes in ER cholesterol levels, suggesting that the erlin-cholesterol interaction is relevant in a cellular context.

Together our results indicate that erlins are cholesterol responsive proteins that directly regulate the SREBP machinery. Our data supports the notion that erlins help to specify a cholesterol-enriched domain in the ER that constitutes a regulatory environment for the cholesterol sensing machinery. The cooperative binding of cholesterol to erlins could contribute fundamentally to the previously observed switch-like behavior of the SREBP machinery in response to changes in ER cholesterol.

**Dynamic regulation of endoplasmic reticulum-plasma membrane junctions monitored by a genetically-encoded fluorescent marker.**

*C-L. Chang<sup>1</sup>, J. Liou<sup>1</sup>; <sup>1</sup>UT Southwestern Medical Center at Dallas, Dallas, TX*

Many cellular functions, including secretion, cell migration and differentiation, depend on store-operated calcium entry (SOCE). A decrease of endoplasmic reticulum (ER) calcium and the subsequent activation of an ER calcium sensor, STIM1, initiate SOCE. Reduced ER calcium induces STIM1 to oligomerize and translocate to the ER-plasma membrane (PM) junctions

where the two membranes are closely apposed to each other within 20nm. The calcium channel Orai1 in the PM is then activated, which enables SOCE. Although ER-PM junctions have been observed by electron microscopy (EM) in many cell types, little is known about their formation and regulation. To help understand the dynamic regulation of ER-PM junctions, we first generated a genetically-encoded fluorescent marker of ER-PM junctions based on the translocation mechanism of STIM1. We have confirmed that this marker selectively localized to ER-PM junctions using confocal microscopy and EM, and that it did not perturb STIM1 and Orai1 translocation to the junctions nor disrupt SOCE. This marker has enabled us to visualize and track ER-PM junctions using live-cell total internal reflection fluorescence (TIRF) microscopy. We found that approximately two hundred stable ER-PM junctions exist in the adhesion surface of a single HeLa cell at resting state. During SOCE, a significant up-regulation of ER-PM junctions was observed. We further employed a cytosolic calcium chelator and a cytosolic caged-calcium reagent to demonstrate that the up-regulation of ER-PM junctions required an increase of cytosolic calcium but not a decrease of ER calcium. In summary, we have generated a marker enabling us to track the dynamic change of single ER-PM junctions in live cells and discovered cytosolic calcium-dependent regulation of ER-PM junctions.

1387

**Ceramide synthase 2 down-regulation affects Golgi membranes and leads to G2 cell cycle arrest.**

*S. D. Spassieva<sup>1</sup>, L. M. Obeid<sup>2</sup>; <sup>1</sup>Medicine, Medical University of South Carolina, Charleston, SC, <sup>2</sup>Stony Brook University, Stony Brook, NY*

Ceramide synthase 2 (CerS2), an endoplasmic reticulum resident, is one of the six mammalian ceramide synthases and it is responsible for the synthesis of very-long chain (VLC) ceramides (C22-C26). Following our previous finding that CerS2 down-regulation leads to G2/M cell cycle arrest, we aimed at understanding the underlying mechanism. Aphidicolin, a reversible DNA polymerase inhibitor, was used to synchronize the cells and study their cell cycle progression in relation to CerS2 down-regulation. First, we tested whether CerS2 expression or VLC sphingolipid levels changed when cells re-assumed cell cycle progression after synchronization with aphidicolin. The data showed that there was no significant change in CerS2 expression, but VLC sphingolipids increased significantly after cells re-assumed cell cycle progression. In addition, our flow cytometry results showed that CerS2 depleted cells re-assumed cell cycle progression after an aphidicolin cell cycle block at a slower rate compared to control cells. Our previous work has shown that CerS2 down-regulation results in not only a decrease in VLC sphingolipids, but also in a compensatory increase in long-chain sphingolipids (C14-C20) leading to aberrant membrane composition. Next, we tested whether altered membrane composition in CerS2 depleted cells affects membrane organization and dynamics during cell division. Membrane organization and dynamics, especially Golgi fragmentation, are important for proper execution of mitosis. Our confocal and electron microscopy data revealed that CerS2 depleted cells showed intracellular membrane disorganization and aberrant mitotic fragmentation of Golgi. In addition, in order to distinguish whether the cell cycle defect was in G2 or M phase we treated CerS2 depleted cells with paclitaxel, a known M phase cell cycle blocker. Our results showed that there was no difference in the cell cycle profile of the cells treated with CerS2 siRNA alone or in combination of paclitaxel, suggesting that CerS2 down-regulation resulted in cell cycle interruption preceding paclitaxel cell cycle block in M phase. In conclusion, our results suggest that CerS2 depletion leads to G2 cell cycle arrest likely because of affecting Golgi organization and membrane dynamics.

1388

**Drosophila wound healing: A localized process of regeneration**

M. T. Juarez<sup>1</sup>, W. McGinnis<sup>1</sup>; <sup>1</sup>Cell and Developmental Biology, University of California, San Diego, La Jolla, CA

An epidermal wound provides signals that initiate a variety of localized responses, some of which act to regenerate and repair the breach in the epidermal barrier. The *Drosophila melanogaster* embryonic epidermis provides an excellent system to discover new genes that regulate a conserved, wound-healing processes. Using fluorescent epidermal "wound" reporters that are locally activated around wound sites, we have screened almost 5,000 *Drosophila* mutants for functions required to activate or delimit wound-induced transcriptional responses to a local zone of epidermal cells. Among the seven new genes required to delimit the spread of wound responses are *Flotillin-2* and *Src42A*. These two genes are also sufficient, when overexpressed at high levels, to inhibit wound-induced transcription in epidermal cells. One new gene required to activate epidermal wound reporters encodes Dual oxidase, an enzyme that produces hydrogen peroxide. We also find that four biochemical treatments (a serine protease, a Src kinase inhibitor, methyl- $\beta$ -cyclodextrin, and hydrogen peroxide) are sufficient to globally activate epidermal wound response genes in *Drosophila* embryos. Several of the biochemical treatments regulate the wound reporters in a complementary manner that parallels the phenotypes observed in the mutants identified from the genetic screen. We explore the epistatic relationships among the factors that induce or delimit the spread of epidermal wound signals. Our results define new genetic functions, and the interactions among them, which regulate the local transcriptional response to puncture wounds to mount a transcriptional response, mediating local repair and regeneration. Many stages of *Drosophila* development are suitable to assay regeneration. To gain more insight into the biological role of inhibiting wound response gene activation, we are testing new wound assays at later stages during *Drosophila* development. Additional data from our genetic screen highlights the function vesicle transport in promoting the localization of epidermal wound reporters. Preliminary data with a lipid raft stain suggests that lipid raft dynamics contribute to a localized wound response. The balance between activator and inhibitor signals may depend on the function of a *Flotillin-2*, *Src42A*, and *Duox* associated microdomain.

**Oligomerization and targeting to the epithelial basolateral surface of occludin is mediated by the MARVEL transmembrane motif.**

Y. Yaffe<sup>1</sup>, J. Shepshelovitch<sup>1</sup>, I. Nevo-Yassa<sup>1</sup>, A. Yeheske<sup>2</sup>, M. Pasmanik-Cho<sup>2</sup>, K. Hirschberg<sup>1</sup>; <sup>1</sup>Pathology, Tel Aviv University, Sackler Medical School, Tel Aviv, Israel, <sup>2</sup>Bioinformatics Unit, Tel Aviv University, G.S.W. Faculty of Life Sciences, Tel Aviv, Israel

The MARVEL motif is an oligomerization and membrane lipid interacting module comprised of four transmembrane helices. MARVEL proteins are associated with the localization to or formation of diverse membrane subdomains via interaction with the proximal lipid environment. The functions of the Ocln MARVEL motif were never addressed. Bioinformatics sequence analyses and sequence based in-silico-structural analysis demonstrated that the MARVEL domain of Ocln protein family has distinct evolutionarily conserved features that are consistent with its basolateral membrane localization. Live cell microscopy, fluorescence resonance energy transfer (FRET) and bimolecular fluorescence complementation (BiFC) were used to analyze the intracellular distribution and self-association of fluorescent protein-tagged full-length human Ocln or the Ocln MARVEL motif excluding the cytosolic C and N termini (amino acids 60–269, FP-MARVEL-Ocln). FP-MARVEL-Ocln efficiently arrived at the plasma membrane (PM) and was sorted to the basolateral PM in filter-grown polarized MDCK cells. An Ocln chimera with its

MARVEL replaced by the apically targeted MAL proteolipid was redirected to the apical surface and disrupted epithelial polarity. A series of conserved aromatic amino acids within the MARVEL domain were found to be associated with Ocln dimerization and prevention of aggregate formation using BiFC. FP-MARVEL-Ocln inhibited membrane pore growth during Triton-X-100 – induced solubilization and was shown to increase the membrane ordered state using the laurdan lipid dye. These data demonstrate that the Ocln MARVEL domain mediates self-association and correct sorting to the basolateral membrane.

**Transmembrane potential modulates microdomain plasma membrane organization.**

J. Malinsky<sup>1</sup>, J. Vecer<sup>2</sup>, P. Vesela<sup>1</sup>, W. Tanner<sup>3</sup>, P. Herman<sup>2</sup>; <sup>1</sup>Microscopy Unit, Institute of Experimental Medicine AS CR, Prague 4, Czech Republic, <sup>2</sup>Faculty of Mathematics and Physics, Charles University, Prague 2, Czech Republic, <sup>3</sup>Institute of Cell Biology and Plant Physiology, University of Regensburg, Regensburg, Germany

Stability of highly ordered, sphingolipid-rich gel microdomains recently described in the plasma membrane of *S. cerevisiae* [1] was studied in response to dissipation of the plasma membrane potential. Fluorescent trans-Parinaric Acid (tPA) partitioning preferentially to ordered domains was used as a sensitive reporter of highly ordered lipid microenvironment [2]. 1,6-Diphenyl-1,3,5-Hexatriene (DPH) served for monitoring of overall membrane order. An effect of various transmembrane-potential modulation techniques was studied on cells in logarithmic and stationary growth phases. Significant drops of long lifetime component in tPA fluorescence, indicating decreased fraction of ordered plasma membrane microdomains, were detected following depolarization treatments of living BY4742 cells in suspension. Homogenization of the lipid microenvironment in the depolarized membrane did not significantly affect overall membrane order reported by DPH fluorescence anisotropy. We conclude that decrease of transmembrane potential correlates with decreased amount of gel sphingolipid microdomains in the yeast plasma membrane. This conclusion accents the role of transmembrane potential in microdomain organization of plasma membrane and complements our earlier observation of membrane depolarization-gated decomposition of ergosterol-rich MCC (Membrane Compartment of Can1) microdomains [3].

**Synthesis of Lipid Rafts-Like Microdomains is Important for Giardial Encystation.**

A. De Chatterjee<sup>1</sup>, A. Varela-Ramirez<sup>1</sup>, S. Roychowdhury<sup>1</sup>, S. Das<sup>1</sup>; <sup>1</sup>Biological sciences, The University of Texas at El Paso, El Paso, TX

Giardiasis, caused by *Giardia lamblia*, is widespread throughout the world. This intestinal parasite, exists in two morphologic forms—trophozoites and cysts. While trophozoites colonize in the small intestine of humans and produce infections, cysts transmit the disease via contaminated water and food. Encystation (or stage-specific differentiation into cysts) is a critical step in the giardial life cycle that allows this parasite to survive in the environment before infecting a new host. Despite all of this information, the mechanism of encystation is yet to be elucidated. For example, it is not known how encystation-specific signals (ESSs) are generated and transduced across the membranes that trigger the cyst formation. Here, we report that *Giardia* synthesizes lipid raft (LR)-like membrane clusters, which could serve as platforms to

transmit ESSs generated in the small intestine. The LR synthesis in different stages of giardial life cycles was monitored by labeling Giardia with fluorescent-conjugated cholera toxin that binds to GM1 ganglioside present in the LR. Nystatin (27  $\mu\text{M}$ ) and filipin III (7.6  $\mu\text{M}$ ), two potent LR inhibitors, blocked the giardial LR synthesis completely. The effects of LR inhibitors on the biogenesis of encystation-specific vesicles (ESVs) and cyst production were evaluated by labeling the cells with anti-trophozoite and anti-cyst antibodies. We found that LR inhibitors significantly interrupted the ESV biogenesis and cyst production. Giardia cultured in a medium containing dialyzed fetal bovine serum (DFBS) with reduced cholesterol also interfered with encystation, and this could be reversed by adding cholesterol to the culture medium. Taken together, our results suggest that Giardia, although considered a primitive eukaryote, has the ability to synthesize raft-like domains, and that these microdomains are essential for encystation and cyst production. We propose that the lipid rafts in Giardia could serve as an ideal target for developing anti-giardial therapy.

**Transient GPI-anchored protein homodimers are units for raft organization and function.**

*K. G. Suzuki<sup>1</sup>, R. S. Kasai<sup>1</sup>, K. M. Hirose<sup>1</sup>, Y. L. Nemoto<sup>1</sup>, M. Ishibashi<sup>1</sup>, Y. Miwa<sup>2</sup>, T. K. Fujiwara<sup>1</sup>, A. Kusumi<sup>1</sup>; <sup>1</sup>Institute for Integrated Cell-Material Sciences, Kyoto University, Kyoto, Japan, <sup>2</sup>University of Tsukuba, Tsukuba, Japan*

The dynamic organization of raft-associated glycosylphosphatidylinositol-anchored protein (GPI-APs) and their stimulation-induced changes in the plasma membrane were investigated, by applying advanced single-molecule fluorescent imaging methods, including single-molecule FRET, simultaneous, dual-color single-molecule tracking, and bimolecular fluorescence complementation. In resting cells, almost all of the GPI-APs investigated in the present research (CD59, DAF, and Thy1) exhibited rapid diffusion in the plasma membrane, and at the same time they continually form transient (~200 ms) homodimers through ectodomain protein interactions, stabilized by the presence of the GPI-anchoring chain and cholesterol (termed GPI-AP homodimer rafts or just homodimer raft for short). Prolonged heterodimers did not form, suggesting a fundamental role for the specific ectodomain protein interaction. In other words, raft-lipid interaction alone, without protein-protein interaction cannot induce 200-ms prolonged homodimer rafts. Since such homodimer rafts were found for three GPI-APs, i.e., CD59, DAF and Thy-1, it is concluded that the dynamic homodimers may be general features of GPI-APs. Because there are no sequence homologies among these molecules, these results suggest that, during the course of evolution inducing various amino acid changes, the properties of forming homodimers rafts are preserved, inferring the critical role of homodimers rafts for the function of GPI-APs.

Under higher physiological expression conditions, homodimers coalesce to form hetero- and homo-GPI-AP oligomer rafts by raft-based lipid interactions. Upon ligation, CD59 homodimer rafts formed stable homotetramer rafts conjugated with its transmembrane ligand, membrane attack complex, which triggered intracellular  $\text{Ca}^{2+}$  responses. Therefore, naturally, this signaling process depended on GPI-anchorage and cholesterol. Transient homodimer rafts are likely one of the key basic units for organization and function of raft domains containing GPI-APs.

1393

**Eisosomes coordinate the organization and composition of the yeast plasma membrane.**

*R. Kabeche<sup>1</sup>, J. B. Moseley<sup>1</sup>; <sup>1</sup>Geisel School of Medicine at Dartmouth, Hanover, NH*

Compartmentalization of the plasma membrane underlies spatiotemporal control of diverse signaling pathways. Eisosomes are prominent structures in the plasma membrane of yeast

cells, yet the function of eisosomes has remained mysterious. We find that fission yeast eisosomes are linear, filamentous structures comprised of the BAR domain protein Pil1 and the peripheral membrane protein Sle1. Pil1 forms the core of fission yeast eisosomes and self-assembles into filaments *in vitro*. Sle1 is required for proper assembly of Pil1 filaments in cells, and contains separable domains for targeting to eisosomes and the plasma membrane. We used this initial characterization to perform a series of genomic screens aimed at elucidating the function of eisosomes. Surprisingly, we find that both Pil1 and Sle1 function with a specific synaptojanin isoform to regulate phosphoinositide levels in cells. Our genetic dissection of this pathway indicates that eisosomes control both the composition and spatial organization of cellular membranes. Further, we show that eisosome-dependent organization of the plasma membrane provides spatiotemporal control of conserved signaling pathways such as TORC2. Our findings indicate that eisosomes are multiprotein structures that control signaling pathways by coordinating the organization and composition of cellular lipids.

## Receptors, Transporters, and Channels

1394

### Identify STIM1 Associated Proteins by Tandem Affinity Purification in Mammalian Cells.

B. Hao<sup>1</sup>, H. Lee<sup>1</sup>, J. Yue<sup>1</sup>; <sup>1</sup>Department of Physiology, The University of Hong Kong, Hong Kong, China

Store operated Ca<sup>2+</sup> entry (SOCE) is well characterized as the key Ca<sup>2+</sup> influx process in non-excitable cells. STIM1 and Orai1 are the essential components enabling the reconstitution of Ca<sup>2+</sup> release activated Ca<sup>2+</sup> (CRAC) channels underlying SOCE activity. STIM1, as an ER Ca<sup>2+</sup> sensor, translocates within ER membrane upon store depletion to ER-PM junction, where it could interact with channel pore subunit, Orai1. Here, we performed Flag and His tagged tandem affinity purification (TAP) to identify STIM1 associated proteins in HeLa cells. Among several hits identified by mass spectrometric analyses, 3 candidates, including S1, S2, and S3, were selected as target proteins for further characterization. S1 only existed in the Stim1 complexes when cells were treated with thapsigargin or histamine in the absence of extracellular Ca<sup>2+</sup>, while S2 and S3 only existed in the Stim1 complexes when cells were incubated in the presence of extracellular Ca<sup>2+</sup>. Subsequently, these 3 candidate genes were individually knocked-down in HeLa cells. In addition, stably cell line overexpressing myc tagged candidate genes were established. The interactions between STIM1 and candidate proteins were validated by coimmunoprecipitation. We are currently examining the function of candidate proteins on SOCE activity in HeLa and Jurkat cells.

1395

### Poor Binding to Serum Proteins may Facilitate Ricin Cellular Toxicity.

J. A. Smith<sup>1</sup>, U. Okafor<sup>1</sup>, J. Hardy<sup>1</sup>, O. A. Vanderpuye<sup>1</sup>; <sup>1</sup>Forensic Science, Albany State University, Albany, GA

The plant protein ricin is one of the most toxic substances known and has no antidote. Toxicity occurs after binding to cell surface galactose and endocytosis. Blood contains high concentrations of galactosylated glycoproteins and thus potentially could compete with ricin binding to cells. It is hypothesized that ricin binds preferentially to cell surfaces rather than fluid phase blood serum glycoproteins. Binding to whole human serum and serum glycoproteins: transferrin, alpha2HSGP and IgG were tested for ricin, Ricinus communis agglutinin-I (RCA-I), Sambucus nigra agglutinin (SNA) and Concanavalin A (ConA) lectins. Staining of nitrocellulose

blots of these proteins revealed that ricin bound poorly to serum when compared with RCA-I, SNA and ConA. In microtiter plate binding assays, ricin also bound poorly to serum when compared with RCA-I. Experiments were done to optimize A549 cell-based microtiter plate binding assays for RCA-I for testing of competition of cell surface lectin binding by serum proteins. In conclusion, ricin binds poorly to serum proteins compared to other lectins including RCA-I which has been described as having similar sugar specificity. These observations are consistent with the idea that serum glycoproteins would not effectively modulate ricin toxicity by competing with its binding to cell surfaces.

1396

**Pro-Inflammatory Cytokine Secretion is Suppressed by TMEM16A or CFTR Channel Activity in Human Cystic Fibrosis Bronchial Epithelia.**

G. Veit<sup>1</sup>, F. Bossard<sup>1</sup>, J. Goepf<sup>1</sup>, A. S. Verkman<sup>2</sup>, L. J. Galletta<sup>3</sup>, J. W. Hanrahan<sup>1</sup>, G. L. Lukacs<sup>1</sup>; <sup>1</sup>Physiology, McGill University, Montreal, QC, Canada, <sup>2</sup>Medicine and Physiology, University of California, San Francisco, CA, <sup>3</sup>Lab. di Genetica Molecolare, Istituto Giannina Gaslini, Genova, Italy

Cystic fibrosis (CF) is caused by the functional expression defect of the CF transmembrane conductance regulator (CFTR), a cAMP-stimulated chloride channel at the apical plasma membrane. Impaired bacterial clearance of airway epithelia together with hyperactive innate immune response are hallmarks of the CF lung disease and the primary cause of morbidity and mortality, yet the existence of and mechanism accounting for the innate immune defect that occurs prior to infection remain controversial.

Here we show that inducible expression of either CFTR or the calcium-activated chloride channel TMEM16A attenuate the secretion of the pro-inflammatory cytokines IL-6, IL-8, CXCL1 and CXCL2 in two human respiratory epithelial models (CFBE41o- and NCI-H441) under air-liquid, but not liquid-liquid interface culture condition. Expression of wild-type but not the dysfunctional G551D-CFTR indicate that the secretion of neutrophil chemoattractant IL-8 was inversely proportional to the CFTR and TMEM16A channel activity in *cfr*<sup>ΔF508/ΔF508</sup> immortalized and primary human bronchial epithelia. These results were confirmed using CFTR-specific small molecule inhibitors and activators. Likewise, direct but not P2Y receptor activated TMEM16A attenuated the IL-8 secretion in CFBE41o- epithelia. Thus augmented proinflammatory cytokine secretion caused by defective anion transport at the apical membrane contributes to the excessive and persistent lung inflammation in CF and, perhaps in other respiratory diseases associated with documented downregulation of CFTR (e.g. chronic obstructive pulmonary disease). Direct pharmacological activation of TMEM16A offers a potential therapeutic strategy to correct the hyperinflammatory phenotype of CF airway epithelia.

1397

**Sphingolipid biosynthesis and inflammatory signaling in asthma.**

S. Ramachandran<sup>1</sup>, A. Engel<sup>1</sup>, G. Barton<sup>1</sup>, J. Thorne<sup>1</sup>; <sup>1</sup>University of California Berkeley, Berkeley, CA

Single nucleotide polymorphisms (SNPs) located within the human chromosomal region 17q21 are strongly associated with the incidence of inherited (so-called early-onset or childhood) asthma. These SNPs lead to increased transcription of nearby genes, including ORMDL3. Studies in budding yeast *Saccharomyces cerevisiae* identified the yeast Ormdl3 orthologs, Orm1 and Orm2, as components of and negative regulators of the enzyme complex, serine:palmitoyl-CoA transferase (SPT), which catalyzes the first step in sphingolipid biosynthesis. Ormdl3 and its paralogs Ormdl1 and Ormdl2 likewise associate with and

negatively regulate mammalian SPT. Given its inhibitory function, higher Ormdl3 level (in the asthma patients carrying the implicated SNPs) should diminish sphingolipid biosynthesis, perhaps causing an imbalance in the sphingolipid content of the plasma membrane, as compared to its glycerolipid composition. Sphingolipid deficiency impairs endocytosis in yeast. If Ormdl3 over-production causes a deficiency in membrane sphingolipids and results in a similar defect in endocytic function, signaling from cell surface receptors of the innate and adaptive immune systems, such as TLRs and the cytokine receptors, that have been implicated in asthma pathogenesis may not be down-regulated efficiently. If so, this scenario could provide an underlying mechanistic explanation for the chronic inflammation of bronchial epithelial tissue that is a hallmark of asthma. As an initial test to this overall hypothesis, we found that treatment of RAW macrophages with myriocin, a small-molecule inhibitor of SPT, blocked LPS-induced internalization of TLR4, but had a significantly weaker effect on fluid-phase pinocytosis (as judged by the rate of uptake of fluorescently-labeled dextran), suggesting that sphingolipid deficiency has a more severe effect on receptor-mediated endocytosis. Analysis of total sphingoid base content by HPLC demonstrated that myriocin treatment was effective in lowering cellular sphingolipid content. Thus, these preliminary data suggest that a deficiency of membrane sphingolipids could potentially influence the function of antigen-sensing immune receptors. We have raised antibodies against mammalian Ormdl3 and its paralogous proteins and are using them to assess the efficiency of various strategies to over-produce Ormdl3 to directly test whether elevated Ormdl3 levels leads to any detectable reduction in sphingolipid content and to a measureable defect in endocytosis.

1398

**Characterization of gene expression in retinal pigmented epithelium of Basigin null mice.**

*F. Warda<sup>1</sup>, L. Shoshan<sup>2</sup>, J. D. Ochrietor<sup>1</sup>; <sup>1</sup>Biological Sciences, University of North Florida, Jacksonville, FL, <sup>2</sup>Physiology, Cinevestav-IPN, Mexico City, Mexico*

The Basigin null mouse is characterized as blind from the time of eye opening with degeneration of the photoreceptor cells beginning at eight weeks of age and continuing until complete ablation of the cell layer by eight months. Numerous studies have targeted the neural retina of these animals and indicate that a metabolic deficiency underlies the retinal dystrophy of Basigin null mice. Specifically, it is thought that inappropriate expression of monocarboxylate transporter 1 (MCT1) by photoreceptor cells and Müller cells accounts for the lack of photoreceptor function. Although it has been established that MCT1 expression in the Basigin null retinal pigmented epithelium (RPE) is altered, little else is known about the biochemistry and physiology of those cells. Therefore, the purpose of this study was to evaluate the expression of several transporters and enzymes within normal and Basigin null RPE as a first step toward understanding the role played by RPE in the Basigin null retinal dystrophy. Immunohistochemistry using antibodies specific for Basigin, MCT1, carbonic anhydrase (CA) XIV, and the Na<sup>+</sup>/K<sup>+</sup> ATPase were performed on frozen sections of normal and Basigin null eye cups. In accordance with previous studies, it was determined that neither Basigin nor MCT1 is expressed at the RPE plasma membrane of Basigin null mice. Expression of CA-XIV was unaltered in the tissue. Most notably, expression of Na<sup>+</sup>/K<sup>+</sup> ATPase changed from apical-only to both apical and basal portions of the RPE. Although the significance of mislocalization of the Na<sup>+</sup>/K<sup>+</sup> ATPase on Basigin null RPE cells is not yet fully understood, it can be inferred that the cellular environment of the neural retina of Basigin null mice is negatively affected by the change in expression of this transporter protein.

1399

### **Nuclear AT1/AT2 Receptors Mediate Angiotensin II Induced Fibrosis-related Gene Expression Expression Changes in Cardiac Fibroblasts.**

A. Tadevosyan<sup>1</sup>, G. Vaniotis<sup>1</sup>, C. Merlen<sup>1</sup>, A. Nante<sup>2</sup>, T. E. Hébert<sup>3</sup>, B. G. Allen<sup>1,3</sup>, S. Nattel<sup>1,3</sup>;  
<sup>1</sup>Medicine, Montreal Heart Institute, Montreal, QC, Canada, <sup>2</sup>Biotechnology Research Institute, Montreal, QC, Canada, <sup>3</sup>Pharmacology, McGill University, Montreal, QC, Canada

Background: Angiotensin II (Ang-II) is central to arrhythmia-promoting fibroblast (FB) remodeling. Classically, Ang-II action is attributed to cell membrane receptors and intracellular second messengers. Here, we examined whether nuclear-delimited AT1 (AT1R) and AT2 (AT2R) receptors influence fibrosis-associated gene expression in atrial FBs and assessed underlying mechanisms. Methods: Canine atrial FBs were isolated. AT1R/AT2R localization was assessed by immunofluorescence and Western blot. Intact nuclei were purified by differential centrifugation. Nitric oxide (NO) production was measured via DAF-2 fluorescence, de novo RNA production by transcription initiation assay, and mRNA expression by qPCR. The expression of approximately 25,000 transcripts was analyzed in isolated nuclei using Agilent Rat Whole Genome microarrays. Results: AT1 and AT2 receptors colocalized with Topro 3 and Lamin A/C, indicating presence in FB nuclei. Ang-II dose-dependently induced de novo RNA synthesis in isolated cardiac nuclei. AT1R (L-162,313) and AT2R (CGP 42112A) specific ligands enhanced transcription initiation in FB nuclei (219±15\* cpm/ng DNA and 148±8\* cpm/ng DNA vs 69±9 control; n=5/group, \*P<0.05). IP3R1 Ca<sup>2+</sup>-channels and eNOS colocalized with AT1R/AT2R on the nucleus. Ang-II enhanced FB nuclear NO production, which was reduced 85%\* by the AT2R blocker PD123177 and 81%\* by the NO synthase inhibitor L-NAME, but not affected by AT1R blocker losartan. AT2R-induced transcription initiation was reduced 79%\* by L-NAME. AT1R-mediated transcription initiation was reduced 55%\* by the IP3R-channel blocker 2-APB (but not L-NAME). Ang-II exposure upregulated ECM-genes (collagen1 1.4-fold\*, fibrillin1 2.0-fold\*, laminin 1.8-fold\*) in isolated atrial FB nuclei while others (MMP2 0.24-fold\* and MMP9 0.59-fold\*) were downregulated. Ang-II also increased the transcription of cell-signaling genes like PLC (3.8-fold\*), IP3R1 (3.5-fold\*), and PDGF (2.5-fold\*). Conclusions: Our results indicate that Ang-II acts through nuclear receptors to regulate ECM and cell signaling genes central to FB remodeling. These nuclear-delimited actions may be important in arrhythmogenic substrate development and could provide novel pharmacological targets.

### **Existence of secretory granules in atrial and ventricular cardiomyocytes: Electron microscopic study of rat heart.**

Y. S. Hur<sup>1</sup>, S. H. Yoo<sup>1</sup>; <sup>1</sup>Department of Biochemistry, Inha University School of Medicine, Incheon, Korea

Secretory granules are signature organelle of all secretory cells. Hence, cells that contain secretory granules are naturally considered to be secretory cells. Deviating from the traditional view of cardiac cells as nonsecretory cells, atrial cardiomyocytes have been shown to contain secretory granules, whereby providing the concept of endocrine heart. Secretory granules from a variety of cell types contain not only the largest amounts of calcium in the cell but also function as the major IP<sub>3</sub>-dependent intracellular Ca<sup>2+</sup> store of secretory cells (reviewed Yoo, S.H., FASEB J. (2010) 24, 653). We have here investigated the distribution of secretory granules in both atrial and ventricular cardiomyocytes of rat heart using electron microscopy. Atrial secretory granules are not rare in the heart, which are often found clustered in limited regions of atrial cardiomyocytes. Similar to the secretory granules of traditional secretory cells atrial secretory granules also contain large concentrations of Ca<sup>2+</sup>. In contrast, secretory granules in ventricular cardiomyocytes are relatively rare although they also clearly exist in the cell; the

number of secretory granules in ventricular cardiomyocytes appears to be far less than that in atrial cells. Our results not only confirm the existence of secretory granules in atrial cardiomyocytes but also demonstrate the existence of secretory granules in ventricular cardiomyocytes with electron microscopy. These results strongly suggest that the endocrine heart is in close physiological tune with the rest of the organism through the signals detected in the form of the volume and pressure of and the molecules contained in the circulating blood.

**Uric acid crosses the placental barrier through paracellular route.**

*T. Kimura<sup>1</sup>, I. Uehara<sup>2</sup>, S. Tanigaki<sup>2</sup>, M. Iwashita<sup>2</sup>, H. Sakurai<sup>1</sup>; <sup>1</sup>Department of Pharmacology and Toxicology, Kyorin University School of Medicine, Tokyo, Japan, <sup>2</sup>Department of Obstetrics and Gynecology, Kyorin University School of Medicine, Tokyo, Japan*

High serum urate level is a good marker for pregnancy induced hypertension (PIH), which is a generic name of diseases that have hypertension and proteinuria in the late stage of pregnancy. However, how urate is handled in the placenta is still unknown. In this study, we examined serum urate levels in maternal blood and umbilical cord blood. We also investigated urate transport mechanisms using the placenta and a model cell culture system.

The maternal and umbilical cord blood samples and placentas were collected from patients undergoing caesarean section at Kyorin University Hospital after obtaining informed consents. Urate and creatinine concentrations were measured by enzyme method. Expressions of urate transporters were detected by RT-PCR and immunohistochemistry. Transcellular [<sup>14</sup>C]-urate uptake and paracellular [<sup>14</sup>C]-urate movement was measured in the monolayer of BeWo cells, a trophoblast-derived epithelial cancer cell line. Barrier function of tight junctions was judged by the transepithelial electrical resistance (TER) and permeability of 3000 dalton dextran.

There were no significant differences in serum urate levels between maternal blood and umbilical cord blood, suggesting that urate is freely moved in the placenta. The results of RT-PCR showed that mRNA of OAT4, OAT10, URATv1 and ABCG2 were expressed in the placenta. Immunohistochemistry revealed that ABCG2 was expressed at the maternal side of the syncytiotrophoblast, OAT4 was expressed at the embryonic side of syncytiotrophoblast, OAT10 was expressed at both sides of syncytiotrophoblast, URATv1-short isoform was expressed at the maternal side of the syncytiotrophoblast and endothelial cells, URATv1-long isoform was expressed in the endothelial cells, respectively. However, to our surprise, BeWo cells did not take up urate despite the fact that they expressed almost the same set of urate transporters as the syncytiotrophoblast. After confirming that BeWo cells formed functional tight junctions on the transwell based on the elevated TER and no permeability of dextran, urate transport between upper and lower transwell chambers was measured. Urate moved both directions through BeWo cell monolayers even when the cells were incubated at 4 °C, suggesting that urate is transported through paracellular route.

**Identification of a Novel Myristoylated Protein Required for the Proper Ciliary Localization of PKD-2.**

*J. E. Maguire<sup>1</sup>, M. M. Barr<sup>1</sup>; <sup>1</sup>Rutgers University, Piscataway, NJ*

The transient receptor potential polycystin (TRPP) channel PKD-2 and the polycystin-1 receptor LOV-1 constitute a putative mechanosensory complex that is required for *C. elegans* male mating behaviors. PKD-2 and LOV-1 localize to cilia found at the end of dendrites of male-specific sensory neurons, which include the CEMs in the head and the RnB and HOB neurons in the tail. Mutations in PKD1 and PKD2, the human homologs of *lov-1* and *pkd-2*, cause autosomal dominant polycystic kidney disease (ADPKD). The mammalian TRPPs localize to

cilia on renal epithelial cells. Hence we use *C. elegans* to identify genes required for polycystin ciliary localization.

The *cil-7(my16)* mutant was identified in a genetic screen for PKD-2::GFP ciliary localization [Cil] defective animals, (Bae, Lyman-Gingerich et al. 2008). In *cil-7(my16)*, we observe an abnormal accumulation of PKD-2::GFP in cilia and distal dendrites. With SNP mapping, deficiency mapping, and Whole Genome Sequencing, we determined that *my16* could be a mutation in either one of two ORFs. A fosmid or a single gene construct containing the second ORF rescued the *my16* Cil phenotype. We conclude that *my16* is a missense mutation in ORF2, which we hereafter refer to as *cil-7*.

*cil-7* encodes a protein that has orthologs in *Caenorhabditis* species, *S. kowakevskii*, *B. floridae*, and *D. melanogaster*. CIL-7 is predicted to have coiled-coil domains and an N-myristoylation pattern, where a myristoyl group would be added onto the second glycine. A large and/or hydrophobic residue in the myristoylation pattern is predicted to inhibit myristoylation (Wright, Heal et al. 2009). The missense mutation in the *cil-7(my16)* allele changes a Serine(3) into a Phenylalanine, most likely affecting the myristoylation state of CIL-7. We are exploring the role of myristoylation on CIL-7 localization and function.

CIL-7 is co-expressed and co-localized with PKD-2 in the CEM, HOB, and ray neurons. Additionally, *cil-7* is also expressed in the IL2 neurons of the core nervous system. The *cil-7* expression pattern is identical to the kinesin-3 KLP-6 that regulates intraflagellar transport in male-specific cilia (Morsci and Barr 2011). Consistent with a role in protein transport, functional CIL-7::GFP moves along dendrites. We are currently testing the hypothesis that CIL-7 regulates dendritic or ciliary protein trafficking, perhaps as an adaptor for KLP-6. We are interested in further characterizing the gene mutated in *my16* animals, and examining genetic interactions between *my16* and other components in the PKD pathway.

### Glycosylation determines sodium-calcium exchanger 3 subcellular distribution during the cell cycle.

T. Liu<sup>1</sup>, J. Zhao<sup>1</sup>, M. Nister<sup>1</sup>; <sup>1</sup>Department of Oncology-Pathology, Karolinska Institutet, Stockholm, Sweden

**Background:** Sodium-calcium exchanger (NCX), as a plasma membrane antiporter, plays an important role in maintenance of the intracellular Ca<sup>2+</sup> homeostasis. Although NCXs have been extensively studied in mammalian systems, the subcellular localization of different NCXs is still undetermined besides the fact that they are destined to be plasma membrane proteins. In this study, we tested the hypothesis that the subcellular localization of the NCX3 protein varies with the cell cycle phases in mammalian cells.

**Methods: Construction of plasmids and site-directed mutagenesis.** The cDNA containing the entire open reading frame (ORF) of the human NCX3 was previously cloned into the pcDNA3.1 expression plasmid, and recombinant NCX3-GFP was attained by polymerase chain reaction (PCR). Site directed mutagenesis was carried out using a protocol based on the QuikChange<sup>®</sup> Site-Directed Mutagenesis Kit (Stratagene). **Indirect immunofluorescence and live cell imaging.** Leica TCS SP5 II confocal system (Leica) and INU2 incubation system for microscopes (TOKAI HIT) constituted the integrated live cell imaging system. 100% pure CO<sub>2</sub> was supplied by AGA.

**Results: Subcellular localization of human NCX3.** To better understand the variable subcellular localization of human NCX3, we overexpressed NCX3 in HEK 293T cells and found at least two patterns of intracellular protein distribution, i) plasma membrane and ii) perinuclear

region associated with endoplasmic reticulum and nuclear envelope. **Tracking the subcellular dynamics of NCX3 with live cell imaging.** To perform live cell imaging, we recombined NCX3 with green fluorescent protein (GFP) and overexpressed it in HEK 293T cells. We discovered that NCX3 subcellular distribution is a dynamic process, which is related to the cell cycle phases. **The human NCX3 protein is post-translationally modified by N-glycosylation.** The treatment of NCX3 expressing HEK 293T cells with tunicamycin (an inhibitor of N-glycosylation) revealed that human NCX3 is glycosylated via N-linked glycosylation and both N-glycosylated and non-glycosylated forms of NCX3 are present in transfected 293T cells. **N-glycosylation is important for targeting of NCX3 to the plasma membrane.** We tested the effect of N-glycosylation on the subcellular distribution of NCX3 by making an NCX3 N-glycosylation-deficient mutant. NCX3 wild-type and the mutant forms thereof were transiently expressed in HEK 293T cells, and their subcellular distribution was investigated by immunofluorescence analysis. It is evident that the N-glycosylation-deficient mutant is predominantly maintained in the cytosol, suggesting that N-glycosylation is required for targeting of NCX3 to the plasma membrane.

*Conclusion:* The subcellular localization of the NCX3 protein varies with the cell cycle phases in mammalian cells. We depict that NCX3 can be N-glycosylated via a single asparagine residue which is normally required for targeting of NCX3 to the plasma membrane.

1404

**A C-terminus mutation of SLC7A9 amino acid transporter frequent in Japanese cystinuria patients retains substrate binding but diminishes the transport activity.**

Y. Kawamoto<sup>1</sup>, S. Nagamor<sup>2</sup>, P. Wiriyasermku<sup>2</sup>, Y. Kana<sup>2</sup>; <sup>1</sup>Faculty of Medicine, Osaka University, Osaka, Japan, <sup>2</sup>Pharmacology, Osaka University Graduate School of Medicine, Osaka, Japan

Cystinuria (MIM 220100) is an inherited disorder caused by the defect of amino acid transport systems for cystine and dibasic amino acids in the apical membrane of renal proximal tubules. The failure of cystine reabsorption results in recurrent nephrolithiasis which leads to severe renal dysfunctions. Mutations in either *SLC7A9* or *SLC3A1* genes result in cystinuria. *SLC7A9* encodes a functional subunit b<sup>0,+</sup> AT that possesses the amino acid transport activity, whereas *SLC3A1* encodes an accessory subunit called rBAT. These two subunits form a heterodimer. Several mutations in *SLC7A9* have been identified in patients of western countries and Japan. Different from western populations, the most frequent mutation found in Japanese patients was a missense mutation P482L of *SLC7A9* which causes severe loss of the amino acid absorption. Residue 482 is near the C-terminus end of the protein. Generally, C-terminus mutations of transporters are not important for the transport activity but alter amounts of expression and localization of proteins on the plasma membrane. However, by means of transfected cells, it is shown that P482L protein has similar expression level and localization to wild-type but loss of transport activity. Therefore, the reason for the loss of transport function by P482L mutation is still unknown.

To study the mutant further, we have generated a P482L knock-in (KI) mouse as a human-disease model. Urine from KI mice was collected for 24h and subjected to the analysis of cystine and dibasic amino acids. The excretion of cystine, arginine, lysine and ornithine in KI mice was between 70 and 100 fold higher than that in wild-type mice. It is similar to that of human cystinuria patients, indicating that the KI mouse can be used as the human cystinuria model. Immunohistochemistry and western blot analysis revealed that the P482L protein had the same expression level and localization as those of wild-type protein at the apical membrane of renal proximal tubules. To study the function of the mutant, the transport and substrate binding activity were measured by using brush border membrane vesicles (BBMV) isolated from

kidney cortex of the KI and wild-type mice. The transport activity of P482L mutant was much lower than that of wild-type, whereas the substrate binding activities of the mutant and wild-type were similar. Likelihood, the P482L mutant has the similar substrate binding ability to the wild-type transporter. Transporters change their conformation upon substrate transport. Disturbing the conformational change leads dysfunction of transporters. Our results indicate that P482L yet binds the substrate but do not change the conformation to transport substrates.

**Diseased mutants of SLC4a11 protein are ER-retained but are functional when rescued to cell surface.**

*S. K. Loganathan<sup>1</sup>, G. L. Vilas<sup>1</sup>, J. R. Casey<sup>1</sup>; <sup>1</sup>Biochemistry and Membrane Protein Disease Research Group, University of Alberta, Edmonton, AB, Canada*

The human cornea is composed of five different layers: the outer epithelium, Bowman's layer, corneal stroma, Descemet's membrane and corneal endothelium. The endothelial cell layer, underlying the cornea normally reabsorbs water from the corneal stroma. Disruption of this process results in corneal edema and significant impairment of vision, leading to some posterior corneal dystrophies (PCDs). Many cases of the PCDs - congenital hereditary endothelial corneal dystrophy (CHED), Harboyan syndrome and Fuchs endothelial corneal dystrophy are caused by the mutations in the SLC4a11 gene. The majority of point mutations in SLC4a11 cause this integral membrane protein to be misfolded and retained in the endoplasmic reticulum (ER). As a result, the function of SLC4a11 protein, which normally localizes to the basolateral plasma membrane of corneal endothelium, is impaired. Here we explored whether ER-retained mutants of SLC4a11 can be rescued to the cell surface. If rescued SLC4a11 retains function, it suggests that techniques to drive ER-plasma membrane rescue could be a viable therapeutic strategy. We chose the CHED mutant, SLC4a11-E143K, as a representative mutant having an ER-retained phenotype when expressed in HEK293 cells. We also made use of the catalytically inactive mutant, SLC4a11-R125H, which processes to the plasma membrane at levels similar to WT, yet does not have functional activity. We previously showed that SLC4a11 forms dimers. Our rationale was thus that SLC4a11-R125H would heterodimerize with ER-retained SLC4a11-E143K to rescue it to the plasma membrane surface. Immunoprecipitation experiments showed that R125H and E143K mutants form heterodimers. Co-expression of catalytically inactive R125H in HEK293 cells rescued E143K, moving it from ER to the plasma membrane. We measured significant functional activity arising in SLC4a11-E143K/R125H co-expressing cells. Hence we conclude that the functional activity arises from the plasma membrane rescued form of SLC4a11-E143K. Thus, therapies aimed at increasing the cell surface processing of ER-retained mutants has potential to treat posterior corneal dystrophies arising from SLC4a11 mutations.

1406

**Membrane trafficking of epithelial anion transporters NaS1 (SLC13A1) and Sat1 (SLC26A1).**

*D. Markovich<sup>1</sup>; <sup>1</sup>Molecular Physiology Group, School of Biomedical Sciences, The University of Queensland, St Lucia, Australia*

Sulfate is an essential anion involved in many cellular processes. Cells obtain sulfate via sulfate transporters located on their plasma membranes. Renal sulfate transporters (NaS1 and Sat1) control sulfate homeostasis. Despite their physiological roles, little is known about the structural identities of NaS1 and Sat1 and sorting mechanisms that regulate their cellular expression. NaS1 encodes a 595 amino acid 13 TMD protein localized to the apical (brush-border)

membranes of epithelial cells. Sat1 encodes a 704 amino acid 12 TMD protein located on the basolateral membrane of cells. The aims of this study were to biochemically characterise the NaS1 and Sat1 proteins, identify the plasma membrane sorting mechanisms and determine the functional roles of non-synonymous SNPs in these proteins. Transient transfection of EGFP/NaS1 in renal epithelial cells (OK, LLC-PK1 and MDCK) demonstrated apical membrane expression, which was not affected by tunicamycin. Transfection of the EGFP/NaSi-1 N591S glycosylation mutant still led to apical expression, suggesting that apical sorting was independent of the glycosylation of this site. Treatment with cholesterol depleting compounds (lovastatin and methyl- $\beta$ -cyclodextrin) was unable to disrupt apical sorting, suggesting that NaS1 apical trafficking may be independent of membrane lipid rafts. NaS1-His proteins analyzed by BN-PAGE appeared as a single complex. Dissociation revealed one additional band, indicating a dimeric structure of the complex. This data demonstrates that NaS1 forms a dimeric protein which is glycosylated at N591, whose sorting to the apical membrane in renal epithelial cells is independent of lipid rafts and glycosylation. Transfection of the Sat1 protein into MDCK and LLC-PK1 cells led to basolateral membrane sorting, as observed in vivo. To identify possible sorting determinants, truncations of the Sat1 cytoplasmic C-terminus were generated and transiently transfected into MDCK cells. Confocal microscopy revealed the removal of the last three residues on the Sat1 C-terminus, a putative PDZ domain, had no effect on the basolateral sorting in MDCK cells. Removal of the last 30 residues led to an intracellular expression for the GFP fusion protein suggesting a possible sorting motif lies between the last 3 and 30 residues of the Sat1 C-terminus. Elimination of a dileucine motif at position 677/678 resulted in the loss of basolateral sorting, suggesting this motif is required for Sat1 targeting to the basolateral membrane in kidney cells. Several non-synonymous SNPs exist in the coding regions of human NaS1 and Sat1 genes. The functional relevance of these SNPs and their effects on membrane protein sorting will be described.

#### **Structural Studies of the FGFR3 Dimer.**

*E. Li<sup>1</sup>, K. Mudumbi<sup>1</sup>, B. Eichman<sup>1</sup>; <sup>1</sup>Saint Joseph's University, Philadelphia, PA*

Fibroblast growth factor receptor 3 (FGFR3) is a member of the receptor tyrosine kinase family of proteins. These receptors are characterized by an extracellular ligand-binding domain, a transmembrane domain (TMD), and a cytosolic kinase domain. Ligand binding and dimerization of FGFR3 in the plasma membrane initiates a series of signaling pathways that regulate cell growth, proliferation and mobility. Previous work with the isolated FGFR3 TM domains has shown that it has the ability to self-dimerize. Furthermore, several mutations in the TMD have been associated with skeletal dysplasias and cancers. The sequence of the TMD contains two adjacent SmXXXSm motifs, where the Sm residues represent small amino acids. The SmXXXSm motif has been shown to play an important role in helix-helix interaction in other transmembrane proteins. Currently, we are using site directed mutagenesis and ToxR activity assays to analyze the importance of this sequence motif for the interaction between the helices, and thus, for FGFR3 dimerization. Our goal is to obtain information about the wild-type FGFR3 dimer structure, as well as the structure formed by FGFR3 carrying pathogenic mutations.

1408

**The Role of the CQC motif in the dimerization of MUC1.**

J. King<sup>1</sup>, N. Iaccarino<sup>1</sup>, G. Montone<sup>1</sup>, I. Schoepe<sup>2</sup>, E. Li<sup>1</sup>; <sup>1</sup>St. Joseph's University, Philadelphia, PA, <sup>2</sup>FAU Erlangen Nueremberg, Erlangen, Germany

MUC1 is a heterodimeric protein consisting of two subunits. The C-terminal subunit (MUC1-C) is made up of a cytoplasmic tail, a transmembrane domain (TMD) and an extracellular domain which interacts non-covalently with the N-terminal subunit (MUC1-N). The MUC1-C subunit has been shown to form homodimers. Homodimerization of MUC1 is required for its nuclear localization and subsequent interactions with various nuclear transcription factors. Such interactions are known to promote the production of proteins involved in cell proliferation and survival signals. Overexpression of MUC1 is shown to be involved in increased metastatic behavior of cancer cells and is considered a marker indicating poor prognosis in breast cancer patients. The cytosolic domain of MUC1-C contains a membrane proximal cysteine-glutamine-cysteine (CQC) motif that has been suggested to be involved in MUC1 dimerization. However, its role in dimerization is still unclear. Currently, we are evaluating the role of the CQC motif in the dimerization of the MUC1 TMD and MUC1-C. We are using the ToxR assay to study the dimerization of MUC1 TMD. In ToxR assays, TMD-TMD interactions are measured in bacterial membranes using a chimeric protein consisting of a periplasmic maltose binding domain, the TMD of interest, and the cytosolic ToxR domain from *Vibrio cholerae*. Thus, the assay allows us to compare levels of dimerization between MUC1 TMDs with and without the CQC motif. In addition, we are using site-directed mutagenesis and chemical crosslinkers (DSS and BS3) to evaluate the role of the CQC motif in the dimerization of MUC1-C in mammalian cells. Our goal is to obtain structural information regarding the MUC1 homodimer and the physical principles driving dimerization of MUC1 in the plasma membrane.

1409

**A Role of TRPM7 in Trace Metal Homeostasis.**

O. J. Gonzalez-Pagan<sup>1,2</sup>, L. W. Runnels<sup>1,2</sup>; <sup>1</sup>Department of Pharmacology, Graduate School of Biomedical Sciences, Piscataway, NJ, <sup>2</sup>Department of Pharmacology, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ

TRPM7 is a ubiquitously expressed channel-kinase widely permeable to a range of divalent metal ions, with a permeability sequence of  $Zn^{2+} \sim Ni^{2+} >> Ba^{2+} > Co^{2+} > Mg^{2+} \geq Mn^{2+} \geq Sr^{2+} \geq Cd^{2+} \geq Ca^{2+}$ . TRPM7's unusual permeability profile raises the possibility that the channel may be regulating the cellular homeostasis of more than one of these essential metal ions. Study of TRPM7 has linked the channel to a number of physiological roles, including cell proliferation and cellular  $Mg^{2+}$  homeostasis. It has been shown that genetic ablation of TRPM7 in DT40 B-cell lymphocytes produces cell cycle arrest that can be rescued by overexpression of the  $Mg^{2+}$  transporter SLC41A2, or by overexpression of a constitutively active form of phosphatidylinositol 3-kinase (PI3K). Despite these advances, TRPM7's role in  $Mg^{2+}$  homeostasis as well as the mechanism(s) by which the channel-kinase influences cell proliferation remains controversial, as conditional knockout of TRPM7 in neural stem cells, thymocytes, and T cells failed to produce any changes in cell proliferation or in  $Mg^{2+}$  homeostasis. To better understand the role of the channel in metal ion homeostasis we've generated recombinant adenoviruses that express TRPM7 channel-dead (TRPM7-E1047K) and TRPM7 channel/kinase-dead (TRPM7-E1047K/G1618D) mutants. Expression of these mutants in mouse embryonic fibroblasts (MEFS) potently inhibits cell proliferation and arrests cells in the S and G2 phases of the cell cycle. In addition, expression of the mutants lowers cellular free  $Mg^{2+}$  and decreases  $Zn^{2+}$  uptake. Consistent with a role for TRPM7 in  $Mg^{2+}$  and  $Zn^{2+}$  homeostasis, overexpression of the  $Mg^{2+}$  transporter SLC41A2 or supplementation of the growth media with high  $Mg^{2+}$  or  $Zn^{2+}$ ,

partially rescues the growth of cells expressing the TRPM7 mutants. To confirm these results we employed mouse embryonic fibroblasts (MEFS) derived from the conditional channel-dead TRPM7-E1047K mouse (TRPM7-E1047K-MEFS), which expresses TRPM7-E1047K in Cre recombinase dependent manner. Viral transduction of Cre recombinase into TRPM7-E1047K-MEFS inhibited cell proliferation compared to wildtype MEFS transduced with Cre recombinase. In addition, supplementation of the growth medium with  $Mg^{2+}$  and  $Zn^{2+}$  suppressed the proliferation defect caused by expression of TRPM7-E1047K. These results support the hypothesis that TRPM7's plays a critical role in both  $Mg^{2+}$  and  $Zn^{2+}$  homeostasis and that TRPM7's regulation of these metal ions is vital to the channel's control of cell growth and proliferation.

1410

**Iron deficiency regulates ZIP14 degradation through a proteasome-dependent pathway.**

*N. Zhao<sup>1</sup>, C. A. Enns<sup>1</sup>; <sup>1</sup>Oregon Health & Science University, Portland, OR*

ZIP14 is a newly identified iron-import protein. It mediates both transferrin-bound iron (TBI) and nontransferrin-bound iron (NTBI) uptakes into cells. Previously, we showed that ZIP14 is subject to posttranscriptional regulation by hereditary hemochromatosis protein, HFE. Lacking HFE leads to genetic iron-overload disorder and HFE expression downregulates cellular iron content. Overexpressing HFE in HepG2 cells downregulates ZIP14 by promoting its degradation. The exact mechanism is not clear. In the present study, we show that ZIP14 increases with iron-overload and decreases with iron-deficiency. This suggests that ZIP14 is an iron transporter responsible for constant cellular iron accumulation under high iron conditions, and that HFE may exert its effect on ZIP14 through lowered cellular iron levels. We further demonstrate that proteasomal inhibition prevents downregulation of ZIP14 induced by iron-deficiency, suggesting the involvement of proteasomes in ZIP14 degradation. Moreover, inhibition of the proteasomal pathway induces a rapid accumulation of the nonglycosylated ZIP14. Biotinylation studies suggest that ZIP14 traffics to the plasma membrane before it undergoes deglycosylation. Proteasomal inhibition studies indicate that the nonglycosylated ZIP14 is found primarily in the cytosol, not associated with membrane. We therefore propose that deglycosylation and membrane extraction are required before proteasomal processing of ZIP14.

1411

**Functional analysis of GJB2 (Cx26) mutations causing palmoplantar keratoderma and deafness.**

*Z. Shuja<sup>1</sup>, G. Mese<sup>2</sup>, T. W. White<sup>1,2</sup>; <sup>1</sup>Graduate Program in Genetics, Stony Brook University, Stony Brook, NY, <sup>2</sup>Department of Physiology and Biophysics, Stony Brook University, Stony Brook, NY*

Mutations in *GJB2*, the gene encoding Cx26, are responsible for causing both non-syndromic and syndromic deafness. Non-syndromic deafness occurs due to a loss in Cx26 function. Interestingly, patients with non-functional Cx26 do not display any adverse skin pathology. Based on this observation, we have hypothesized that Cx26 function is not required for the maintenance of epidermal homeostasis; however, some mutations in *GJB2* can produce a novel gain of function resulting in syndromic deafness associated with skin disease. In addition to hearing loss, patients with Cx26 mutations exhibit a variety of phenotypes such as palmoplantar keratoderma (PPK), pseudoainhum and leukonychia. Previous functional studies of syndromic deafness Cx26 mutations have shown that trans-dominant inhibition of other connexins found in the skin by mutant Cx26 may represent one possible gain of function mechanism. We have tested two additional Cx26 mutants, Cx26-S183F and Cx26-H73R, in an effort to determine

mechanisms contributing to palmoplantar keratoderma and hearing loss. Using a *Xenopus laevis* oocyte expression system, we found no functional activity in cells injected with Cx26-S183F mRNA, suggesting a lack of homomeric/homotypic gap junction formation. In assays where cells co-expressed wild-type (WT) Cx26 and Cx26-S183F mRNA, functional gap junctions were able to form. Remarkably, when cells co-expressed WT Cx43 and Cx26-S183F, there was a significant ( $p < 0.01$ ) reduction in conductance, suggesting a trans-dominant inhibition of WT Cx43. The mean conductance of cell pairs expressing both Cx26-S183F and WT Cx43 ( $0.56 \mu\text{S}$ ) was reduced by 89% when compared to cells co-expressing WT Cx26 and WT Cx43 ( $5.26 \mu\text{S}$ ). In experiments where cells co-expressed WT Cx26 and Cx26-H73R mRNA, gap junctions were able to form. However, when cells co-expressed WT Cx43 and Cx26-H73R mRNA, trans-dominant inhibition of WT Cx43 was again shown by a 92% decrease in conductance when compared to cells co-expressing WT Cx26 and WT Cx43. Taken together, Cx26-S183F and Cx26-H73R fail to inhibit WT Cx26 conductance, however, both mutants were able to trans-dominantly inhibit WT Cx43 thereby suggesting a mechanistic gain of function which may contribute to palmoplantar keratoderma.

1412

**Pannexin1 expression and interplay with P2X<sub>7</sub> receptors in hTERT immortalized human bladder urothelial cells.**

H. Negoro<sup>1</sup>, L. S. Liou<sup>2</sup>, D. C. Spray<sup>3</sup>, S. O. Suadicaní<sup>1</sup>; <sup>1</sup>Department of Urology, Albert Einstein College of Medicine, Bronx, NY, <sup>2</sup>Urology Department, Cambridge Health Alliance, Cambridge, MA, <sup>3</sup>Dominick P. Purpura Department of Neuroscience, Albert Einstein College of Medicine, Bronx, NY

Urothelial cells respond to bladder distension with ATP release, and ATP signaling to the CNS and within the bladder wall has been proposed to relay the degree of bladder fullness and modulate detrusor activity, which are essential for proper micturition. There is evidence that more than one ATP release mechanism operates in urothelial cells, including TRPV, ACh and P2 receptors. In other cell types, Pannexin1 (Panx1) channels provide a pathway for mechanically-induced ATP efflux and ATP-induced ATP release through its interaction with P2X<sub>7</sub> receptors (P2X<sub>7</sub>Rs). In this study we investigated whether Panx1 channels participate in urothelial ATP release and signaling. Panx1 expression and function in hTERT-immortalized human bladder urothelial cells were investigated by PCR, Western blotting, ATP release, YoPro dye (375 Da) uptake and Ca<sup>2+</sup> imaging. PCR and Western blotting indicated that urothelial cells express both Panx1 and P2X<sub>7</sub>R. Mechanical stimulation by hyposmotic shock induced YoPro uptake, which was inhibited by mefloquine (Panx1 blocker; MFQ 100nM) and also by A438079 (P2X<sub>7</sub>R blocker; 10μM). Mechanical stimulation induced by changing the bathing solution triggered ATP release ( $7.0 \pm 2.0 \text{ nM}/\mu\text{g}$  protein, N=3), which was 4 times higher ( $26.1 \pm 5.4 \text{ nM}/\mu\text{g}$  protein, N=3) when cells were bathed in low divalent cation solution (LDPBS), a condition known to enhance P2X<sub>7</sub>R activation. This higher ATP release in LDPBS was prevented by MFQ. ATP signaling between urothelial cells, evaluated as the extent of intercellular Ca<sup>2+</sup> wave (ICW) spread induced by focal mechanical stimulation of single cells, was sensitive to exposure to LDPBS, apyrase (ATP scavenger, 50U/mL) and MFQ. Radius of ICW in LDPBS was 70% higher than in control conditions ( $246.2 \pm 3.7 \mu\text{m}$  vs  $145.8 \pm 7.5 \mu\text{m}$ , N=6 fields;  $P < 0.01$ ) and such potentiation was prevented by MFQ ( $175.0 \pm 16.9 \mu\text{m}$ , N=9 fields;  $P < 0.05$ ). In apyrase, ATP signaling was restricted to cells closer to the mechanically stimulated cell in both control ( $24.5 \pm 4.2 \mu\text{m}$ , N=6 fields) and LDPBS ( $49.1 \pm 9.5 \mu\text{m}$ , N=4 fields) conditions. In LDPBS, MFQ combined with apyrase abrogated ATP signaling in 7 out of 12 fields analyzed. These findings indicate that Panx1 is expressed and interacts with P2X<sub>7</sub>R in human urothelial cells, and that

these channels not only provide a pathway for mechanically-induced ATP release but also participate in urothelial autocrine/paracrine ATP signaling. (Support: NIH DK081435)

**Adenosine metabolism and physiological effects in podocytes.**

*C. A. Jaramillo<sup>1</sup>, S. Alarcón<sup>1</sup>, C. Quezada<sup>1</sup>, R. San Martín<sup>1</sup>; <sup>1</sup>Bioquímica y Microbiología, Universidad Austral de Chile, Valdivia, Chile*

**Introduction.** A key feature of both type 1 and type 2 diabetes is an altered circulating insulin level and persistently high glucose levels. The deficit or the excess of insulin have been associated with proteinuria in both types of diabetes, independently of insulin resistance. This situation resembled the injurious effects on the filtration barrier and glomerular cells integrity when the doses of the VEGF are up or down regulated. Since we have shown that adenosine is a key regulator of VEGF production in the glomerulus, our aim will be to find out whether changes in the extracellular levels of the nucleoside are induced by insulin and consequently, unbalanced VEGF could explain the alterations on podocyte function.

**Results.** Primary cultured podocytes expressing the specific marker synaptopodin were obtained from glomeruli of rats. Exposure of podocytes to insulin decreased the production of VEGF in a doses dependent manner. The expression of the equilibrate nucleoside transporters -1 and -2 (ENT-1 and ENT-2) was recognized in this cell type. Exposure of podocytes to high glucose concentration (25mM) reduced the ENT-1 mRNA levels and triggered the extracellular increase of adenosine content. The ENT-2 mRNA level was not affected by the high glucose-containing medium but was significantly increased by treatment with insulin. Concomitantly, exposure to insulin restored the high glucose-mediated increase of adenosine levels. Signaling through adenosine A2B receptor subtype leads to the activation of RhoA and actin redistribution. Further, the production of VEGF was strongly induced.

**Conclusions.** The sodium-independent and facilitative transporters ENT-1 and ENT-2 play a major contribution on adenosine availability for signaling through adenosine receptor. While ENTs activity mediates adenosine uptake to be metabolized intracellularly, the nucleoside can become accumulated outside when the transport activity is reduced. In this way, increasing glucose concentrations and insulin deficiency in experimental and human diabetes could mediate the glomerulopathy with augmented adenosine levels. Further, adenosine causes podocyte dysfunction by inducing the VEGF production and rearrangement of the cytoskeleton, both effects probably relevant in affecting the integrity of the glomerular filtration barrier.

**Vasopressin regulated diffusion of AQP3 in MDCK cells.**

*S. Marlar<sup>1</sup>, E. A. Christensen<sup>2</sup>, J. S. Koffman<sup>1</sup>, L. N. Nejsum<sup>1</sup>; <sup>1</sup>Department of Molecular Biology and Genetics, Aarhus University, Aarhus, Denmark, <sup>2</sup>University of Southern Denmark, Odense, Denmark*

Fine tuning of urine concentration occurs in the kidney collecting duct, where it is regulated by vasopressin which controls the level of apical AQP2 and thus water influx across the epithelial cell layer. Basolateral aquaporins, AQP3 and AQP4, represent the exit pathways for water entered by AQP2 in the apical membrane of collecting duct principal cells. To maintain body water homeostasis, it is extremely important that these water channels are specifically positioned in the subcellular domains at the right quantity. AQP2 localization is regulated by

vasopressin within minutes of stimulation facilitating increased influx of water; however, the short-term effect of vasopressin on basolateral AQP3 and AQP4 is unknown. We hypothesize that the plasma membrane dynamics of AQP3 might be regulated by vasopressin to facilitate the efflux of water absorbed by AQP2. To study the effect of vasopressin on AQP3 in a cell culture model, we labeled individual EGFP-tagged AQP3 proteins extracellular with quantum dots and followed the mobility at the single protein level. We stimulated cells with forskolin to mimic vasopressin stimulation and also studied AQP3 mobility during disruption of different cytoskeletons. k-space image correlation spectroscopy (kICS) was used for quantitative analysis of the diffusing proteins. Within 15-30 minutes of forskolin stimulation, the AQP3 diffusion coefficient increased significantly. In addition, disruption of the actin cytoskeleton, but not microtubules, caused a slight increase in diffusion of AQP3. These kinetic data support our hypothesis that AQP3 is regulated alongside AQP2 upon vasopressin stimulation. The increased dynamics may aid in facilitating an increased water efflux, perhaps by preventing AQP3 endocytosis.

#### **Non-enzymatic modulation of AQP1 activity by CAII.**

G. L. Vilas<sup>1</sup>, J. R. Casey<sup>2</sup>, R. T. Alexander<sup>1</sup>; <sup>1</sup>Department of Physiology, University of Alberta, Edmonton, AB, Canada, <sup>2</sup>Department of Biochemistry, University of Alberta, Edmonton, AB, Canada

Aquaporins are a family of membrane proteins that function as water channels, facilitating the movement of water molecules across the plasma membrane, down a concentration gradient. The first family member AQP1, is predominantly expressed in red blood cells and the kidney. The basic structural and functional unit of the kidney is the nephron where AQP1 is expressed in both the proximal tubule and thin descending limb. Its presence there is essential for the reabsorption of two thirds of the 180L of water filtered by the glomerulus daily. Carbonic anhydrase II (CAII) is ubiquitously expressed. It catalyzes the reversible hydration of carbon dioxide. Apart from playing a pivotal role in acid-base balance, CAII also modulates the activities of other proteins through direct protein-protein interaction. Specifically CAII binds to and enhances the activity of the sodium/hydrogen exchanger NHE1, sodium bicarbonate cotransporter NBC1, monocarboxylate transporter MCT1 and the chloride/bicarbonate exchanger AE1. Sequence analysis of human AQP1 revealed the presence of two C-terminal contiguous motifs that match the CAII binding sites found in AE1. Moreover, osmotic swelling assays showed that the water flux of membrane-enriched cortical kidney fractions from CAII<sup>-/-</sup> mice was approximately 50% lower than wild-type mice. These results lead us to hypothesize that water flux through AQP1 was enhanced by an interaction with CAII. To test this possibility we performed osmotic swelling assays on *Xenopus laevis* oocytes and HEK293 cells transiently expressing different combinations of AQP1, CAII and the catalytically inactive CAII isoform, V143Y. We found that CAII enhances the water channel activity of AQP1 regardless of catalytic activity, in both model systems. Future studies are aimed at clearly delineating the site of interaction between CAII and AQP1. Regardless this interaction is likely highly relevant to both respiratory and renal physiology.

#### **The Role of ERp44 on the Maturation of Serotonin Transporter Protein.**

Y. Li<sup>1</sup>, F. Kilic<sup>1</sup>; <sup>1</sup>University of Arkansas for Medical Science, Little Rock, AR

Serotonin transporter (SERT) is an oligomeric glycoprotein with three Cysteine residues on the external loops. Here, initially we investigated an association between SERT and ERp44, an

endoplasmic reticulum (ER) luminal chaperone protein; then we studied the role of their association in disulfide formation on SERT because ERp44 facilitates the maturation of disulfide-linked oligomeric proteins.

Mutation in the thioredoxin-like domain of ERp44 (C29S) hampers its association with SERT. Then, once the retention mechanism is waved, in ERp44 silenced cell lines, the plasma membrane expression levels of SERT was elevated while the serotonin (5-HT) uptake rates of ERp44 silenced cells were decreased. Next, MTSEA-biotin, a membrane impermeable compound which specifically labels the free Cys residues from the extracellular surface, was applied on control and ERp44-silenced cell lines. MTSEA-biotin had higher binding efficiency to SERT in ERp44 cells than the one in control cell lines indicating the presence of more accessible Cys residues on SERT in silenced cells to be labeled than in control cell lines. These data support our hypothesis that ERp44 plays an important role in the maturation of SERT molecules via facilitating the disulfide formation which become a prerequisite step for the assembly of SERT monomers in an oligomeric form.

### **Silencing Of Arachin Encoding mRNAs By Glutamate Dehydrogenase-Synthesized RNA.**

*D. L. Johnson<sup>1</sup>, S. South<sup>1</sup>, S. Hyllam<sup>1</sup>, G. Osuji PhD<sup>1</sup>; <sup>1</sup>CARC, Prairie View A&M, Prairie View, TX*

Peanut (*Arachis hypogaea* L) seeds are extremely rich in protein. However peanut allergy is one of the most frequent causes of death resulting from food allergy. The protein found in peanut seeds that is responsible for peanut allergy is known as arachin. Peanut allergen arachin 1 (68KDa) can cause severe type1 hypersensitive reaction such as anaphylaxis. *Arachis hypogaea* Virginia peanut were cultivated and treated with mineral nutrient in ten experimental plots at Prairie View A&M University field plots in Waller County. Peanut seeds were harvested at maturity and homogenized in phosphate buffer to extract the arachin. The mRNA synthesis of arachin for each sample was analyzed by Northern blot analysis. Mineral nutrients induce glutamate dehydrogenase (GDH) to isomerize and to synthesize RNAs. Arachin mRNAs are silenced by homologous GDH-synthesized RNAs. The mRNA bands for the allergenic protein arachin (2.3Kb) for Phosphorus and Potassium (PK) and NPKS treated peanuts were Silenced. The silencing of mRNA that encodes for the arachin protein resulted in the abolishment of allergenic protein on (sodium dodecyl sulfate polyacrylamide gel) SDS-PAG.

## **Nuclear Lamins**

### **O-GlcNAc regulates emerlin binding to BAF in a chromatin- and lamin B-enriched 'niche'.**

*K. L. Wilson<sup>1</sup>, J. M. Berk<sup>1</sup>, A. W. Dawdy<sup>2</sup>, J. Shabanowitz<sup>2</sup>, S. Maitra<sup>2</sup>, D. F. Hunt<sup>2</sup>; <sup>1</sup>Cell Biology, Johns Hopkins School of Medicine, Baltimore, MD, <sup>2</sup>Chemistry, Univ. Virginia, Charlottesville, VA*

Emerlin, a membrane component of nuclear 'lamina' networks with lamins and barrier-to-autointegration factor (BAF), is highly O-GlcNAc-modified ('O-GlcNAcylated') in mammalian cells. Mass spectrometry analysis revealed eight sites including S53, S54, S87, S171 and S173. Emerlin O-GlcNAcylation was reduced ~50% by S53A or S54A mutation in vitro and in vivo; S173A reduced O-GlcNAcylation only in vivo. We separated two populations of emerlin, A-type

lamins and BAF: one solubilized easily; the other required sonication and included histones and B-type lamins. Emerin and BAF associated only in sonicated fractions. Comparing GFP-emerin (wildtype, mutant) association with endogenous partners *in vivo*, only BAF was affected: S173D reduced BAF association 63%, and also 'primed' GFP-emerin hyperphosphorylation. Thus, essential enzyme O-GlcNAc-transferase controls an S53/S54-dependent region near the LEM-domain, and controls a molecular switch in emerin defined by S173, O-GlcNAcylation of which promotes emerin-BAF association in the chromatin/lamin B 'niche'. These results reveal a mechanism for crosstalk between O-GlcNAcylation (mitosis, epigenetics, nutrient sensing) and conserved chromatin-tethering lamina components.

**Assembly properties of human disease associated lamin A mutants: An *in vitro* – *in vivo* comparison.**

H. Herrmann<sup>1</sup>, M. Hergt<sup>1</sup>, D. Moeller<sup>1</sup>, M. Mauermann<sup>1</sup>, P. Taimen<sup>2</sup>, R. D. Goldman<sup>3</sup>; <sup>1</sup>Functional Architecture of the Cell, German Cancer Research Center, Heidelberg, Germany, <sup>2</sup>Department of Pathology, University of Turku and Turku University Hospital, Turku, Finland, <sup>3</sup>Department of Cell and Molecular Biology, Northwestern University, Chicago, IL

We have synthesized human wild-type lamin A and various disease associated mutant lamin A variants. Firstly, we compared their assembly using standard protocols for the generation of filaments and paracrystals, respectively (Aebi, U. et al. (1986) Nature 323, 560-564). Assembly products obtained were visualized by transmission electron microscopy of negatively stained samples. Then, we followed their assembly by a new assembly regime that employs stepwise dialysis from high salt containing buffers into physiological conditions. Using this procedure, we were able to collect intermediates during different stages of assembly and thereby tracked structures not discernible any more in the – mostly rather large - end products.

These studies were followed in parallel at the cellular level. We transfected cultured cells with constructs coding for mCherry-tagged lamin A as well as the mutants analysed *in vitro*. In human U2OS cells, most of the mutants did not integrate into the nuclear envelope, very different from the wildtype lamin A but were also found in extranuclear structures. This property was in stark contrast for the rather regular assembly observed *in vitro*. The mutant S143F, for instance, was not found in the nuclear envelope in many cells but in small dots outside the nucleus. Moreover, it caused strong reorganization of both emerin and LBR. When lamin S143F was not located in the nuclear envelope, it was found in contact with extra-nuclear LBR. Similar results were observed for the mutant T10I. However, the *in vitro* organization for both proteins was completely different. Whereas T10I exhibited entirely normal paracrystal formation, S143F was missing the ordered 24.5-nm repeat pattern but still formed extended fibers. Such a difference was even more so observed for S143P, which was indeed "super-aggregating" into huge round, interconnected structures instead of the needle-like paracrystals or fibers seen with wild-type lamin A and S143F, respectively, under the same conditions. With these comparative studies we believe that we can help to distinguish those mutants that cause disturbances in lamin assembly from those that build normal polymers but cause a fatal molecular change in the binding epitope normally recognized by lamin interacting proteins.

1420

**Divalent cations alter farnesylated lamin tail domain structure and are required for membrane association.**

A. Kalinowski<sup>1</sup>, Z. Qin<sup>2</sup>, M. Buehler<sup>2</sup>, M. Loesche<sup>1</sup>, K. N. Dahl<sup>1</sup>; <sup>1</sup>Carnegie Mellon University, Pittsburgh, PA, <sup>2</sup>Massachusetts Institute of Technology, Cambridge, MA

Lamin proteins contribute to nuclear structure and function, primarily at the inner nuclear membrane. Posttranslational processing pathway of lamin A includes farnesylation of the C-terminus, likely to increase membrane association, and subsequent proteolytic cleavage of the C-terminus. Hutchinson Gilford progeria syndrome (HGPS) is a premature aging disorder wherein a mutant version of lamin A,  $\Delta 50$  lamin A, retains its farnesylation. We examine purified tail domains of prelamin A and  $\Delta 50$  lamin A to determine the role of the farnesylation in protein-protein and protein-membrane interactions. We find that divalent cations are required for association of farnesylated tail domains with tethered bilayer membranes. The farnesylated form of  $\Delta 50$  lamin A tail domain binds the membrane interface only in the presence of  $\text{Ca}^{2+}$  or  $\text{Mg}^{2+}$  and also forms multiple layers on the membrane. Aggregation of prelamin A suggests stronger protein-protein association than protein-membrane association. Thermodynamic experiments and molecular dynamics simulations show that the farnesyl group is sequestered within a hydrophobic region of the tail domain in the absence of divalent cations for prelamin A and  $\Delta 50$  lamin A. With calcium bound to the tail domain, the structure of the Ig-fold is altered, increasing the solvent accessibility of the C-terminus. This data collectively shows a divalent cation-induced conformational change in  $\Delta 50$  lamin A, which may be important in disease pathogenesis. Also, divalent cations may provide a regulatory role in the post-translational processing of wild type lamin A.

1421

**Expression of different nuclear lamins during *Xenopus laevis* development may contribute to nuclear scaling.**

X. Li<sup>1</sup>, D. L. Levy<sup>1</sup>; <sup>1</sup>Molecular Biology, University of Wyoming, Laramie, WY

Nuclear size differs in different organisms, cell types, and stages during development. Understanding how nuclear size is regulated is important because abnormal nuclear size and morphology are associated with some diseases state. Nuclear lamins have been demonstrated to regulate nuclear size, but how different lamin isoforms affect nuclear size is unknown. In order to address this question, we are using the frog *Xenopus laevis* as our model system. During *X. laevis* embryo development, the nuclear size decreases both prior to the midblastula transition (MBT) and post-MBT. It was shown that pre-MBT nuclear size is regulated in part by nuclear import. We focus on post-MBT nuclear scaling, when different lamin types and isoforms are expressed as development proceeds. Our approach is to microinject one-cell *X. laevis* embryos with different lamin mRNAs and quantify effects on nuclear size. Our data show that lamin A expression decreases nuclear size while lamin B1 increases nuclear size in post-MBT embryos, consistent with the developmentally regulated expression patterns of these two proteins. Interestingly, lamin B3 effects on nuclear size depend on the expression level. Higher levels of lamin B3 expression decrease nuclear size while lower concentrations increase nuclear size. These results indicate that different lamin isoforms differentially affect post-MBT nuclear size. Future experiments will address the role of lamin B2 in regulating nuclear size, how different lamins act together, and the contributions of other nuclear structural components.

1422

**Hierarchical determination of nuclear deformability by lamin isoforms during adult hematopoiesis.***J-W. Shin<sup>1</sup>, K. R. Spinler<sup>1</sup>, J. Swift<sup>1</sup>, D. E. Discher<sup>1</sup>; <sup>1</sup>Biophysical Engineering Laboratory, University of Pennsylvania, Philadelphia, PA*

Bone is a porous tissue where marrow resident hematopoietic cells must migrate through. It has been known that different blood cells show distinct deformability, and mature blood cells become softer during differentiation from immature progenitors so that they can better traffic from marrow through the endothelial barrier and into the circulation. However, the molecular basis of this phenomenon remains to be understood. Cellular deformability is determined both by membrane and nuclear elasticity, the latter that is dynamically regulated by changes in gene expression and structural reorganization, which are driven by nuclear lamins. We developed a novel protein expression analysis algorithm, “mass spectrometry calibrated intracellular flow cytometry”, to comprehensively profile lamin isoform expression across different human blood cell types. This approach reveals the hematopoietic lineage map of nuclear deformability, which is verified by nuclear micropipette aspiration. Lymphoid and myeloid lineages show decreased total lamin intensity and pliable nuclei, consistent with their ability to transmigrate into blood. In contrast, megakaryocytes (MKs) remain in marrow because their polyploid nuclei are too large and rigid, indicated by high lamin intensity, but they do extend membrane projections into blood, where shear generates circulating platelets. Erythroid lineages share the same progenitor with MKs and migrate into blood as enucleated RBCs, likely because of high lamin A/C intensity relative to B in the progenitors and stiff chromatin. As predicted from the lineage map, lamin A/C overexpression increases MK and erythroid differentiation, while the knockdown increases migration through pores. Increasing the lamin A/C to B ratio by lamin B1 knockdown decreases nuclear deformability. Together, the study suggests that nuclear deformability is hierarchically programmed by differential expression of the nucleoskeletal lamin A/C and B isoforms during hematopoietic differentiation, which in turn influence the ability of blood cells to migrate through marrow in 3D.

1423

**A-type lamins relocate the IL-2 locus and enhance T cell activation.***M. I. Robson<sup>1</sup>, J. González-Granado<sup>2</sup>, V. Andrés<sup>2</sup>, E. C. Schirmer<sup>1</sup>; <sup>1</sup>School of Biological Sciences, Wellcome Trust Center For Cell Biology, Edinburgh, United Kingdom, <sup>2</sup>Centro Nacional de Investigaciones Cardiovasculares, Madrid, Spain*

A-type lamins are intermediate filaments of the nuclear envelope that provide mechanical stability to the nucleus and regulate a wide range of cellular functions, including higher-order chromatin organization, replication, transcription, DNA repair, proliferation, differentiation, and migration. Whilst A type lamins are found in most differentiated somatic cells they were believed to be largely absent from the immune system. Here we show that lamins A/C are in fact expressed in T-lymphocytes upon T-cell receptor (TCR)-mediated activation and enhance T-cell responses. A-type lamins augment mRNA expression and protein release of interleukin-2 (IL-2), a key factor in T-cell function and the regulation of the immune response. This increased activation of the IL-2 locus occurs concomitantly with relocation of the IL-2 locus from the nuclear periphery to the nucleoplasm. By contrast progerin, a lamin A mutant responsible for the premature aging disorder Hutchinson-Gilford progeria syndrome, is unable to mediate the same repositioning and inducing effect. Moreover, treatment of progerin cells with farnesyl transferase inhibitors rescues the normal repositioning phenotype further supporting that the repositioning and enhanced gene expression is mediated by lamin A. These results demonstrate that A-type lamins are needed for optimal T-cell activation.

1424

**The nuclear mechanostat that scales with tissue stiffness and amplifies lineage: lamin-A,C.**

J. Swift<sup>1</sup>, I. Ivanovska<sup>1</sup>, T. Harada<sup>1</sup>, J. Pinter<sup>1</sup>, A. Buxboim<sup>1</sup>, J-W. Shin<sup>1</sup>, M. Tewari<sup>1</sup>, D. W. Speicher<sup>2</sup>, D. E. Discher<sup>1</sup>; <sup>1</sup>Bioengineering, University of Pennsylvania, Philadelphia, PA, <sup>2</sup>Wistar Institute, Philadelphia, PA

Tissue can be soft like brain, stiff like muscle, or rigid like bone. Proteomic profiling of human and mouse tissues and cells reveals that the nucleoskeletal protein lamin-A,C scales with various collagens and with tissue microelasticity,  $E$ . Among the many cell structure and nuclear components quantified here, lamin-A,C acts most clearly as a “mechanostat” in increasing as  $\sim E^{0.7}$ , whereas B-type lamins are nearly constant. Lamin-A,C dominates in stiff tissues and has been implicated in aging and diseases that impact muscle, bone, and fat but rarely brain or marrow, and nuclei in stiff tissue cells also prove much stiffer than nuclei from softer tissues. Mesenchymal stem cell differentiation in vitro further shows that lamin-A,C amplifies lineage signals from matrix, with low lamin-A,C favoring a soft tissue fate and high levels favoring stiff tissue. Regulation of lamin-A,C occurs at multiple levels, with conformational changes in isolated nuclei revealing its direct response to stress. Systematic relations thus exist between tissue stress and stiffness and the nucleus.

1425

**Isolated nuclei stiffen in response to force on nesprin-1.**

C. Guilluy<sup>1</sup>, L. Sharek<sup>1</sup>, L. Osborne<sup>1</sup>, R. Garcia-Mata<sup>1</sup>, R. Superfine<sup>1</sup>, K. Burrridge<sup>1</sup>; <sup>1</sup>University of North Carolina, Chapel Hill, NC

Mechanical forces influence many aspects of cell behavior. Forces are detected and transduced into biochemical signals by force bearing molecular elements located at the cell surface, in adhesion complexes or in cytoskeletal structures. The nucleus is physically connected to the cell surface through the cytoskeleton and the linker of nucleoskeleton and cytoskeleton (LINC) complex, allowing rapid mechanical stress transmission from adhesions to the nucleus. Whereas it has been demonstrated that nuclei experience force, the direct effect of force on the nucleus is not known. Here we show that isolated nuclei are able to respond to force by adjusting their stiffness to resist the applied tension. Using magnetic tweezers, we found that applying force on nesprin-1 triggers nuclear stiffening that does not involve chromatin or nuclear actin, but requires an intact nuclear lamina and SUN proteins. Our results demonstrate that mechanotransduction is not restricted to cell surface receptors and adhesions but can occur within the nucleus, indicating that cellular organelles can behave as independent mechanosensitive structures contributing to an integrated mechanoresponse.

1426

**How deeply cells feel: from soft matrices of controlled thickness to nuclear readouts.**

A. Buxboim<sup>1</sup>, Y-R. C. Kao<sup>2</sup>, J. Swift<sup>3</sup>, D. Discher<sup>3</sup>; <sup>1</sup>Physics and Astronomy, The University of Pennsylvania, Philadelphia, PA, <sup>2</sup>Biotechnology, The University of Pennsylvania, Philadelphia, PA, <sup>3</sup>Chemical and Biomolecular Engineering, The University of Pennsylvania, Philadelphia, PA

Lacking eyes to see and ears to hear, cells physically sense their microenvironment and feel into the depths of a matrix by actively deforming their surroundings. To study how deeply cells feel, mesenchymal stem cells, as prototypical but particularly sensitive adhesive cells, were cultured on collagen-coated gels-based microfilms of controlled elasticity ( $E$ ) and thickness ( $h$ ). Cellular morphologies and nuclear deformations were distinctively smaller on soft compared with soft but thin or stiff films. As indicated by the transition from small to large spreading, the

tactile length scale for mechanosensitivity was 6-10 microns. Transcriptional analysis and protein profiling revealed a set of four most malleable nuclear envelope genes in tissues and in a dish as related to matrix-induced nuclear deformations. Overexpression and siRNA knockdown of Lamin-A,C, which is widely implicated in cell differentiation and development, directed inside-out nuclear remodeling that involved the regulation of the other three mechano-malleable components. The dynamics of nuclear spreading on rigid glass was equivalent to steady-state morphologies on soft-to-stiff matrices, and was linked with protein-level nuclear remodeling. Lamin-A,C expression levels maintained proportionality with cellular contractility by myosin activity. Taken together, the interplay between nuclear remodeling, myosin activity and matrix are indicative of gene expression regulation by the physics of the microenvironment.

1427

### Mutations in the nuclear envelope proteins lamin A/C and emerin modulate actin dynamics and impair MKL1/SRF transcriptional activity.

C. Ho<sup>1</sup>, D. Jaalouk<sup>2</sup>, M. Vartiainen<sup>3</sup>, J. Lammerding<sup>1</sup>; <sup>1</sup>Cornell University, Ithaca, NY, <sup>2</sup>American University of Beirut, Beirut, Lebanon, <sup>3</sup>University of Helsinki, Helsinki, Finland

**Background:** Mutations in the *LMNA* gene encoding the nuclear envelope protein lamins A and C cause Emery-Dreifuss muscular dystrophy (EDMD), dilated cardiomyopathy (DCM), and a broad spectrum of other diseases (laminopathies). The mechanisms by which the nearly ubiquitously expressed lamins A/C can lead to tissue-specific phenotypes remain incompletely understood, but the muscle-specific phenotypes suggests a mechanosensitive component. Myocardin-related transcription factor A (MRTF-A) is an important pathway in cellular mechanosensing that responds to dynamic changes in the actin cytoskeleton by translocating from the cytoplasm to the nucleus, where it acts as co-activators for serum response factor (SRF) to induce expression of cytoskeletal genes.

**Objective:** To test the hypothesis that lamin A mutations associated with muscular laminopathies can result in impaired MRTF-A signaling and thereby contribute to striated muscle dysfunction in EDMD and DCM.

**Methods:** We examined MRTF-signaling in cells and tissue sections from lamin A/C-null (*Lmna*<sup>-/-</sup>) and *Lmna* N195K (*Lmna*<sup>N195K/N195K</sup>) mice, which represent models of EDMD and DCM, as well as wild-type littermates for defects in MRTF-A translocation. We used GFP-fusion constructs, biochemical methods, and immunostaining to characterize the actin-MRTF-A-SRF signaling pathway in these cells. Activation of downstream genes was assessed by Real-Time PCR and luciferase reporter constructs.

**Results:** Nuclear translocation of MRTF-A in response to serum stimulation was almost completely abrogated in *Lmna*<sup>-/-</sup> and *Lmna* N195K mouse embryonic fibroblasts (MEFs) and these cells had impaired activation of SRF-target genes. Skeletal and cardiac muscle sections confirmed impaired nuclear translocation of MRTF-A *in vivo*. The impaired nuclear translocation of MRTF-A in lamin mutant cells did not represent a general defect in nuclear import/export but resulted from altered actin dynamics in the mutant cells. Since emerin, a nuclear envelope protein, was recently shown to promote actin polymerization and is mislocalized in lamin A/C-mutant cells, we examined whether emerin could be involved in the observed defects in MRTF-A translocation defect by modulating nuclear or cytoskeletal actin dynamics. Emerin-null MEFs displayed similar defects in actin organization and MRTF-A translocation as the lamin mutant cells, and ectopic expression of emerin rescued the defects in MRTF-A translocation and actin dynamics in emerin-null and lamin mutant MEFs.

**Conclusions:** We identified a new mechanism by which lamins A and C, mediated by emerin, can modulate actin polymerization and thereby alter activity of MRTF-A and SRF-dependent genes, providing a possible explanation for the muscle-specific phenotype in several laminopathies.

## The Nuclear Envelope and Nuclear Pore Complexes

1428

### Dramatic changes in the shape and function of intestinal cell nuclei are enhanced by progerin expression.

*E. M. Zeituni<sup>1</sup>, Y. Zheng<sup>1,2</sup>, S. Farber<sup>1,2</sup>; <sup>1</sup>Department of Embryology, The Carnegie Institution for Science, Baltimore, MD, <sup>2</sup>Department of Biology, Johns Hopkins University, Baltimore, MD*

As we face an epidemic of obesity that has been debilitating the health and economies of Western societies, understanding the mechanisms through which humans acquire and process nutrients from food has never been more critical. Amazingly many fundamental aspects of nutritional lipid uptake and dispersal by the absorptive cells of the intestine, called enterocytes, are poorly understood. Using zebrafish, we are examining the impact of a high-fat diet on enterocyte morphology and function. We have determined that zebrafish enterocytes undergo numerous structural changes typical of mammalian enterocytes during feeding. These include increases in size, expansion of endoplasmic reticulum, fusion of mitochondria, and the formation of lipid droplets. Interestingly, we observed a novel phenomenon: the rapid and reversible distortion of the nuclear periphery upon feeding. This dramatic structural change of the nucleus is coupled with interesting transcriptional changes. Since the nuclear lamina helps regulate both the shape of the nucleus and the transcription of genes, we examined the role of nuclear lamins in these processes in enterocytes. Using zebrafish that express a mutant allele of lamin A, called progerin, we studied the impact of a disrupted nuclear lamina on the morphology of enterocytes and on their ability to absorb and process lipids.

### Analysis of factors involving three distinct stages during apoptotic nuclear condensation using a cell-free system.

*S. Tone<sup>1</sup>, K. Sugimoto<sup>2</sup>, K. Ajiro<sup>3</sup>, F. Kuribayashi<sup>1</sup>; <sup>1</sup>Dept. of Biochem., Kawasaki Medical School, Kurashiki, Japan, <sup>2</sup>Grad. Sch. Life & Environ. Sci., Osaka Prefecture Univ, Sakai, Japan, <sup>3</sup>Research Center for Stem Cell Engineering, National Institute of Advanced Industrial Science and Technology, Tsukuba, Japan*

In apoptotic execution step, cells perform final processes, such as DNA cleavage and nuclear condensation before engulfment by other cells.

The molecular mechanisms for nuclear condensation are still unclear, while upstream cytoplasmic pathways are well characterized.

Earnshaw and his colleagues (Lazebnik et al. 1993) and others have been developed a cell-free system which allows isolated nuclei could undergo apoptosis in vitro as intact cells did. Using this system, we have previously demonstrated that nuclei exhibited consistent structural changes and apoptotic nuclear condensation could be classified into three distinct steps, stage 1 ring, stage 2 necklace and stage 3 nuclear collapse (Tone et al. 2007). Time-lapse imaging of individual nuclei showed all nuclei could follow a reproducible program of nuclear condensation, suggesting the existence of an ordered biochemical pathway. DNase activity was not required

for stage 1 ring condensation, which could occur in apoptotic extracts depleted of all detectable DNase activity. DNase(s) were however, essential for stage 2 necklace condensation. In the present study, we confirmed the necessity of caspase-6 activity for stage 3 nuclear collapse, because stage 3 was suppressed by preincubation of extracts with pan-caspase inhibitor, zVAD. In addition, incubation of stage 2 necklace nuclei with caspase-6 caused nuclear collapse. Finally, for the activity inducing stage 1 ring condensation, phosphorylation for histone 2B Ser 17 (H2BS17) could be involved, because an antibody specific for phospho H2BS17 could detect positive band not only in nuclei incubated with apoptotic extracts but also in ring stage nuclei made by DNase-depleted extracts. This suggests that kinase could phosphorylate H2B resulting chromatin remodeling, ring condensation. In conclusion, kinase activity in stage 1, DNase activity in stage 2, and caspase activities in stage 3, are essential for each condensation stages.

### XPC-centrin interactions in *Dictyostelium*.

S. Mana-Capelli<sup>1</sup>, J. Lu<sup>2</sup>, D. A. Larochelle<sup>3</sup>; <sup>1</sup>MGM, UMass Medical School, Worcester, MA, <sup>2</sup>Biochemistry and Molecular Biology, Clark University, Worcester, MA, <sup>3</sup>Biological Sciences, Clark University, Worcester, MA

*Dictyostelium discoideum* Rad4 (DdRad4) is a DNA repair protein. The yeast and human homolog of DdRad4, XPC, has been shown to interact with centrin proteins but little is known about the possible interaction of the two proteins in *D. discoideum*. Past research has shown that a knockout of the centrin protein DdCenB in *D. discoideum* causes nuclear and mitotic defects. The amino acids that mediate the interaction between human XPC and centrin2 have been well characterized and are conserved in their respective *D. discoideum* homologs. This prompted us to directly examine the interaction between DdCenB and DdRad4. The c-terminal region of DdRad4 was expressed as a GST-tagged protein in bacterial cells and purified using glutathione-coated beads. These beads were subsequently mixed with cell lysates from GFP-DdCenB expressing cells and probed for the presence of DdCenB. GST-Rad4 beads were able to pull down GFP-DdCenB, whereas GST-beads alone were not. Because both DdCenB and DdRad4 localize to the nucleus, we next wanted to test if the known interaction of DdCenB with chromatin was DdRad4-dependent. Western blot analysis of cells expressing GFP-DdCenB, but lacking DdRad4 (DdRad4-KO), were used. If DdRad4 is required for DdCenB-chromatin interaction then we would expect to see no histone protein pulled down along with GFP-DdCenB from these lysates. This, however, was not the case and a significant histone band was indeed observed, confirming that the DdCenB interaction with chromatin is independent of DdRad4. Finally, we wanted to test if the nuclear localization of DdCenB was also independent of DdRad4. Confocal images of DdRad4-KO cells expressing GFP-DdCenB reveal that DdCenB does not require DdRad4 for its nuclear localization. Furthermore, DdRad4-KO cells were found to have an increased growth rate, as well as mitotic defects similar to that of DdCenB knockout cells. Novel data suggest that DdRad4 is involved in both mitosis and cytokinesis. Taken together these findings suggest that DdRad4 is a multifunctional protein involved in both the cellular response to DNA damage and the progression of the cell through both mitosis and cytokinesis.

**Human ASUNDER promotes dynein recruitment and centrosomal tethering to the nucleus at mitotic entry.**

J. N. Jodoin<sup>1</sup>, M. Shbouf<sup>2</sup>, P. Sitaram<sup>1</sup>, H. Zein-Sabatto<sup>1</sup>, B. Reversade<sup>2,3</sup>, E. Lee<sup>1</sup>, L. A. Lee<sup>1</sup>;  
<sup>1</sup>Cell and Developmental Biology, Vanderbilt University Medical Center, Nashville, TN, <sup>2</sup>Institute of Medical Biology, A\*STAR, Singapore, Singapore, <sup>3</sup>Department of Pediatrics, National University of Singapore, Singapore, Singapore

Recruitment of dynein motors to the nuclear surface is an essential step for nucleus-centrosome coupling in prophase. In cultured human cells, this dynein pool is anchored to nuclear pore complexes through RanBP2-BICD2 and Nup133-CENP-F networks. We previously reported that the *asunder* (*asun*) gene is required in *Drosophila* spermatocytes for perinuclear dynein localization and nucleus-centrosome coupling at G2/M of male meiosis. We show herein that male germline expression of mammalian ASUNDER (ASUN) protein rescues *asun* flies, demonstrating evolutionary conservation of function. In cultured human cells, we find that ASUN downregulation causes reduction of perinuclear dynein in prophase of mitosis. Additional defects following loss of ASUN include nucleus-centrosome uncoupling, abnormal spindles, and multinucleation. Co-immunoprecipitation and overlapping localization patterns of ASUN and LIS1, a dynein adaptor, suggest that ASUN interacts with dynein in the cytoplasm via LIS1. Our data indicate that ASUN controls dynein localization via a mechanism distinct from that of either BICD2 or CENP-F. We present a model in which ASUN promotes perinuclear enrichment of dynein at G2/M that facilitates BICD2- and CENP-F-mediated anchoring of dynein to nuclear pore complexes.

**The nuclear envelope protein emerin functions with myosin IIB to organize actin flow and nuclear movement in polarizing cells.**

W. Chang<sup>1</sup>, E. S. Folker<sup>1</sup>, H. J. Worman<sup>2</sup>, G. G. Gundersen<sup>1</sup>; <sup>1</sup>Department of Pathology and Cell Biology, Columbia University, New York, NY, <sup>2</sup>Department of Medicine, Columbia University, New York, NY

Nuclear positioning is a tightly regulated process and plays important roles in cellular and developmental events, including differentiation, cell division, fertilization, and cell migration. To study nuclear positioning during cell migration we utilize wounded monolayers of starved NIH 3T3 fibroblasts as a model system. In this system, nuclear movement occurs during centrosome orientation and is triggered by addition of the serum factor lysophosphatidic acid (LPA), which results in the Cdc42-dependent activation of myosin and generation of polarized, retrograde actin flow (Gomes et al., Cell 2005). A nuclear membrane structure composed of nesprin-2G and SUN2, termed transmembrane actin-associated nuclear lines (TAN-lines), attaches dorsal actin cables to the nucleus to move the nucleus rearward (Luxton et al., Science, 2010). Interestingly, we found that emerin, a nuclear protein that localizes to both the inner and outer nuclear membranes and interacts with nesprin and SUN proteins, was required for proper nuclear movement and accompanying centrosome orientation in NIH 3T3 fibroblasts. Knock down of emerin prevented LPA-induced nuclear movements in most cells, and when nuclei moved, they moved chaotically, rather than directionally rearward. Analysis of TAN line dynamics using GFP-mini-nesprin-2G revealed that TAN lines formed normally, but slipped over the nucleus rather than moving with it, similar to the phenotype in lamin A/C null cells (Folker et al., PNAS, 2011). Analysis of actin flow using LifeAct-mCherry revealed that dorsal actin cables formed normally, but their orientation was random, rather than parallel to the leading edge and their flow was nondirectional. Cells knocked down for myosin IIB, but not myosin IIA, showed

similar chaotic nuclear movements and actin cable flows, suggesting emerin may function with myosin IIB to control nuclear movement by organizing actin flow. Consistent with this, we found that emerin specifically interacted with myosin IIB and that myosin IIB accumulated near the nucleus in an emerin dependent fashion after LPA or V12-Cdc42 stimulation of nuclear movement. We conclude that emerin functions with myosin IIB to polarize the flow of actin cables and control the directionality of nuclear movement in cells. Our results suggest a novel function for the nuclear envelope in the organization of contractile actin flow in cells.

1433

**UNC-84 is an inner nuclear membrane SUN protein that directly connects lamin in the nucleoplasm to KASH proteins in the perinuclear space.**

*N. Cain<sup>1</sup>, C. Bone<sup>1</sup>, E. Tapley<sup>1</sup>, D. Starr<sup>1</sup>; <sup>1</sup>MCB, University of California Davis, Davis, CA*

Positioning of the nucleus is essential for many cellular processes, including cell polarization, fertilization, cell motility, and cell division. In most eukaryotes, a nuclear envelope bridge consisting of an inner nuclear membrane SUN protein and an outer nuclear membrane KASH protein form the LINC complex (for LInker of the Nucleoskeleton to the Cytoskeleton) to link the cytoskeleton to the nucleoskeleton. In *C. elegans*, the inner nuclear membrane SUN protein UNC-84 recruits the KASH protein UNC-83 to the outer nuclear membrane. UNC-83 then recruits microtubule motors dynein and kinesin-1 to move nuclei. However, many questions remain regarding the structure of *C. elegans* nuclear envelope bridges and their ability to withstand forces generated in the cytoplasm and transferred to the nucleoskeleton. Recently, the structure of a human KASH-SUN pair was solved, allowing predictions to be made about the structure and function of LINC complexes in vivo. Here, we present a functional analysis of the nucleoplasmic, nuclear-envelope-luminal and SUN domains of UNC-84. We observed an interaction between the UNC-84 N-terminus and lamin in a yeast two-hybrid assay. This interaction was weakened by the P91S mutation previously found to partially disrupt nuclear migration. Preliminary data suggests that UNC-84 is part of an interaction network at the inner nuclear membrane that includes the NET5/Samp1/Ima1 homolog. In the perinuclear space, the majority of the linker domain between the trans-membrane domain and SUN domain is not required to facilitate nuclear migration, because a deletion of approximately 300 residues between the transmembrane domain and the SUN domain remains functional. A 50 amino acid span immediately upstream of the SUN domain, which we hypothesize to include a trimerization domain, is required for function. Additionally, mutations in conserved residues in the UNC-84 SUN domain predicted to facilitate KASH binding disrupt in vivo nuclear migration events. We propose that the N-terminus of UNC-84 directly binds lamin to transfer forces from the LINC complex to the nucleoskeleton. Furthermore, our model predicts that UNC-84 spans the perinuclear space before directly binding KASH proteins near the outer nuclear membrane.

1434

**Architecture and function of the trypanosome nuclear envelope revealed using high resolution interactome mapping.**

*S. Obado<sup>1</sup>, J. DeGrasse<sup>1</sup>, K. DuBois<sup>2</sup>, M. Field<sup>2</sup>, B. Chait<sup>1</sup>, M. Rout<sup>1</sup>; <sup>1</sup>Rockefeller University, New York, NY, <sup>2</sup>Cambridge University, Cambridge, United Kingdom*

The nuclear pore complex (NPC) is a macromolecular assembly embedded within the nuclear envelope (NE) that mediates transport between the nucleus and cytoplasm. Both the NPC and NE serve as structural platforms from which intranuclear compartments and the nuclear lamina are organized, playing a key regulatory role in gene expression through influencing nuclear architecture and acting as a point for the control for various nuclear functions. Each NPC is a large (~50 MDa in yeast) cylindrical octagonally symmetric complex comprised of ~480

components (termed nucleoporins or Nups) built from a common set of ~30 different proteins. Currently, detailed compositional and structural information of NPCs is only available in yeast and metazoa, which are closely related. We previously identified 22 Nups in *Trypanosoma brucei* (TbNups) using a proteomics based approach, and tagged each ORF genomically with GFP. Further understanding of NPC/NE interactions within the trypanosome genome, and hence uncovering precise functions, requires a detailed description of the NPC/NE protein interactome. Using GFP as an affinity handle, we are currently dissecting the interactions formed by these proteins in an effort to build a structural map of the NPC/NE. Using a novel cryogrinding approach, we have affinity isolated core scaffold sub-complexes that form the inner and outer ring of the NPC. We demonstrate a highly efficient method for isolation of trypanosome protein complexes, finding several novel nucleoporins that represent trypanosome-specific subunits. These results are already shedding new light on the evolution of the NPC and the nuclear architecture of the last common eukaryotic ancestor.

1435

### **The Molecular Architecture of Nuclear Transport.**

*E. Villa*<sup>1</sup>, *M. Schaffer*<sup>1</sup>, *J. Plitzko*<sup>1</sup>, *W. Baumeister*<sup>1</sup>; <sup>1</sup>Max Planck Institute of Biochemistry, Martinsried, Germany

The nuclear pore complex (NPC) is one of the largest macromolecular machines in the cell, composed of hundreds of proteins, selectively controlling all traffic between the nucleus and the cytoplasm. The architecture of the NPC is central to understanding nuclear transport. However, due to its sheer size, its local environment and its dynamic nature, determining its structure at molecular resolution remains a challenge for conventional techniques. Cryo-electron tomography (cryo-ET) provides unprecedented insights into the 3-D macromolecular organization of cells in their native state, yet the thickness of most cells makes them inaccessible to cryo-ET. Focused ion beam (FIB) milling can be used to prepare 200-500 nm lamellae from intact cells, opening large windows into the cell's interior, enabling the use of cryo-ET to study it at molecular resolution. Combining FIB milling, cryo-ET, and image processing enables the study of the NPC in its native environment, free of the distortions caused by purification. This approach has not only revealed the NPC architecture at unparalleled resolution, but also captured different conformational states in action. I will discuss how the structure obtained by cryo-ET will serve as a scaffold upon which data from a wide range of techniques can be integrated, unveiling the molecular mechanisms of nuclear transport.

1436

### **The *Xenopus* embryonic protein XDppa2 couples chromatin-induced microtubule disassembly to nuclear re-formation.**

*J. Z. Xue*<sup>1</sup>, *E. M. Woo*<sup>1,2</sup>, *L. Postow*<sup>1</sup>, *B. T. Chait*<sup>2</sup>, *H. Funabiki*<sup>1</sup>; <sup>1</sup>Laboratory of Chromosome and Cell Biology, Rockefeller University, New York, NY, <sup>2</sup>Laboratory of Mass Spectrometry and Gaseous Ion Chemistry, Rockefeller University, New York, NY

During mitosis, the metazoan nucleus is dismantled and must be reassembled at its conclusion to complete chromosome segregation and cell division. If this process is compromised, aberrant nuclear assembly and morphology may lead to altered gene expression, tissue pathology and developmental defects. *Xenopus sperm* are an ideal system for studying nuclear assembly and morphology regulation; upon exposure to egg cytoplasm, sperm nuclei undergo a dramatic shape transition from compact crescents to expansive spheres. Here we show that this process requires the embryonic protein XDppa2, which promotes microtubule disassembly in the vicinity

of chromosomes. In extracts depleted of XDppa2, chromosomes are associated with excess microtubules at mitotic exit, leading to a delay in nuclear expansion and aberrant nuclear morphology. These abnormal nuclei recruit less lamin B and fewer nuclear pore complexes, leading to defective genome replication. We show that nuclear assembly is exquisitely sensitive to the balance of microtubule assembly and disassembly, and is compromised both by excessive microtubule stabilization and in the complete absence of microtubules. Moreover, this sensitivity is only observed during the early stages of nuclear assembly and not during late nuclear assembly, highlighting the importance of temporally-regulated microtubule dynamics.

We will present recent work on the interactions between nuclear envelope components and microtubules that impinge on nuclear structure, as well as the mechanism by which XDppa2 is activated. Chromatin is essential for XDppa2 activation, and promotes multimerization and chromatin-dependent SUMOylation of XDppa2. Thus these mechanisms spatially and temporally regulate microtubule dynamics, ensuring the fidelity of nuclear assembly. XDppa2 and its homologues are essential for embryonic survival and only expressed in embryonic tissues, where maintenance of nuclear organization may be important for gene expression and subsequent developmental programmes. Moreover, like many embryonic genes human Dppa2 is overexpressed in certain cancers, and thus may contribute to common proliferative pathways between embryonic and cancerous cells.

1437

**Engineered nuclear pore complexes unveil how FG domains form a functional permeability barrier.**

*B. Hülsmann<sup>1</sup>, D. Görlich<sup>1</sup>; <sup>1</sup>Max-Planck-Institute for Biophysical Chemistry, Göttingen, Germany*

Nuclear pore complexes (NPCs) conduct and control traffic between the nucleus and the cytoplasm. They suppress fluxes of inert macromolecules and thus prevent intermixing of nuclear and cytoplasmic contents. Shuttling nuclear transport receptors (NTRs), however, cross the NPC- barrier in a highly facilitated manner and thereby supply nuclei with proteins and the cytoplasm with nuclear products like ribosomes.

FG repeat-containing nucleoporins (FG Nups) are critical for the barrier. They are anchored to the NPC scaffold and their FG motifs bind NTRs during facilitated translocation. While the crucial importance of FG domains is well established, currently discussed models differ widely in their explanation as to how FG domains confer transport selectivity. To test the predictions of various models we used *Xenopus laevis* egg extracts to assemble nuclei and analysed the embedded NPCs for active transport as well as passive exclusion of inert molecules. Depletion of the Nup54&#8901;58&#8901;62 and Nup62&#8901;88&#8901;214 complexes prior to nuclear assembly caused surprisingly mild functional defects in assembled nuclei. By contrast, NPCs additionally depleted of Nup98 lacked a passive permeability barrier and showed no active transport. These defects were rescued by bacterially expressed Nup98 derivatives that contained FG domains with high cohesiveness along their entire sequence. Nup98 derivatives containing non-cohesive FG domains did not rescue, even if they were fully proficient in NTR-binding.

We describe an experimental system that, for the first time, allows testing the functionality of FG domains in vitro within engineered NPCs, i.e. in their physiological context. Our data indicate that the NPC barrier critically depends on multivalent cohesion between FG domains and argue against models that do not accommodate cohesion into barrier function. Instead, our data support the assumption that the barrier is a sieve-like FG hydrogel as proposed by the "selective phase model". Similar reconstitution experiments will ultimately unveil all the requirements as to

how a functional NPC barrier is formed. We argue that the experimental system established will be pivotal to grasp the nature of the strikingly selective boundary between nucleus and cytoplasm.

1438

**Depletion of Nucleoporins from HeLa Nuclear Pore Complexes to Facilitate the Production of Ghost Pores for *in vitro* Reconstitution.**

A. L. DiGuilio<sup>1</sup>, J. S. Glavy<sup>1</sup>; <sup>1</sup>Stevens Institute of Technology, Hoboken, NJ

During cell division, Nuclear Pore Complexes (NPCs) are broken down into protein subcomplexes that are the basis for reassembly in daughter cells. This is the driving force for the establishment of an *in vitro* reconstitution system to study aspects of NPC reassembly. In this study, nuclear envelope (NE) was isolated from HeLa cells. NE was treated with increasing concentrations of heparin to extract nucleoporins (Nups) for the production of “ghost pores”, which are pores severely deficient in Nups, while still containing Pore Membrane proteins (POM) needed to anchor the NPC. Ghost pores have been subjected to incubation with previously stripped Nups and some re-binding has been shown to occur by western blot analysis. A portion of transport proteins like FG-Nups, Nup62 and Nup54 were found well embedded within the pore region, nevertheless we have shown affinity for re-attachment either to ghost pores or to one another for these proteins. Also nuclear basket FG-Nup Nup153 re-associates, presumably at the nuclear side of the NPC, perhaps as a foundation for re-formation of the nuclear basket. Several scaffold Nups from the Nup107-160 and Nup93 subcomplexes can re-associate to potentially restore the structural integrity of the NPC. Further investigations with ghost pores will lead to a better understanding of the process of NPC reassembly.

1439

**The nuclear pore complex protein Ndc1 regulates the LINC complex to promote nuclear positioning in migrating fibroblasts.**

D. S. Osorio<sup>1</sup>, J. Borrego-Pinto<sup>1,2</sup>, E. R. Gomes<sup>1</sup>; <sup>1</sup>Inserm Umr S 787 – Myology Group, Pierre et Marie Curie University, Paris, France, <sup>2</sup>Cell Biology and Biophysics Unit, European Molecular Biology Laboratory (EMBL), Heidelberg, Germany

Positioning of the nucleus within cells has a role in different processes such as cell migration and muscle differentiation. In migrating fibroblasts, the nucleus moves rearwards prior to cell migration and this movement is dependent on the actin cytoskeleton and on LINC complex proteins Nesprin2G (N2G) and SUN2. In order to identify novel proteins involved in this process, we performed a live-imaging screen for inhibition of nuclear movement through short interfering RNA (siRNA) against a set of 230 potential/confirmed nuclear envelope proteins from published organellar proteomics studies. Ndc1, a conserved transmembrane protein of the nuclear pore complex (NPC) was one of our hits. Depletion of Ndc1 caused the inhibition of centrosome reorientation and nuclear positioning in a fixed cell assay. Furthermore, cell migration was also impaired in this condition, similar to what was observed for N2G siRNA treated cells. Although the full knock down of Ndc1 caused general disruptions of the nuclear envelope, potentially due to its role in nuclear pore assembly, a partial knockdown was sufficient to inhibit nuclear movement without affecting nuclear envelope proteins and structure. We therefore probed for a specific interaction between and LINC complex members that could explain the nuclear movement involvement. We found that the N-terminal region of Ndc1 interacted with the luminal region of SUN2. This region of Ndc1 is distinct from the proposed NPC interacting region localized on the conserved C-terminus. Expression of full length siRNA resistant Ndc1 or Ndc1 lacking the c-terminus were able to rescue centrosome reorientation in Ndc1 siRNA cells, suggesting that the interaction of Ndc1 with the nuclear pore is not required for nuclear

movement. Furthermore, SUN2 does not colocalize with nuclear pores and we found a population of nuclear envelope Ndc1 not at the NPC. We propose a model where a non-NPC population of Ndc1 is involved in the regulation of SUN2-N2G LINC complex during nuclear movement.

1440

### **Molecular mechanisms underlying extensive elongation and coiling of the *Marsilea* nucleus.**

C. M. Van der Weele<sup>1</sup>, S. M. Wolniak<sup>1</sup>; <sup>1</sup>Cell Biology & Molecular Genetics, University of Maryland-College Park, College Park, MD

The nuclei in spermatids of the male gametophyte of *Marsilea vestita* change dramatically from being spherical to an elongated coil with 9 gyres. The change is rapid and is completed in <3 hours. As the nucleus elongates, it becomes appressed against a large mitochondrion and a ribbon of crosslinked microtubules. On the dorsal face of the ribbon, there are 140 basal bodies, which had formed *de novo* two hours earlier in development. The chromatin becomes highly condensed and arranged against the nuclear envelope and nuclear pores become localized on the ventral side of the elongating nucleus. We are investigating the roles of the cytoskeleton, nuclear envelope proteins and the process of chromatin condensation in nuclear shaping during spermatid differentiation in this organism. Rapid gametophyte development relies mainly on the translation of stored transcripts. A transcriptome was constructed *de novo* from RNA isolates obtained from different time intervals during gametophyte development. Here, we focused on nuclear pore protein transcripts (e.g., nuclearporins, or nups), nuclear movement domain containing proteins (e.g., SUN, KASH) and transcripts of proteins affecting the microtubule cytoskeleton (e.g., alpha tubulin, tubulin-specific chaperone A and tubulin polyglutamylase). Among these transcripts was a group of mRNAs that was present at all time intervals and a second group that was only present during spermatid differentiation (nup GLE1, nup 188). RNAi experiments were combined with histology and immunohistochemistry to assess the roles of these transcripts in nuclear elongation and coiling. Analysis of the transcriptome revealed that there is extensive processing of stored transcripts. Transcript availability for translation involves several levels of regulation. A central regulator in RNA processing is a single RRM domain containing protein, named MvU620. Knockdowns of MvU620 inhibited nuclear shaping and blocked the formation of the microtubule ribbon. Deep sequencing of transcripts in MvU620-knockdowns showed some of the transcripts in the second group (e.g., tubulin polyglutamylase, tubulin specific chaperone A, nup GLE1) appear to be incompletely spliced, which is being further investigated using RT-PCR. These results show that a novel RNA-binding protein plays a central role in the regulation of RNA processing that is essential for nuclear shaping in a rapidly developing spermatid. Supported by NSF grant 0842525 to SMW.

## **Endocytic Trafficking II**

1441

### **The functions of anionic phospholipids during endocytic site initiation and vesicle formation.**

Y. Sun<sup>1</sup>, D. Drubin<sup>1</sup>; <sup>1</sup>MCB, UC Berkeley, Berkeley, CA

Anionic phospholipids PI(4,5)P2 and phosphatidylserine (PS) are enriched in the cytosolic leaflet of the plasma membrane where endocytic sites form. In this study, we investigated the roles of PI(4,5)P2 and PS in endocytic site initiation and vesicle formation in *Saccharomyces*

cerevisiae. Live-cell imaging of endocytic protein dynamics in an *mss4ts* mutant, which has severely reduced PI(4,5)P<sub>2</sub> levels, revealed that PI(4,5)P<sub>2</sub> is required for endocytic membrane invagination but less important for endocytic site initiation. We also demonstrated that in various deletion mutants of genes encoding components of the Rcy1-Ypt31/32 GTPase pathway, endocytic proteins dynamically assemble not only on the plasma membrane but also on intracellular membrane compartments, which are likely derived from early endosomes. In *rcy1* knock-out cells, fluorescent biosensors indicated that PI(4,5)P<sub>2</sub> only localized to the plasma membranes while PS localized to both the plasma membrane and intracellular membranes. Furthermore, we found that polarized endocytic patch establishment is defective in the PS-deficient *cho1* knock-out mutant. We propose that PS is important for directing endocytic proteins to the plasma membrane and that PI(4,5)P<sub>2</sub> is required to facilitate endocytic membrane invagination.

1442

#### **Ubiquitination of endocytic machinery regulates coat formation.**

*J. S. Weinberg<sup>1</sup>, D. Drubin<sup>1</sup>; <sup>1</sup>Molecular and Cell Biology, University of California-Berkeley, Berkeley, CA*

Endocytosis in yeast requires the regulated recruitment and disassociation of over 60 proteins at discreet plasma membrane puncta. The post-translational modifications that act as signals in this highly processive and ordered process are of great interest. Ubiquitination of several endocytic proteins has been reported, but neither phenotypes nor functional consequences of these modifications are known. Here we report that ubiquitination of Ede1p, the yeast Eps15 homolog, affects the stability and disassembly of the endocytic coat. We identified the deubiquitinase Ubp7p as a late arriving endocytic protein, which likely removes the ubiquitin on Ede1p. Deletion of Ede1p does not fully suppress the deubiquitinase deletion phenotype, suggesting that Ede1p is not the only endocytic target whose deubiquitination affects coat formation.

1443

#### **Molecular brightness analysis reveals phosphatidylinositol 4-kinase II $\beta$ association with clathrin coated vesicles in living cells.**

*Y. Chen<sup>1</sup>, J. Li<sup>1</sup>, J. D. Mueller<sup>1</sup>, B. Barylko<sup>2</sup>, J. P. Albanese<sup>2</sup>; <sup>1</sup>Physics, University of Minnesota, Minneapolis, MN, <sup>2</sup>Department of Pharmacology, UT Southwestern Medical Center, Dallas, TX*

Mammalian cells express two classes of phosphatidylinositol 4-kinase (PI4K), designated Types II and III, which phosphorylate phosphatidylinositol to generate PI4P. A number of studies indicate that these enzymes are important for Golgi trafficking and early as well as late stages of endocytosis. In this study, we focus on PI4KII $\beta$ , a protein that is evenly distributed between membrane and soluble fractions and is believed to participate in stimulus-dependent phosphoinositide signaling. Using molecular brightness analysis, we found that EGFP-tagged PI4KII $\beta$  exists as two distinct species in the cytoplasm, a soluble monomer and a high order complex enriched with multiple copies of PI4KII $\beta$ . This observation is confirmed by autocorrelation analysis which identifies two species with distinct mobilities. We further demonstrate that the high order complex enriched with PI4KII $\beta$  is sensitive to inhibition of palmitoylation, indicating that it is associated with membranes, very likely vesicles. Indeed, we show that the high order PI4KII $\beta$  complex is sensitive to expression of dynamin 2-K44A, a dominant-negative inhibitor of endocytosis. We further directly detect that PI4KII $\beta$  co-moves with clathrin light chain on vesicles using dual-color heterospecies partition analysis. This analysis allows us to isolate the co-mobile species in the presence of strong background contribution from the monomeric pool of PI4KII $\beta$ . Our results strongly suggest that PI4KII $\beta$  is

involved in an early stage of endocytosis, and associated with clathrin-coated vesicles. Moreover, we establish molecular brightness as a powerful tool to characterize cellular cytosolic vesicles that are otherwise difficult to characterize by other techniques. This work is supported by the National Institutes of Health (R01 GM64589) and the National Science Foundation (PHY-0346782).

### **Crosslinking-Induced Endocytosis of Acetylcholine Receptors by Quantum Dots.**

*C. W. Lee<sup>1</sup>, H. Zhang<sup>1</sup>, L. Geng<sup>1</sup>, H. B. Peng<sup>1</sup>; <sup>1</sup>Division of Life Science, Hong Kong University of Science & Technology, Kowloon, Hong Kong*

In majority of patients with myasthenia gravis (MG), anti-acetylcholine receptor (AChR) antibodies are generated in their immune system, which target the postsynaptic AChR clusters and membrane integrity of neuromuscular junctions (NMJs) leading to muscle weakness. The antibody-induced endocytosis of AChRs in the postsynaptic membrane represents the initial step in MG pathogenesis; however the molecular mechanisms underlying AChR endocytosis remain largely unknown. Here, we used multivalent quantum dots (QDs) to mimic the pathogenic antibodies for inducing the crosslinking and internalization of AChR from the postsynaptic membrane. By labeling the muscle cells with biotin-conjugated  $\alpha$ -bungarotoxin followed by QD-conjugated streptavidin, we were able to differentiate the surface versus internalized AChRs by comparing their size, fluorescence intensity, trajectory, and subcellular localization of the QD signals. These crosslinking-induced internalized AChRs were highly co-localized with an early endosomal marker. Furthermore, QD-induced AChR endocytosis was mediated via clathrin-dependent, and caveolin-independent, mechanisms. Nocodazole or cold temperature treatment, that largely disrupted microtubule structures, arrested the movement of QD-induced AChR vesicles inside the cells. Furthermore, activation of agrin/MuSK signaling pathway, by either agrin treatment or over-expression of MuSK and rapsyn, significantly suppressed QD-induced internalization of AChRs, suggesting synaptogenic signals increase the stability of surface AChRs. Lastly, QD-induced AChR crosslinking potentiated the dispersal of pre-patterned AChR clusters upon synaptic induction. Taken together, this study reports a novel approach to study the trafficking mechanisms of AChRs upon receptor crosslinking and endocytosis, and demonstrates the involvement of agrin-MuSK signaling in the crosslinking-induced AChR endocytosis.

This study is supported by a research development grant (186316) from Muscular Dystrophy Association to C.W.L. and a GRF grant (662312) from Hong Kong Research Grants Council to C.W.L. and H.B.P.

### **HK-ATPase trafficking and apical vacuolar membrane stability requires non-muscle myosin II in gastric parietal cell.**

*P. Natarajan<sup>1</sup>, T. E. Machen<sup>1</sup>, J. G. Forte<sup>1</sup>; <sup>1</sup>Molecular and Cell Biology, University of California, Berkeley, Berkeley, CA*

The essential role for non-muscle myosin II (Myo II) network and dynamics in cytokinesis, cell migration, polarity, epithelial morphogenesis and nucleus positioning has been well documented. However, the impact of myosin II on the regulated membrane trafficking and recruitment of HK-ATPase H<sup>+</sup> pump (HK) of gastric parietal cells from tubulovesicles in resting cells into the apical membrane of the stimulated cells has been elusive. Here, we use primary cultures of rabbit parietal cells to show that Myo II is required for proper positioning of apical

vacuole (AV's) and stimulus-dependent recruitment of HK-containing tubulovesicles into AV membranes. Myo II is localized to the AV membrane in non-stimulated cells, but relocates to cytoplasm and basal membrane when cells are stimulated to secrete acid by histamine. Inhibition of Myo II function by ML-7 (myosin light chain kinase inhibitor), but not Y-27632 (ROCK inhibitor) or blebbistatin (inhibitor of non-muscle myosin ATPase activity), destabilizes and relocates actin and ezrin, both of which are normally associated with AV membranes, to the basal membrane. Moreover, ML-7 completely prevented histamine-stimulated HK vesicle transport to the AV membrane. These results indicate that Myo II is critical for positioning and morphological configuration of AV membranes in resting parietal cells and for the proper trafficking of HK-containing tubulovesicles to the AV during histamine-stimulation.

**A Secretagogue-induced microtubule dynamics facilitate HK-ATPase vesicle transport in gastric parietal cell.**

*P. Natarajan<sup>1</sup>, A. Sawaguchi<sup>2</sup>, C. T. Okamoto<sup>3</sup>, J. G. Forte<sup>1</sup>; <sup>1</sup>Molecular and Cell Biology, University of California, Berkeley, Berkeley, CA, <sup>2</sup>Department of Anatomy, Ultrastructural Cell Biology, University of Miyazaki, Kiyotake, Miyazaki, Japan, <sup>3</sup>Department of Pharmacology and Pharmaceutical Sciences, University of Southern California, Los Angeles, CA*

Microtubule (MT) dynamics-based polarized vesicular transport is well documented in epithelial and neuronal cells, but how microtubule dynamics facilitate stimulus-associated HK-ATPase containing tubulovesicle (TV) transport to the apical vacuolar membrane (AV membrane) in the gastric parietal cell is not clear. Ultrastructure studies of high-pressure frozen parietal cells showed that microtubules were associated closely with tubulovesicles. These associations frequently included some electron dense material. These findings were confirmed by computer-assisted 3D electron tomography. Then we demonstrated by immunostaining that cytoplasmic MTs extend towards the periphery when parietal cells are stimulated by histamine, but in control cells they were more centrally located. Sub-cellular fractionation of gastric glands showed association of kinesin 1 and dynein (microtubule motor protein) in the TV-enriched fraction. This relatively close association was further confirmed by high salt and alkaline wash experiments. Immunoprecipitation followed by mass spec (LC/MS/MS) analysis showed that kinesin 1 binds with three kinesin light chains (KL1,2 and 3), and that dynein intermediate chain binds dynein and IQGAP but not Clip170 (Linker for IQGAP and molecular motors). Interestingly, interaction of dynein with IQGAP doesn't require Clip170. These data suggest that specific kinesin light chain and IQGAP might play a role to select cargo protein/vesicle. Surprisingly, nocodazole doesn't inhibit histamine stimulated HK-ATPase-containing TV transport to the AV membrane. Thus, MTs and molecular motor dynamics may facilitate long-distance transport of TV to AV membrane in gastric parietal cell to attain maximal acid secretion.

**Cell adhesion defines the topology of endocytosis and impacts signaling pathways.**

*J-P. Grossier<sup>1</sup>, T. Duong<sup>1</sup>, B. Goud<sup>1</sup>, K. Schauer<sup>1</sup>; <sup>1</sup>Institut Curie, Paris, France*

To understand which role cell adhesion plays in endocytosis we studied uptake of transferrin (Tfn) and epidermal growth factor (EGF) in cells whose adhesion geometry was defined by micropatterns that force cells to adopt a reproducible interaction with the extracellular matrix. We quantified the 3D organization of endocytosed molecules with probabilistic density maps that provide information about the behavior of the majority of endocytosed molecules. We found an unexpected asymmetry in clathrin -dependent and independent endocytosis of transferrin (Tfn) and epidermal growth factor (EGF), respectively: Tfn was enriched in adhesive areas on the top of adhesive patterns, whereas EGF was concentrated at the dorsal surface of the cell.

This spatial separation was not due to the distribution of corresponding receptors. Clathrin-dependent endocytosis of Tfn above the micropattern was due to the selective recruitment of AP2 and clathrin to adhesive areas. Consistently, clathrin-independent uptake of EGF at high concentrations (>100 ng/ml), used in this study for fluorescent visualization, was absent from adhesive areas. We found that the actin cytoskeleton played an important role in restricting uptake sites without being essential for continued operation of receptor-mediated endocytosis. Alterations in actin dynamics changed uptake topology of Tfn and EGF and diminished EGF-mediated downstream signaling revealing how cells may sense their environment and respond to stimulations in a polarized fashion. We propose that variations in cellular adhesion geometry convert receptor mediated endocytosis into spatial signal transduction.

### Specific $\alpha$ -arrestins Regulate GPCR Internalization in *Saccharomyces cerevisiae*.

C. G. Alvaro<sup>1</sup>, A. F. O'Donnell<sup>1,2</sup>, D. C. Prosser<sup>3</sup>, B. Wendland<sup>3</sup>, J. Thorner<sup>1</sup>; <sup>1</sup>Department of Molecular and Cell Biology, University of California - Berkeley, Berkeley, CA, <sup>2</sup>Molecular and Cell Biology, University of California - Berkeley, Berkeley, CA, <sup>3</sup>Department of Biology, John Hopkins University, Baltimore, MD

G-protein-coupled receptors (GPCRs) are the largest class of cell surface receptors and initiate cellular responses to a myriad of extracellular stimuli. Because prolonged GPCR-mediated signaling can be detrimental, post-agonist desensitization is exquisitely regulated. One mechanism for down-regulation of GPCR-initiated signaling, receptor endocytosis, proceeds through a series of characteristic steps, including GPCR phosphorylation, ubiquitylation, recruitment to clathrin-coated pits, and internalization. In mammalian cells, members of a small family of dedicated trafficking adaptors, the  $\beta$ -arrestins, block signaling and reportedly mediate GPCR internalization. The *S. cerevisiae* genome lacks any obvious  $\beta$ -arrestin homologs, but encodes a more numerous class of related proteins,  $\alpha$ -arrestins, which possess multiple copies of a motif (PPxY) required for interaction with the HECT domain-containing ubiquitin ligase Rsp5. It is well established in yeast that  $\alpha$ -arrestins are required for efficient internalization of nutrient transporters. Given the lack of  $\beta$ -arrestins in yeast, we explored whether any of the  $\alpha$ -arrestins are required for internalization of either of the two GPCRs that initiate the mating pheromone pathway — Ste2 on *MATa* haploids that binds  $\alpha$ -factor and Ste3 on *MAT $\alpha$*  haploids that binds a-factor. We have found that specific  $\alpha$ -arrestins regulate the mating pathway in a haploid-specific manner. *MATa* cells lacking two paralogous  $\alpha$ -arrestins Rod1 and Rog3 (and/or the  $\alpha$ -arrestin Ldb19) are detectably more sensitive to  $\alpha$ -factor than wild-type cells, as judged by the standard halo bioassay for pheromone-induced G1 arrest. Similarly, *MAT $\alpha$*  haploids lacking two other paralogous  $\alpha$ -arrestins, Aly1 and Aly2, as well as Ldb19, are detectably more sensitive to a-factor than otherwise wild-type cells. Given that the main difference between these two cell types is the GPCR itself, these findings suggest specific cargo-adaptor interaction between GPCRs and  $\alpha$ -arrestins. Phenotypic rescue experiments in *MATa* haploids showed that removal of PPxY motifs in Rod1 and Ldb19 disrupts their ability to complement, indicating that interaction with Rsp5 is required for their function. As judged by fluorescence microscopy, the level of fluorescently tagged versions of Ste2 and Ste3 at the plasma membrane in *MATa rod1 $\Delta$  rog3 $\Delta$*  cells and *MAT $\alpha$  aly1 $\Delta$  aly2 $\Delta$* , respectively, is elevated compared to wild-type controls. These findings indicate that, in yeast, efficient endocytosis of GPCRs is dependent on discrete members of the  $\alpha$ -arrestin family.

1449

**A calcineurin-dependent switch controls the trafficking function of  $\alpha$ -arrestin Aly1/Art6.**

A. F. O'Donnell<sup>1,2,3</sup>, L. Huang<sup>2,4</sup>, J. Thorner<sup>3</sup>, M. Cyert<sup>2</sup>; <sup>1</sup>Department of Cell Biology, University of Pittsburgh, Pittsburgh, PA, <sup>2</sup>Department of Biology, Stanford University, Stanford, CA, <sup>3</sup>Department of Molecular and Cell Biology, University of California, Berkeley, Berkeley, CA, <sup>4</sup>School of Life Sciences, Tsinghua University, Beijing, China

Protein endocytosis triggered by external stimuli is critical for cell growth and survival. In yeast, certain nutrients, when present in excess, induce endocytosis of the cognate permeases to prevent possible toxic accumulation of metabolites. Although permease internalization is regulated by the corresponding nutrient, the molecular basis of this effect has been elusive. Recent work revealed that  $\alpha$ -arrestins, a family of trafficking adaptors, stimulate ubiquitin-dependent and clathrin-mediated endocytosis by interacting with both the target permease and the ubiquitin ligase Rsp5. Here we show that  $\alpha$ -arrestin Aly1/Art6 is a phosphoprotein that specifically interacts with and is dephosphorylated by the Ca<sup>2+</sup>- and calmodulin-dependent phosphoprotein phosphatase calcineurin/PP2B. Dephosphorylation of Aly1 at a subset of calcineurin-regulated phospho-sites is required for Aly1-mediated endocytosis of the aspartic acid and glutamic acid transporter Dip5, but does not alter ubiquitination or stability of Aly1. Dephosphorylation has no significant effect on the previously identified role for Aly1 in intracellular sorting of the general amino acid permease Gap1. These results suggest that phosphorylation of Aly1 inhibits its endocytic function and, conversely, that nutrient-induced activation of calcineurin serves as a regulatory switch by stimulating dephosphorylation of Aly1 to promote its endocytic function.

1450

**Yeast alpha-arrestins play a cargo-selective role in Rho1-mediated clathrin-independent endocytosis.**

D. C. Prosser<sup>1</sup>, B. Wendland<sup>1</sup>, J. Thorner<sup>2</sup>, A. F. O'Donnell<sup>1,3</sup>; <sup>1</sup>Biology, The Johns Hopkins University, Baltimore, MD, <sup>2</sup>Molecular and Cell Biology, University of California, Berkeley, Berkeley, CA, <sup>3</sup>Cell Biology and Physiology, University of Pittsburgh, Pittsburgh, PA

Although most cell types use both clathrin-mediated (CME) and clathrin-independent (CIE) endocytic pathways, yeast have been thought to rely solely upon CME for internalization of plasma membrane cargo. We recently uncovered a second endocytic pathway in yeast that acts independently of clathrin and CME machinery, but instead relies on the small GTPase Rho1 and its effector, the formin Bni1. While factors regulating cargo entry through CME have been identified, mechanisms for cargo delivery into the Rho1-dependent CIE pathway are currently unclear. A recent mass spectrometry screen identified Rom2, which is a guanine nucleotide exchange factor that acts upstream of Rho1, as a candidate binding partner for the  $\alpha$ -arrestin Aly1. Since yeast  $\alpha$ -arrestins are involved in cargo ubiquitination during CME by recruiting the E3 ligase Rsp5, we hypothesized that  $\alpha$ -arrestins may additionally regulate cargo entry during CIE via interactions with components of the Rho1-dependent CIE pathway. We show that high-copy expression of the individual arrestins Aly1, Aly2 and Ldb19 promotes clathrin-independent internalization of the pheromone receptor Ste3. High-copy Ldb19 (but not Aly1 or Aly2) also promotes Mup1 internalization, suggesting that arrestins act in a cargo-specific manner during CIE. Surprisingly, mutation of the canonical Rsp5-binding sites on arrestins did not impair their ability to promote clathrin-independent internalization of Ste3 or Mup1. Thus, our findings suggest that  $\alpha$ -arrestins are involved in yeast CIE through a mechanism that is distinct from their known role in CME.

1451

**Ivy1 is a regulated interactor of the Rab7 GTPase Ypt7 that controls endosome-vacuole fusion.***J. Numrich<sup>1</sup>, H. Artl<sup>1</sup>, C. Ungermann<sup>1</sup>; <sup>1</sup>University of Osnabrück, Osnabrück, Germany*

The yeast vacuole is a highly dynamic organelle, which undergoes fission and fusion during osmotic stress or vacuolar inheritance. The homotypic fusion of vacuoles is a well-studied process, which depends on a fusion machinery mainly consisting of SNAREs, the Rab7 homolog Ypt7 and its effector HOPS. Beside homotypic fusion events, heterotypic fusion events including the fusion of late endosomes and autophagosomes occur at the vacuole for the delivery of vacuolar hydrolases. All these fusion processes are also dependent on Ypt7 and its effector HOPS. Before fusion with the vacuole can occur, several steps are needed for maturation of these organelles. The processes that contribute to maturation are in the process of being understood but the question when exactly is an organelle ready for fusion is still unanswered.

A possible regulator interfering with fusion processes at the vacuole is Ivy1, which has been implicated as a Ypt7 and HOPS binding protein. I will present insights on the function of Ivy1 as an inhibitor of vacuole fusion in vivo and in vitro. The ability of recombinant Ivy1 to inhibit vacuole fusion in vitro strengthens our hypothesis that Ivy1 is a regulator of fusion processes at the vacuole. Furthermore, preliminary data suggest that the function of Ivy1 can be regulated by posttranslational modification.

**Role of ligand size and binding accessibility on clathrin- and caveolae-independent CAM-mediated endocytosis.***D. Serrano<sup>1,2</sup>, R. Chadha<sup>3</sup>, C. Garnacho<sup>4</sup>, S. Muro<sup>4,5</sup>; <sup>1</sup>Biological Sciences, University of Maryland, College Park, MD, <sup>2</sup>Cell Biology and Molecular Genetics, University of Maryland, College Park, MD, <sup>3</sup>Department of Biology, University of Maryland, College Park, MD, <sup>4</sup>Institute for Bioscience and Biotechnology Research, University of Maryland, College Park, MD, <sup>5</sup>Fischell Department of Bioengineering, University of Maryland, College Park, MD*

Intercellular adhesion molecule 1 (ICAM-1) is a transmembrane glycoprotein overexpressed by endothelial cells particularly at sites of inflammation, making it a suitable candidate for targeted drug delivery. Drug carriers displaying multiple copies of an ICAM-1-targeting moiety (such as antibodies or peptides) bind multivalently to ICAM-1 and induce a pathway known as cell adhesion molecule (CAM)-mediated endocytosis, which differs from clathrin- and caveolae-dependent uptake. CAM-mediated endocytosis depends on enzymatic production of ceramide at sites of carrier engulfment, which leads to rearrangement of the actin cytoskeleton. This allows for uptake of carriers of different sizes, from 100 nm up to 5  $\mu$ m in diameter. Here, we explored how carrier size affects CAM-mediated endocytosis, particularly in the context of using targeting moieties that have different lengths and, hence, different accessibility to ICAM-1. We coated 100 nm, 1  $\mu$ m or 4.5  $\mu$ m model polymer carriers with either a 150 kDa antibody or a 17-mer peptide, both of which specifically bind ICAM-1. We then determined binding and internalization levels of these carriers by endothelial cells using fluorescence microscopy. Carriers of 100 nm in diameter coated with anti-ICAM bound at levels 1.5-fold higher compared to peptide-coated counterparts. Increasing the size of anti-ICAM carriers to 1  $\mu$ m or 4.5  $\mu$ m led to a reduction in carrier binding levels, which was also observed with peptide-coated carriers but to a greater extent. This suggests that increasing carrier size affected ICAM-1 accessibility, but this effect was greater with peptides than with antibodies. In the case of all sizes, antibody-

coated carriers showed higher levels of internalization compared to peptide-coated counterparts. However, this effect was not due directly to lower binding levels because incubation of antibody carriers on cells expressing low levels of ICAM-1 (hence, exhibiting low levels of carrier binding) led to equally efficient internalization compared to conditions of high ICAM-1 expression. Thus, we asked if the differences in internalization might be due to differences in the signaling events associated in CAM-mediated uptake. We found that both antibody and peptide carriers elicited evident rearrangement of the actin cytoskeleton. However, only antibody-coated carriers were associated with detectable ceramide enrichment at sites of engulfment. Overall, our results indicate that coating short peptides instead of antibodies on carriers diminished binding accessibility to ICAM-1, and, independently, ICAM-1-associated signaling, and internalization of carriers. ### Trafficking of N-cadherin via macropinocytosis in migrating cells.

C-Y. Tai<sup>1</sup>, Y-T. Chiu<sup>1,2</sup>; <sup>1</sup>*Institute of Molecular Biology, Academia Sinica, Taipei, Taiwan*,  
<sup>2</sup>*Department of Life Science, Institute of Genome Science, National Yang-Ming University, Taipei, Taiwan*

N-cadherin is a calcium-dependent homophilic adhesion molecule important for cell-cell adhesion and migration. During cell migration, N-cadherin concentrates at leading edge and ruffles. These ruffles constantly fold back and form macropinosomes to regulate membrane reorganization and nutrient uptake. N-cadherin has been implicated in regulating the closure of macropinosomes via homophilic interactions.

To visualize the dynamics of surface N-cadherin in migrating cells, we monitored the behaviors of N-cadherin fusing with pHluorin [pHluorin-N-cadherin]. We have observed that the surface N-cadherin distributed evenly on the membrane ruffles and internalized by macropinocytosis judging by vesicle size and dextran uptake ability. When the fine localization of N-cadherin at leading edge was resolved by the photoactivated localization microscopy (PALM), rather than uniformly distributed, many N-cadherin molecules formed large yet discrete clusters. These large clusters have distinct behaviors than surrounding non-clustered N-cadherin proteins by fluorescence recovery after photobleaching (FRAP) assay. When in macropinosomes, N-cadherin precedes the arrival of Rab5 because of its presence on ruffles prior to the formation of macropinosomes. Of all macropinosomes arose from ruffles, all of them contained N-cadherin, and a few lack of Rab5 signals disappeared before reaching cell center. Interestingly, blockade of N-cadherin homophilic interaction using N-cadherin interfering antibody (GC-4) decreases the association of Rab5 with macropinosomes. This result suggests that N-cadherin is not only a passenger of macropinosomes, it also plays a role in regulating the stability and maturation of macropinosomes. Together, our results indicate a novel role for N-cadherin in macropinosome formation, and the role of macropinosome in cell migration will be discussed.

### Coronin 1B marks dynamic clathrin- and caveolin-independent endocytic sites in mammalian cells.

A. Grassart<sup>1</sup>, J. B. Doyon<sup>1</sup>, J. E. Bear<sup>2</sup>, N. Sauvonnet<sup>3</sup>, D. G. Drubin<sup>1</sup>; <sup>1</sup>*MCB, UC Berkeley, Berkeley, CA*, <sup>2</sup>*Department of Cell and Developmental Biology and Lineberger Comprehensive Cancer Center, University of North Carolina- HHMI, Chapel Hill, NC*, <sup>3</sup>*Institut Pasteur-CNRS ura2582, Paris, France*

Distinct endocytic pathways in mammalian cells have been classified based on the presence or absence of proteins such as clathrin, caveolin, dynamin and Rho GTPases. Although several

clathrin- and caveolin-independent pathways have been described, these pathways are largely defined by the absence of the proteins named above rather than by the presence of any specific, defining proteins. In the present study, we investigated the dynamics of coronin 1B at the plasma membrane and observed that it localizes to short-lived patches that lack clathrin and caveolin. Using live cell-imaging analysis, we observed that coronin 1B colocalizes with dynamin2 and the actin-related factors WIP, cortactin, Arp3 and cofilin in a specific temporal sequence. We also determined that these coronin 1B patches are directly involved in the internalization of the IL-2 receptor. We observed that the cortactin and coronin1b recruitment are dynamin dependent during IL-2R endocytosis. Interestingly, we also provide evidence for mutual dynamic coordination of cortactin and coronin 1B during the last step of the IL-2R endocytosis. Therefore, our results establish a strong dependency on the actin machinery during the clathrin- and caveolin-independent IL-2R endocytosis pathway. Importantly, this work provides direct evidence for a modular organization for the molecular machinery involved in this clathrin-and caveolin-independent endocytosis pathway and reveals similarities with yeast endocytosis.

**Oligomers of the ATPase EHD2 confine caveolae to the plasma membrane through association with actin.**

*M. Stoeber<sup>1</sup>, I. K. Stoeck<sup>1</sup>, C. Haenni<sup>1</sup>, A. Helenius<sup>1</sup>; <sup>1</sup>Institute of Biochemistry, Swiss Federal Institute of Technology (ETH), Zurich, Switzerland*

Caveolae are specialized domains present in the plasma membrane (PM) of most mammalian cell types. They function in signalling, membrane regulation, and endocytosis. We found that the Eps-15 homology domain-containing protein 2 (EHD2, an ATPase) associated with the static population of PM caveolae. Recruitment to the PM involved ATP binding, interaction with anionic lipids, and oligomerization into large complexes (60–75S) via interaction of the EH domains with intrinsic NPF/KPF motifs. Hydrolysis of ATP was essential for binding of EHD2 complexes to caveolae. EHD2 was found to undergo dynamic exchange at caveolae, a process that depended on a functional ATPase cycle. Depletion of EHD2 by siRNA or expression of a dominant-negative mutant dramatically increased the fraction of mobile caveolar vesicles coming from the PM. Overexpression of EHD2, in turn, caused confinement of cholera toxin B in caveolae. The confining role of EHD2 relied on its capacity to link caveolae to actin filaments. Thus, EHD2 likely plays a key role in adjusting the balance between PM functions of stationary caveolae and the role of caveolae as vesicular carriers.

1456

**Cavin regulates caveolar endocytosis by forming "crescents" that girdle caveolae, stabilizes them in relatively flat conformations, and links them to cortical actin filaments.**

*N. Morone<sup>1</sup>, R. Parton<sup>2</sup>, J. Heuser<sup>1</sup>; <sup>1</sup>Kyoto University, Kyoto, Japan, <sup>2</sup>The University of Queensland, Queensland, Australia*

Caveolae are cave-like or flask-shaped invaginations of the plasmalemma that abound in three major cell-types: endothelia, fat, and muscle, but are found in virtually all cells (except neurons and immune-cells). Their function has remained entirely enigmatic for over 50 years, leading to many plausible theories, including endocytosis, transcytosis, fatty acid uptake, etc., but no definitive conclusions. The major 22kDa protein that coats them and stabilizes their structure by 'hairpin'-insertion into the plasmalemma was decades ago named "caveolin", but a second protein component has recently been discovered in them, variously called p60, PTEN, or more appropriately, "cavin." Recent studies claim that knockout of this "cavin" protein makes caveolae

disappear, and that exogenous expression of this protein in naturally cavin-null cells makes caveolae reappear, suggesting that this protein somehow acts in concert with caveolin to organize or stabilize caveolae. Possibly, cavin accomplishes this by linking caveolae to the cortical cytoskeleton under the plasmalemma. Here, we will demonstrate that the "deep-etch" technique of EM can confirm many of these recent claims about the protein cavin. Furthermore, it demonstrates that when one over-expresses cavin in the standard sort of cultured cell that already has caveolae and cavin, the structural consequences are dramatic. This not only greatly increases the abundance of caveolae over normal, but more importantly, exaggerates the prominence of one particular component of caveolae that has long been seen by "deep-etch" EM, but is not visible by other techniques: namely, the peripheral, crescent-shaped 'girdle' of granular proteins that commonly surrounds caveolae and links them to cortical actin filaments. In cavin-overexpressing cells, these "crescents" are much more frequent than normal, and are observed particularly frequently on a population of unusually flat caveolae that are relatively rare in control cells. In this poster, we will also demonstrate that these static 'deep-etch' EM observations can be confirmed and 'brought to life' in the light microscope by using fluorescent cavin-derivatives conjugated to GFP or to Dendra. Taken together, these EM and LM observations permit us to conclude that the new protein 'cavin' does indeed play an important role in caveolar formation and organization.

1457

#### **Raft-dependent Endocytosis of Autocrine Motility Factor Regulates Gp78 Ubiquitin Ligase Activity via Rac1.**

*J. Shankar<sup>1</sup>, L. Kojic<sup>1</sup>, P. S. Pierre<sup>1</sup>, M. Fu<sup>1</sup>, B. Joshi<sup>1</sup>, I. R. Nabi<sup>1</sup>; <sup>1</sup>Cellular and Physiological Sciences, University of British Columbia, Vancouver, BC, Canada*

Gp78 is a cell surface receptor that also functions as an E3 ubiquitin ligase in the endoplasmic reticulum-associated degradation (ERAD) pathway. The Gp78 ligand is the glycolytic enzyme phosphoglucose isomerase (also called autocrine motility factor or AMF), which functions as a cytokine upon secretion by tumor cells. AMF is internalized via a raft-dependent pathway to the smooth endoplasmic reticulum, however the relationship between AMF and Gp78 ubiquitin ligase activity remains unclear. AMF endocytosis is inhibited by both the dynamin inhibitor, dynasore, and the raft disrupting agent, m $\beta$ CD, distinguishing the AMF endocytic route from the dynamin-independent CLIC/GEEC raft endocytosis of cholera toxin b subunit. Gp78 knockdown reduces AMF uptake and AMF stimulates downregulation of cell surface Gp78 that is prevented by dynamin inhibition of AMF endocytosis with dynasore. AMF uptake is not affected by overexpression of dominant-active or dominant-negative RhoA or Cdc42 but was found to be Rac1-dependent, inhibited by both expression of dominant-negative Rac1 and the Rac1 inhibitor NSC23766. AMF stimulated activation of Rac1 but not RhoA. AMF induced Rac1 activation was not observed in Gp78-knockdown cells and significantly reduced by dynasore treatment suggesting that AMF signaling to Rac1 requires Gp78-mediated endocytosis. Gp78 induces mitochondrial fission and degradation of the mitochondrial fusion proteins, Mitofusin 1 and 2. AMF prevented Gp78-induced mitochondrial fission and mitofusin degradation. The ability of AMF to inhibit Gp78 degradation of the mitofusins was prevented by dynasore, the Rac1-inhibitor NSC23766 and the PI3K inhibitor LY294002 that also inhibits AMF endocytosis. This defines a critical role for the raft-dependent endocytosis of AMF in its ability to signal through Gp78 to Rac1 and to regulate Gp78 ubiquitin ligase activity. It further identifies AMF as an extracellular regulator of Gp78 function in ERAD. Both AMF and Gp78 are closely associated with tumor cell motility and metastasis and the Rac1-dependent, raft-mediated endocytosis of AMF may represent an important regulator of Gp78 function in tumor progression. Supported by CIHR MT-15132.

1458

**Cavins and Caveolins independently regulate the CLIC/GEEC endocytic pathway.**

*N. Chaudhary<sup>1</sup>, M. Howes<sup>1,2</sup>, R. G. Parton<sup>1,2</sup>; <sup>1</sup>The Institute of Molecular Bioscience, University of Queensland, Brisbane, Australia, <sup>2</sup>The Centre for Microscopy and Microanalysis, University of Queensland, Brisbane, Australia*

Caveolins and cavins are crucial components of caveolae, which recently have been shown to have non-caveolar functions including regulation of cell polarization and clathrin independent endocytosis (CIE). However the mechanisms involved in these important cellular functions remains unknown. Here we report that specific members of the cavin family of peripherally-associated caveolar proteins, are potent inhibitors of CIE. Cavins act to inhibit endocytosis of CD44, a marker of the clathrin independent carriers endocytic pathway (CLIC/GEEC), in a process independent of caveola formation. CD44 endocytosis is upregulated in cells lacking, or with reduced expression, of cavin1 and cavin3. Ectopic expression of cavin1 and 3, but not cavin2 or cavin4, specifically inhibits the CLIC/GEEC pathway even in cells that lack caveolins and so cannot generate caveolae. Caveolin-1 and Caveolin-3 also inhibit the CLIC/GEEC pathway upon expression whereas the pathway is upregulated in Caveolin-1 deficient cells. Inhibition by caveolins is dependent on an intact scaffolding domain and is associated with inhibition of diffusion of lipid microdomain components; inhibition can be rescued by treatments known to increase plasma membrane diffusion of the components. In the absence of cavins (and caveolae) caveolin-1 is itself endocytosed preferentially through the CLIC pathway but the pathway is unpolarized in cavin1 deficient migrating cells. This work provides new insights into the regulation of non-caveolar clathrin-independent endocytosis by specific caveolar proteins illustrating the complex crosstalk between these pathways. We show for the first time a role for specific cavins in regulating the CLIC/GEEC pathway, providing a new tool to study this pathway and showing caveola-independent actions. We propose a novel mechanism for inhibition of the CLIC/GEEC pathway by caveolin.

**Possible Protein Interaction between Maspardin and ALDH18A1 in Mast Syndrome.**

*M. A. Mason<sup>1</sup>; <sup>1</sup>Biological Sciences, Texas A&M University - Commerce, Mansfield, TX*

Hereditary Spastic Paraplegias (HSPs) are a family of neurological disorders characterized by weakness and spasticity of the lower limbs and sensory impairment. Mast syndrome is a complicated, autosomal recessive form of HSP exhibiting symptoms of dementia, thinning of the corpus callosum, white matter abnormalities, and spastic paraparesis. Patients with Mast syndrome carry a mutation along their SPG21 gene producing a premature stop codon. Thus, Mast syndrome is likely due to loss of functional maspardin protein. Previous studies demonstrate maspardin interacts with ALDH16A1 and following maspardin deletion aldehyde dehydrogenase ALDH18A1, another member of the ALDH superfamily, was upregulated 1.66 fold suggesting an interaction between ALDH18A1 and maspardin may occur. Patients with a missense mutation, R84Q, occurring along ALDH18A1 gene exhibit progressive neurodegeneration and bilateral subcapsular cataracts. In recent studies, variants of ALDH18A1 were found to be significantly associated with dementia with Alzheimer's Disease in Down syndrome patients suggesting a link between ALDH18A1 and other neurodegeneration diseases. Interestingly, a new HSP has been found to be caused by a mutation within the ALDH18A1 gene and is being investigated. In vitro immunoprecipitation (IP) analysis in mouse embryonic fibroblast (MEFs) has suggested an interaction occurs. In vitro IP utilized Protein A (*S. aureus*) beads to physically isolate maspardin using  $\alpha$ -maspardin antibody at the N terminus.

IP reaction was separated via 8% SDS-PAGE and blotted with  $\alpha$ -ALDH18A1 primary antibody and  $\alpha$ -goat secondary antibody for luminescence via western blot analysis. Reverse IP using  $\alpha$ -ALDH18A1 antibody to concentrate ALDH18A1 will also be conducted as well as IPs in neurons. Confocal microscopy is currently being utilized to visualize potential ALDH18A1 and maspardin colocalization in MEFs and neurons.

1460

### **Exo84 Interacts with EHD1/3 for the Recycling of Cargos from Endosomes to the Plasma Membrane.**

J. A. Schmidt<sup>1</sup>, S. Caplan<sup>2</sup>, W. Guo<sup>1</sup>; <sup>1</sup>University of Pennsylvania, Philadelphia, PA, <sup>2</sup>UNMC, Omaha, NE

Exo84 is a member of the exocyst complex implicated in the tethering of exocytic vesicles to the plasma membrane for exocytosis. Here we demonstrate that Exo84 interacts with Eps15-homology domain (EHD) proteins 1 and 3, which are important factors in endocytic trafficking pathways. Exo84 is localized to Rab8 and MICAL-L1 positive membrane tubules. EHD proteins co-localize with Exo84 on these endosome tubules, and are responsible for recruiting exocyst to these membrane domains. Exo84 is also responsible for efficient transport of endocytic cargos – a process that may also be regulated by the small GTPase RalA for which Exo84 is an effector. Our study demonstrates the cooperation between the vesicle fission machinery EHDs and the vesicle tethering exocyst complex for the recycling of proteins from endosomes to the plasma membrane.

## **Post-Golgi Trafficking**

### **Basolateral sorting machinery is recruited to the apical membrane infection site in epithelial cells infected by Enteropathogenic *E.coli***

G. A. Pedersen<sup>1</sup>, M. Ulrichsen<sup>1</sup>, E. Stenkjær<sup>1</sup>, M. Amieva<sup>2</sup>, L. N. Nejsum<sup>1</sup>;

<sup>1</sup>Department of Molecular Biology & Genetics, Aarhus University, Aarhus C, Denmark, <sup>2</sup>Dept of Pediatrics and Microbiology & Immunology, Stanford University, Stanford, CA

Epithelial polarity depends on correct protein trafficking to the apical and basolateral domains through coordinated sorting mechanisms. In order to understand basolateral protein sorting mechanisms we studied how Enteropathogenic *E.coli* (EPEC) infection of polarized epithelial cells alters cell polarity. EPEC is a foodborne pathogen that colonizes the epithelium of the small intestine by attaching to the apical side of epithelial cells. Infection leads to local disruption of cell polarity in the host cell by recruitment of basolateral proteins to the apical infection site and breakdown of cell-cell junctions.

To address the reversal of cell polarity we studied how EPEC directs basolateral proteins to the apical infection site. We found that two basolateral transmembrane proteins, AQP3 and E-cadherin, were recruited to the infection site. Both proteins were recruited in the presence of cycloheximide, indicating that newly synthesized proteins from the trans Golgi network were not the source of the recruited proteins. We also found that recruitment of AQP3 and E-cadherin took place during infection with a mutant EPEC strain that does not disrupt tight junctions suggesting that the recruitment is not achieved through membrane diffusion but rather via an intracellular route. We found that the exocyst component Sec8 is recruited to the bacterial attachment site in the apical membrane suggesting that vesicles from the TGN are redirected to

the infection site. In accord with this hypothesis, we found that Rab5, Rab7 and Rab9, markers of early and late endosomes, were all present at the infection site. Furthermore, VAMP-3, a t-SNARE, involved in docking and fusion of vesicles, was also located at the infection site suggesting that exocytosis occurs at the bacterial attachment site. Based on these results we propose that the major source of proteins recruited to the infection site is derived from the pool of existing proteins in the basolateral membrane by rerouting of endocytosed proteins.

**The zebrafish *kimble* mutation disrupts post-Golgi transport and is required for chondrocyte cell survival and endochondral ossification.**

D. S. Levic<sup>1</sup>, E. Knapik<sup>1,2</sup>; <sup>1</sup>Cell and Developmental Biology, Vanderbilt University Medical Center, Nashville, TN, <sup>2</sup>Medicine, Vanderbilt University, Nashville, TN

Vesicular trafficking is a fundamental cellular process and is central to maintaining organization and function along the secretory pathway. Chondrocytes are especially dependent upon this process due to their high secretory activity in building and maintaining cartilage ECM. Using a forward genetics approach in zebrafish, we have identified a mutation in the exocytic pathway that leads to widespread chondrocyte cell death. Using electron microscopy (EM) and immunofluorescence we show that mutant chondrocytes initially secrete cartilage ECM proteins but then progressively accumulate vesicles at the cell cortex. TUNEL analysis indicates that these chondrocytes undergo apoptosis at later stages, resulting in cartilage elements devoid of functional chondrocytes. As a result, endochondral bones fail to form along mutant cartilage, although dermal bones do develop in *kimble* mutants. Additional EM analysis prior to onset of cell death shows that mutant chondrocytes assume a unique hourglass cell morphology in which the cell body and the nucleus are misshapen. Ultimately, dying chondrocytes accumulate condensed rough endoplasmic reticulum and multi-membrane vesicles, resembling autophagosomes. This process has been identified as a unique form of apoptosis previously termed chondroptosis. We are currently working to determine the mechanism by which this component of the exocytic pathway contributes to cell polarity and chondrocyte survival.

1463

**Zebrafish *round* mutation reveals a novel component of post-Golgi trafficking machinery.**

G. Unlu<sup>1,2</sup>, E. Knapik<sup>1,2</sup>; <sup>1</sup>Cell & Developmental Biology, Vanderbilt University, Nashville, TN, <sup>2</sup>Department of Medicine, Division of Genetic Medicine, Vanderbilt University, Nashville, TN

Vesicular trafficking and secretion of extracellular matrix proteins are essential for cartilage formation and skeletal morphogenesis. Chondrocytes are highly secretory cell types that synthesize and transport a large number of diverse matrix proteins. In a large-scale mutagenesis screen for genes required for craniofacial morphogenesis, the zebrafish *round* mutations were identified. The mutation *round* (*rnd*<sup>m211</sup>, *rnd*<sup>m641</sup>, *rnd*<sup>m713</sup>, *rnd*<sup>m715</sup>) is an ENU induced, recessive mutation resulting in abnormal cartilage growth and differentiation. Using a positional cloning strategy, we have mapped the *round*<sup>m641</sup> locus to a gene that is predicted to function as guanine nucleotide exchange factor (GEF) for Rab6, a small GTPase that directs targeting of secretory vesicles to plasma membrane. Histological and immunofluorescence analyses indicate that collagen secretion is disrupted in *round* mutant chondrocytes. Moreover, unlike other mutations in the pre-Golgi secretory pathway components, *round* mutation also leads to mislocalization of glycosylated plasma membrane proteins. These preliminary data strengthen the idea that *round* mutation may disrupt Rab6 activation, thereby impairing proper targeting of collagen carrying secretory vesicles to plasma membrane. We are using gene

network prediction and detailed phenotypic analysis to begin to construct a model for the developmental requirements of the round locus in extracellular matrix secretion.

1464

**Protein sorting to dense core granules (mucocysts) in *Tetrahymena* depends on classical transmembrane receptors.**

J. S. Briguglio<sup>1</sup>, L. J. Bright<sup>1,2</sup>, A. P. Turkewitz<sup>1</sup>; <sup>1</sup>Department of Molecular Genetics and Cell Biology, The University of Chicago, Chicago, IL, <sup>2</sup>(current address) Department of Biology, Indiana University, Bloomington, IN

Mucocysts in *Tetrahymena* are dense-core vesicles that dock at the plasma membrane and undergo rapid exocytosis to release their densely packed contents in response to extracellular stimulation. While the cargo proteins have been studied in detail, the basis for their sorting to mucocysts is unknown. We used an expression-based screen to detect genes that were co-regulated with genes encoding the known cargo proteins, and identified a small set of genes that are likely, based on the reported functions of their homologs in other organisms, to be involved in membrane trafficking. These genes include a family of four classical transmembrane receptors, called TSR1-4, which we have characterized by gene disruption and tagging. TSR3 is an essential gene and knockdown leads to gross perturbation of cellular endomembranes. TSR2 and 4, in contrast, appear to be specialized for mucocyst biogenesis. Cells that are individually disrupted in either TSR2 or TSR4 synthesize aberrant mucocysts that are incapable of undergoing efficient regulated exocytosis. TSR4 by itself is necessary for the trafficking to mucocysts of one class of cargo proteins, for which a sorting signal has been identified. In contrast, a second class of granule cargo proteins are sorted to mucocysts independently of these receptors. In addition, both TSR2 and TSR4 appear to serve as sorting receptors for proteases that function during mucocyst maturation in proprotein processing, for which strong candidates emerge from the expression-based screen. Live cell imaging of the GFP-tagged TSR4 product, expressed at the endogenous locus, also supports a model in which TSR receptors are essential for trafficking a subset of newly-synthesized mucocyst cargo. Since TSR receptors and other proteins identified in the screen have clear homologs in many eukaryotic lineages, the results also offer insight into the evolutionary relationship between regulated exocytic vesicles in ciliates and those in other organisms.

1465

**AP-1A is required for normal secretory granule maturation in AtT-20 cells.**

M. Bonnemaïson<sup>1</sup>, R. Mains<sup>2</sup>, B. Eipper<sup>1,2</sup>; <sup>1</sup>Molecular, Microbial and Structural Biology, Univ Connecticut Hlth Ctr, Farmington, CT, <sup>2</sup>Neuroscience, Univ Connecticut Hlth Ctr, Farmington, CT

Neuroendocrine cells synthesize, process, store and secrete peptide hormones. Upon exit from the trans-Golgi network, peptides and their processing enzymes are packaged into immature secretory granules (ISGs), which are not responsive to secretagogues. The maturation process through which they become secretagogue responsive remains unclear. Peptidylglycine- $\alpha$ -amidating monooxygenase 1 (PAM-1), a transmembrane protein spanning the membrane of SGs, can serve as an indicator of SG maturation. Upon entry into ISGs, PAM-1 is cleaved in the luminal domain generating a soluble protein, PHM, and a membrane protein, PALm; secretion of soluble PHM from mature SGs is secretagogue-responsive. The formation of specialized SGs such as the glue granules in *Drosophila*, Weibel-Palade bodies in endothelial cells and rhoptries in *Toxoplasma gondii* requires the adaptor protein 1A (AP-1A) complex. AP-1A is a heterotetrameric complex composed of two large subunits ( $\beta$ 1 and  $\gamma$ ), a medium subunit ( $\mu$ 1A)

and a small subunit ( $\sigma_1$ ). AP-1A interacts with cargo proteins via  $\mu$ 1A or  $\gamma/\sigma_1$  and with clathrin via  $\beta$ 1 to transport proteins between the TGN and endosomes in clathrin-coated vesicles. In neuroendocrine cells, ISG maturation involves AP-1A mediated removal of non-granule proteins. To explore the role of AP-1A in the formation and maturation of SGs in neuroendocrine cells, AtT-20 corticotrope tumor cells expressing PAM-1 were stably infected with lentivirus expressing shRNA against  $\mu$ 1A or a non-target shRNA control. Western blots revealed that the average level of  $\mu$ 1A was reduced by 50% in fifteen clones when compared with control and non-infected cells. Cellular PHM and PALm was reduced compared to PAM-1 levels in  $\mu$ 1A knock-down ( $\mu$ 1A KD) cells suggesting a change in PAM-1 routing in the regulated secretory pathway. PHM secretion in response to stimulation by 2mM BaCl<sub>2</sub> was reduced to half in  $\mu$ 1A KD cells. Pulse/chase metabolic labeling and immunoprecipitation revealed similar PAM-1 synthetic rates in control and  $\mu$ 1A KD cells. After a 2 hour chase, secretion of newly synthesized PHM by control cells was stimulated by secretagogue; in contrast, secretion of newly synthesized PHM produced in  $\mu$ 1A KD cells was not stimulatory. These data indicate that AP-1A is required for the normal trafficking of PAM and the subsequent maturation of SGs in neuroendocrine cells.

1466

### **The relationship between post-translational processing of proglucagon and sorting to secretory granules in neuroendocrine cells.**

L. M. Guizzetti<sup>1,2</sup>, I. Cameron<sup>3</sup>, R. McGirr<sup>2</sup>, S. Dhanvantari<sup>1,2,3,4</sup>; <sup>1</sup>Medical Biophysics, Western University, London, ON, Canada, <sup>2</sup>Diabetes/Metabolism and Imaging, Lawson Health Research Institution, London, ON, Canada, <sup>3</sup>Pathology, Western University, London, ON, Canada, <sup>4</sup>Medicine, Western University, London, ON, Canada

Introduction: Proglucagon is an endocrine prohormone that is processed into three major peptide hormones: glucagon, glucagon-like peptide 1 (GLP-1) and GLP-2. Proglucagon is processed in a tissue-dependent manner, to yield glucagon in pancreatic  $\alpha$ -cells, and both GLP-1 and GLP-2 in intestinal L-cells and certain brainstem neurons. Regulated secretion depends upon both post-translational processing and sorting into secretory granules. Proglucagon is initially cleaved at the di-basic Lys70Arg71 site to yield glicentin and major-proglucagon fragment, and both are further processed to the major peptide hormones within granules. We hypothesize that cleavage at Lys70Arg71 is necessary for sorting into granules. We mutated the Lys70Arg71 cleavage site to neutral Gln70Gln71 to determine the requirement of post-translational processing of proglucagon on sorting into granules. Results: Sequences encoding either wild-type hamster proglucagon or the Gln70Gln71 mutant were fused to the N-terminus of EGFP and verified by DNA sequencing. Proglucagon-EGFP fusion proteins were expressed in the neuroendocrine cell line, PC12. EGFP alone was used as a negative expression control. Western blot analyses of EGFP in cell extracts revealed that WT proglucagon was cleaved at Lys70Arg71 while cleavage was blocked in the Gln70Gln71 mutant. Additional bands were consistent with cleavage at the C-terminal Lys159Lys160 mediated by CPE, and at Lys62Arg63 mediated by PC2. Detection of these cleavage products is consistent with proper sorting of WT and Gln70Gln71 mutant proglucagon into granules. Sorting of both the WT and mutant proglucagon into granules was seen by deconvolution immunofluorescence microscopy. Both WT proglucagon and the Gln70Gln71 mutant exhibited significant co-localization with the granule marker, chromogranin A, as measured by Pearson's correlation coefficient (PCC > 0.8). No significant differences (two-tailed t-test, p=0.282) between WT-proglucagon (n=19, PCC=0.84) and the Gln70Gln71 mutant (n=28, PCC=0.80) were observed. Conclusion: Our results indicate that proglucagon is efficiently sorted into granules independent of post-translational processing at Lys70Arg71.

1467

**Pancreatic beta cells lack the GAD65-independent membrane anchoring pathway for GAD67.**

*J. Kanaani (Kanaaneh)<sup>1</sup>, H. Fjordvang<sup>2</sup>, N. Billestrup<sup>2</sup>, S. Baekkeskov<sup>1</sup>; <sup>1</sup>Department of Medicine, Microbiology/Immunology, and Diabetes Center, University of California San Francisco, San Francisco, CA, <sup>2</sup>Department of Biomedical Sciences, Panum Institute, University of Copenhagen, Copenhagen, Denmark*

The two isoforms of the GABA-synthesizing enzyme glutamic acid decarboxylase, GAD65 and GAD67, are expressed in pancreatic beta cells and in GABA-ergic neurons. GAD65 is a target of autoimmunity associated with beta cell destruction and development of type 1 diabetes and in impairment of GABA-ergic neurotransmission in a rare neurological disorder stiff-man syndrome. In contrast, the highly homologous GAD67 isoform is not a target of autoimmunity. The two isoforms differ mainly in the N-terminal domain that in GAD65 harbors signals, including palmitoylation of cysteines 30 and 45, required for targeting to Golgi membranes and post-Golgi trafficking to cytosolic vesicles in non-neuronal cells and synaptic vesicles in neuroendocrine cells. In contrast, GAD67 protein remains hydrophilic but has been shown to acquire membrane association by two different mechanisms. One mechanism involves association of GAD67 with the hydrophobic GAD65 isoform in a heterodimeric conformation. The second mechanism is independent of GAD65 and may involve association with another membrane moiety. Each mechanism mediates robust membrane anchoring and targeting of GAD67 to Golgi membranes and cytosolic vesicles, similar to that of GAD65 itself. In this study, we have shown that while GAD67-GFP singly transfected into GAD65-negative MDCK, CHO, and COS-7 cells is targeted to the Golgi compartment and peripheral vesicles, it remains soluble and cytosolic in the insulinoma cell lines INS-1 and MIN-6. Furthermore, studies of transfected GAD67-GFP and endogenous GAD67 in GAD65-negative mouse islet single cells show that the protein is absent from Golgi membranes and vesicular compartment and does not co-localize with markers for ER, mitochondria, and insulin. These results suggest that insulinoma cell lines and mouse islet single cells do not harbor the GAD65-independent membrane anchoring machinery identified in neurons and several non-neuronal cell types. However, membrane targeting of GAD67-GFP in INS-1 and mouse islet single cells can be rescued by co-expression with GAD65-mCherry. Moreover, in rat islet single cells, which express both GAD65 and GAD67 isoforms, endogenous GAD67 co-localizes with GAD65 in the Golgi compartment and cytosolic vesicles.

**ADAP1 and Arf6 Regulate Neuronal Secretory Granule Trafficking.**

*S. N. Ewell<sup>1</sup>, J. L. Larimore<sup>1</sup>, A. Theibert<sup>1</sup>; <sup>1</sup>Neurobiology, The University of Alabama at Birmingham, Birmingham, AL*

ADP ribosylation factor 6 (Arf6) is a member of the Arf family of small GTPases shown to function in vesicular membrane trafficking and cytoskeletal organization. Arf6 cycles between its GTP and GDP bound states, facilitated by GTP exchange factors (GEFs) and GTPase activating proteins (GAPs), respectively. Our laboratory has investigated the neuronal functions of Arf6 and ADAP1, an Arf6 GAP expressed in neurons. We demonstrated that ADAP1 and Arf6 co-localize with secretory granules in neurons, and that siRNA-mediated knockdown of ADAP1 or Arf6 levels resulted in increased secretory granule size and an inhibition of the rate of trafficking of chromogranin B, a regulated secretory granule cargo. Recently, we investigated the role of ADAP1 and Arf6 in trafficking of brain derived neurotrophic factor (BDNF), a factor which has been shown to be involved in neuronal development and synaptic plasticity. In

neurons and neurosecretory cells, both ADAP1 and Arf6 co-localize with BDNF in secretory granules. Furthermore, knock down of ADAP1 or Arf6 leads to a significant increase in the colocalization of BDNF-GFP with furin, a peptidase localized to immature secretory granules, suggesting that ADAP1 and Arf6 participate in the maturation of BDNF secretory granules. Together our data indicate a role for ADAP1 and Arf6 in the trafficking of chromogranin B and BDNF-containing regulated secretory granules in neurons.

**Membrane trafficking of the D1 dopamine receptor to primary cilia.**

A. E. Leaf<sup>1</sup>, A. Marley<sup>1</sup>, M. von Zastrow<sup>1</sup>; <sup>1</sup>Psychiatry, University of California, San Francisco, San Francisco, CA

Spatial organization of signaling receptors on the cell surface and within the cell is critical to how cells execute and regulate signaling events. Signaling receptors must be targeted to the appropriate membrane domain through membrane trafficking events in order to carry out their function. The primary cilium, an antennae-like protrusion of the plasma membrane, is an example of a membrane domain with a high concentration of specific signaling receptors. One signaling receptor that localizes to the cilium is the D1 dopamine receptor (D1), which is highly concentrated on the cilia membrane relative to the rest of the plasma membrane. Although recent studies have identified several proteins that may be involved in trafficking signaling receptors to cilia, the basic process by which specific proteins are targeted to the cilium remains unclear. Photoactivation of a subset of the ciliary D1 indicates that D1 is highly mobile within the cilium, however, the photoactivated D1 fluorescence stays constant within the cilium over shorter time periods. These data support the idea of a diffusion barrier at the base of the cilium. Interestingly, D1 does not appear to be static in the cilium over longer time periods since more D1 can be photoactivated 30 minutes after exhaustive photoactivation of ciliary D1. My preliminary studies supports linear time dependence for the amount of new D1 in the cilium suggesting active transport to the cilium at a rate of about 1.5 percent new receptor delivered per minute. Comparison of the cell surface pool of D1 to the photoactivated D1 fluorescence before and after subsequent photoactivation indicates that new ciliary D1 traffics to the cilium from the plasma membrane as opposed to internal vesicles from the biosynthetic pathway. Future studies will further investigate the mechanism by which the D1 receptor concentrates in the cilium, contributing towards our understanding of how signaling receptors localize and function in primary cilia.

**Linking vesicle formation to vesicle targeting through multifunctional scaffold proteins.**

D. Deretic<sup>1</sup>, J. Wang<sup>1</sup>; <sup>1</sup>Surgery/Ophthalmology, University of New Mexico, Albuquerque, NM

The delivery of the sensory receptor rhodopsin to the base of the cilium is mediated by traffic intermediates known as rhodopsin transport carriers (RTCs). Formation of RTCs is regulated by the protein complexes coordinated by Arf4 and the Arf GAP ASAP1. ASAP1 acts both as a scaffold for protein complex assembly that links the post-TGN carriers to the Rab11a-Rabin8-Rab8 ciliary targeting complex and a temporal regulator through GTP hydrolysis on Arf4. In this study we performed the Proximity Ligation Assay (PLA) in photoreceptor cells to reveal precise subcellular localization of rhodopsin interactions with its trafficking regulators in situ. Interactions of rhodopsin and ASAP1 with Arf4 were detected nearly exclusively at the Golgi/TGN, whereas rhodopsin-ASAP1-Rab11a-Rabin8-Rab8 interactions encompassed the TGN-derived nascent buds and the RTCs. Since ASAP1 recognizes the FR ciliary targeting motif of rhodopsin, we generated the [FR-AA]Rhodopsin-GFP-VxPx mutant and compared its localization in IMCD3 cells to that of Rhodopsin-GFP-VxPx. Ciliary localization of Rh-GFP-VxPx was completely

abolished in the FR-AA mutant. We compared the direct binding of Rh-GFP-VxPx, or the FR-AA mutant to ASAP1 by PLA in IMCD3 cells and found that the FR-AA mutant is defective in ASAP1 binding. Similar to ASAP1, Rab8 bound Rh-GFP-VxPx, but did not interact with the FR-AA mutant, which accumulated below the cilium. Our data indicate that the advancement of rhodopsin from the Golgi/TGN into post-TGN carriers proceeds in several orderly stages and that the assembly of the ASAP1-Rab11-Rabin8-Rab8 complex at the TGN is a crucial step in directing rhodopsin to the ciliary membrane. Since rhodopsin FR-AA mutant defective in ASAP1 binding also fails to interact with Rab8 and reach the primary cilium, our data further indicate that the vesicle formation at the TGN is tightly linked to the engagement of the targeting complex to ensure their proper delivery to the final destination.

1471

### **Shared Protein Complexes of Primary Cilia Link Craniofacial Disorders and Polycystic Kidney Disease.**

*S. Jerman<sup>1</sup>, H. Ward<sup>1</sup>, M. MacDougall<sup>2</sup>, A. Wandinger-Ness<sup>1</sup>; <sup>1</sup>Pathology, University of New Mexico HSC, Albuquerque, NM, <sup>2</sup>School of Dentistry, University of Alabama, Birmingham, AL*

Primary cilia are specialized cellular organelles that are central to organ development and homeostasis based on their function as a signaling hub in the control of cell growth and differentiation. Craniofacial disorders and polycystic kidney disease frequently present together in human patients and are likely precipitated by defects in a common pathway affecting the primary cilium. How the soluble ciliary protein that underlies oral-facial-digital syndrome type 1 (OFD1) interconnects to the ciliary membrane proteins (polycystin-1 and polycystin-2) that cause polycystic kidney disease is unknown. To probe these interconnections, comparative evaluations of protein localization, trafficking and assembly were conducted on renal epithelia and oral cavity-derived odontoblasts. Direct PCR-based visualization of ciliary protein-protein interactions confirmed by co-immunoprecipitations identified a multimeric protein complex consisting of the polycystins, epidermal growth factor receptor, and OFD1. Ciliary protein complex assembly was dependent on the cholesterol membrane domain organizing, flotillin-1 and -2 proteins, demonstrating for the first time the spatial organization of key signaling proteins in specialized ciliary microdomains. Temporal analyses of membrane trafficking revealed polycystin-1 dependence on a C-terminal VxPx amino acid motif and the Arf4 GTPase for Golgi export and ciliary delivery. A conserved VxPx motif was also identified in the epidermal growth factor receptor and served to bind purified, active Arf4. The composite data support a conserved ciliary trafficking mechanism and assembly of a signaling protein complex in discrete microdomains in renal and odontoblast cells, defects in which may explain overlapping pathologies of kidney and craniofacial disorders.

1472

### **Tubulin detyrosination promotes monolayer formation and apical trafficking in epithelial cells.**

*S. Zink<sup>1</sup>, L. Grosse<sup>1</sup>, A. Freikamp<sup>1</sup>, S. Bänfer<sup>1</sup>, F. Müksch<sup>1</sup>, R. Jacob<sup>1</sup>; <sup>1</sup>Department of Cell Biology and Cell Pathology, Philipps University Marburg, Marburg, Germany*

The role of posttranslational tubulin modifications in the development and maintenance of a polarized epithelium is not well understood. We studied the balance between detyrosinated (glu-) and tyrosinated (tyr-) tubulin in the formation of MDCK cell monolayers. Increased quantities of detyrosinated microtubules were detected during assembly into confluent cell sheets. These tubules were composed of alternating stretches of glu- and tyr-tubulin. Constant induction of tubulin tyrosination, which depleted the number of glu-tubulin by overexpression of tubulin

tyrosine ligase (TTL), disrupted monolayer establishment. Glu-tubulin depleted cells assembled into isolated islands and developed a prematurely polarized architecture. Thus, tubulin detyrosination is required for the morphological differentiation from non-polarized cells into an epithelial monolayer. Moreover, membrane trafficking, in particular to the apical domain, was slowed down in TTL-overexpressing cells. This effect could be reversed by TTL knockdown, which suggests that glu-tubulin-enriched microtubules serve as cytoskeletal tracks to guide membrane cargo in polarized MDCK cells.

1473

**Regulation of vesicle transport to the apical membrane by kinesins in epithelial cells.**

W. O. Smith<sup>1</sup>, G. Kreitzer<sup>1</sup>; <sup>1</sup>Cell and Developmental Biology, Weill Cornell Graduate School, New York, NY

Epithelial tissue function is required for maintaining homeostasis of the body, acting as a barrier to outside environments and allowing for the unidirectional transport of molecules. To establish this barrier, epithelial cells must polarize to create an apical domain and a basolateral domain. These domains differ in function by maintaining a unique lipid and protein composition. Previous work in the lab has characterized the transport of the p75 neurotrophin receptor (p75), which is targeted apically in polarized Madin-Darby Canine Kidney (MDCK) cells. Post-Golgi transport of p75 to the cell surface occurs along microtubules by different kinesin motor proteins in non-polarized and polarized cells. In non-polarized cells, the kinesin-3 family members Kif1A and Kif1B $\beta$  mediate post-Golgi transport. In polarized cells, the kinesin-1 family member Kif5B mediates post-Golgi transport. These kinesins are expressed in both non-polarized and polarized cells, so this switch in kinesin use must be regulated. Currently, what regulates these kinesin-vesicle interactions is unknown. We hypothesize that these kinesin-vesicle interactions are regulated by three potential mechanisms: kinesin interaction with different Rab GTPases, kinesin interaction with different adaptor proteins, and kinesin autoregulation. To identify new trafficking regulators, we plan to compare the proteomes of different post-Golgi kinesin cargoes. We have begun by isolating post-Golgi vesicles from non-polarized and polarized cells. Cell homogenates are fractionated on a density gradient and identified by known organelle markers. We then isolate kinesin cargoes by using vesicle affinity for bead-immobilized Kif1A or Kif5B tails. p75-GFP containing vesicles act as a control for kinesin specificity. These isolates will be analyzed by mass spectrometry to identify differences between non-polarized and polarized kinesin-specific cargoes. Proteomes can then be compared for similarities and differences to identify potential trafficking regulators.

1474

**The Rab GTPases Ypt31/32 and Sec4 may simultaneously associate with myosin V during secretory vesicle transport.**

Y. Jin<sup>1,2</sup>, A. Joglekar<sup>2</sup>, L. S. Weisman<sup>1,2</sup>; <sup>1</sup>Life Sciences Institute, University of Michigan, Ann Arbor, MI, <sup>2</sup>Department of Cell & Developmental Biology, University of Michigan, Ann Arbor, MI

Vesicle transport requires four steps; vesicle formation, movement, tethering and fusion. We recently found that in yeast, the myosin V, Myo2 is present at all steps. Through its cargo-binding domain, Myo2 interacts with several proteins that function in this pathway<sup>a,b</sup>. Two Rab GTPases, Ypt31/32 are required for post-Golgi vesicle formation. A third Rab GTPase, Sec4, and the exocyst act in tethering and fusion of these vesicles with the plasma membrane. Myo2 binds directly to Ypt31/32, Sec4 and Sec15. These results suggest the testable hypothesis that Myo2 binds to each protein sequentially. Conventional biochemical approaches or static images of micrographs will not suffice to test the hypothesis, because most of the vesicles form and

complete their movement within a few seconds. Note that the average velocity of a Sec4-positive secretory vesicle is 3  $\mu\text{m/s}$  *in vivo*, and a yeast is approximately 5  $\mu\text{m}$ .

As a first approach, we generated a yeast strain that expresses both GFP-Ypt31 and RFP-Sec4 expressed *via* their own promoters. We obtained the unexpected result that Ypt31 and Sec4 always co-localize on vesicles during vesicle movement. This finding raises the possibility that Myo2 simultaneously binds to Ypt31/32 and Sec4 throughout vesicle formation and fusion.

**The Epac1-Rap1 pathway regulates Weibel-Palade body exocytosis from endothelial cells through the activation of Rac1 via PREX-1.**

K. V. Hooren<sup>1</sup>, M. Fernandez-Borja<sup>1</sup>, R. Bierings<sup>1</sup>, J. Voorberg<sup>1</sup>; <sup>1</sup>Sanquin Research, Amsterdam, Netherlands

Vascular endothelial cells provide a dynamic interface between circulating blood and underlying tissues that is critically involved in maintaining vascular integrity and homeostasis. Rapid release of bio-active components from intracellular storage pools serves a crucial role in maintaining vascular homeostasis. A significant number of haemostatic components and inflammatory mediators originate from endothelial cell-specific, cigar-shaped organelles called Weibel-Palade bodies (WPBs). WPBs function as storage vesicles for von Willebrand factor (VWF), a multimeric adhesive glycoprotein crucial for platelet plug formation, the leukocyte receptor P-selectin and a number of bioactive compounds that include the chemoattractants IL-8 and eotaxin-3. WPBs release their content following stimulation with agonists increasing intracellular Ca<sup>2+</sup>, like thrombin, or agonists increasing intracellular levels of cAMP, such as epinephrine. The physiological importance of the cAMP-mediated pathway is illustrated by the rise in VWF levels in patients with von Willebrand's disease and mild haemophilia A following administration of the vasopressin analogue desmopressin (DDAVP) or epinephrine.

Previously, we have shown that the exchange protein activated by cAMP, Epac1 and its substrate, the small GTPase Rap1 are involved in cAMP-mediated release of WPBs. In this study, we explored potential downstream-effectors of Rap1 in cAMP-mediated WPB release. Using a pulldown for putative downstream targets of activated Rap1 in endothelial cells we identified the PI3K-dependent Rac exchange factor 1 (PREX-1). We show that endothelial activation using epinephrine and forskolin, but also by the Epac1-specific cAMP-analogue 8-pCPT-2'-O-Me-cAMP-AM (Me-cAMP-AM) leads to the activation of the small GTPase Rac1. Furthermore, we show that RNAi-mediated downregulation of Epac1 or PREX-1 both result in a reduced activation of Rac1 in response to Me-cAMP-AM. However, to abolish activation of Rac1 in response to epinephrine preincubation with the PKA inhibitor PKI is also required suggesting that Rac1 can be activated by PKA- as well as Epac1-dependent mechanisms. Depletion of Rac1 by RNAi resulted in reduced epinephrine-induced VWF secretion. Also, the Rac1 inhibitor EHT1864 and PI3K inhibitor Ly294002 reduced epinephrine-induced WPB release. Taken together our findings suggest that Epac1-Rap1-mediated WPB release proceeds through activation of Rac1 by PREX-1, thereby regulating release of haemostatic, inflammatory and angiogenic components from WPBs.

**Roles of the Small G Protein Arl5b in Intracellular Membrane Transport.**

F. J. Houghton<sup>1</sup>, D. Bourges<sup>1</sup>, D. K. Ang<sup>1</sup>, P. A. Gleeson<sup>1</sup>; <sup>1</sup>University of Melbourne, Parkville, Australia

Many small G proteins, including Rabs and Arfs are involved in controlling the regulation of membrane transport in mammalian cells. A sub-class of Arfs, the Arf-like proteins or Arls, are less well defined. Arl1 is the most well characterised Arl, located at the Golgi. At the *trans*-Golgi network (TGN), activated Arl1 interacts with effector proteins called golgins, such as p230/golgin245 and golgin97 (Lu *et al* 2001, Lu *et al* 2003, Panic *et al* 2003). Arl1 is important for maintaining the Golgi structure and in the regulation of specific Golgi transport pathways. Here we have investigated other small G proteins and have identified Arl5b as a TGN localised protein (Houghton *et al* 2012). A stable cell line of HeLa over-expressing a GFP-tagged membrane-bound mutant of Arl5b (HeLaArl5b(Q70L)-GFP) was generated. The localisation of Arl5b(Q70L)-GFP using confocal and structured illumination microscopy (SIM) revealed the close association of Arl5b with specific TGN golgins at the TGN. Using a flow cytometric assay to assess the kinetics of anterograde transport, depletion of Arl5b by RNAi had no effect on the transport of the cargo E-cadherin to the cell surface. On the other hand, using 3D confocal microscopy, depletion of Arl5b significantly reduced the endosome-to-TGN transport of the membrane cargos TGN38 and Shiga toxin (STxB). The block in cargo transport to the Golgi was rescued with an siRNA-1-resistant Arl5b mutant. Enhanced transport rates of TGN38 were observed in cells overexpressing Arl5b-GFP. Collectively these results suggest that Arl5b is a TGN-localised small G protein that plays a key role in regulating transport along the endosome-TGN pathway. The influence of Arl5b in regulating the transport of a variety of cargos is currently under investigation.

**Examining the role of the yeast Lgl homolog, Sro7, as a Rab GTPase effector in polarized exocytosis.**

K. Watson<sup>1</sup>, B. Temple<sup>2</sup>, P. Brennwald<sup>1</sup>; <sup>1</sup>Cell and Developmental Biology, University of North Carolina at Chapel Hill, Chapel Hill, NC, <sup>2</sup>Structural Bioinformatics Core, University of North Carolina at Chapel Hill, Chapel Hill, NC

The tumor suppressor lethal giant larvae (Lgl) plays a crucial role in cell polarity and differentiation, however, the molecular mechanism by which Lgl carries out its function is unclear. Studies of the yeast Lgl homolog, Sro7, have demonstrated a function in polarized exocytosis that is linked to its regulated interaction with the SNARE protein, Sec9. Recent evidence suggests that Sro7 may also act directly in vesicle tethering as an effector of the Rab GTPase, Sec4, and has genetic properties consistent with it functioning downstream of Sec4 in a pathway parallel to that of the exocyst complex. However, the molecular details of how Sro7 acts as an effector of Sec4 and the importance of this physical interaction to both Sro7 and Sec4 function remain unclear. Using the recently determined crystal structure as a guide, we interrogated a set of 12 conserved surface patches on Sro7 to identify potential Sec4 docking sites. Proteins containing charge-reversal mutations at each of these sites were purified and examined for their ability to bind GTP-Sec4. While 10 of the 12 mutants had binding properties indistinguishable from wild-type Sro7, we identified two surface sites that when subjected to charge-reversal, showed a dramatic loss in binding to GTP-Sec4. These same mutant proteins bound normally to the t-SNARE, Sec9. Importantly, genetic analyses of the Sro7 charge-reversal mutants demonstrated a precise correlation between those mutants which had lost the ability to suppress temperature-sensitive growth of mutant exocyst strains and those mutants that had a severe defect in binding to GTP-Sec4. This provides the first direct evidence that

Sec4-GTP binding by Sro7 is likely to be critical for its function in vivo. Moreover, we are utilizing this structural data combined with computational docking studies to determine if these sites represent part of a binding pocket on Sro7 for Sec4-GTP. Understanding the structural, biochemical and genetic landscape of this interaction will reveal critical molecular insights into the function of an Lgl family protein in polarized trafficking.

**A Novel GTP-binding protein-adaptor protein complex responsible for export of Vangl2 from the trans Golgi network.**

Y. Guo<sup>1</sup>, R. Schekman<sup>1</sup>; <sup>1</sup>University of California at Berkeley, Berkeley, CA

Planar cell polarity (PCP) requires the asymmetric sorting of distinct signaling receptors to distal and proximal surfaces of polarized epithelial cells. We have examined the protein and sorting signal requirements for transport of one PCP signaling protein, Vangl2, from the trans Golgi network (TGN) in transfected mammalian cells. Using siRNA knockdown experiments, we find that the GTP-binding protein, Arfrp1, and the clathrin adaptor complex 1 (AP-1) are required for Vangl2 transport from the TGN. In contrast, Frizzled 6, which localizes to the opposing epithelial surface from Vangl2, does not depend on Arfrp1 or AP-1 for traffic to the cell surface. Mutagenesis studies identified a YYXXF sorting signal in the C-terminal cytosolic domain of Vangl2 that is required for Vangl2 traffic and interaction with the mu subunit of AP-1. We propose that Arfrp1 exposes a binding site on AP-1 that recognizes the Vangl2 sorting motif for capture into a transport vesicle destined for the proximal surface of a polarized epithelial cell.

**Atypical ubiquitination of CRN7 by Cul3-KLHL20 complex regulates post-Golgi carrier formation.**

W-C. Yuan<sup>1,2</sup>, Y. Tan<sup>1</sup>, Y-R. Lee<sup>1</sup>, S-Y. Lin<sup>1</sup>, M-Y. Lin<sup>1</sup>, K-H. Khoo<sup>1</sup>, R-H. Chen<sup>1,2</sup>; <sup>1</sup>Institute of Biological Chemistry, Academia Sinica, Taipei, Taiwan, <sup>2</sup>Institute of Biochemical sciences, College of Life Science, National Taiwan University, Taipei, Taiwan

Protein ubiquitination controls many aspects of membrane trafficking. KLHL20 is a BTB-kelch protein and functions as a substrate adaptor of Cul3-family ubiquitin ligases. Here, we show that KLHL20 is mainly localized on the Golgi apparatus, and is required for maintaining Golgi architecture and the actin-dependent post-Golgi transport of cargos. The Cul3-KLHL20 complex catalyzes a K33-linked polyubiquitination of coronin7 (CRN7), a protein shuttling between cytosol and Golgi and regulating post-Golgi transport. This ubiquitination event does not lead to CRN7 degradation but potentiates the recruitment of Crn7 to clathrin adaptor AP-1 complex. CRN7 regulates the assembly of F-actin foci at trans-Golgi network, thus facilitating the formation of carrier tubule. Our study reveals a crucial role of Cul3-KLHL20 in post-Golgi actin remodeling and carrier biogenesis through an atypical ubiquitination of CRN7.

1480

**Transformation of Polarized Epithelial Cells by Apical Mistrafficking of Epiregulin.**

B. Singh<sup>1</sup>, G. Bogatcheva<sup>1</sup>, M. K. Washington<sup>2</sup>, S. Hill<sup>3</sup>, K. L. Rose<sup>3</sup>, R. J. Coffey<sup>1,4,5</sup>; <sup>1</sup>Medicine, Vanderbilt University, Nashville, TN, <sup>2</sup>Pathology, Vanderbilt University, Nashville, TN, <sup>3</sup>Biochemistry, Vanderbilt University, Nashville, TN, <sup>4</sup>Epithelial Biology Center, Vanderbilt University, Nashville, TN, <sup>5</sup>Department of Veteran Affairs Medical Center, Nashville, TN

Establishment and maintenance of apico-basolateral trafficking pathways is critical to epithelial homeostasis. Although loss of polarity and trafficking fidelity is thought to occur as a

consequence of transformation, herein we show that selective mistrafficking of a growth factor from the basolateral to apical cell surface may drive transformation. The EGF receptor (EGFR) ligand epiregulin (EREG) is delivered preferentially to the basolateral cell surface of polarized MDCK cells. EREG basolateral trafficking is regulated by a conserved tyrosine residue within a YXX $\Phi$  motif (Y<sub>156</sub>ERV) in its cytoplasmic domain. YXX $\Phi$  is an AP clathrin adaptor complex-dependent basolateral sorting motif whose function is impaired by phosphorylation of this tyrosine. Substitution of this tyrosine to alanine or phenylalanine redirects EREG to the apical cell surface. EREG basolateral trafficking is AP1B and AP2-independent and this tyrosine is phosphorylated. Moreover, apical mistrafficking of EREG has a distinctive phenotype. In contrast to transient EGFR activation after basolateral EREG stimulation, apical EREG leads to prolonged EGFR activation without negative regulatory Y1045 phosphorylation. MDCK cells stably expressing apically mistrafficked EREG form larger, poorly differentiated, invasive tumors in nude mice compared to wild-type EREG-expressing cells. This phenotype was recapitulated in Matrigel culture where apical mutant EREG increased the number of surviving luminal cells. We propose that apical mistrafficking of EREG crystallizes an apical EGFR signaling complex that is uncoupled from basolateral regulatory restraints.

1481

**Actin-mediated traffic control: RhoA-mDia1 pathway involvement in regulating the secretion of monocyte-chemottractant protein 1.**

Z. Z. Lieu<sup>1</sup>, A. Bershadsky<sup>1,2</sup>; <sup>1</sup>*Mechanobiology Institute, National University of Singapore, Singapore, Singapore*, <sup>2</sup>*Department of Molecular Cell Biology, Weizmann Institute of Science, Rehovot, Israel*

Formin family proteins promote actin polymerization by affecting both nucleation and elongation of actin filaments. Recently, RhoA-mDia1 pathway was shown to regulate Golgi architecture and dynamics [1]. Here, we have used chemokines as model exocytic cargo to elucidate the role of formins in Golgi to plasma membrane transport. Monocyte-chemottractant protein 1 (MCP-1/CCL2) is an important chemokine secreted during immune response. However, the role of actin, in general, and formins, in particular in regulating intracellular trafficking of this chemokine is poorly understood. We expressed fluorescently tagged CCL2 construct and observe its dynamics in transfected cells. Transfected CCL2 is localised to the Golgi and is transported in round vesicular carriers along microtubule tracks to the plasma membrane. Activation or RNAi silencing of the mDia1 formin, affects the speed and altered the morphology of the CCL2-positive carriers. Active RhoA or constitutively active mDia1 expression reduced the speed of CCL2-positive carriers while RNAi silencing of mDia1 apparently increase this speed. In cells overexpressing activated mDia1, an increase in intracellular CCL2 was detected in vesicular structures and these CCL2 positive vesicles were still localised on microtubule tracks but were unable to move towards the plasma membrane. Movements of CCL2 in cells expressing activated mDia1 were rescued by treatment with latrunculin A, an actin depolymerization agent, indicating the effect is due to actin polymerization. The changes in velocity coincide with the level of CCL2 secretion. In cells expressing activated mDia1, there was a 40% decrease in CCL2 secretion, whereas an increase of 50% in CCL2 secretion was observed in RNAi expressing cells. Notably, the drop in CCL2 secretion in cells overexpressing constitutive activated mDia1 was similar to that in control cells treated with 1 $\mu$ M of nocodazole, suggesting that mDia1 effect on the movement of CCL2 carriers along microtubules is responsible for the observed secretion changes. We hypothesized that RhoA-mDia1-driven activation of actin polymerization can be involved in physiological regulation of chemokine CCL2 secretion via controlling the microtubule based movement of exocytic carriers along microtubule track.

**Tracking the role of endocytosis in the polarization of the Rho GTPase Cdc42.**

L. Watson<sup>1</sup>, G. Rossi<sup>1</sup>, P. Brennwald<sup>1</sup>; <sup>1</sup>Cell Biology and Physiology, University of North Carolina at Chapel Hill, Chapel Hill, NC

In budding yeast, the generation of a concentrated pool of Cdc42 on the plasma membrane is thought to be essential for its ability to control global cell polarity. Cdc42 establishes cell polarity by coordinating the organization of the actin cytoskeletal and membrane trafficking pathways towards a specific site on the plasma membrane. Consequently, the regulation of these two pathways by Cdc42 is tightly coupled with the maintenance of Cdc42's own polarization. However, much remains to be understood of the role of polarized exocytosis in the maintenance of the Cdc42 plasma membrane polarity patch. Exploiting a novel *in vivo* assay for secretory vesicle association, we have demonstrated that Cdc42 is associated with post-Golgi vesicles at concentrations that are comparable to, or greater than, its concentration at the polarity patch. This supports the possibility that fusion of vesicles carrying Cdc42 with specific sites on the plasma membrane can serve to promote, rather than dilute, the concentrated Cdc42 polarity patch. Previous studies have suggested that endocytosis may play an important role in recycling Cdc42 from the plasma membrane. Using the aforementioned assay, we screened through a large collection of endocytic genes and found that 1) disruption of several of these genes severely reduced Cdc42's association with post-Golgi vesicles and 2) this effect was independent of the cargo-specific adaptors yAP1801/1802 and the AP-2 complex. In contrast, we found that loss of the sole Rho GDI in yeast had no effect on vesicle association or concentration. These data support the notion that endocytic recycling of Cdc42 from the plasma membrane to post-Golgi vesicles may act distinctively from the GDI-mediated pathway in generating and maintaining Cdc42 polarity at the plasma membrane.

**Molecular dynamics of PCSK9 trafficking at the Golgi and its effect on LDLR degradation.**

H. Ait Hamouda<sup>1,2</sup>, L. Villeneuve<sup>1</sup>, A. Demers<sup>1</sup>, G. Mayer<sup>1,2</sup>; <sup>1</sup>Institut de Cardiologie de Montréal, Montréal, QC, Canada, <sup>2</sup>Pharmacology, Université de Montréal, Montréal, QC, Canada

Coronary heart diseases (CHD) are a leading cause of death in Western societies. Hypercholesterolemia is a major risk factor for CHD. It is characterized by high levels of circulating low-density lipoprotein cholesterol (LDL, also called "bad cholesterol"). The prolonged presence of LDL in the circulation increases the risk of the formation of atherosclerotic plaques, which can lead to obstruction of arteries and myocardial infarction. LDL is normally extracted from the blood by binding to the LDL receptor (LDLR) thereby mediating its endocytosis in the liver. Human genetic studies have identified PCSK9 as the third gene responsible of autosomal dominant hypercholesterolemia after LDLR and its ligand apolipoprotein B100. PCSK9 interacts with the LDLR and induces its degradation thereby causing plasma LDL levels to rise. PCSK9 gain-of-function (GOF) mutations are associated with elevated plasma LDL levels and premature CHD while PCSK9 loss-of-function (LOF) mutations reduce the risk of CHD by ~88% owing to a strong reduction of circulating LDL. Accordingly, PCSK9 is recognized as a major pharmacological target to lower the risk of CHD. PCSK9 binds the LDLR at the cell surface and/or in the Golgi apparatus of hepatocytes and causes its degradation in lysosomes by a mechanism not yet clearly understood. The goal of this study was to determine why some human PCSK9 mutations fail to induce LDLR degradation while

others increase it in lysosomes. Several PCSK9 LOF and GOF mutations were fused to the fluorescent protein mCherry to study their molecular mobility in living liver cells. Our quantitative analysis of fluorescence recovery after photobleaching (FRAP) showed that PCSK9 GOF mutations e.g., D129G, have a higher protein mobility (>35% compared to WT) at the trans-Golgi network (TGN). Their mobility was further increased (>90% compared to WT) in presence of a Golgi transmembrane protein that interacts with PCSK9. The LOF mutation R434W, which fail to accumulate in the TGN and to induce LDLR degradation, presented a much slower diffusion (<25% compared to WT). In addition, our confocal and electron microscopy analyses demonstrate for the first time that PCSK9 is localized in multivesicular bodies and concentrated in the TGN of human hepatocytes. Furthermore, our results demonstrate that PCSK9 localization in the TGN is mediated through its C-terminal cysteine-rich domain, which is essential for LDLR degradation. These results provide important new evidences on the mechanism of action of PCSK9 and may ultimately help in the development of inhibitors of the PCSK9-induced LDLR degradation.

### Testing the influence of a phospholipid flippase on membrane curvature in giant unilamellar vesicles.

T. T. Sebastian<sup>1</sup>, C. A. Day<sup>2</sup>, L. Theorin<sup>3</sup>, A. K. Kenworthy<sup>2</sup>, T. G. Pomorski<sup>3</sup>, T. R. Graham<sup>1</sup>;  
<sup>1</sup>Department of Biological Sciences, Vanderbilt University, Nashville, TN, <sup>2</sup>Department of Molecular Biology and Biophysics, Vanderbilt University, Nashville, TN, <sup>3</sup>Department of Plant Biology and Biotechnology, University of Copenhagen, Frederiksberg, Denmark

Vesicular transport of proteins between organelles is a process that is essential for cell health and viability. Integral membrane proteins, called phospholipid flippases, play important roles in the formation of these transport vesicles at sites of membrane budding. Flippases work by establishing and maintaining membrane asymmetry. This is achieved by translocation of specific phospholipids from the extracellular or luminal leaflet of the membrane bilayer to the cytosolic side. It is thought that the resulting imbalance in phospholipid number between the bilayers causes membrane bending, captured by accessory and coat proteins, and leads to the formation of mature cargo-containing transport vesicles. Drs2p is the founding member of these flippases (type IV P-type ATPases) in *Saccharomyces cerevisiae*, and is involved in clathrin-coated vesicle formation at the *trans*-Golgi network (TGN).

To elucidate the influence that flippase activity has on membrane morphology, we are reconstituting Drs2p in giant unilamellar vesicles (GUVs). Drs2p was purified using previously established protocols and was then reconstituted into proteoliposomes containing phosphatidylcholine (PC) and varying levels of phosphatidylserine (PS, the preferred substrate for Drs2p). These proteoliposomes were electroformed into GUVs that are 10-200µm in diameter and are visualized using fluorescence microscopy. Drs2p was activated by addition of ATP and imaged in real time to determine if there were any changes in membrane morphology. We observe that 20% PS-GUVs that contain active Drs2p tubulate after ATP addition. However, we continue to work on appropriate controls and improved imaging techniques to determine if the flippase activity of Drs2p is driving membrane tubulation. These studies should provide a better idea of the role that flippases play in the formation of transport vesicles.

### Elucidating gsk-3 substrate and inhibitor binding sites as a tool for inhibitor refinement.

A. Licht-murava<sup>1</sup>, B. Plotkin<sup>1</sup>, M. Eisenstein<sup>2</sup>, H. Eldar-Finkelman<sup>1</sup>; <sup>1</sup>Tel-Aviv University, Tel-Aviv, Israel, <sup>2</sup>Weizmann Institute of Science, Rehovot, Israel

a molecular understanding of substrate recognition of protein kinases provides an important basis for the development of substrate competitive inhibitors. here, we explored substrate recognition and competitive inhibition of glycogen synthase kinase (gsk)-3 $\beta$  using molecular and computational tools. in previous work, we described gln89 and asn95 within gsk-3 $\beta$  as important substrates binding sites. here, we show that the cavity bordered by loop 89-qdkrfkn-95, located in the vicinity of the gsk-3 $\beta$  catalytic core, is a promiscuous substrate binding subsite. mutations within this segment highlighted phe93 as an additional essential contact residue for substrates' recognition. however, unlike gln89 and asn95, phe93 was also important for the binding of our previously described substrate competitive inhibitor, I803 [keappappqs(p)p], and its cell-permeable variant I803-mts. the effects of the substitution of charged or polar residues within I803 further suggested that binding to gsk-3 $\beta$  is governed by hydrophobic interactions. our computational model of gsk-3 $\beta$  bound to I803 was in agreement with the experimental data. it revealed I803 binding with a hydrophobic surface patch and identified interactions between pro8 (I803) and phe93 (gsk-3 $\beta$ ). computational modeling of new I803 variants predicted that inhibition would be strengthened by adding contacts with phe93 or by increasing the hydrophobic content of the peptide. indeed, the newly designed I803 variants showed improved inhibition. our study identified different and overlapping elements in gsk-3 $\beta$  substrate and inhibitor recognition and provides a novel example for model-based rational design of substrate competitive inhibitors for gsk-3.

### GSK3 modulates tau phosphorylation in an age dependent manner.

A. P. Salcedo-Tello<sup>1</sup>, K. Hernandez<sup>1</sup>, C. Arias<sup>1</sup>; <sup>1</sup>Medicina Genomica y Toxicologia Ambiental, Instituto de Investigaciones Biomedicas.UNAM, Mexico City, Mexico

Alzheimer disease (AD) and related tauopathies are characterized by progressive neurodegeneration involving abnormal phosphorylation of the microtubule associated protein tau. Glycogen synthase kinase (GSK3) has been identified as one of the major candidates mediating tau hyperphosphorylation. In AD postmortem brain, tau phosphorylation has been found augmented at several epitopes modified by GSK3. GSK3 activity is modulated by the canonical Wnt signaling pathway. Moreover, the expression of the Wnt antagonist Dickkopf-1 (Dkk1) is increased in brains of AD patients and in AD transgenic mouse models, suggesting that dysfunction of Wnt signaling could contribute to AD pathology. However, the role of Wnt signaling dysregulation on GSK3 activity and its consequences on tau hyperphosphorylation during aging is still unknown. Thus, the aim of this study is to investigate the effects of the specific inhibitor of GSK3 (6BIO) and Dkk1 on tau phosphorylation in some sites relevant for AD (Ser199/202/214/396/404) in a model of metabolically active hippocampal slices from young and aged rats. We found that GSK3 inhibition significantly decreases tau phosphorylation on Ser199/202/396 and 404 in hippocampus from both, young and aged rats. These results suggest that the phosphorylation of those epitopes strongly depends of GSK3 activity. In contrast, phosphorylation of tau Ser214 was not affected by pharmacological inhibition of GSK3 or by DKK1, implicating that this epitope does not directly depend of GSK3 activity. While inhibition of Wnt signaling by Dkk1 increased tau phosphorylation in GSK3-dependent sites in

hippocampal slices from old rats, in young rats tau phosphorylation was not significantly modified. At present our results support the notion of a site and age dependent GSK3 regulation of tau phosphorylation.

**An Alzheimer's Associated Neurotoxic Lipid Remodels Phosphatidylinositol-4,5-bisphosphate and Inhibits Tor Signaling in *Saccharomyces cerevisiae*.**

M. A. Kennedy<sup>1</sup>, K. Neiwola-Staszewska<sup>2</sup>, A. Johnston<sup>3</sup>, L. Harris<sup>3</sup>, F. Reggiori<sup>4</sup>, S. Bennett<sup>1</sup>, R. Loewith<sup>2</sup>, K. Baetz<sup>1</sup>; <sup>1</sup>Biochemistry, University of Ottawa, Ottawa, ON, Canada, <sup>2</sup>Molecular Biology, University of Geneva, Geneva, Switzerland, <sup>3</sup>Agriculture and Agri-Food Canada, Ottawa, ON, Canada, <sup>4</sup>UMC Utrecht, Utrecht, Netherlands

Increasing evidence suggests that the alkylacylglycerophospholipid, PC(O-16:0/2:0), contributes to the neurotoxicity observed in Alzheimer's disease (AD). Our previous work revealed a role for phospholipase D (PLD) in buffering the toxic effects of PC(O-16:0/2:0) in yeast and human neurons but suggested other signaling pathways may also be required to buffer the toxic effects of PC(O-16:0/2:0). To directly address this we compared transcriptional changes between untreated and PC(O-16:0/2:0) treated *Saccharomyces cerevisiae*. This analysis revealed a significant enrichment in TOR-dependent transcripts including those involved in ribosomal biogenesis and the cellular stress response. Genetic evidence confirmed a role for TOR signalling in PC(O-16:0/2:0)-mediated toxicity as TOR2 temperature sensitive alleles exhibited increased sensitivity to the lipid. In agreement with these findings, biochemical assays revealed a pronounced reduction in Sch9 and Ypk1 phosphorylation, targets of TORC1 and TORC2 respectively, in PC(O-16:0/2:0) treated cells. The phosphatidylinositol-4,5-bisphosphate (PI(4,5)P<sub>2</sub>) binding proteins Slm1/2 play a critical role in regulating TORC2-mediated phosphorylation of Ypk1/2 therefore we investigated the effects of PC(O-16:0/2:0) treatment upon the distribution of PI(4,5)P<sub>2</sub> and the key metabolic enzyme Mss4. Interestingly, live cell imaging revealed that both PI(4,5)P<sub>2</sub> and GFP-tagged Mss4 were redistributed to distinct phosphatidylinositol enriched structures (PES) in the presence of PC(O-16:0/2:0) but not other lipids, chemicals or culture conditions. In addition, the effect of PC(O-16:0/2:0) appears to be specific to certain membrane components as we have not observed an effect upon many other membrane associated proteins. Congruent with our findings, Slm1-GFP and the TORC2 complex member Bit61-GFP, but not Ypk1, were found to relocalize to the PES suggesting that PC(O-16:0/2:0) may disrupt the recruitment of substrates, including Ypk1, to TORC2. We further report that remodelling of PI(4,5)P<sub>2</sub> and associated proteins is dependent upon PC(O-16:0/2:0)-induced changes in sphingolipid biosynthesis. In conclusion, our work identifies PC(O-16:0/2:0) as a novel mediator of PI(4,5)P<sub>2</sub> distribution and Tor signalling in yeast. Further work will be needed to determine whether AD associated changes in PC(O-16:0/2:0) metabolism are involved in precipitating the dysregulation of PI(4,5)P<sub>2</sub> metabolism which is also observed in patients with AD.

**Efficient traffic to the vacuole is necessary for TORC1 activity.**

D. E. Ejzykowicz<sup>1</sup>, F. Ruiz<sup>1</sup>, K. M. Locken<sup>1</sup>, E. Gharakhanian<sup>1</sup>; <sup>1</sup>Department of Biological Sciences, California State University Long Beach, Long Beach, CA

The target of rapamycin (TOR) is a conserved Ser/Thr kinase that regulates cell growth and metabolism in response to environmental factors like nutrient availability and stress. The direct target of Tor complex 1 (TORC1) in the yeast *Saccharomyces cerevisiae* is the Sch9 protein, which contains six amino acids in the C terminus, that are directly phosphorylated by Tor1p.

Phosphorylation of Sch9p is lost when cells are treated with rapamycin, an inhibitor of Tor1. Tor1 inactivation also results in cell cycle arrest and activation of macroautophagy. A genome screening for vacuolar trafficking defects in our lab resulted in 13 mutants hypersensitive to hygromycin B (*hhy* mutants). All *HHY* genes are involved in vesicular traffic and all *hhy* mutants show Tor1 mislocalization in the presence of hygromycin. Among them, 9 exhibit even increased sensitivity to hygromycin and are referred to as super-hypersensitive to hygromycin (*shhy*) mutants. All *SHHY* gene functions converge at the trans Golgi and late endosome interface and *shhy* mutants exhibit increased sensitivity to rapamycin treatment, indicating compromised Tor signaling. Treatment of *shhy* mutants with hygromycin for four hours results in an inability to restart growth, further suggesting TORC1 signaling defect. In this study, we probe the state of TORC1 activity in *shhy* mutants in the presence and absence of hygromycin B. In order to study TORC1 activity, we monitored the phosphorylation of Sch9p. *shhy* mutants showed compromised Tor1 kinase signaling, which becomes more accentuated in the presence of hygromycin B. Since TORC1 inactivation results in activation of autophagy, we decided to test autophagy in those *shhy* mutants. All *shhy* mutants showed a defect in autophagy when tested in starvation plates with phloxine B. As Tor1 vacuolar localization is compromised in *shhy* mutants, these results suggest that physical Tor1 presence at the vacuole is necessary for TORC1 activity as well as onset of autophagy. Rapamycin and hygromycin are antibiotics produced by the same bacterium *Streptomyces hygroscopicus*, and although they use different mechanisms of action, they both affect the TORC1 pathway in yeast. Our results combined suggest that intact traffic at the trans Golgi and vacuole interface is necessary for Tor1 localization and function, and that hygromycin is targeting that interface in *shhy* mutants.

### Control of the *S. cerevisiae* Fps1 glycerol channel by its regulator Rgc2 and the MAPK Hog1.

J. Lee<sup>1</sup>, W. Reiter<sup>2</sup>, I. Dohnal<sup>2</sup>, S. Beese-Sims<sup>3</sup>, G. Ammerer<sup>2</sup>, D. Levin<sup>1</sup>; <sup>1</sup>Molecular and Cell biology, Goldman School of Dental Medicine, Boston University, Boston, MA, <sup>2</sup>Christian Doppler Laboratory for Proteome Analysis, University of Vienna, Vienna, Austria, <sup>3</sup>Department of Genetics, Harvard Medical School, Harvard University, Boston, MA

Under conditions of hyper-osmotic stress, many fungi maintain osmotic equilibrium by producing and retaining high concentrations of glycerol as a compatible solute. Intracellular glycerol concentration is regulated in *S. cerevisiae* by the plasma membrane aquaglyceroporin, Fps1. Increased external osmolarity induces Fps1 closure, whereas decreased osmolarity causes channel opening, both within seconds of the change in external osmolarity. This channel is required for survival of a hypo-osmotic shock when yeast cells must export glycerol rapidly to prevent bursting. Relative to other characterized aquaglyceroporins, Fps1 possesses N-terminal and C-terminal cytoplasmic extensions that are important for its regulation. The pathway responsible for Fps1 regulation in response to changes in osmolarity has not been delineated, but involves the MAPK Hog1 (High Osmolarity Glycerol response), which is known to bind to the N-terminal domain of Fps1. Fps1 activity is also controlled by a pair of positive regulators, Rgc1 and Rgc2 (for Regulators of the Glycerol Channel), which are phosphorylation targets of Hog1. Loss of either FPS1, or RGC1 and RGC2 function results in excess turgor pressure and consequent cell wall stress. Here we demonstrate how Hog1 modulates Fps1 channel activity through Rgc2.

We identified seven S/T-P phosphorylation sites in Rgc2 by mass spectrometry, some of which were demonstrated in a quantitative analysis to be Hog1-dependent and induced by hyper-osmotic shock. Mutation of these phospho-sites to Ala (Rgc2-7Ala) caused a constitutively

open Fps1 channel phenotype, supporting the conclusion that Hog1 drives Fps1 closure by phosphorylation of Rgc2. We found by co-immunoprecipitation experiments that, in the absence of osmotic stress, Rgc2 associates with the C-terminal domain of Fps1 through its Pleckstrin Homology (PH) domain. In response to hyper-osmotic shock, Rgc2 dissociated from Fps1 in a Hog1-dependent manner. Consistent with this result, the Rgc2-7Ala mutant failed to dissociate from Fps1 in response to hyper-osmotic shock, suggesting that Fps1 is maintained in the open state through its association with Rgc2. This conclusion was supported by the finding that a PH domain mutant of Rgc2, which fails to associate with Fps1, displayed a closed channel phenotype. Finally, an N-terminally truncated Fps1 mutant, which lacks its Hog1-binding site, was stably associated with Rgc2 in response to hyper-osmotic shock. This supports a model in which Hog1 must be poised on the N-terminus of Fps1 to respond rapidly to osmotic stress by phosphorylating Rgc2 bound to the C-terminus of Fps1, thereby driving release of Rgc2 and allowing Fps1 closure.

**Ectopic activation of cell wall integrity MAP kinase pathway from endosomal compartments in *Saccharomyces cerevisiae* upon phosphatidylinositol (4,5)-bisphosphate depletion.**

*T. Fernandez-Acero*<sup>1,2</sup>, *I. Rodriguez-Escudero*<sup>1,2</sup>, *M. Molina*<sup>1,2</sup>, *V. J. Cid*<sup>1,2</sup>; <sup>1</sup>Dpt. of Microbiology II, Universidad Complutense de Madrid, Madrid, Spain, <sup>2</sup>Instituto Ramon y Cajal de Investigación Sanitaria, Madrid, Spain

Class I phosphatidylinositol 3-kinase (PI3K) catalyzes the conversion of PtdIns(4,5)P<sub>2</sub> into PtdIns (3,4,5)P<sub>3</sub>. In mammalian cells, this second messenger controls important functions, like cellular proliferation and inhibition of apoptosis. In consequence, hyperactivation of this protein is commonly observed in tumors. The model yeast *Saccharomyces cerevisiae* constitutively lacks class I PI3K activity. Heterologous expression of hyperactive versions of this protein in yeast leads to the growth inhibition due to the depletion of the essential plasma membrane pool of PtdIns (4,5)P<sub>2</sub>. This yeast model has proven to be useful for applied purposes such as the screening of PI3K inhibitors, but also provides a tool to study the roles of PtdIns(4,5)P<sub>2</sub> in the yeast cell. A global transcriptomic analysis upon mammalian PI3K expression in *S. cerevisiae* lead to a pattern reminiscent of that of cell wall stress conditions. Consistently, PI3K but not a kinase-dead mutant version triggered the phosphorylation of the cell wall integrity (CWI) MAPK, as well as the expression of a typical CWI transcriptional reporter. Consistent with loss of PtdIns(4,5)P<sub>2</sub>, depolarization of the actin cytoskeleton and a retard in the internalization of the vital endocytic marker FM4-64 were observed. Interestingly, instead of marking polarized sites at the cellular cortex, the upstream CWI pathway component Pkc1, which is recruited to sites of Rho1 activation, was abnormally located to intracellular compartments that were associated to Ypt31/32-containing endosomes. We propose that loss of essential cortical phosphoinositides triggers alternative activation of the CWI pathway from endosomal compartments.

**Independent pathways downstream of the Wnd/DLK MAPKKK regulate synaptic structure, injury signaling and axonal transport.**

*S. Klinedinst*<sup>1</sup>, *X. Wang*<sup>1</sup>, *C. A. Collins*<sup>1</sup>; <sup>1</sup>Molecular, Cellular and Developmental Biology, Univeristy of Michigan, Ann Arbor, MI

MAP Kinase signaling cascades orchestrate diverse cellular activities with common molecular players. To achieve specific cellular outcomes in response to specific signals, scaffolding proteins play an important role. Here we investigate the role of the scaffolding protein JIP1 in neuronal signaling by a conserved axonal MAP Kinase Kinase Kinase (MAPKKK), known as

Walleranda (Wnd) in *Drosophila*, DLK in vertebrates and *C. elegans*. Recent studies in multiple model organisms suggest that Wnd/DLK regulates both regenerative and degenerative responses to axonal injury. Here we report a new role for Wnd in synaptic development, which implies that Wnd is also active in uninjured neurons. This synaptic role of Wnd can be functionally separated from Wnd's role in axonal regeneration and injury signaling by the requirement for the JIP1 scaffold and the p38b MAP kinase. JIP1 and p38b mediate the synaptic function of Wnd, but are not required for injury signaling or new axonal growth after injury. Previous studies indicate that JIP1 is transported to the presynaptic axon terminus by the kinesin-1 motor, and mutations in either *jip1* or *wnd* cause defects in axonal transport. Our genetic analysis indicates that JIP1's role in axonal transport can also be functionally separated from its signaling role in synaptic development. We conclude that Wnd regulates multiple independent pathways in *Drosophila* motoneurons, and that JIP1, which localizes to presynaptic axon terminals, scaffolds a specific downstream cascade required for the organization of presynaptic microtubules during synaptic development.

### **Dephosphorylation Pattern of MAPK in Single Oocyte after Fertilization.**

Z. Lu<sup>1</sup>, D. Carroll<sup>1</sup>; <sup>1</sup>Biology, Florida Institute of Technology, Melbourne, FL

The mitogen-activated protein kinase (MAPK) pathway is a highly conserved signal transduction cascade regulating cell proliferation, differentiation and apoptosis. In oocytes of many animals, the MAPK pathway is activated during meiosis, followed by inactivation after fertilization. The timing of MAPK dephosphorylation after fertilization is studied in single starfish oocytes for the first time. The starfish is an excellent model system for this study because large numbers of immature oocytes can be obtained at prophase of meiosis I. Maturation is initiated upon addition of 1-methyladenine and the oocytes become competent for fertilization within 40 minutes. Using the metric of fertilization envelope elevation, fertilization is tightly synchronized in an egg population and samples can be easily taken every few minutes. In this study, single starfish eggs or zygotes were taken from the larger population and snap frozen in liquid nitrogen for analysis of MAPK phosphorylation by western blotting. Compared with the gradual decrease in MAPK phosphorylation observed in groups of oocytes, the dephosphorylation appears more abrupt in single oocytes. In eight oocytes which were simultaneously taken at 20 minutes after fertilization, four of them show very weak but detectable signal MAPK activity, while the other four oocytes still display high level of MAPK activity. In the view of groups of oocytes, the percentage of the oocytes with MAPK dephosphorylation is increased as the time going after fertilization. In the first 10 minutes after fertilization, less than 10% of the oocytes show reduced MAPK phosphorylation. This increases to approximately 70% within at 40 minutes after fertilization. At the time of 60minutes after fertilization, 100% of the oocytes accomplish MAPK dephosphorylation. The single cell system applies a more accurate way to study the mechanisms of MAPK pathway regulation. It also helps to also hoped that this system will reveal the negative regulation pathway of the MAPK cascade following fertilization in the starfish.

### **The Role of MAPKKs in Self-Renewal and Pluripotency of Mouse Embryonic Stem Cells.**

W. Guo<sup>1</sup>, H. Lee<sup>1</sup>, J. Yue<sup>1</sup>; <sup>1</sup>Physiology, The University of Hong Kong, Hong Kong, China

The ERKs1/2 MAP kinases (MAPKs) are involved in many cellular processes such as cell proliferation, cell differentiation, cell movement, and cell death. ERKs 1/2 are activated by MAPK kinases (MAPKKs), which in turn are activated by MAPKK kinases (MAPKKKs). Raf family, including A-Raf, B-Raf and C-Raf, are the MAPKKKs in activating ERKs1/2. Ying et al.

reported that the self-renewal of mouse embryonic stem (ES) cells is enabled by the elimination of differentiation-inducing signaling from MAPKs. Yet, the effects of MAPK inhibition on modulating self-renewal and pluripotency of mouse ES cells are still unknown. Here we individually knocked-down A-Raf, B-Raf and C-Raf in D3 mouse ES cell line. We found that the activation of ERKs1/2 in ES cells was not affected by these single knockdowns. Therefore, the A, B, C-Raf triple knockdown ES cells were generated, and the activation of ERKs1/2 was significantly down-regulated in the triple knockdown cells compared with that in control cells. We are currently generating the double knockdown of varied combinations of Rafs in ES cells and exploring the role of these MAPKKs on self-renewal and pluripotency of ES cells.

**Combined transcriptome and proteome analysis of POPX2 related signaling pathways in breast cancer**

S. Zhang<sup>1</sup>, C. Koh<sup>1</sup>;

<sup>1</sup>School of Biological Sciences, Nanyang Technological University, Singapore, Singapore

POPX2, a serine/threonine phosphatase belonging to the PP2C family, has been implicated in the regulation of breast cancer cell motility and invasiveness. The levels of POPX2 were high in the more invasive MDA-MB-231 cells compared with low invasive MCF7 breast cancer cells. Silencing POPX2 in the MDA-MB-231 cells resulted in lower motility and invasiveness. However, the underlying mechanism was not known. In order to find the POPX2 substrates and further map POPX2 related signaling pathways in breast cancer, a combined transcriptome and proteome study was carried out by using DNA microarray and SILAC (Stable Isotope Labeling of Amino acid in Cell culture)-based mass spectrometry, respectively. A combined KEGG pathway analysis was undertaken to determine complementary mechanisms of regulation between the transcriptome and proteome. A high percent of genes and proteins were distributed in pathways related to cancer, MAPK signaling, actin cytoskeleton regulation and the cell cycle. Focal adhesion regulation was found to be the only commonly enriched KEGG pathway. The role of POPX2 in focal adhesion and actin cytoskeleton regulation were further validated by immunostaining. Since the method we exploited for proteome fractionation also enriched the phosphopeptides, the phosphoproteome was analyzed. We found MAPK1 (ERK2) and MAPK3 (ERK1) to be regulated by POPX2 signaling. In addition, a MAPK1/3 sub-network was found to be over-represented through protein network analysis.

**The Nuclear Translocation of JNK and p38 MAPKs.**

E. Zehorai<sup>1</sup>; <sup>1</sup>*Biological Regulation, Weizmann Institute of Science, Rehovot, Israel*

Rapid and massive nuclear translocation of signaling proteins is an important step in the induction of transcription upon extracellular stimulation. Despite the importance of this process, the molecular mechanisms that govern this process have been elucidated only for few signaling components. In these cases, signaling proteins that utilize the classical nuclear localization

signal (NLS) interact with Impa and Impb, to facilitate their nuclear translocation. However, it is clear today that many other signaling proteins translocate to the nucleus upon stimulation using distinct, NLS-Imp $\alpha/\beta$ - independent mechanisms.

In a search for NLS-independent shuttling proteins, we have resorted to the MAPK family members JNK and p38. Unlike ERK1/2, the subcellular localization of JNKs and p38s has not been properly established so far. In this study we show that in resting cells, JNK1/2 and p38 $\alpha/\beta$  are localized mainly in the cytoplasm, and translocate to the nucleus upon stimuli, independent of their activation. We further found that despite the pronounced similarity between the MAPK family members, none of the JNK or p38 proteins contain the ERK1/2-NTS in their KID regions. Furthermore, mutations in the aligned residues of this region resulted in a marginal effect on the nuclear translocation of JNK1/2 and p38 $\alpha/\beta$ , indicating that the mechanism of the translocation is not only NLS- but also NTS- independent. We hypothesized that the nuclear translocation is still dependent on other, ill-defined, b-like importins. Therefore, we used Co-IP and SiRNA experiments with all these importins, and found that the translocation of JNK1/2 and p38 $\alpha/\beta$  is mediated through their interactions with either Imp7 or Imp9, which require further dimerization with Imp3. Thus, the stimuli-dependent nuclear translocation of these MAPKs is mediated by the dimerization of different b-like importins. As such, it consists an unexplored layer of transcriptional regulation.

#### **Engineered manipulation of signaling networks: Novel control of kinase activation and interactions dissects parallel Src pathways.**

A. V. Karginov<sup>1</sup>, D. Tsygankov<sup>2</sup>, M. E. Berginski<sup>3</sup>, E. D. Trudeau<sup>2</sup>, P-H. Chu<sup>2</sup>, J. J. Yf<sup>2</sup>, S. M. Gomez<sup>3</sup>, T. C. Elston<sup>2</sup>, K. M. Hahn<sup>2</sup>; <sup>1</sup>Pharmacology, University of Illinois at Chicago, Chicago, IL, <sup>2</sup>Pharmacology, UNC-Chapel Hill, Chapel Hill, NC, <sup>3</sup>Biomedical Engineering, UNC-Chapel Hill, Chapel Hill, NC

Spatio-temporal control of signaling is orchestrated by a complex network of interactions between scaffolding and enzymatic components. Current tools typically cannot activate a specific protein and simultaneously cause it to interact with one specific downstream target, which would be of great value in dissecting the organization of signaling networks. Here we provide such a tool, and use it to determine the role of individual Src-mediated signaling pathways in stimulation of different cell morphological changes. Protrusive activity of a cell and its adhesion to extracellular matrix is regulated by Src via multiple interactions. Focal adhesion kinase (FAK) and p130Cas can bind and activate Src, propagating signals through parallel pathways. Localization of Src in the cytoplasm or at the plasma membrane also determines the function of Src. Thus, we focused specifically on activation of Src acting through FAK or through p130Cas, or at different locations (cytoplasm versus plasma membrane). An engineered, "insertable" FKBP12 protein (iFKBP) was introduced into the catalytic domain of Src, while FKBP12-rapamycin binding domain (FRB) was attached to the specific downstream effector. This rendered the kinase inactive until rapamycin, added to the extracellular medium, induced heterodimerization with FRB. Using this technology we restricted Src activation to the complex it formed with FRB-bearing downstream targets. Simple activation of Src, without targeting specific downstream molecules, led to cell spreading, reorganization of focal adhesions, and the production of filopodia and lamellipodial protrusions. Using the new approach, dubbed RapR-TAP, we showed that activation of Src specifically in complex with FAK led to focal adhesion rearrangement and only slow lamellipodial protrusion, while activation in complex with p130Cas led to rapid spreading and filopodia formation, but no apparent effects on focal adhesions. Comparing Src activation in the cytosol versus at the plasma membrane showed that membrane localization is necessary to stabilize protrusions, whereas cytoplasmic Src drives

rearrangement of focal adhesions. The novel method presented here isolates specific differences between parallel Src-induced signaling events, and demonstrates the feasibility of a broadly generalizable strategy to activate specific kinase-mediated signaling pathways in living cells.

**Investigation of Src regulation.**

*F. von Raussendorf<sup>1</sup>, I. Yudushkin<sup>1</sup>; <sup>1</sup>Medical Biochemistry, Max F. Perutz Laboratories, Vienna, Austria*

Src activity is regulated by its autophosphorylation on Tyr416 and phosphorylation of the C-terminal Tyr527, though the efficiency of these reactions has never been examined. To study regulation of Src activity we have employed a recently published method by Karginov et al. (2010). By inserting FK506-binding protein 12 (FKBP) into the kinase domain (RapR-kinase), stability and thus kinase activity is diminished. Rapamycin treatment and heterodimerisation with FRB (FKBP12-rapamycin binding domain of mTOR) increases rigidity and re-establishes kinase activity, producing an engineered allosteric switch. The kinase activity was monitored via substrate phosphorylation, but the question about the phosphorylation state of Src kinase itself remained open. We wanted to investigate whether phosphorylation of the inhibitory C-terminal Tyr527 and activatory Tyr416 of RapR-Src changes when the kinase is turned on by addition of rapamycin and FRB. Using the allosteric switch we have examined the phosphorylation of Tyr527 and Tyr416 in RapR-Src<sup>WT</sup> and RapR-Src<sup>D388R</sup> (kinase-dead) in the destabilised and induced state. Against expectations the phosphorylation levels did not seem to change upon addition of rapamycin and FRB. Surprisingly the kinase-dead Src appeared to be only marginally phosphorylated on both Tyr416 and Tyr527. Tyr416 is usually autophosphorylated by Src in trans. Since RapR-Src<sup>KD</sup> is not catalytically active, it can't autophosphorylate on Tyr416. Although Src<sup>KD</sup> is still a substrate for endogenous Src and can be phosphorylated, endogenous levels are insufficient to phosphorylate much of the overexpressed RapR-Src<sup>KD</sup>. Tyr527 is phosphorylated mainly by C-terminal Src kinase (Csk). Since the kinase-dead Src should still be available as a substrate, this lack of phosphorylation begs the question of whether its own activity might be needed. It has been postulated that Src family kinases exist in a complex with the membrane-bound Cbp/PAG (Csk binding protein) (Ingley et al, 2006). The active kinase phosphorylates Cbp at Tyr317, thus inducing recruitment of cytoplasmic Csk to the complex. Csk can then phosphorylate the C-terminal tyrosine of the kinase and inhibit its activity. I'm currently carrying out further experiments to investigate the recruitment mechanism of Csk in Src regulation.

### Critical Role for Histone Deacetylase 6 (HDAC6) in the Regulation of IL-6, and the JAK/STAT3 Signaling Cascade in Macrophages.

P. Perez-Villarreal<sup>1</sup>, M. Lienlaf<sup>1</sup>, F. Cheng<sup>1</sup>, T. Knox<sup>1</sup>, H. Wang<sup>1</sup>, D. Marante<sup>1</sup>, S. Yoder<sup>2</sup>, K. Woan<sup>1</sup>, J. Canales<sup>1</sup>, J. Pinilla-Ibarz<sup>3</sup>, E. Seto<sup>4</sup>, E. Sotomayor<sup>3</sup>, A. Villagra<sup>1</sup>; <sup>1</sup>Immunology, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL, <sup>2</sup>Molecular Genomics Core, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL, <sup>3</sup>Immunology and Malignant Hematology, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL, <sup>4</sup>Molecular Oncology, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL

Histone Deacetylases (HDACs) have divergent effects over the production of anti- and pro-inflammatory cytokines in antigen-presenting cells (APCs). We have previously shown that modulation of specific HDACs can alter the immunogenicity of APCs, either to an activating or tolerogenic phenotype. Recently, we identified HDAC6 as a positive regulatory factor in the production of IL-10. However, the participation of this HDAC in other immune related cellular processes remains unknown. In this work we present evidence of the important role of HDAC6 in the modulation of the JAK/STAT3 pathway through the IL-6 regulation. We generated knockdown cell lines of HDAC6 (HDAC6KD) and non-target (NT) cells as a control in RAW264.7 murine macrophages using lentiviral shRNA. Two HDAC6KD and two NT cell lines were treated with LPS or were left untreated and then analyzed by microarray. In HDAC6KD cells we found 1542 genes were down-regulated and 775 up-regulated in HDAC6KD cells. Their ontology distribution revealed significant changes in immune-related (632) and apoptosis/cell cycle control (47) genes. Most importantly, IL-6 was one of the most highly down-regulated genes in HDAC6KD cells. Significantly down or up regulated genes were analyzed by their ontology distribution and selected genes were validated by qRT-PCR, ELISA, or immunoblots. Our analysis revealed that the STAT3 and SP1 target genes were down regulated in HDAC6KD cells. Also, we observed by immunoprecipitation that the acetylation status of these proteins was diminished in HDAC6KD cells when compared against control (NT) cells which had been treated with LPS. Next, we analyzed the relevance of these findings by studying the tolerogenic JAK/STAT3 signaling pathway, which is known to be activated by IL-6 and critical in the final outcome of APCs in response to stimuli. Our observations included a complete abrogation in the phosphorylation of JAK2 and STAT3 proteins in HDAC6KD cells in response to LPS, which was reverted when these cells were treated with exogenous IL-6. Our final results demonstrate a critical role of HDAC6 in the modulation of important regulatory cytokines in macrophages, such as IL-6 and IL-10, and the potential role of HDAC6 in the regulation of the JAK/STAT3 pathway. These findings provide insight into the molecular mechanisms controlling the immunogenicity of APCs, supporting the use of HDAC6 inhibitors to enhance immune activation, positioning HDAC6 as a potential therapeutic target.

### In vitro reconstitution of T cell receptor signaling.

E. Hui<sup>1</sup>, R. Vale<sup>1</sup>; <sup>1</sup>University of California - San Francisco, San Francisco, CA

The mechanism by which a T cell is activated by a foreign antigen is still poorly understood. The earliest signaling event after TCR-antigen binding is the phosphorylation of the cytosolic tails (termed ITAM motifs) of the TCR complex, which leads to the recruitment and activation of a cytosolic kinase ZAP70 and subsequent downstream signaling events. The phosphorylation state of the ITAMs is controlled by a complex network formed by the membrane associated Src family kinase (SFK) Lck, the transmembrane tyrosine phosphatase CD45 and the inhibitory kinase Csk. Antigen-TCR engagement perturbs this network leading to net phosphorylation. However, the quantitative behavior of the kinase/phosphatase network that controls ITAM

phosphorylation is still poorly understood, in part because of many complexities in the system including the allosteric regulatory mechanism of Lck, positive and negative roles of CD45, and the spatial distribution of these proteins in the cellular environment. In order to better understand the behavior of the kinase/phosphatase network that controls the phosphorylation of ITAMs, we have reconstituted purified kinases and phosphatase of the TCR signaling network onto artificial liposomes. To measure phosphorylation of membrane-bound TCR zeta chain, we have developed a fluorescence based assay. Using this assay, we show that kinase and phosphatase reactions occur ~700-fold faster on membranes than in solution. By measuring TCR zeta chain phosphorylation as a function of both kinase and phosphatase concentrations, we document the behavior of the TCR/kinase/phosphatase network and produce a phase diagram for TCR phosphorylation. We also have dissected the effect of mutations that alter the allosteric regulation of the Lck kinase, and demonstrate stimulation of TCR phosphorylation when TCR and the Lck are co-clustered on the artificial liposomes. These studies provide a framework for better understanding the biochemistry of TCR triggering.

**The relationship between expression of A-Kinase Anchoring Proteins and phosphorylation of Akt/PKB in neonatal rat Schwann cell proliferation.**

*D. Yurko<sup>1</sup>, R. Stah<sup>2</sup>, D. Carey<sup>2</sup>, A. L. Asirvatham<sup>3</sup>; <sup>1</sup>Biochemistry Department, Misericordia University, Dallas, PA, <sup>2</sup>Weis Center for Research, Geisinger Clinic, Danville, PA, <sup>3</sup>Biology, Misericordia University, Dallas, PA*

Development of the peripheral nervous system is dependent upon the proliferation of Schwann cells which rely on the heregulin/neuregulin family of growth factors secreted by neurons. In neonatal rat Schwann cell cultures heregulin stimulates robust cell division only if forskolin, an agent that elevates cAMP is also added. The molecular mechanism mediating this synergistic response is unknown. Earlier investigations have revealed that A-Kinase anchoring proteins (AKAPs) of the cAMP/PKA pathway play an important role in mediating Schwann cell growth. Results from previous studies have shown that transfection of Schwann cells with SiRNA oligos synthesized against AKAP150 and AKAP95 reveal a reduction in protein levels of both AKAPs, associated with a decline in cell proliferation and a decrease in expression of Akt/PKB. The goal of this study was to determine if there was an association between the expression of AKAPs and phosphorylation of Akt when Schwann cells were stimulated with heregulin and forskolin. To perform this study, neonatal rat Schwann cells were cultured with no mitogens (control) followed by incubation with heregulin, forskolin or heregulin and forskolin (H+F). Immunoblot analysis of heregulin-stimulated cells revealed an upregulation of AKAP95 (85.69% ± 10.07) in comparison to treatment with forskolin (74.37% ± 21.61) or H+F (61.08% ± 19.97). This upregulation was accompanied by an increase in phospho-Akt expression (88.87% ± 22.70) for heregulin-stimulated cells, in contrast to treatment with forskolin (61.45% ± 14.11) or H+F (65.48% ± 10.71). Alternatively, the expression of AKAP150 was significantly increased in forskolin-treated cells (74.37% ± 21.61) in comparison to heregulin (63.48 ± 15.56), or H+F (51.84% ± 16.16) stimulation. Forskolin-treated cells also showed a significant increase in Akt (114.49% ± 33.83) in comparison to heregulin (79.95% ± 20.46) and H+F treatment (86.48% ± 31.62). However, as the levels of AKAPs decreased, the percent expression of phospho-Akt over Akt in heregulin (115.72% ± 11.5) or H+F treatment (111.43% ± 20.59) increased, in contrast to forskolin-treated cells (73.38% ± 9.62). In summary, mitogen-stimulated Schwann cells exhibited a decrease in the expression of both AKAPs, but an increase in phosphorylation of Akt. These preliminary observations suggest that a relationship between expression of AKAP proteins and phosphorylation of Akt may be necessary to mediate Schwann cell proliferation when stimulated with heregulin and forskolin.

## Post-Translational Modifications in Signaling

1501

### Lysine Protein Acetylation During NGF-Stimulated Neuriteogenesis Differentiation Of PC12 Cells.

S. Shukla<sup>1</sup>, N. D. Chaurasiya<sup>2</sup>, L. A. Walker<sup>3</sup>, B. L. Tekwani<sup>3</sup>; <sup>1</sup>Department of Pharmacology, School of Pharmacy, University of Mississippi, University, MS, <sup>2</sup>National Center for Natural Products Research, School Pharmacy, University of Mississippi, University, MS, <sup>3</sup>National Center for Natural Products Research & Department of Pharmacology, School of Pharmacy, University of Mississippi, University, MS

Neuriteogenesis is a key cellular process necessary for proper development of the adult nervous system and neuronal regeneration. Neurite extension from the soma depends on precise cytoskeletal and adhesion dynamics induced by sensing of extracellular signals. This process is similar to directional pseudopodial formation involving regulated actin-mediated membrane protrusion and signal transduction processes. Neuronal differentiation relies on a complex signaling network. Reversible acetylation and deacetylation of certain proteins may play important role(s) in this regulation. Alterations in these pathways may result into deregulation of neuriteogenesis and neuroregeneration. Histone acetyltransferases (HATs) and histone deacetylases (HDACs) catalyze the acetylation and deacetylation, respectively, of proteins at Lys (K) residues. HDAC inhibitors having neuroprotective, neurotrophic, and anti-inflammatory effects can correct these deficiencies and has emerged as a promising new strategy for therapeutic intervention in neurodegenerative disease. The interest of this work is to understand role of proteins acetylation/deacetylation functions, in neuronal differentiation, employing rat adrenal pheochromocytoma (PC 12) cell line. These cells resemble the phenotype of sympathetic ganglion neuron upon differentiation with NGF. PC 12 cell stop dividing and terminally differentiate when treated with nerve growth factors (NGF). These make PC 12 as a useful model system for neuronal differentiation. The NGF differentiated PC12 cells were less susceptible to cytotoxic effects of TSA, a pan inhibitor of Class 1 and 2 HDACs. TSA treatment did not affect the overall process of NGF-stimulated neuriteogenesis in PC12 cells. Longer TSA treatment durations of >24 hr did not show significant effect on status of protein acetylation as probed by anti-acetylated lysine antibody. During short treatment durations (1-8 hr) there was an increase in signals for acetylated proteins in cells treated either with TSA alone or with TSA and NGF compared with control and cells treated with NGF. Two low molecular weight proteins were found to show a significant increase in signals along with few other unknown protein bands. However, there was no significant change in the acetylating pattern in protein for cells treated with NGF compared to untreated undifferentiated control cells. There was no change in the expression level of HDAC2 a nuclear enzyme and HDAC6 a cytosolic enzyme during NGF stimulated neuronal differentiation and also in the presence of TSA. TSA treatment resulted in significant increase in numbers of neuronal nodes, a parameter measured for relative branching of neurons. The results indicate the role of lysine protein acetylation in neuriteogenesis. Characterization of hyperacetylated proteins, besides histones, will provide useful information on role of this post-translational signal transduction pathway in the process of neuronal differentiation.

1502

**Evidence for the recycling of Porcupine: a Conserved Membrane-bound O-acyltransferase Involved in the Post-translational Lipid Modification of Wnts.**

*D. N. Hernandez<sup>1</sup>, L. Galli<sup>1</sup>, V. Lingappa<sup>2</sup>, L. Burrus<sup>1</sup>; <sup>1</sup>Biology, SFSU, San Francisco, CA, <sup>2</sup>Prosetta Antiviral Inc., San Francisco, CA*

Wnts are secreted signal molecules that are important for patterning of tissues during embryogenesis and cell homeostasis. Wnt secretion is dependent on the lipidation of one or two conserved residues. Lipidation of the conserved serine is facilitated by Porcupine (Porcn), a membrane-bound O-acyltransferase. To better understand the role of Porcn in Wnt secretion, we sought to characterize the subcellular localization of overexpressed and endogenous Porcn. Immunohistochemical studies from our lab and others have shown that tagged-Porcn variants are localized to the Endoplasmic Reticulum (ER), where it is thought to palmitoylate Wnt proteins. Interestingly, biochemical studies from our lab also show the presence of Porcn in lipid rafts and on the cell surface. These data led us to hypothesize that Porcn undergoes dynamic membrane trafficking in cells. To test this hypothesis, we first developed polyclonal rabbit antibodies against Porcn. Antibodies were then validated for specificity to Porcn using competitive assays with Porcn peptide in Western blot and immunohistochemical assays. We then used this antibody to define the subcellular localization of endogenous Porcn. After optimizing fixation and solubilization procedures, we immunostained COS7 cells and collected images via confocal microscopy. In contrast to overexpressed Porcn, the majority of endogenous Porcn was detected in a Golgi-like structure. Overexpressed GalT-GFP, which localizes to the Golgi, overlaps with endogenous Porcn; further supporting the presence of Porcn in the Golgi. Additionally, staining of cells treated with Brefeldin A, a compound that promotes the retrograde transport of Golgi proteins to the ER, shows a loss of Golgi specific Porcn staining and further confirms the localization of Porcn to the Golgi. To test whether endogenous Porcn is found in lipid rafts, we immunostained cells for Flotillin-1 (a lipid raft marker) and Porcn. Endogenous Porcn in cell lines partially co-localizes with Flotillin-1, thus, supporting the localization of Porcn to lipid rafts. Together, these findings suggest Porcn undergoes dynamic membrane trafficking in the Wnt secretion pathway and suggest the possibility that Porcn has functions that extend beyond its role in the ER.

1503

**Identification of N-terminal residues of Sonic hedgehog important for palmitoylation by Hedgehog Acyltransferase.**

*R. Y. Hardy<sup>1,2</sup>, M. D. Resh<sup>1</sup>; <sup>1</sup>Department of Cell Biology, Memorial Sloan-Kettering Cancer Center, New York, NY, <sup>2</sup>Graduate Program in Biochemistry, Cell, and Molecular Biology, Weill Cornell Graduate School, New York, NY*

Sonic Hedgehog (Shh) is a secreted morphogen that regulates embryonic development. After removal of the signal peptide, Shh is processed to the mature, active form through autocleavage and a series of lipid modifications, including the attachment of palmitate. Covalent attachment of palmitate to the N-terminal cysteine of Shh is catalyzed by Hhat (Hedgehog acyltransferase) and is critical for proper signaling. The sequences within Shh that are responsible for palmitoylation by Hhat are not known. Here we show that the first six amino acids of mature Shh (CGPGRG) are sufficient for Hhat-mediated palmitoylation. Alanine scanning mutagenesis was used to determine the role of each amino acid and the positional sequence requirements in a cell-based Shh palmitoylation assay. Mutation of residues in the "GPGR" sequence to Ala had no effect on palmitoylation provided that a positively charged residue was present within the first 7 residues. A neighboring positively charged residue could compensate for the loss of the

other N-terminal positive residue. A similar requirement for N-terminal positively charged residues was also observed in Spitz, a second substrate of Rasp, the *Drosophila melanogaster* Hhat homolog. The N-terminal position exhibited a strong, but not exclusive requirement for Cys. Constructs with an N-terminal Ala were not palmitoylated. However, an N-terminal Ser served as a substrate for Hhat, but not Rasp, highlighting a critical difference between the mammalian and fly enzymes. These findings define residues and regions within Shh that are necessary for its recognition as a substrate for Hhat-mediated palmitoylation. Finally, we report the results of a bioinformatics screen to identify other potential Hhat substrates encoded in the human genome.

**Regulation of protease-activated receptor-1 signaling by extracellular loop 2 N-linked glycosylation: A possible bias signaling "switch"?**

A. G. Soto<sup>1</sup>, J. Trejo<sup>1</sup>; <sup>1</sup>Pharmacology, UCSD, La Jolla, CA

Protease-activated receptor-1 (PAR1) is a G protein-coupled receptor (GPCR) irreversibly proteolytically activated by thrombin. Thrombin binds to and cleaves the N-terminus of PAR1 unmasking a new N-terminus that functions as a tethered ligand by binding intramolecularly to the extracellular surface of the receptor to initiate signaling. N-linked glycosylation is an enzymatic process that links glycans to asparagine residues within the NXS/T consensus sequence (X=any amino acid except proline). To study the effects of PAR1 extracellular loop 2 (ECL2) N-linked glycosylation in signaling we generated asparagine to alanine mutants. Here, we report that the PAR1 ECL2 domain is highly modified by N-linked glycosylation. Moreover, the PAR1 ECL2 glycosylation mutant displayed an enhanced efficacy in Gq mediated thrombin signaling. The increase in PAR1 ECL2 mutant signaling was not due to defects in desensitization, receptor cleavage kinetics, or recycling back to the cell surface after activation. In addition, there was only a modest effect on activated receptor internalization. Interestingly, in converse the PAR1 ECL2 mutant displayed a significant decrease in G12/13 mediated RhoA activation. We employed BRET to study possible differences in receptor interactions with various adaptor proteins. Our BRET data revealed differences in PAR1 wildtype versus ECL2 mutant G13 protein interaction, as well as beta-arrestin 2 associations. Thus, these findings suggest that PAR1 N-linked glycosylation at ECL2 affects the conformation of the receptor that results in differential coupling to signaling effectors and components of the endocytic machinery leading to the altered signaling and trafficking.

**Ciliopathy proteins regulate broad paracrine signaling by context-specific proteasomal degradation of signaling mediators**

Y. Liu<sup>1</sup>, I-C. Tsai<sup>1</sup>, M. Morleo<sup>2</sup>, E. Oh<sup>1</sup>, C. Leitch<sup>3</sup>, F. Massa<sup>2</sup>, B-H. Lee<sup>4</sup>, D. Parker<sup>1</sup>, D. Finley<sup>4</sup>, N. Zaghoul<sup>3</sup>, B. Franco<sup>2</sup>, N. Katsanis<sup>1</sup>;

<sup>1</sup>Duke University, Durham, NC, <sup>2</sup>Telethon Institute of Genetics and Medicine (TIGEM), Naples, Italy, <sup>3</sup>University of Maryland School of Medicine, Baltimore, MD, <sup>4</sup>Harvard Medical School, Boston, MA

The ciliopathies are a group of disorders caused by structural or functional defects in cilia and their anchoring structures, the basal bodies. The proteins which are causally linked to ciliopathies are important for paracrine signal transduction. To understand the mechanism by which ciliopathy proteins regulate signaling transduction, we first examine the function of BBS1

and BBS4, two ciliopathy proteins causing Bardet-Biedl syndrome (BBS), in Notch signaling. Here we show that loss of BBS1 or BBS4 leads to persistent Notch signaling in zebrafish embryos and cells, resulting from the stabilization of the Notch receptor intracellular domain (NICD) and JAG1 ligand. These findings mirror the accumulation of  $\beta$ -catenin in the absence of BBS proteins, leading us to posit a broad proteasome-dependent role for these proteins. Consistent with this notion, we were able to ameliorate BBS-established Notch and Wnt signaling defects, either by overexpression of proteasome activator proteins, or by treating cells and embryos with the chemical proteasome agonist sulforaphane (SFN). These observations were not unique to BBS and Notch signaling. Similar accumulation of Sonic hedgehog components GLI2/3FL and SUFU was observed in neurons from *Ofd1* (another ciliopathy protein) mutant mice and could be rescued by SFN. Moreover, we tested the effect of loss of basal body proteins on NF- $\kappa$ B, which has not been associated previously with basal body dysfunction. Loss of BBS1, BBS4 or OFD1 leads to decreased NF- $\kappa$ B activity and concomitant I $\kappa$ B $\beta$  accumulation, which can also be ameliorated with SFN. Finally, we show that both BBS4 and OFD1 interact with proteasomal subunits. Depletion of ciliopathy proteins disturbs proteasome function by changing the centrosomal distribution of proteasome regulatory subunits and its composition in whole 26S proteasome. Taken together, our data indicate that basal body-proteasome regulation is a common mechanism governing the regulation of paracrine signaling, and suggest that activation of the proteasome might be of clinical benefit to some ciliopathy patients.

#### **New insights into nicotinamide signaling associated with insulin production in pancreatic beta cells.**

M. Hiramoto<sup>1</sup>, W. Nishimura<sup>1</sup>, M. Kawaguchi<sup>1</sup>, H. Udagawa<sup>1</sup>, T. Uebanso<sup>1</sup>, E. Takahashi<sup>2</sup>, K. Kano<sup>2</sup>, Y. Kaburagi<sup>2</sup>, N. Ishibashi<sup>1</sup>, K. Eto<sup>1</sup>, T. Nammo<sup>1</sup>, K. Yasuda<sup>1</sup>; <sup>1</sup>Department of Metabolic Disorder, Diabetes Research Center, Research Institute, National Center for Global Health and Medicine, Tokyo, Japan, <sup>2</sup>Department of Diabetic Complications, Diabetes Research Center, Research Institute, National Center for Global Health and Medicine, Tokyo, Japan

**Objective:** Nicotinamide has pleiotropic effects on pancreatic beta cells such as protecting against cell damages and promoting functional differentiation. In this study, we tried to clarify the nicotinamide signaling networks in pancreatic beta cells.

**Methods:** We immobilized nicotinamide on magnetic nanobeads (Tamagawa Seiki), and then screened for nicotinamide-binding proteins from cell lysates of rat pancreatic beta cell line INS-1. The binding molecules were purified and identified using mass spectrometry and the identified molecules were analyzed their association with nicotinamide using specific antibodies and recombinant proteins. We also investigated gene expression profiles in INS-1 cells and mouse islets with or without nicotinamide treatment using quantitative real-time PCR and oligo microarrays (Affymetrix Rat 230 2.0 or Mouse 430 2.0, respectively).

**Results:** About 100 nicotinamide-binding factors including RNA- or DNA-binding proteins were identified, and the associations of some of the identified molecules with nicotinamide were confirmed *in vitro*. Microarray analysis revealed Nicotinamide-induced changes of the expression in a variety of genes, ranging from transcription factors, protein folding factors to anti-apoptotic factors, and quantitative PCR analysis characterized the fluctuations of the gene expression after nicotinamide treatment. Nicotinamide treatment increased the gene expressions of *Ins2* and *MafA*, which is a crucial transcription factor for insulin gene expression. In addition, insulin content in INS-1 cells was also increased by nicotinamide treatment.

Conclusion: We identified nicotinamide-binding factors and nicotinamide-regulated genes in pancreatic beta cells, which would provide important clues for nicotinamide signaling networks for beta cell functions, especially for insulin production in the present study.

**Nardilysin regulates the mammalian circadian clock via modulating PER2 stability.**

Y. Hiraoka<sup>1</sup>, H. Yoshitane<sup>2</sup>, R. Nunokawa<sup>2</sup>, Y. Fukada<sup>2</sup>, T. Kimura<sup>1</sup>, E. Nishi<sup>1</sup>; <sup>1</sup>Department of Cardiovascular Medicine, Graduate School of Medicine, Kyoto University, Kyoto, Japan, <sup>2</sup>Department of Biophysics and Biochemistry, Graduate School of Science, The University of Tokyo, Tokyo, Japan

Circadian rhythms are regulated by endogenous molecular oscillators called circadian clocks. In mammals, the transcription factor heterodimer CLOCK:BMAL1 activates the expression of Period and Cryptochrome genes. PER and CRY proteins in turn heterodimerize and repress CLOCK:BMAL1 activity to inhibit their own expression. In addition to the core transcriptional feedback loop, posttranslational modifications of clock proteins are crucial for the correct operation of molecular clockworks. For example, phosphorylation of PER proteins by casein kinase I (CKI), which affects nuclear translocation and timely degradation via ubiquitin-proteasome pathway, is a vital part of clock regulation. However, it remains unclear how CKI are regulated. Here, we show that a metalloendopeptidase nardilysin (N-arginine dibasic convertase; NRDC) acts as a potent circadian clock regulator via modulating PER2 stability. Circadian period shortened in NRDC deficient (NRDC-KO) mice. In livers from NRDC-KO mice, nuclear PER2 proteins were retained longer than wild-type (WT) mice. When expressed in cells, NRDC formed a complex with PER2. Moreover, co-expression experiment showed that NRDC makes a complex with PER2 and CKI $\delta$ /CKI $\epsilon$ . These results suggest that NRDC may regulate PER2 stability by modulating CKI activity.

**Alterations in mTOR pathway signaling following status epilepticus in immature vs. mature rats.**

J. N. Lugo<sup>1</sup>, A. Brewster<sup>2</sup>, W. L. Lee<sup>2</sup>, Y-C. La<sup>2</sup>, A. Anderson<sup>3</sup>; <sup>1</sup>Psychology and Neuroscience, Baylor University, Waco, TX, <sup>2</sup>Baylor College of Medicine, Houston, TX, <sup>3</sup>Pediatrics, Baylor College of Medicine, Houston, TX

Chemoconvulsants such as pilocarpine are used to induce episodes of prolonged continuous seizure activity (status epilepticus, SE). In adult rats, this initial insult leads to the generation of unprovoked seizures (epilepsy). A similar insult in immature rats does not lead to spontaneous seizures later in life; however, the insult does result in long-lasting cellular and molecular changes that alter hippocampal plasticity in adulthood. While the effects of SE on mTOR signaling in the adult brain have been widely studied, relatively less is known about the effects of SE on mTOR signaling in the immature brain. We examined hippocampal mTOR pathway activation through the phosphorylation (P) of the downstream molecules ribosomal S6 protein, eukaryotic initiation factor binding protein 1 (4EBP1), and AKT, in developing and adult rats following pilocarpine-induced SE compared to age-matched shams. We performed a time course of mTOR activation over development to guide our choice of time points for the SE experiments. Western blotting revealed a significant decrease in hippocampal levels of P-S6, P-4EBP1 and P-AKT over postnatal development. However, at postnatal day (PD) 10 these levels remained significantly elevated compared with PD35 and adult (>6 months) (P14 days) increase in the levels of P-S6 and P-4EBP1, and a transient decrease in P-AKT (3 days) (n=5-8). In conclusion, the effects of SE on mTOR activation are different in immature vs. mature

hippocampus. While additional investigations are necessary to further characterize this effect, our findings may have implications for therapeutics in epilepsy.

1509

**CDK1 cooperates with PLK1 to ensure the temporal regulation of kinetochore microtubule dynamics and spindle checkpoint.**

M. Wang<sup>1</sup>, H. Yu<sup>1</sup>, Y. Chu<sup>2</sup>, Y. Huang<sup>3</sup>, R. Yu<sup>2</sup>, C. Fu<sup>1</sup>, G. Fang<sup>1</sup>, X. Yao<sup>2</sup>, D. Zhen<sup>1</sup>; <sup>1</sup>Cellular Dynamics, Hefei National Laboratory for Physical Sciences at Nanoscale, Hefei, China, <sup>2</sup>Physiology, Morehouse School of Medicine, Atlanta, GA, <sup>3</sup>Georgia Cancer Coalition, Atlanta, GA

Chromosome segregation during mitosis involves a dynamic interaction between spindle microtubules and kinetochore, a macromolecular complex that localizes at the centromeres of mitotic chromosomes. Cdk1 controls many aspects of mitotic chromosome behavior and spindle microtubule dynamics to ensure accurate chromosome segregation. PLK1 is a highly conserved mitotic kinase and activation of PLK1 requires phosphorylation of the T-loop. Here we show that phosphorylation of PLK1 T-loop by CDK1 in conserved Thr214 is essential for temporal control of kinetochore microtubule dynamics and spindle checkpoint signaling. Phosphorylates PLK1 at Thr214 suppresses microtubule dynamics and promotes the stabilization of initial kinetochore-microtubule attachments in prometaphase. Using fluorescence resonance energy transfer-based reporter of PLK1 activity at the kinetochore and quantitative analysis of native PLK1 substrate phosphorylation, we show that constitutively phosphorylation of Thr214 reduces inter-kinetochore tension and turnover of kinetochore microtubules, resulting in increased microtubule attachment errors and a checkpoint dependent mitotic arrest. Therefore, we reason that phosphorylation of PLK1 by CDK1 is essential to ensure the temporal regulation of kinetochore microtubule dynamics and spindle checkpoint control.

1510

**Redistribution of the fission yeast Clp1/Cdc14 phosphatase upon genotoxic stress is influenced by multiple protein kinases.**

M. R. Broadus<sup>1</sup>, K. L. Gould<sup>1,2</sup>; <sup>1</sup>Cell and Developmental Biology, Vanderbilt University School of Medicine, Nashville, TN, <sup>2</sup>Howard Hughes Medical Institute, Nashville, TN

The Cdc14 phosphatases, a proline directed protein phosphatase family, are important for mitotic exit and antagonize Cdk1 phosphorylation. In order to gain access to their substrates, Cdc14 phosphatases must be released from nucleolar sequestration during mitosis. Additionally, Clp1/Flp1, the *Schizosaccharomyces pombe* Cdc14 ortholog, and Cdc14B, a mammalian ortholog, are relieved of nucleolar sequestration in interphase upon DNA replication stress or damage, respectively. This suggests that Cdc14 phosphatases contribute to the cellular response elicited upon genotoxic insults. A complete mechanistic understanding of how Cdc14 phosphatases are released from their nucleolar sequestrations under these conditions is incomplete. We show that redistribution of Clp1 upon genotoxic stress is governed by complex phosphoregulation. We found that the cell wall integrity mitogen-activated protein kinase, Pmk1, the cell cycle kinase, Cdk1, and the Rad3 checkpoint effector kinases, Cds1 and/or Chk1, phosphorylate Clp1 directly promoting genotoxic stress-induced nucleoplasmic accumulation. More specifically, Pmk1 and Cdk1 phosphorylate Clp1 TP sites preferentially upon hydrogen peroxide treatment, while Cds1 and/or Chk1 preferentially phosphorylate RxxS sites upon hydroxyurea treatment. Abolishment of both Clp1 TP and RxxS phosphosites eliminates the redistribution of Clp1 upon genotoxic stress. Alternatively, preventing Clp1 autodephosphorylation at Clp1 TP sites results in constitutive nucleoplasmic localization. Also, we provide further mechanistic information and insight into cell cycle mediated nucleolar release

of Clp1. Our data elucidates a better understanding of pathways contributing to Clp1 localization, which may shed light on mechanisms controlling Cdc14B phosphatases in higher eukaryotes.

1511

#### **4E-T Phosphorylation by JNK Promotes Stress-dependent P-body Assembly.**

*M. Cargnello<sup>1</sup>, J. Tcherkezian<sup>1</sup>, J. Dorn<sup>1</sup>, E. Huttlin<sup>2,3</sup>, P. Maddox<sup>1,4</sup>, S. Gygi<sup>2,3</sup>, P. Roux<sup>1,4</sup>; <sup>1</sup>IRIC-University of Montreal, Montreal, QC, Canada, <sup>2</sup>Cell Biology, Harvard Medical School, Boston, MA, <sup>3</sup>Taplin Biological Mass Spectrometry Facility, Harvard Medical School, Boston, MA, <sup>4</sup>Pathology and Cell Biology, IRIC-University of Montreal, Montreal, QC, Canada*

Processing Bodies (P-bodies or PBs) are cytoplasmic granules involved in mRNA storage and degradation that participate in the regulation of gene expression. PBs concentrate non-translated mRNAs and several factors involved in mRNA decay and translational repression, including the eIF4E-transporter (4E-T). 4E-T is required for PB assembly, but little is known about the molecular mechanisms that regulate its function. Here, we demonstrate that oxidative stress promotes multisite 4E-T phosphorylation. We show that the c-Jun N-terminal kinase (JNK) is targeted to PBs in response to oxidative stress and promotes the phosphorylation of 4E-T. Quantitative mass spectrometry analysis reveals that JNK phosphorylates 4E-T on six proline-directed sites that are required for the formation of 4E-T complex upon stress. We have developed an image-based computational method to quantify the size, number and density of PBs in cells and we find that while 4E-T is required for steady state PB assembly, its phosphorylation facilitates the formation of larger PBs upon oxidative stress. Using polysomal mRNA profiling we assessed global and specific mRNA translation, but did not find that 4E-T phosphorylation impacts on translational control. Collectively, these data support a model whereby PB assembly is regulated by a two-step mechanism involving a 4E-T-dependent assembly stage in unstressed cells and a 4E-T phosphorylation-dependent aggregation stage in response to stress stimuli.

1512

#### **Persistent ATF2 Signaling is a Potential Determinate of Cell Fate post Radiation Exposure.**

*D. M. Sridharan<sup>1</sup>, W. C. Wilson<sup>1</sup>, M. K. Whalen<sup>1</sup>, J. M. Pluth<sup>1</sup>; <sup>1</sup>Cancer and DNA Damage response, Lawrence Berkeley National Laboratory, Berkeley, CA*

Oxygen derived radicals such as superoxides, hydrogen peroxide, singlet oxygen and hydroxyl radicals are generated as a byproduct of normal aerobic metabolism and are toxic to cells. These reactive oxygen species are also produced as a consequence of radiation exposure and have been implicated in the etiology of a wide range of human diseases, including cancer. Protein phosphorylation events are key to integrating the cellular communication post radiation exposure to the downstream biological response and essential to ensure normal cellular homeostasis. Persistent phosphorylation of certain signaling proteins has been correlated to prolonged oxidative stress. Interestingly, prolonged phosphorylation of several proteins involved in DNA damage response has been noted in both precancerous lesions and various tumors. The link between persistent phospho-signaling and cellular oxidative stress is unclear and could potentially shed light on the mechanisms that enhance cancer risk.

ATF2 (Activating Transcription factor), which is phosphorylated at Ser490-498 in response to DNA damage and at Thr69-71 during oxidative stress-mediated transcriptional response is a potential node in both these pathways. We have hypothesized that the nature of ATF2 signaling initiated and the magnitude of response will correspond to the complexity of radiation damage

and provide clues to a cell's sensitivity to oxidative stress and increased cancer susceptibility. Mammary epithelial and fibroblast cells derived from reduction mammoplasty from the same individual are being studied to better understand why certain cell types are more cancer susceptible. These cells were exposed to different radiation qualities and the profiles of pATF2 were examined at various times by flow based assays and fluorescent microscopy. To investigate the radiation quality dependence of cancer risk, we are studying a surrogate cancer endpoint of cancer risk, namely changes in telomere length, using a novel flow cytometry based assay. Our studies indicate that at late times post radiation exposure, a fraction of cells continue to show high amounts of residual ATF2 signaling. Our data has shown that cellular localization, degree of activation and persistent signaling of ATF2 and its site dependent phosphorylation is dependent on the nature and complexity of damage elicited by different radiation qualities. Studies reveal a dose-dependent shortening of telomere length in both mammary epithelial and fibroblast cells post radiation exposure, with shorter telomeres more evident with high LET exposures. We have also observed an interesting correlation between the persistent signaling of ATF2 and changes in telomere length. A compilation of the findings to date will be presented.

1513

**Proline rich sequences of the ubiquitin ligase Itch bind SH3 domains with individual specificities.**

*G. Desrochers<sup>1</sup>, L. Corbeil<sup>1</sup>, A. Angers<sup>1</sup>; <sup>1</sup>Département de Sciences Biologiques, Université de Montréal, Montréal, QC, Canada*

Itch is an ubiquitin ligase that belongs to the C2-WW-HECT (CWH) family containing well-characterized ligases such as Nedd4 in humans and Rsp5p in yeasts. In addition to the conserved domains common to all CWH proteins, Itch has a unique proline-rich region (PRD) that allows it to interact with SH3-domain containing proteins.

The PRD of Itch contains several minimal SH3 binding motifs that could potentially accommodate many substrates. Yet, only a few SH3 interacting partners are identified and little is known about their binding preferences towards Itch PRD.

We use bioluminescence resonance energy transfer (BRET) to evaluate Itch affinity with SH3-domain containing proteins. We confirm the previously reported interaction between Itch and endophilin, and identify novel SH3 partners: pacsin, amphiphysin as well as the isolated SH3 domains of intersectin. Pull-down experiments and far-Western blot further confirmed that pacsin and amphiphysin are indeed novel partners, but only weak interaction was found with the full length form of intersectin. As suggested by Itch ligase activity, we also show Itch-induced ubiquitylation of these potential substrates.

We next address the possibility that different SH3 proteins may bind different motifs inside Itch PRD. Using in vitro pull-down assays with different sub-sequences of the PRD, we were able to compare the affinity of different SH3 for these sequences. We found that endophilin and amphiphysin bind distinct yet overlapping motifs in the N-terminal region of the PRD, distinct from the preferred binding site reported for  $\beta$ -PIX (Janz et al, 2007).

Thus, Itch PRD contains several minimal SH3 binding motifs able to accommodate different SH3 partners. These proteins also have distinct binding preferences towards Itch PRD. These results will certainly help the prediction of novel SH3 substrates for Itch. They will also allow the design of Itch mutants abolishing specific SH3 interactions, thus helping to establish the biological significance of these interactions.

**USP7/HAUSP mediated stabilization of Foxp3 increases Treg suppressive capacity.**

V. Fleskens<sup>1,2</sup>, J. van Loosdregt<sup>1,2,3</sup>, J. Fu<sup>4</sup>, A. Brenkman<sup>5</sup>, C. Bekker<sup>1,6</sup>, C. Pals<sup>1</sup>, J. Meerding<sup>3</sup>, C. Berkers<sup>7</sup>, J. Barbi<sup>4</sup>, A. Gröne<sup>8</sup>, A. Sijts<sup>6</sup>, M. Maurice<sup>1</sup>, E. Kalkhoven<sup>5</sup>, B. Prakken<sup>3</sup>, H. Ovaa<sup>7</sup>, F. Pan<sup>4</sup>, D. Zaiss<sup>6</sup>, P. Coffier<sup>1,2,3</sup>; <sup>1</sup>Department of Cell Biology, University Medical Centre Utrecht, Utrecht, Netherlands, <sup>2</sup>Department of Immunology, University Medical Centre Utrecht, Utrecht, Netherlands, <sup>3</sup>Center for Molecular & Cellular Intervention, University Medical Centre Utrecht, Utrecht, Netherlands, <sup>4</sup>Immunology and Hematopoiesis Division, Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University School of Medicine, Baltimore, MD, <sup>5</sup>Department of Metabolic Diseases, University Medical Center Utrecht, and Netherlands Metabolomics Center, Utrecht, Netherlands, <sup>6</sup>Department of Infectious Diseases & Immunology, Faculty Veterinary Medicine Utrecht, Utrecht, Netherlands, <sup>7</sup>Division of Cell Biology, The Netherlands Cancer Institute, Amsterdam, Netherlands, <sup>8</sup>Department of Pathobiology, Faculty Veterinary Medicine Utrecht, Utrecht, Netherlands

Regulatory T cells (Treg) are a specific subset of T lymphocytes responsible for suppression of the immune response to maintain immunological self-tolerance. The Forkhead box (Fox) transcription factor Foxp3 is a lineage commitment factor for Treg, and stable Foxp3 expression levels are required for both their development and functional maintenance.

Here we demonstrate that Foxp3 protein levels are post-translationally regulated through poly-ubiquitination on multiple lysine residues, resulting in proteasome-mediated degradation. The deubiquitinase (DUB) USP7 was found to be upregulated and active in Treg and associated with Foxp3 in the nucleus. Ectopic expression of USP7 decreased poly-ubiquitination of Foxp3, thereby increasing both Foxp3 protein levels and transcriptional activity. Conversely, either treatment with a pan DUB inhibitor or USP7 knockdown decreased endogenous Foxp3 expression levels in Treg. Furthermore, USP7 knockdown significantly decreased Treg mediated suppression *in vitro*. In addition, in an induced colitis mouse model, either inhibition of DUB activity or USP7 knock down in Treg abrogated their ability to resolve inflammation *in vivo*. Taken together, our data provides a novel molecular mechanism in which rapid temporal control of Foxp3 levels in T cells can be regulated by USP7, thereby modulating Treg numbers and function.

1515

**Deubiquitinating enzyme Ubp3 as a novel regulator for PKA signaling.**

Y. Li<sup>1</sup>, Y. Wang<sup>1</sup>; <sup>1</sup>Department of Biology, Saint Louis University, Saint Louis, MO

The cAMP-dependent protein kinase (PKA) is a highly conserved key component in nutrient signaling pathway. In yeast, PKA responds to glucose and antagonistically interacts with TOR pathway to control cell growth. The molecular mechanisms that regulate PKA signaling remain to be fully understood. Here, we show that a deubiquitinating enzyme Ubp3 is a new regulator of PKA signaling. Disrupting the Ubp3 activity leads to hyper-activation of PKA signaling, as evidenced by increased phosphorylation of PKA substrates, decreased accumulation of glycogen, increased sensitivity to heat shock, and an enlarged cell size. The levels of intracellular cAMP and the active form of Ras proteins are also significantly elevated in the *ubp3Δ* mutants. Consistent with a model that the elevated level of cAMP may be responsible for the abnormal PKA signaling displayed by the *ubp3Δ* mutant, overexpression of *PDE2*, which encodes a phosphodiesterase that hydrolyses cAMP, significantly suppressed the hyper-activation of PKA signaling in *ubp3Δ* cells. Together, these data suggest that Ubp3 is a new negative regulator of PKA signaling and it acts likely at a step upstream of Ras.

1516

**a modulating effect of il-32 $\alpha$  on transcriptional regulator plzf in pma treated thp-1 promonocytic cells.**

Y. Park<sup>1</sup>, J-W. Kang<sup>1</sup>, D. Lee<sup>1</sup>, J-H. Kim<sup>1</sup>, M. Kim<sup>1</sup>, Y. Bak<sup>1</sup>, Y. Yang<sup>2</sup>, H-G. Lee<sup>3</sup>, J. Hong<sup>4</sup>, D-Y. Yoon<sup>1</sup>; <sup>1</sup>Konkuk University, Seoul, Korea, <sup>2</sup>Sookmyung Women's University, Seoul, Korea, <sup>3</sup>Korea Research Institute of Bioscience and Biotechnology, Daejeon, Korea, <sup>4</sup>Chunhbuk National University, Cheongju, Korea

human il-32 $\alpha$  has been reported as a proinflammatory cytokine that expresses in the activated natural killer cells and t-cells. although several variants such as  $\beta$  and  $\gamma$  isoforms have been known to induce inflammation, the precise role of each isoforms remains elusive. in this study, we observed that il-32 $\alpha$  isoform interacted with promyelocytic leukemia zinc finger gene (plzf), a transcriptional regulator belonging to the poz/domain and kruppel zinc finger (pok). plzf has many functional properties: inhibits cell growth, concentrated into punctated nuclear subdomains and is a sequence-specific transcriptional regulator recruiting a histone deacetylase-repressing complex. we cotransfected hek293 cells with il-32 $\alpha$  and plzf, then treated these cells with phorbol 12-myristate 13-acetate (pma). the interaction between il-32 $\alpha$  and plzf was pma-dependent, which means that pkc may mediate the bindings of these factors. we further examined whether il-32 $\alpha$  would modulate the function of plzf transcriptional regulator in stable il-32 $\alpha$ - expressing thp-1 cells. we observed that cxcr10, ifit2 and plscr1, target genes of plzf, were down-regulated in thp-1-il-32 $\alpha$  stable cells compared with control thp-1 cells. plzf is modified by sumo or ubiquitin conjugation and these modifications regulate the biological function of plzf. we showed that il-32 $\alpha$  regulates these modifications of plzf in a pkc dependent manner. taken all these results, il-32 $\alpha$  modulates the transcriptional regulator activity of plzf via direct binding, ubiquitination and inhibiting sumoylation in pma-treated thp-1 cells.

**An induced dicentric chromosome promotes genomic rearrangement.**

K. E. Gascoigne<sup>1</sup>, I. M. Cheeseman<sup>1</sup>; <sup>1</sup>Whitehead Institute for Biomedical Research, Cambridge, MA

Chromosomal rearrangements are prevalent in cancer and can impact cellular function at many levels, including changes in gene expression and the production of unique fusion proteins with altered functions. Several mechanisms have been implicated in the induction of chromosome rearrangements, including the induction of 'break - bridge - fusion' cycles caused by telomere erosion, which lead to the end-to-end fusion of chromosomes. Such fused chromosomes contain are dicentric, and thus have two points of attachment to the microtubule spindle during mitosis. It is supposed that during mitosis, the dicentric chromosome is broken leading to additional translocation events and the propagation of genomic instability over multiple cell divisions. While this process has been observed cytologically in cancer cells, the mechanism by which a dicentric chromosome can lead to cancer causing genetic alterations remains unknown. We have developed an experimental system to transiently induce the conversion of a single defined chromosome to a dicentric chromosome with high temporal control. We find that the behavior of a dicentric chromosome is highly variable and cell type specific. An induced dicentric chromosome is often damaged and mis segregated during mitosis, and that this can

lead to its translocation with itself as well as other chromosomes. We are currently using this system to probe the role a single dicentric chromosome can play in cellular transformation.

1518

**Visualizing Chromatin Ultrastructure by Combining EdU Labeling with Stochastic Optical Reconstruction Microscopy.**

*W. Zhang<sup>1</sup>, B. Huang<sup>1</sup>; <sup>1</sup>Pharmaceutical Chemistry, UCSF, San Francisco, CA*

Understanding chromatin packaging is essential to know how gene expression is spatially and temporally regulated. To visualize chromatin packaging, electron microscopy and fluorescence microscopy are the two most popular tools. Although electron microscopy has revealed many important chromatin structures such as the chromatin fiber, understanding the nature of these structures in the nucleus would need a less invasive and perturbation approach. Conventional optical microscopy can probe thick specimen with few perturbation, while its spatial resolution is only near 200 nm due to optical diffraction limitation. Recently developed super-resolution microscopy techniques, including Stochastic Optical Reconstruction Microscopy (STORM), have solved this resolution problem. STORM has been used to image DNA in the nucleus using fluorescent protein fusion of histones or in situ hybridization. Here, we demonstrate the visualization of chromatin ultrastructures by direct chemical labeling of the DNA backbone to improve labeling density and reduce perturbation to the DNA structures. By incorporating a nucleoside analogue 5-ethynyl-2'-deoxyuridine (EdU) to replace dTTPs during DNA replication, followed by click reaction with photoswitchable dyes, we achieved high density labeling of DNA backbones in insect cells. STORM images were capable of revealing newly replicated chromatin fibers. Moreover, facilitated by relaxed inhibition of replication origin, the re-initiation of specific origins in *S. cerevisiae* enabled us to label a specific stretch of DNA in the nucleus. Combining with other genetic tools, this method could be applied to the study of replication fork structure, heterochromatin packaging, and epigenetic regulation of gene expression in eukaryotes.

1519

**Single Molecule dynamics of short nucleosome arrays.**

*C. Limouse<sup>1</sup>, C. J. Fuller<sup>2</sup>, A. F. Straight<sup>2</sup>, H. Mabuchi<sup>1</sup>; <sup>1</sup>Applied Physics, Stanford University, Stanford, CA, <sup>2</sup>Biochemistry, Stanford University, Stanford, CA*

In the eukaryotic nucleus, chromatin forms a 3D structure that exhibits multiple levels of folding, and compacts the genome to an extent that is both site-specific and highly dynamic. Despite its central role in regulating DNA templated processes such as transcription or replication, we have limited understanding of the mechanisms that direct the folding of chromatin into a heterogeneous and modular landscape. While numerous biochemical determinants have been implicated in the regulation of chromatin compaction, there still lacks a unifying description that relates biochemical composition to structure, and connects local physical properties of the fiber (e.g. persistence length or self-interaction properties) to larger scale folding. Part of the challenge lies in the absence of a robust technique capable of measuring structural and dynamical information at the scale of a few nucleosome repeats (few tens of nm). We have developed novel fluorescence assays based on Single Molecule Tracking Spectroscopy (SMTS) that allow us to investigate the dynamics of short reconstituted nucleosome arrays. SMTS relies on a feedback-enabled confocal microscopy setup, where an optical modulation scheme senses the displacement of a freely diffusing fluorescently labeled array and a feedback loop actively cancels Brownian motion. Long observation periods (tens of seconds) are achieved and permit extraction of the diffusion coefficient of individual arrays. We have applied STSM to measure changes in condensation in response to changes in ionic environment. An advantage of STMS

over bulk diffusometry methods is the single-fiber resolution which enables probing of a population of arrays of different compactions. We next present a fluorescence correlation assay (tracking-FCS) that we are currently applying to measure the relative motion between the two ends of an array. Unlike in FRET, where the 2 dyes need to be separated by less than a few nm, the 2 dyes in tracking-FCS can be distant by several tens of nm permitting measurement of the internal dynamics of short arrays on  $\mu$ s to s timescales. We finally present a method to characterize self-association between multiple fibers driven by divalent ions or chromatin binding proteins. In this assay, individual oligomers are tracked one-by-one and fluorescence quantification combined with diffusometry allows us to study self-associated fiber morphology.

**Live cell imaging of endogenous repetitive genomic loci using TALE proteins.**

S. Cao<sup>1</sup>, A. Hendel<sup>2</sup>, A. F. Straight<sup>1</sup>; <sup>1</sup>Biochemistry, Stanford University, Stanford, CA, <sup>2</sup>Pediatrics, Stanford University, Stanford, CA

The study of chromosome dynamics in living cells has provided important insight into the mechanisms of chromosome condensation, chromosome segregation and nuclear organization. The earliest methods for tracking the movements and organization of chromosomes used transmitted light microscopy to follow whole chromosome movement. Fusing fluorescent proteins to chromosome binding proteins made it possible to follow the dynamics of chromosomal domains that are bound by the fusion proteins using fluorescence microscopy. Chromosomal integration of tandem arrays of bacterial operator sequences (e.g. lacO) and expression of fluorescent protein fusions to bacterial repressor proteins enable the tracking of individual chromosomal loci in living cells. However, operator/repressor systems for labeling chromosomes require engineering the chromosome by integration of operator arrays. To follow an endogenous chromosomal locus in living cells without modifying the genome we have begun to develop methods to label chromosomal domains in live cells based solely upon the underlying DNA sequence. Transcription activator like effector (TALE) proteins contain 34 amino acid modules, each capable of recognizing a single nucleotide within a DNA molecule. By joining multiple modules, we have generated TALE proteins targeting specific genomic loci. We constructed TALE-YFP fusion proteins that recognize the DNA binding site for Centromere protein B (Cenp-B) and the telomeric repeat sequences. Expression of these engineered sequence recognition proteins in human cells labelled the centromeres and telomeres in living cells. We are currently using this method to follow the dynamics of repetitive genomic regions in live cells and expanding this approach to non-repetitive elements in the genome.

**The KNL-2 Myb domain directs epigenetic centromere specification via a conserved, structure based mechanism.**

V. De Rop<sup>1</sup>, M. J. Osborne<sup>1</sup>, A. Padeganeh<sup>1</sup>, C. Moevus<sup>1</sup>, J. Ryan<sup>1</sup>, J. F. Dorn<sup>1</sup>, N. Siddiqui<sup>1</sup>, K. L. Borden<sup>1</sup>, P. S. Maddox<sup>1</sup>; <sup>1</sup>Pathology and Cell Biology, Institute for Research in Immunology and Cancer, Montréal, QC, Canada

Centromeres are chromosomal loci that direct kinetochore assembly in mitosis. Unlike genetic features, centromere DNA sequence is not conserved through phylogeny nor is it sufficient for centromere function. Therefore, it is commonly accepted that centromeres are epigenetically defined; a process mediated by the histone H3 variant CENTromere Protein-A (CENP-A). Extensive biochemical studies have identified most of the players involved in CENP-A loading at centromeres, however understanding the molecular mechanisms has to be achieved. Particularly, the first protein which binds centromeric chromatin for loading of newly synthesized

CENP-A to centromere has to be identified. Kinetochores NulL-2 (KNL-2) was identified in *C. elegans* by functional genomics as required for CENP-A localization at centromeres. Sequence analysis reveals a conserved MYB like DNA binding domain within KNL-2. In other well studied MYB proteins, this domain is known to bind DNA with high specificity via the 3rd of three helices. Thus, KNL-2 might bind centromeric chromatin via its Myb domain and subsequently recruit proteins important for CENP-A loading at centromeres. To test this model, we first solved the 3 dimensional structure of *C. elegans* KNL-2 Myb (CeMyb) domain using Nuclear Magnetic Resonance (NMR). This revealed an expected helix-loop-helix structure; which is the same for Human KNL-2 Myb (HsMyb) domain (available on pdb). With further biochemical approaches, we have found that the HsMyb and CeMyb domains are able to bind genomic DNA *in vitro*. Although those two domains do not bind any specific DNA sequence by Electrophoretic Mobility Shift Assay (EMSA), we show by Total Internal Reflection Fluorescence (TIRF) microscopy a specific binding of the domains to CENP-A chromatin. Therefore, the KNL-2 Myb domain is sufficient to recognize and bind a specific structure generated by the presence of CENP-A nucleosomes at centromeres. To characterize the binding of the Myb domains with DNA, a  $^1\text{H}$ - $^{15}\text{N}$  Heteronuclear Single Quantum Coherence (HSQC) NMR spectra of the MYB domain in presence of centromeric DNA sequence ( $\alpha$ -satellite sequence) revealed the amino acids that are potentially interacting with the DNA. For CeMyb domain, the identified residues surprisingly all reside within the first helix. The NMR results were further confirmed by EMSA showing a deletion of the first helix of the Myb domain that is not able to bind DNA. Although not conserved at the sequence level, the KNL-2 Myb domains display conserved activity for CENP-A chromatin binding. Thus, the mechanism controlling centromere specification may be ubiquitous in metazoans.

1522

### DNA Topoisomerase II acts as a mitotic scaffold protein in chromosome assembly in *C. elegans*.

R. Ranjan<sup>1</sup>, P. S. Maddox<sup>1</sup>; <sup>1</sup>Pathology, IRIC, Montreal, QC, Canada

**Introduction:** Assembly of mitotic chromosomes is a dynamic event, occurring rapidly during prophase of each cell cycle. Given the complexity of this process, genetic and biochemical approaches have identified surprisingly few factors involved in condensation, notably histone H1, the condensin complex, DNA TOPOisomerase II (TOPO II) and CENtrome-re-Protein A (CENP-A). TOPO II can cut and reseat DNA and has been hypothesized to act in a structural capacity, but how it acts in mitotic chromosome condensation remains unknown.

**Methods and Results:** To define the roles of known and novel proteins in chromosome condensation, we are performing high-resolution live imaging of the *C. elegans* zygote. Images of fluorescently-tagged core histones are thresholded and segmented to quantify the distribution of chromatin within the prophase nucleus over time. When TOPO II is depleted by RNAi, chromosomes collapse prematurely during prophase. When the catalytic activity of TOPO II is inhibited with Dexrazoxane or Etoposide, chromosomes do not collapse prematurely; rather, chromatin remains diffuse throughout prophase. These results indicate that independent of its catalytic activity, TOPO II acts to scaffold condensation. Indeed, TOPO II decatenation activity is required for primary chromatin organization. We are able to distinguish and define scaffolding and catalytic functions of TOPO II *in vivo* using our assays. Interestingly, TOPO II partial depletion reveals that the majority of TOPO II, 70%, functions as a scaffold whereas 30% functions as a catalytic enzyme. Fixed cell immunostaining of prometaphase chromosomes revealed that TOPO II, Condensin, and CENP-A form spatially independent chromosome axes. Co-depletion of TOPO II with Condensin or CENP-A does not rescue premature chromosome collapse, indicating that these three proteins have different and independent mechanisms of function.

**Conclusion:** We conclude that metaphase chromosomes are built by the distinct scaffold activities of three proteins: TOPO II, CENP-A and Condensin. Importantly, our analysis revealed that depletion of these candidate proteins results in quantitatively distinct phenotypes, indicating that they function in discrete events during mitotic chromosome assembly.

1523

**Differences in chromatin accessibility modulated by different histone variants in *C. elegans*.**

A. N. Nabhan<sup>1,2</sup>, S. Calhoun<sup>3</sup>, A. Sharma<sup>3</sup>, R. Esquerra<sup>3</sup>, F. Guerrero<sup>1</sup>, G. Narlika<sup>2</sup>, D. Chu<sup>3</sup>;  
<sup>1</sup>Biology, San Francisco State University, San Francisco, CA, <sup>2</sup>Biochemistry, University of California, San Francisco, San Francisco, CA, <sup>3</sup>San Francisco State University, San Francisco, CA

The introduction of histone variants enables eukaryotic cells to alter chromatin structure and modulate cellular processes that include gene regulation, DNA damage and heterochromatin formation. However, how different histone variants function remains a mystery. Our study aims to characterize two *C. elegans* H2A variants, HTZ-1 and HTAS-1, with significant variation from H2A (59% and 51% identical, respectively). While HTZ-1 is ubiquitously expressed, HTAS-1 is found only in sperm, where DNA becomes tightly compacted and transcriptionally repressed for transit to the new embryo. The disparity these two proteins exhibit in localization is reflected structurally: HTZ-1 has an extended acidic patch within its docking domain while HTAS-1 has an extended N terminus. How do such structural differences enable these variants to function in distinct cell types?

To understand how HTZ-1 and HTAS-1 modulate chromatin structure, we expressed recombinant *C. elegans* H2A, HTZ-1, HTAS-1 in *E. coli*. We probed the secondary structure of H2A and its variants as monomers and heterodimers (H2A-H2B) using circular dichroism. HTAS-1 and HTZ differ in the amount of alpha helical content each histone possesses with HTAS-1 being significantly more structured while HTZ-1 is slightly less structured relative to canonical H2A. Consistent with previous studies, we have found Htz-1 structure is stabilized by its interaction with H2B. However, this is curiously not true for HTAS-1, which is more structured as a monomer.

Nucleosome core particles (NCPs) containing H2A, HTZ-1, and HTAS-1 were then formed by combining them with *C. elegans* H2B, H3, and H4. The stability of NCPs, which is inversely proportional to DNA accessibility, was measured as a function of ionic concentration using tandem FRET and electrophoresis. Initial analysis shows HTZ-1 decreases NCP stability. Another factor affecting chromatin accessibility, reversible nucleosome unwrapping, was monitored using restriction enzyme activity on a restriction site buried within the nucleosome. This analysis reveals that while HTZ-1 promotes reversible unwrapping of DNA relative to canonical H2A, HTAS-1 inhibits it.

Our study is the first in vitro study of the *C. elegans* NCP and provides a mechanistic basis for understanding genome wide studies of histone variants for this model organism. Thus far our results indicate HTZ-1 may act to destabilize NCPs and make DNA more accessible, thus enabling transcription by unfolding chromatin to binding factors. In contrast, HTAS-1 may inhibit accessibility, consistent with a function in chromatin compaction and gene repression observed during sperm development.

1524

### The JIL-1 Kinase Does Not Phosphorylate H3S28 or Recruit 14-3-3 to Active Genes in *Drosophila*.

C. Wang<sup>1</sup>, C. Yao<sup>1</sup>, Y. Li<sup>1</sup>, W. Cai<sup>1</sup>, J. Girton<sup>1</sup>, J. Johansen<sup>1</sup>, K. M. Johansen<sup>1</sup>; <sup>1</sup>Roy J. Carver  
Department of Biochemistry, Biophysics & Molecular Biology, Iowa State University, Ames, IA

JIL-1 is the major kinase controlling phosphorylation of histone H3S10 and has been demonstrated to function to counteract heterochromatinization and gene silencing (Wang et al., J. Cell Sci. 124:4309). However, an alternative model has been proposed in which JIL-1 is required for transcription to occur, additionally phosphorylates H3S28, and recruits 14-3-3 to active genes (Ivaldi et al., Genes Dev. 21:2818; Kellner et al., Genome Res. 22:1081; Karam et al., PLoS Genetics: e1000975). Since these findings are incompatible with the results of Cai et al. (Development 135:2917) demonstrating that there are robust levels of transcription in the complete absence of JIL-1 and that JIL-1 is not present at developmental or heat shock-induced polytene chromosome puffs, we reexamined JIL-1's possible role in H3S28 phosphorylation and 14-3-3 recruitment. Using two different H3S28ph antibodies we show by immunocytochemistry and immunoblotting that in *Drosophila* the H3S28ph mark is not present at detectable levels above background on polytene chromosomes at interphase but only on chromosomes at pro-, meta-, and anaphase during cell division in S2 cells and third instar larval neuroblasts. Moreover, this mitotic H3S28ph signal is also present in the *JIL-1* null mutant at undiminished levels suggesting that JIL-1 is not the mitotic H3S28ph kinase. We also demonstrate that H3S28ph is not enriched at heat shock puffs. Using two different pan-specific 14-3-3 antibodies as well as an enhancer trap 14-3-3-GFP line we show that 14-3-3, while present in salivary gland nuclei, does not localize to chromosomes but only to the nuclear matrix surrounding the chromosomes. In our hands 14-3-3 is not recruited to developmental or heat shock puffs. Furthermore, using a LacI-JIL-1 targeting system to ectopic sites on polytene chromosomes we show that only H3S10ph is present and upregulated at such sites, not H3S28ph or 14-3-3. Thus, our results argue strongly against a model where JIL-1 is required for H3S28 phosphorylation and 14-3-3 recruitment at active genes. Supported by NIH grant GM62916.

### The CENP-A-specific assembly factor HJURP induces chromatin expansion at non-centromeric loci.

M. C. Barnhart-Dailey<sup>1</sup>, I. K. Nardi<sup>1</sup>, J. A. Ward<sup>1</sup>, D. R. Foltz<sup>1</sup>; <sup>1</sup>Biochemistry and Molecular Genetics, University of Virginia, Charlottesville, VA

The centromere-specific histone H3 variant, CENP-A, is targeted to centromeres in a complex with its chaperone HJURP, Holliday junction recognition protein. HJURP binds to the pre-nucleosomal CENP-A protein when it exists as a soluble heterodimer with H4 and escorts it specifically to centromeric chromatin in a Mis18 complex dependent manner. The HJURP/CENP-A/H4 pre-nucleosomal complex localizes to centromeric chromatin during a window in early G1 phase when CENP-A is deposited. The Scm3 domain of HJURP is conserved from yeast to humans and is sufficient to bind CENP-A and execute functional CENP-A nucleosome assembly. However, vertebrate HJURP is significantly larger than yeast Scm3 proteins and contains a central conserved/mid domain. The role of this domain in centromere maintenance and CENP-A deposition is unknown. Previously, our lab demonstrated that targeting HJURP to a non-centromeric site within the genome is sufficient to induce the deposition of new CENP-A nucleosomes at that site. Here, we show that the recruitment of HJURP results in a striking unfolding of the targeted chromatin domain. Moreover, we find that the central conserved/mid domain is required for HJURP to induce the chromatin unfolding. This chromatin unfolding resulted in escalated CENP-A deposition levels.

However, the large degree of unfolding was inhibitory to CCAN recruitment, despite the presence of a large quantity of CENP-A at the expanded region. These results suggest that CCAN proteins may be most efficiently recruited to centromeres with a defined arrangement of CENP-A nucleosomes. The replenishment of CENP-A nucleosomes at the centromere occurs during early G1 into pre-existing centromeric chromatin. This differs from the replenishment of canonical histones that occurs on recently replicated DNA in S phase, whose chromatin has been previously disassembled to accommodate the replication machinery. While we observe this striking unfolding, there is no precedent for drastic expansion of endogenous centromeres when HJURP is recruited during G1. This suggests that cells have a mechanism to counter the HJURP-induced unfolding at endogenous centromeres and that chromatin unfolding may be a transient step in centromeric nucleosome deposition. It is plausible HJURP-induced chromatin unfolding is a crucial intermediate step in CENP-A nucleosome assembly at centromeric DNA.

1526

### Localization dynamics and complex interactions of the human Mis18 complex.

M. E. Stellfox<sup>1</sup>, C. M. Knippler<sup>1</sup>, I. K. Nardi<sup>1</sup>, D. R. Foltz<sup>1</sup>; <sup>1</sup>Biochemistry and Molecular Genetics, University of Virginia, Charlottesville, VA

Centromeres are chromosomal domains that couple the pulling forces of microtubules to each chromosome in order to faithfully segregate the duplicated genome during mitosis. In human cells, centromeric location is specified epigenetically rather than by a specific DNA sequence. The epigenetic mark that dictates centromere identity is considered to be the presence of nucleosomes that contain the histone H3 variant, centromere protein A (CENP-A). Following S phase, newly synthesized nucleosomes must be deposited into chromatin in order to compensate for nucleosomal dilution that occurs during DNA replication. However, human cells do not deposit newly synthesized CENP-A nucleosomes until after mitotic exit, throughout G1. While centromere architecture varies widely among species, the deposition of CENP-A is controlled by a group of conserved proteins, which includes the CENP-A chaperone and assembly factor, Holliday junction recognition protein (HJURP) and the Mis18 complex. The human Mis18 complex consists of Mis18 $\alpha$ , Mis18 $\beta$  and Mis18 binding protein 1 (Mis18BP1<sup>KNL-2</sup>). Our lab has previously shown that the recruitment of Mis18 $\alpha$  and Mis18BP1<sup>KNL-2</sup> to centromeres is required for HJURP localization and subsequent CENP-A deposition. Mis18BP1<sup>KNL-2</sup> contains two annotated domains, an N-terminal SANT-associated (SANTA) domain as well as a C-terminal SANT (Swi3, Ada2, N-CoR, TFIIIB) domain. In order to determine the contribution of these regions to the centromere recruitment of the Mis18 complex, we examined the localization of N- and C-terminal Mis18BP1<sup>KNL-2</sup> fragments. Only the N-terminal portion of Mis18BP1<sup>KNL-2</sup>, containing the SANTA domain, is able to support localization to centromeric chromatin. The C-terminal fragment, containing the SANT domain, was not found to localize to centromeres. Recruitment of Mis18BP1<sup>KNL-2</sup> to centromeres has been linked to an interaction with centromere protein C (CENP-C). Targeting the N-terminal, SANTA containing fragment, to a non-centromeric locus was sufficient to recruit CENP-C. The N-terminus was also sufficient to recruit the entire Mis18 complex, including Mis18 $\alpha$  and Mis18 $\beta$ . Therefore, the SANT domain is not required for the centromeric localization of Mis18BP1<sup>KNL-2</sup>, or for its interaction with Mis18 $\alpha$ , Mis18 $\beta$  or CENP-C. Identifying these required centromere-targeting and complex-formation interactions within the Mis18 complex is a key component in elucidating the CENP-A deposition pathway in human cells.

1527

**Rabl Organization of Chromosomes in the Yeast Nucleus**B. Avsaroglu<sup>1</sup>, J. Ham<sup>2</sup>, G. Bronk<sup>1</sup>, J. E. Haber<sup>2</sup>, J. Kondev<sup>1</sup>;<sup>1</sup>Physics, Brandeis University, Waltham, MA, <sup>2</sup>Biology, Brandeis University, Waltham, MA

The spatial organization of genomes plays an important role in cell biology as it influences chromosome functions such as recombination and repair of broken DNA. The Rabl model proposed in the late 1800's describes the organization of budding yeast chromosomes during interphase, with the centromeres tethered at the spindle pole body (SPB) and the telomeres tethered to the nuclear periphery. Here we address the question, to what extent does the Rabl organization of chromosomes whose conformations are described by a simple polymer model, quantitatively account for the positioning of genetic loci within the interphase nucleus? To investigate this question we performed a combined experimental and theoretical study of the organization of yeast chromosome III. By imaging two fluorescent markers, one at the SPB and the other proximal to the HML locus that is involved in DNA recombination during mating type switching, we measured the distribution of distances. In addition to wild type cells, *yku70Δ* and *esc1Δ* mutants with disrupted telomere tethering and mutants that have a proximal HML marker tethered to the nuclear periphery were also considered. We compared our experimental results with a random-walk polymer model that takes into account different tethering scenarios and confinement of chromosomes in the nucleus, and found that the model recapitulates the observed spatial organization of chromosome III in yeast in quantitative detail. The Rabl model makes specific predictions for chromosome organization in yeast, and suggests new experiments to test them.

**Mitotic map of condensin I in vertebrate cells.**

J. Kim<sup>1,2</sup>, N. Wong<sup>1,2</sup>, K. Choo<sup>1,2</sup>, W. C. Earnshaw<sup>3</sup>, N. Davidson<sup>1,2</sup>, J. Maksimovic<sup>1,2</sup>, A. O'Shlack<sup>1,2</sup>, P. Kalitsis<sup>1,2</sup>, D. F. Hudson<sup>1,2</sup>; <sup>1</sup>Murdoch Childrens Research Institute, Parkville, Melbourne, Australia, <sup>2</sup>The Department of Paediatrics, The University of Melbourne, Parkville, Melbourne, Australia, <sup>3</sup>Wellcome Trust Centre for Cell Biology, Institute of Cell and Molecular Biology, The University of Edinburgh, Edinburgh, UK

In order for DNA to be segregated properly during mitosis, chromosomes must be packaged and shaped correctly prior to anaphase onset in a process termed chromosome condensation. Condensin I is a multi-subunit protein complex, consisting of two core subunits SMC2 and 4, and three auxiliary components CAP-H, CAP-D2, CAP-G. Condensin I associates with chromosomes after the nuclear envelope breaks down, and is required for correct chromosome condensation and segregation. While its role in chromosome condensation is well-established, where condensin I binds in the vertebrate genome is a key outstanding question. This presentation will illustrate the first genome-wide map of condensin I in vertebrate cells, which will shed light on the role of condensin I in chromosome condensation and help to understand its increasing link to diseases.

To create the first genome-wide map of condensin I, conditional knockouts of SMC2 and CAP-H in chicken DT40 cells were complemented with an affinity tagged SMC2 and CAP-H, respectively, allowing stringent purification of condensin I-associated DNA. The affinity purified DNA was analyzed using the next-generation sequencing.

Condensin I in vertebrate was found to be enriched on tRNA and rRNA genes, in agreement with previous studies in yeast. Strikingly, a high enrichment was observed consistently at gene

promoter regions, suggesting that condensin I may have an additional role beyond chromosome condensation.

1529

**Motion analysis of DNA to deduce the visco-elastic properties of chromatin upon DNA damage.**

*J. S. Verdaasdonk<sup>1</sup>, E. Yeh<sup>1</sup>, R. Barry<sup>1</sup>, S. Goodwin<sup>1</sup>, W. J. Soh<sup>2</sup>, K. Bloom<sup>1</sup>; <sup>1</sup>Biology, UNC Chapel Hill, Chapel Hill, NC, <sup>2</sup>National University of Singapore, Singapore, Singapore*

Cells must maintain chromosome integrity despite constant exposure to a variety of sources of DNA damage including radiation, carcinogens and DNA replication errors. It is essential that double-strand breaks (DSBs) are repaired accurately prior to chromosome segregation, as errors can lead to chromosomal rearrangements, cancer or cell death. Previous studies have shown that chromatin exhibits energy-dependent increased mobility and expansion upon damage. Here we examine the mechanisms underlying the damage-induced decompaction and increased motion using polymer theories to deduce the contributions of the elastic and viscous moduli. We find that the visco-elastic nature of the chromatin is altered upon DSB induction – shifting from being primarily viscous at intermediate time scales (10-50 sec) to predominantly elastic. This mechanical change provides insights into the underlying mechanisms by which chromatin modifications promote DNA repair.

1530

**Transcription Factor Binding to a DNA Zip Code Controls Interchromosomal Clustering at the Nuclear Periphery.**

*D. G. Brickner<sup>1</sup>, S. Ahmed<sup>1</sup>, L. Meldi<sup>1</sup>, A. Thompson<sup>2</sup>, W. Light<sup>1</sup>, M. Young<sup>1</sup>, T. Hickman<sup>3</sup>, F. Chu<sup>3</sup>, E. Fabre<sup>4</sup>, J. Brickner<sup>1</sup>; <sup>1</sup>Molecular Biosciences, Northwestern University, Evanston, IL, <sup>2</sup>Genetics, Stanford University, Palo Alto, CA, <sup>3</sup>Molecular, Cellular & Biomedical Sciences, University of New Hampshire, Durham, NH, <sup>4</sup>Genomes & Genetics, Institut Pasteur, Paris, France*

Active genes in yeast can be targeted to the nuclear periphery through interaction of cis-acting "DNA zip codes" with the nuclear pore complex. We find that genes with identical zip codes cluster together. This clustering was specific; pairs of genes that were targeted to the nuclear periphery by different zip codes did not cluster together. Insertion of different zip codes at an ectopic site induced clustering with endogenous genes having that zip code. Targeting to the nuclear periphery and interaction with the nuclear pore is a pre-requisite for gene clustering, but clustering can be maintained in the nucleoplasm. Finally, we find that specific transcription factors and other DNA binding proteins recognize the GRS zip codes to mediate both targeting to the NPC and interchromosomal clustering. These results suggest that zip code-mediated clustering of genes at the nuclear periphery influences the three-dimensional arrangement of the yeast genome.

1531

**Dimerization of the CENP-A assembly factor HJURP is required for centromeric nucleosome deposition.**

*E. Zasadzinska<sup>1</sup>, M. C. Barnhart-Dailey<sup>1</sup>, P. H. Kuich<sup>1</sup>, D. R. Foltz<sup>1</sup>; <sup>1</sup>Biochemistry and Molecular Genetics, University of Virginia, Charlottesville, VA*

Histone variants use unique assembly factors to determine the temporal and spatial pattern of variant-containing nucleosome deposition. CENP-A is the histone H3 variant that acts as the

epigenetic mark of centromere position. The deposition of new centromeric nucleosomes requires the CENP-A specific chromatin assembly factor HJURP. CENP-A and HJURP interact as a soluble prenucleosomal complex and are recruited to centromeres during G1 when new CENP-A deposition occurs. Crystallographic and biochemical data demonstrate that HJURP binds a single CENP-A-histone H4 heterodimer. However, the formation of stable CENP-A nucleosomes requires a conserved dimerization interface, suggesting that HJURP forms octameric CENP-A nucleosomes. How an octameric CENP-A nucleosome forms from individual CENP-A-histone H4 heterodimers is unknown. Here we show the CENP-A assembly factor HJURP forms a homodimer through its second HJURP\_C domain. HJURP exists as a dimer as a soluble pre-assembly complex and at chromatin during G1 when new CENP-A is deposited by HJURP. Dimerization of HJURP is essential for the deposition of new CENP-A nucleosomes. The recruitment of HJURP to centromeres occurs independent of dimerization and CENP-A binding. These data provide a mechanism whereby the CENP-A prenucleosomal complex achieves assembly of the octameric CENP-A nucleosome by formation of a prenucleosomal complex that contains CENP-A molecules through the dimerization of the CENP-A chaperone HJURP.

1532

**Probing Genome-Nuclear Lamina Interactions in Mouse Myoblasts.***F. Wu<sup>1</sup>, J. Yao<sup>1</sup>; <sup>1</sup>Cell Biology, Yale University, New Haven, CT*

Cytological studies have revealed that a number of genes are preferentially positioned to the nuclear periphery, and changes in their radial positioning are often correlated with changes in gene activities. We are using the myogenic differentiation system to study how subnuclear gene positioning confers regulatory functions on gene transcription. By high resolution cell imaging, we have revealed that the histone mark H3K4me3 and its associated factor TAF3 are localized away from the nuclear periphery (Yao et al, *Genes & Development*, 25: 569-580), which suggests that differential compartmentalizations of histone marks may characterize the chromatin states at the nuclear periphery and influence gene transcription.

We aim to further examine this observed subnuclear compartmentalization at the molecular level. DNA adenine methyltransferase identification (DamID) assay has been used to map genome-nuclear lamina interactions in *Drosophila* and mammalian cells, providing an approach to identify DNA sequences at the nuclear periphery genome-wide. Here, we have used the DamID assay coupled with next generation sequencing and bioinformatic analyses to identify genomic regions that have significantly higher frequencies interacting with the nuclear lamina in mouse 3T3 fibroblasts and C2C12 myoblasts. In 3T3 cells, these regions overlap with 98% of the Lamin Associated Domains (LAD) previously identified (Peric-Hupkes et al, *Molecular Cell*, 38: 603-13). Proximities of these regions to the nuclear periphery were confirmed with fluorescence in situ hybridization. We are analyzing these genomic regions relative to reported genomic and epigenomic features in C2C12 myoblasts, such as transcription start sites, histone modifications and gene expression. We are also examining the localizations of additional histone modifications relative to the nuclear periphery by cell imaging. These findings will be discussed.

1533

**Micromechanical properties of mammalian meiotic chromosomes: a high frequency model of genomic instability.**

J. E. Hornick<sup>1</sup>, F. E. Duncan<sup>1</sup>, M. Sun<sup>2</sup>, J. F. Marko<sup>2,3,4</sup>, T. K. Woodruff<sup>1</sup>; <sup>1</sup>Dept of Ob/Gyn, Northwestern University, Chicago, IL, <sup>2</sup>Department of Molecular Biosciences, Northwestern University, Evanston, IL, <sup>3</sup>Department of Physics and Astronomy, Northwestern University, Evanston, IL, <sup>4</sup>National Cancer Institute Physical Science and Oncology Center, Northwestern University, Evanston, IL

Prior to cell division, eukaryotic cells undergo a dramatic reorganization whereby their chromosomes are bundled and condensed into compact mitotic or meiotic forms. Proper chromosome condensation is essential for accurate segregation of homologous chromosomes or sister chromatids. The folding of the flexible chromatin fiber into its compacted form is due, in part, to the multi-subunit protein, condensin, and cells deficient in condensin fail to fold chromatin properly, resulting in anaphase bridges. Meiosis is a specialized process with two sequential cell divisions that occur in the absence of an intervening interphase to produce haploid gametes. Compared to mitosis, meiosis in the mammalian egg is remarkably error-prone, and the error frequency increases in female gametes of advanced reproductive age. These errors contribute to aneuploidy and result in pregnancy loss or birth defects, however, their origins and age dependency is not understood. Thus, the mammalian egg represents a robust and unique model system to study molecular mechanisms of chromosome segregation as well as the errors that result in aneuploidy. However, the role of the micromechanical properties of mammalian chromosomes during meiosis is unknown. Measurement of the micromechanical properties of isolated individual chromosomes has provided a powerful tool for understanding the organization of chromosomes in mitotic cells of several species. Here, we demonstrate that we can efficiently isolate individual chromosomes from mammalian (mouse) eggs arrested at metaphase of meiosis II and that these isolated meiotic chromosomes have reversible elasticity and a force constant on the subnanonewton scale. Moreover, we can identify condensin localization on native chromosomes for the first time. We have expanded these studies to investigate the changes in the structure between chromosomes isolated from eggs from young and old mice. Such analysis in a well-established model of increased genomic instability not only will reveal the relationship between changes in the micromechanical properties of meiotic chromosomes and aneuploidy, but will also have broad implications for reproductive health and associated interventions.

**Scaling Chromosome Condensation to Cell Size.**

A-M. Ladouceur<sup>1</sup>, J. Dorn<sup>1</sup>, P. Maddox<sup>1</sup>; <sup>1</sup>Université de Montréal, Montréal, QC, Canada

During embryonic development in metazoans (like the common model organisms *Caenorhabditis elegans* or *Xenopus laevis*), cells decrease in volume by up to two orders of magnitude (from 1,2 mm to 12  $\mu$ m in *X. laevis*), a consequence of multiple rounds of cell divisions without growth of the embryo. Using *X. laevis* or *C. elegans* embryos as model organisms, it has been shown that mitotic structures including mitotic spindle length, centrosome size and nucleus size all scale with cell size. However, the exact molecular mechanisms regulating how organelles scale their size to the continuously changing size of the cells are poorly understood. Due to technical limitations, scaling of mitotic chromosome condensation has received less attention. Despite dramatic changes in cell size, the genome size is constant in all diploid cells of an organism. Therefore, it is expected that during

anaphase, condensed mitotic chromosomes must be half the length of the mitotic spindle to be properly segregated to each daughter cells. Using the determined development of *C. elegans* embryos we show that prometaphase condensed chromosomes are smaller in length as cell reduces in size. To assess the hypothesis of a cell autonomous regulated mechanism, we RNAi depleted an importin  $\alpha$  protein (*ima-3*), resulting in reduced embryo size and therefore the size of the cells. Surprisingly, we found that experimental reduction of cell size resulted in a corresponding reduction of chromosome size. This chromosome-cell size scaling fit with is seen in WT embryos at a later developmental stage. Currently, we are examining two models that could explain this chromosome-cell size scaling. First, the limiting component model proposes that there is a fixed amount of 'X' factor in the embryo which is redistributed and diluted to each daughter cells after each mitotic divisions. Second, a DNA to cytoplasm ratio could dictate chromosome size. The total amount of 'X' factor would be the same in all cells but as cell reduces in size, the proteins are more concentrated and perhaps more active. To elucidate this mechanism, we used a worm strain with one longer chromosome than the chromosomes present in a wild-type strain resulting from a X/autosomeV end-to-end fusion. We reasoned this longer chromosome would sensitize a worm to any defect in chromosome condensation or segregation in smaller cells of the developing embryo. In fact, a RNAi depletion of one of the condensin I subunits increases the lethality by 3 fold compare to a control RNAi, although it is near 100% viable in a WT strain. Thus we are using RNAi and high resolution imaging to determine the mechanisms of mitotic chromosome size regulation.

1535

**The nuclear architectural protein NuMA targets the ISWI ATPase SNF2h to DNA breaks.**

*P-A. Vidi<sup>1</sup>, J. Liu<sup>1</sup>, S. Jayaraman<sup>1</sup>, D. Salles<sup>2</sup>, G. Dorfman<sup>3</sup>, P. Abad<sup>1</sup>, M. Gray<sup>1</sup>, P. Moghe<sup>3</sup>, L. Wiesmüller<sup>2</sup>, J. Irudayaraj<sup>1</sup>, S. Lelièvre<sup>1</sup>; <sup>1</sup>Purdue University, West Lafayette, IN, <sup>2</sup>University of Ulm, Ulm, Germany, <sup>3</sup>Rutgers University, Piscataway, NJ*

Chromatin remodeling plays an active role in the DNA damage response (DDR). The current view is that chromatin remodelers, including members from the ISWI family, shape the chromatin landscape to facilitate the repair process and to restore damage sites after repair. The ISWI ATPase SNF2h has been proposed to continuously sample chromatin by transient, genome-wide, associations with nucleosomes. SNF2h rapidly accumulates at sites of DNA damage but the mechanism leading its stabilization at damaged sites is unknown. The nuclear architectural protein NuMA has been linked to chromatin organization during breast epithelial differentiation and to H2AX phosphorylation ( $\gamma$ H2AX), an early chromatin response to DNA damage. These observations led us to propose that NuMA coordinates large scale chromatin rearrangement during the DDR.

Here, we identify NuMA as a binding partner of SNF2h in immunoprecipitation experiments. NuMA silencing impairs SNF2h recruitment at DNA breaks in laser-microirradiated cells and fluorescence correlation spectroscopy measurements indicate that NuMA regulates SNF2h diffusion in the nucleoplasm. Although NuMA distributes throughout the nucleus during the interphase, it significantly accumulates at microirradiated sites. This phenomenon is exacerbated upon ATM inhibition. Moreover, NuMA knock-down impairs homologous recombination repair (HRR) and leads to a rapid loss of  $\gamma$ H2AX in cells exposed to ionizing radiations. This effect is not mediated by cell cycle alteration. Both HRR and  $\gamma$ H2AX maintenance have previously been linked to the function of ISWI complexes.

NuMA might provide a dynamic lattice reinforced at DNA damage sites and essential for the stabilization of chromatin remodeling complexes. Our previous work has established a mutual influence between NuMA and the extracellular matrix during mammary epithelial cell differentiation. NuMA may therefore act as a transducer of microenvironmental cues on nuclear organization, thereby regulating genome functions and maintenance.

**Investigating regulation of linker histone H1 on mitotic chromosomes in *Xenopus*.***K. Miller<sup>1</sup>, R. Heald<sup>1</sup>; <sup>1</sup>Molecular and Cell Biology, UC Berkeley, Berkeley, CA*

Histone chaperones are a group of cytoplasmic proteins that aid in dynamic chromatin organization during different cellular processes. Linker histone H1 is a highly dynamic and fundamental chromatin-bound protein required for mitotic chromosome condensation. Here, we report that the histone chaperone Nucleosome Assembly Protein 1 (Nap1), a chaperone that associates with linker histone H1, is required for mitotic chromosome condensation and mitotic spindle assembly. Depletion of Nap1 in *Xenopus* egg extracts causes defects in both remodeling of sperm chromatin and a decrease in microtubule polymerization around these structures. Examination of depleted extracts reveals an increase in H1 association with sperm chromatin, without an increase in core histone localization. Add-back of a truncated mutant of Nap1 does not rescue this effect. Experiments are currently under way to examine how depletion of Nap1 affects the dynamic behavior of H1, how specific the actions of Nap1 are to H1, and how different domains of Nap1 may be modified in a cell-cycle specific manner to regulate H1 function. Our findings illustrate the importance of proper linker histone regulation on mitotic chromosome structure and highlights histone chaperone Nap1 as a novel spindle assembly factor.

**On the Role of Active Fluctuations in Genetic Regulation.***K. Raghunathan<sup>1</sup>, J. Milstein<sup>2</sup>, J-C. D. Meiners<sup>1</sup>; <sup>1</sup>Departments of Biophysics and Physics, University of Michigan, Ann Arbor, MI, <sup>2</sup>Physics, University of Toronto, Toronto, ON, Canada*

Cells are not just small test tubes, but present a mechanically complex, ever fluctuating environment in which essential biological processes take place. We investigate how the complex nanomechanical environment of the cell affects the dynamic motion of DNA, and how this in turn affects the formation of regulatory DNA-protein complexes. Using single-molecule particle tracking on doubly-labeled DNA constructs in living cells we show that the fluctuations of the DNA in living cells are two orders of magnitude larger than in dead, yet structurally intact cells. We attribute this enhanced motion to the activity of molecular motors in the cellular environment, which exert random forces on the DNA that are much stronger than thermal forces. This dovetails with our observations in FCS studies of genomic DNA in live prokaryotes, which show a dramatically enhanced persistence of spatiotemporal correlations on the millisecond to second time scale. We will discuss whether observations like this and underlying mechanisms like active motor-induced fluctuations and mechanical constraints on the DNA in vivo can explain the perhaps unexpected high efficiency of regulatory mechanisms. Protein-mediated repressor loops like the lac-repressor, for instance, can repress gene expression several hundredfold, whereas these loops have been show to be open much of the time in single-molecule in-vitro studies, rendering them apparently rather inefficient. To investigate the effects of an actively fluctuating mechanical environment of the cell quantitatively, we simulated such an environment in vitro by introducing fluctuating tensile forces into a single-molecule model system using axial optical tweezers. Increasing the fluctuations in the molecule over its thermal conformational fluctuations by just 5% enhanced loop formation rates twofold. Based on such observations we hold the view that the crowded, constrained, and actively fluctuating environment of the living cell is most likely responsible for much enhanced DNA-protein complex formation in vivo, a mechanism that may well be quite general when it comes to explaining the amazing efficiency of macromolecular assembly in living cells.

**Mitotic Stability Functions of the INO80 Chromatin-Remodeling Complex.**A. J. Morrison<sup>1</sup>; <sup>1</sup>Department of Biology, Stanford University, Stanford, CA

ATP-dependent chromatin-remodeling complexes influence diverse nuclear processes, such as transcription, replication, and DNA damage responses, by specifying nucleosome positioning and composition. The *S. cerevisiae* INO80 complex is composed of 15 subunits, several of which contribute to different functions of the chromatin-remodeling complex. For example, deletion of certain INO80 subunits specifically disrupts double-strand break repair, while another subunit is phosphorylated by the ATM/ATR homologues in yeast, Mec1/Tel1, to influence cell cycle checkpoint pathways. Less defined components of the INO80 complex include actin-related proteins (Arps), which have sequence similarity to actin and are evolutionarily-conserved components of chromatin-remodeling complexes. There are six nuclear Arps in *S. cerevisiae*, all of which are found within the complexes of the SWI/SNF and INO80 chromatin-remodeling subfamilies. The INO80 complex contains Actin and Arps 4, 5 and 8, of which Arp5 and 8 are unique to the INO80 chromatin-remodeling complex. Previous research demonstrates that Arp5 and 8 contribute to the *in vitro* chromatin-remodeling activity of the INO80 complex, while the precise mechanisms by which they function *in vivo* are unclear.

Here we demonstrate that subunits of the *S. cerevisiae* INO80 complex have heterogeneous functions in mitotic stability pathways. Specifically, deletion of *ARP5* and *IES6* results in significant fitness defects when cells are treated with microtubule destabilizing agents. Biochemical characterizations reveal that Arp5 and Ies6 form a functional module within and outside of the INO80 complex. Functional assays demonstrate that the Arp5-Ies6 subcomplex is involved in mitotic stability pathways, as deletion causes ploidy alterations. Deletion of *ARP5* and *IES6* results in mitotic defects, specifically chromosome segregation is delayed or absent in mutant cells. Genetic data demonstrates that these INO80 subunits are involved in the spindle positioning pathway, specifically microtubule regulation. These results demonstrate that the Arp5 and Ies6 subunits have critical genome maintenance functions during mitosis.

1539

**Paired Sense and Antisense RNA Transcription during Chromosomal Kissing.**J. H. Frenster<sup>1</sup>, J. A. Hovsepian<sup>2</sup>; <sup>1</sup>Medical Oncology, Stanford University School of Medicine, Atherton, CA, <sup>2</sup>Diagnostic Imaging, Stanford University School of Medicine, Atherton, CA

Mammalian cells often display chromosomal kissing of one or more distinct chromosomes, resulting in paired sense and antisense RNA synthesis at that kissing gene locus.

Kioussis D, "Gene regulation: Kissing Chromosomes", *Nature* vol. 435, no. 7042, pp. 579-580 (June 2, 2005),

Xu N, Tsai C-L, and Lee JT, "Transient Homologous Pairing Marks the Onset of X Inactivation", *Science* vol. 311, no. 5764, pp. 1149-1152 (February 24, 2006).

Chambeyron S, and Bickmore WA, "Chromatin decondensation and nuclear reorganization of the HoxB locus upon induction of transcription", *Genes & Development*, vol. 18: no. 10, pp. 1119-1130 (May 15, 2004).

Frenster JH, "Ultrastructural Continuity Between Active and Repressed Chromatin", *Nature* vol. 205, no. 4978, pp. 1341-1342 (March 27, 1965).

We have used high-resolution electron microscopy to determine the ultrastructure of active euchromatin 10 nm microfibrils within interphase calf thymus lymphocyte nuclei. Interphase euchromatin microfibrils display localized areas of chromatin looping up to 1,000 nm in length. A minority of loops reach out to loops on adjacent chromosomes, forming short linear side-by-side duplexes 20 nm in diameter, and up to 20 nm in length. Such paired-chromatin structures may provide a paired template for paired sense-antisense gene transcription, resembling DNA-DNA microstructures described previously for oncogenic viral integration.

Frenster JH, "Model of Single-Stranded Integration of Oncogenic Viral Genomes", *Biophys. J.* vol. 15: 137a (1975): Feb. 18, 1975.

These paired DNA-DNA tetraplexes can be formed by paranemic (sliding) DNA bonds, rather than by the more usual plectonemic (intertwined) DNA bonds, as described earlier by Lewin B, "Genes", Ed. 7, 428 (2000, Oxford Press).

### **Comparative Analysis of Genomic Alternations Between Chinese Hamster and CHO Cell Line.**

*N. Vishwanathan<sup>1</sup>, M. Sharma<sup>2</sup>, A. Yongky<sup>1</sup>, N. Jacob<sup>1</sup>, T. Ramaraj<sup>3</sup>, F. Yusuff<sup>4</sup>, T. Lee<sup>4</sup>, J. Chin<sup>4</sup>, A. Bharti<sup>3</sup>, E. Retzel<sup>3</sup>, B. L. Loo<sup>4</sup>, D. Lee<sup>4</sup>, M. Yap<sup>4</sup>, G. Karypis<sup>2</sup>, W-S. Hu<sup>1</sup>; <sup>1</sup>Chemical Engineering and Mat Sci, University of Minnesota, Minneapolis, MN, <sup>2</sup>Department of Computer Science, University of Minnesota, Minneapolis, MN, <sup>3</sup>National Center for Genomic Resources, Santa Fe, NM, <sup>4</sup>Biotechnology Institute, Biopolis, Singapore*

Chinese hamster ovary (CHO) cell lines, established over five decades ago, are among the most important cell lines used in biomedical research for decades. The low diploid number of chromosomes ( $2n = 22$ ) in the Chinese hamster and the relative ease of deriving mutant lines made these cell lines a valuable cytogenetic tool. In the past two decades, CHO has also become the most prominent host cell for producing therapeutic proteins, acquiring much genomic reorganization in the process. Recently, the genome of a CHO-K1 cell line has been sequenced. Given its importance in biomedical research and in the biopharmaceutical industry, it is of great interest to understand better the genomic foundation that gives rise to the many features that have given CHO cells such prominence.

We have independently sequenced and assembled the genome of a female Chinese hamster by Illumina deep sequencing; and have performed a comparative analysis with the sequenced CHO-K1 genome. The depth of the sequencing attained enabled us to analyze heterozygosity and possible chromosomal reorganization.

At a first glance, a high level of sequence variation was observed between the two genomes. A closer examination of the deeply sequenced regions and further superimposition of RNA seq results uncovered a high level of false positive calls of sequence variants. Using a stringent criterion for base variant calls, the mutation rate of the CHO-K1 genome was deciphered to be substantially lower than the first estimate.

The comparison of the CHO-K1 and Chinese hamster genomes was also performed at a scaffold level. Scaffolds longer than 1 Mbp in size from both assemblies were aligned to each other and scanned for potential rearrangements. Although a majority of scaffolds showed identical order of alignments, reordering was observed in several other scaffolds. The alternation in sequence alignment could either be an assembly error or genuine chromosomal reorganization. Using a long 10 Kbp insert mate pair sequence library, that associate two reads spanning over an estimated 10 Kbp region, we verified the authenticity of rearrangements for a few representative scaffolds.

The availability and application of these genomic resources will facilitate physiological comprehension of cellular behavior, providing further opportunities to enhance CHO cells in their role as recombinant protein producers.

## Stem Cells and Pluripotency I

1541

### Application of collagen scaffolds for differentiation of mouse induced pluripotent stem cells into cardiomyocytes.

*W-C. Chiang<sup>1</sup>, C-Y. Su<sup>1</sup>, H-I. Chiu<sup>2</sup>, H-C. Chiu<sup>2</sup>, C-M. Lo<sup>1</sup>; <sup>1</sup>Biomedical Engineering, National Yang-Ming University, Taipei, Taiwan, <sup>2</sup>School of Medicine, National Yang-Ming University, Taipei, Taiwan*

The surface on which cells are grown plays a key role in determining cell behavior in vitro and in optimizing culture conditions for a particular cell type. The elasticity of the extracellular matrix microenvironment has been identified as an important factor to direct developmental pathways of stem cells. In this study, mouse induced pluripotent stem cells (iPSCs) were cultured on gelatin-coated type I collagen scaffolds which were freeze-dried and then cross-linked with 1-Ethyl-3-(3-dimethylaminopropyl)carbodiimide (EDC) and N-Hydroxysulfosuccinimide (NHS). While native collagen scaffolds without cross-linking showed a fiber-like structure, EDC/NHS cross-linked scaffolds demonstrated better interconnectivity and formed a sheet-like sponge structure. Compared with mouse iPSCs cultured on native collagen scaffolds, the cardiomyocyte differentiation of mouse iPSCs on cross-linked scaffolds showed a significant increase in the differentiation rate, especially when higher concentration of EDC/NHS cross-linkers were used to cross-link the scaffolds. In addition, beating cardiomyocytes differentiated from mouse iPSCs were not observed on native scaffolds but on cross-linked scaffolds due to increase in stiffness. The overall results suggest that three dimensional type I collagen scaffolds with suitable cross-linking can recapitulate the mechanical stimuli required for directing the differentiation of iPSCs into cardiomyocytes and these stimuli can play an important role in determining iPSC fate.

### Image cytometry provides an optimal approach for automated characterization of stem cell pluripotency and differentiation.

*J. R. Haskins<sup>1</sup>, C. Zellefrow<sup>1</sup>, A. Sinor-Anderson<sup>1</sup>, J. Hasskamp<sup>1</sup>; <sup>1</sup>Thermo Fisher Scientific, Pittsburgh, PA*

There is no doubt that stem cell research holds incredible promise in many areas of discovery research, as well as potential human therapeutic applications. Understanding the complex signaling processes, differentiation mechanisms and general physiology of stem cells is critical to their utilization, and often involves painstaking, manual experiments that provide only subjective results. Image cytometry offers a rapid, automated and quantitative approach to investigating stem cell biology at the cellular level, enabling increased productivity and the promise to accelerate this critical area of biological research. Human foreskin iPS cells or HSF-6 human embryonic stem cells were either maintained in a pluripotent state or differentiated into mesoderm, endoderm or ectoderm using standard directed protocols. Indirect immunofluorescence was utilized to stain cells with standard pluripotency and differentiation markers (Oct4, SMA, FOXO2, and/or  $\beta$ -III tubulin). In addition, mouse cortical stem cells were directed to differentiate into neurons, astrocytes and oligodendrocytes and stained for  $\beta$ -III

tubulin, GFAP or O4, respectively. Image cytometry was used to quantitatively characterize the resulting cellular populations. This work demonstrates the advantages of image cytometry, current applications of the technology in stem cell research and demonstrates how image cytometry can provide a reliable technique for determining the pluripotency of stem cells, as well as allow rapid characterization of differentiated cells.

1543

**Heterogeneous expression of pluripotency-associated gene in mouse embryonic stem cells visualized by bioluminescence microscopy.**

*Y. Hatta-Ohashi<sup>1</sup>, T. Takahashi<sup>1</sup>, H. Suzuki<sup>1</sup>; <sup>1</sup>Medical Technology R&D Division, Olympus Corporation, Tokyo, Japan*

The embryonic stem (ES) cells consist of various cell subsets which express different levels of pluripotency associated genes such as Nanog, Oct4, and Sox2. The heterogeneous expression of the transcription factors associated with pluripotency within ES cells has been shown by the use of RT-PCR, luciferase reporter assay, flow cytometry, and immunohistochemistry. Although these conventional methods provide the end-point data of gene expression, they cannot monitor the temporal changes within individual cells. Therefore, the temporal and spatial analysis of gene expression at the single cellular level is required for studies on self-renewal and differentiation processes of ES cells. To understand the exact profile of gene expression in the process of ES cell differentiation, gene expression of Nanog in mouse ES cells were monitored by using the single cellular bioluminescence imaging system (LV200, Olympus). The time course imaging analysis using luciferase as a reporter revealed that the promoter activity of Nanog gene mostly fluctuated and the pattern of fluctuation varied among the colonies of ES cells. The promoter activity of Nanog gene decreased in the most of ES cells after FGF-induced differentiation, whereas higher Nanog expression was sustained in small subpopulation of ES cells. We also found that Nanog promoter activity revealed the heterogeneous response in each cell by dual inhibition of mitogen-activated protein kinase signaling pathway using PD184352 and SU5402. Several studies reported that transcription factors associated with pluripotency are expressed in a heterogeneous fashion in ES cell cultures, however, this is the first study to show the temporal and spatial dynamics in Nanog expression of the identical cells at the single cellular level by using real-time imaging method. Our luminescence imaging system has the potential to provide some insight into possible diversity between ES cells in pluripotency and cell fate decision research.

1544

**Patient-derived Neural Progenitors: Setting the Stage for Neurodegeneration.**

*A. Flierl<sup>1</sup>, J. Hesley<sup>2</sup>, J. Langston<sup>1</sup>, B. Schuele<sup>1</sup>; <sup>1</sup>Parkinson's Institute, Sunnyvale, CA, <sup>2</sup>Molecular Devices, LLC, Sunnyvale, CA*

Parkinson disease (PD) is a multi-factorial progressive neurodegenerative disorder resulting in loss of dopaminergic neurons in the substantia nigra and characteristic intracellular inclusions called Lewy bodies. Genetic predisposition, such as mutations of the alpha-synuclein (SNCA, PARK1/4) gene e.g. point mutation and copy number variants of the SNCA gene locus (SNCA-Tri), can accelerate disease progression and can result in autosomal-dominant PD.  $\alpha$ -synuclein has been suggested to affect the function of membrane associated processes, specifically impairing mitochondrial morphology, dynamics and function in the highly energy-dependent dopaminergic neurons. The impact of PD mutations on the stability and developmental potential of neuronal stem cells may also have wide ranging implications for the development, maintenance, and quality of neuronal networks.

Here, we investigated if changes and impairment in mitochondrial function are already present in neuronal precursor cells (NPCs) derived from induced pluripotent stem cells of a patient with an SNCA triplication. Using medium to high throughput biochemical and imaging assays, we assessed cellular morphology and mitochondrial function in SNCA-Tri NPCs under normal and glucose-deprived growth conditions and under environmental stress. SNCA-Tri NPCs displayed overall normal cellular and mitochondrial morphology, but have a 2-fold increase of alpha-synuclein protein levels. SNCA-Tri NPCs showed changes in growth, mitochondrial protein import, cellular energy metabolism and specifically mitochondrial function especially when exposed to environmental or toxin stress. SNCA-Tri NPCs exhibited higher basal levels of reactive oxygen species and a reduced capacity to mitigate the impact of oxidative stress. These cells were also more sensitive to mitochondrial permeability transition pore opening and to apoptotic cell death.

Given the role of mitochondria not only in cellular energy metabolism, but also their crucial role in development, genetic alterations such as the SNCA gene triplication may set the stage for decreased developmental fitness, accelerated aging and increased neuronal cell loss in patients with genetic forms of PD.

These observations of “stem cell pathology” could have wide ranging implications on both quality and quantity of the neuronal networks in PD and may be applicable to a broader range of neurodegenerative disorders.

1545

#### **The RB tumor suppressor restricts reprogramming by directly silencing pluripotency genes.**

*M. S. Kareta<sup>1,2,3,4</sup>, L. Gorges<sup>1,2,3</sup>, S. Hafeez<sup>2,4</sup>, L. F. Batista<sup>2,5</sup>, S. E. Artand<sup>2,5</sup>, J. Sage<sup>1,2,3</sup>, M. Wernig<sup>2,4</sup>; <sup>1</sup>Department of Pediatrics, Stanford University, Stanford, CA, <sup>2</sup>Institute of Stem Cell Biology and Regenerative Medicine, Stanford University, Stanford, CA, <sup>3</sup>Department of Genetics, Stanford University, Stanford, CA, <sup>4</sup>Department of Pathology, Stanford University, Stanford, CA, <sup>5</sup>Department of Medicine, Stanford University, Stanford, CA*

The reprogramming of differentiated cells to an embryonic stem cell-like state provides a powerful system to explore fundamental mechanisms of development, including how mammalian cells establish and maintain pluripotency and long-term self-renewal capability. Based on the similarities between embryonic stem cells and cancer cells, we investigated the potential role of the retinoblastoma tumor suppressor and cell cycle regulator RB in the reprogramming of fibroblasts into induced pluripotent stem cells (iPS cells). Here we show that loss of RB function leads to both an acceleration of the reprogramming process and the generation of more iPS clones from fibroblasts. This effect is largely due to a restrictive role for RB at the early stages of reprogramming. Surprisingly, however, RB inactivation does not enhance the formation of iPS clones by accelerating the proliferation of cells undergoing reprogramming. Rather, a genome-wide investigation of RB targets indicates that RB binds to regulatory regions of pluripotency genes such as *Sox2* and *Oct4* and contributes to their full repression in differentiated cells. This effect correlates with the maintenance of a repressive chromatin structure at these loci. Accordingly, *Rb*-deficient fibroblasts can be reprogrammed into iPS cells even in the absence of exogenous *Sox2*, which is normally required to initiate reprogramming from fibroblasts. These experiments identify a novel barrier in the reprogramming process, mainly the repression of some pluripotency genes such as *Sox2* by RB, which provides a new link between tumor suppressor mechanisms and cellular reprogramming.

1546

**Enhanced in vivo regenerative potential of fetal-derived muscle stem cells***M. Tierney<sup>1</sup>, A. Sacco<sup>1</sup>; <sup>1</sup>Muscle Development & Regeneration, Sanford-Burnham Medical Research Institute, La Jolla, CA*

Adult muscle stem cells (MuSC) are primarily responsible for the homeostatic maintenance and repair of skeletal muscle, residing in a quiescent state until stimulated by external cues. Their developmental precursors, fetal MuSC, are an actively cycling population of Pax7-expressing cells required for embryonic myogenesis and represent a related but intrinsically different cell population. In an effort to decipher their intrinsic properties, we compared their self-renewal and regenerative potential with adult MuSC. Both populations were successfully isolated via flow cytometry using the cell surface markers alpha-7 integrin and CD34 and uniformly expressed Pax7. Fetal MuSC were readily able to form myotubes in vitro, whereas single cell analyses demonstrated comparable clonogenicity. Interestingly, a subset of cycling fetal MuSC did not express MyoD when expanded in culture, suggesting that they are resistant to myogenic commitment. When transplanted in vivo, fetal MuSC displayed a robust proliferative potential and successfully fuse with a substantial number of resident myofibers. Engrafted fetal MuSC were also able to respond to serial injury and give rise to an expanded pool of progenitors, strongly indicating stem cell function. Lastly, fetal single myofibers can be successfully isolated with their associated MuSC in situ, partitioned beneath the developing basal lamina. Ongoing work has revealed differential behavior and self-renewal potential of fetal and adult MuSC in suspension cultures. Future lineage tracing experiments are planned to establish the developmental relationship of adult and fetal MuSC, as well as the timing and extent of fetal MuSC contribution to the quiescent adult satellite cell pool.

1547

**BAF53A enforces the epidermal progenitor state by re-targeting the SWI/SNF/BAF chromatin remodeling complex away from differentiation gene promoters.***X. Bao<sup>1</sup>, J. Tang<sup>2</sup>, V. Lopez-Pajares<sup>1</sup>, S. Tao<sup>1</sup>, K. Qu<sup>1</sup>, G. R. Crabtree<sup>2</sup>, P. A. Khavari<sup>1</sup>; <sup>1</sup>Dermatology, Stanford University, Stanford, CA, <sup>2</sup>Howard Hughes Medical Institute, Stanford University, Stanford, CA*

Epidermal progenitors suppress expression of terminal differentiation genes. Recently, epigenetic mediators of DNA and histone modification have been identified as dynamically regulating such repression, including DNMT1, JMJD3, Polycomb, and HDAC1/2. These data indicate a role for multiple classes of epigenetic regulators in this process, however, the impact of epigenetic chromatin remodelers, such as the ATPase driven multi-subunit BAF (SWI/SNF) complex, is not fully characterized. To address this, we performed loss of function studies of multiple complex subunits in epidermal tissue. Conditional BAF53A (ACTL6A) gene deletion in mice was found to abolish epidermal progenitor maintenance and to induce differentiation, leading to a failure of epidermal self-renewal. Similar findings in organotypic human epidermis were observed with BAF53A depletion via RNAi, where ectopically expressed BAF53A also suppressed differentiation, indicating that BAF53A enforces the undifferentiated cell state. Depletion of key components of multiple histone acetyltransferase and chromatin remodeling complexes with which BAF53A can physically associate identified a phenocopy only with the BAF250A (ARID1A) BAF complex subunit. Paradoxically but consistent with prior knockout mouse studies, depletion BRG1/BRM ATPase subunits impaired differentiation gene induction, suggesting that BAF53A functions as an anti-differentiation component of the BAF complex. Consistent with this, BAF53A is down-regulated during normal differentiation. Mechanistically, chromatin immunoprecipitation (ChIP) experiments demonstrated that BAF53A impairs binding

of the BRG1/BRM-containing BAF complex to differentiation gene promoters, including key regulators such as of KLF4, blocking their induction. These data indicated that BAF53A maintains the undifferentiated progenitor state by opposing BAF complex-enabled differentiation via genomic re-targeting of this chromatin remodeling complex away from differentiation gene promoters.

1548

### **Dissecting the role of histone variant macroH2A in iPS reprogramming and cancer progression.**

*A. Gaspar-Maia<sup>1</sup>, E. Bernstein<sup>1</sup>; <sup>1</sup>Oncological Sciences, MSSM, New York, NY*

MacroH2A is a unique histone variant, consisting of an N-terminal region similar to canonical histone H2A and a non-histone macro domain at its carboxyl terminus, making it the largest known histone variant. The role of macroH2A as a transcriptional repressor has yet to be clarified, and its biological role development and cancer progression are now being unraveled.

Here we show that during development and differentiation, macroH2A1 and macroH2A2 isoforms become enriched in the chromatin fraction, and we hypothesized that macroH2A could create an epigenetic barrier to somatic cell reprogramming towards pluripotency. We show that dermal fibroblasts derived from macroH2A1 and macroH2A2 double knockout (dKO) mice are more efficiently reprogrammed than their wild type counterparts. Using macroH2A single knockout cells and rescue studies, we demonstrate that macroH2A isoforms act synergistically in this process. Furthermore, macroH2A is deposited to regulatory regions of pluripotency factors upon differentiation. Finally, macroH2A dKO iPS cells maintain their ability to differentiate in vitro and in teratomas. Therefore, we propose that macroH2A isoforms are dispensable for differentiation, but provide a redundant silencing layer or terminal differentiation 'lock' that, in turn, presents as an epigenetic barrier when differentiated cells are challenged to reprogram.

Our lab has demonstrated that macroH2A isoforms are lost during melanoma progression. Coupled to our reprogramming studies, we hypothesize that macroH2A may act as global repressor that is evicted from chromatin as a cancer cell becomes more aggressive and undifferentiated. We have observed low levels of macroH2A in triple negative breast cancer cell lines and our data suggests that over-expressing macroH2A in these cells may decrease their tumorigenicity. We are also interested in understanding whether progenitor and tumor initiating cell populations rely on macroH2A downregulation for their maintenance.

1549

### **microRNA dynamics in the maintenance and reprogramming of mouse pluripotent stem cells.**

*B. Chang<sup>1</sup>, M. Kudla<sup>2</sup>, C. Schaniel<sup>1</sup>, G. J. Hannon<sup>2</sup>, I. Lemischka<sup>1</sup>; <sup>1</sup>Mount Sinai School of Medicine, New York, NY, <sup>2</sup>Cold Spring Harbor Laboratory, Cold Spring Harbor, NY*

Several microRNA families, such as the 290-cluster and 302-cluster families have been classified as embryonic stem cell specific and have been demonstrated to serve as cell cycle regulators vital to the maintenance of self-renewal. In order to gain a comprehensive understanding of the function of microRNAs within pluripotent cells we examine them within mouse embryonic stem cells over a time course of differentiation induced by loss of key transcription factors, Nanog or Pou5f1(OCT3/4).

We find using deep sequencing that, as expected, the milieu of microRNAs varies with loss of these key pluripotency genes and further show that they are differentially incorporated into the RISC complex via HITS-CLIP studies. In particular, the microRNAs shown from previous

ChIPseq studies to have Nanog and Pou5f1 at their transcript start sites (TSS), e.g. the 290-cluster, are coordinately lost upon transcription factor perturbation and that the respective microRNA target mRNA are released from repression. This demonstrates a complex and multilayered regulatory mechanism mediated by core pluripotency genes beyond transcriptional regulation to non-coding RNA-based epigenetic regulation. Within the same time course, we also measure by mRNAseq the transcriptome to provide additional knowledge of potential microRNA mediated target regulation.

To augment our understanding of this transcription factor-microRNA coordinated regulation in the context of pluripotency, we also examine the expression of microRNAs during reprogramming of mouse embryonic fibroblasts to induced pluripotent stem cells using the four canonical transcription factors, Pou5f1, Sox2, Klf4 and c-Myc using a Tet-inducible cassette. Here we also see a direct upregulation of pluripotency-related microRNAs over the course of reprogramming.

We observe both transcriptional activation and repression of microRNAs with Pou5f1 located near their transcript start sites (TSS) during loss of Pou5f1 and overexpression of Pou5f1 during reprogramming. We seek to integrate our knowledge of microRNA function during the loss and gain of pluripotency to provide a model of microRNA function and participation in the maintenance of self-renewal and pluripotency associated with embryonic stem cells.

#### **Clonal Level Lineage Commitment of Mouse Hematopoietic Stem Cells In Vivo.**

R. Lu<sup>1</sup>, A. Czechowicz<sup>1</sup>, J. Seita<sup>1</sup>, I. L. Weissman<sup>1</sup>; <sup>1</sup>Institute for Stem Cell Biology and Regenerative Medicine, Stanford University, Stanford, CA

Hematopoietic stem cells (HSCs) sustain the blood and immune systems through a complex lineage commitment process. While this process has been extensively studied at the population level, little is known about the lineage commitment of individual HSC clones. Here, we provide a comprehensive map of *in vivo* HSC clonal development that reveals new HSC regulatory mechanisms undetectable at the population level.

The clonal map was derived from the simultaneous tracking of hundreds of individual mouse HSCs *in vivo* using genetic barcodes. These unique barcodes were delivered into HSCs using a lentiviral vector to obtain a one-to-one mapping between barcodes and HSCs. Barcoded HSCs were then transplanted into recipient mice using standard procedures. Recipients were either conditioned with irradiation (myeloablative) or with an anti-ckit antibody (non-myeloablative) prior to transplantation, or were not conditioned with any regimen. Genetic barcodes from donor derived HSCs and their progeny were examined twenty-two weeks after transplantation using high-throughput sequencing.

While irradiation-mediated transplantation has been widely used as a gold standard to study HSCs, our data suggests that irradiation conditioning alters HSC lineage commitment at the clonal level. After syngeneic transplantation into mice absent of any conditioning regimen, all donor-derived HSC clones homogeneously regenerate blood without exhibiting any measurable dominance or lineage bias. In contrast, when recipient mice are pre-conditioned with irradiation, only a small fraction of donor-derived HSC clones differentiates, while dominantly expanding and exhibiting lineage bias. Interestingly, when recipient mice are pre-treated with an anti-ckit antibody, the lineage commitment of some HSC clones resembles those transplanted into unconditioned mice, exhibiting no clonal dominance or lineage bias. Other clones in the same

mice resemble those transplanted into irradiated mice, exhibiting both clonal dominance and lineage bias.

We have identified the cellular origins of clonal dominance and lineage bias, and have uncovered the lineage commitment pathways that lead HSC clones to differential blood production. This study reveals surprising alterations in HSC regulation by irradiation, and identifies the key hematopoiesis stages that may be manipulated to control blood production and balance.

**Regulation of stem cell growth and differentiation by polypeptide multilayer films.**

*H-C. Chiu<sup>1</sup>, C-C. Hsu<sup>2</sup>, S-Y. Wang<sup>2</sup>, Y-R. Chen<sup>2</sup>, H-I. Chiu<sup>1</sup>, C-M. Lo<sup>2</sup>; <sup>1</sup>School of Medicine, National Yang-Ming University, Taipei, Taiwan, <sup>2</sup>Department of Biomedical Engineering, National Yang-Ming University, Taipei, Taiwan*

Cell growth and differentiation is critical for many physiological events such as embryonic development and wound healing. Polypeptide multilayer films are promising for the development of artificial extracellular matrix for the regulation of stem cell differentiation since they are entirely synthetic and can mimic crucial features of ECM proteins. In addition, this material allows for modulation of thickness, stiffness, and adhesiveness. In this study, mouse induced pluripotent stem cells (iPSCs) were cultured on EDC/NHS cross-linked and gelatin-coated polypeptide multilayer films built up by the alternate adsorption of poly-L-lysine (PLL) and poly-L-glutamic acid (PLGA), and the growth and differentiation of these cells were evaluated. The results showed that though mouse iPSC colonies maintained similar initial adhesion and attachment regardless of layer number of films, they demonstrated better cell spreading and growth on even number layer of films, where the top layers are PLGA films. In addition, compared with cells cultured on 2-layer film, the cardiomyocyte differentiation of mouse iPSCs on 4- and 6-layer films showed a significant increase in the differentiation rate, especially when EDC/NHS cross-linkers with higher concentration were used to form the films. This cellular response on 4- and 6-layer films was coupled with increase in the growth rate. These observations indicate that mouse iPSC growth and differentiation on polypeptide multilayer films can be regulated by the type of the outermost polypeptide layer, the concentration of cross-linkers, and the number of layers in the film.

1552

**Understanding pathogenesis of lissencephaly-a severe neurodevelopmental disorder-with patient-derived induced pluripotent stem cells.**

*M. Bershteyn<sup>1</sup>, Y. Hayash<sup>2</sup>, E. Hsiao<sup>1</sup>, S. Yamanaka<sup>2</sup>, A. Wynshaw-Boris<sup>1</sup>; <sup>1</sup>Pediatrics, UCSF School of Medicine, San Francisco, CA, <sup>2</sup>Gladstone Institute of Cardiovascular Disease, San Francisco, CA*

Miller-Dieker Syndrome (MDS) is the most severe form of lissencephaly or “smooth” brain-a neuronal migration disorder that arises during early development, leading to disorganized cortical layering and devastating neurological consequences such as mental retardation and intractable epilepsy. MDS is always caused by heterozygous deletions of the 17p13.3 locus harboring about twenty genes, with the critical missing region spanning from LIS1 to YWHAE. Attempts to generate mice with such a large deletion have thus far been unsuccessful. While it is commonly accepted that defective neuronal migration is the primary cause of lissencephaly, it is unknown whether brain cells of human patients develop, migrate, mature or function properly. To facilitate our understanding of MDS pathogenesis and to begin elucidating the contributions

of genes within the deleted locus, we generated induced pluripotent stem cells (iPSCs) from fibroblasts of two MDS patients. We found that MDS fibroblasts can be efficiently reprogrammed into functional iPSCs that exhibit wild type characteristics in self-renewal and differentiation capacity in vitro and in vivo. We then optimized a neural differentiation strategy to produce cortical neural progenitors (NPCs) and neurons. We found that while MDS-iPSCs can be specified into cortical NPCs with high efficiency, upon specification they exhibit severely impaired viability and cannot be expanded through suspension or monolayer culture, likely due to increased apoptosis. Since expansion of proliferative neural stem and transit-amplifying cells is a key feature of human brain development that contributes to the structural complexity and foldedness of the neocortex, our results suggest that impaired proliferation of neural stem cells may be a more significant factor in lissencephaly pathogenesis than previously appreciated.

### **Genetic and Pharmacological Properties of Human Cardiac Stem Cell-Derived Cardiomyocytes.**

*J. Sharma<sup>1</sup>, J. Jain<sup>1</sup>, R. Punzalan<sup>1</sup>, C. Sharma<sup>1</sup>, M. Sharma<sup>1</sup>, J. Cleary<sup>1</sup>, E. Gomez<sup>1</sup>, G. Tran<sup>1</sup>, N. Amezcua<sup>1</sup>; <sup>1</sup>Celprogen, San Pedro, CA*

Human Adult Cardiac stem cells (hACSCs) can be directed to differentiate into cardiomyocyte-like cells. These cells express cardiac-specific markers and display functional similarities to their adult counterparts. Based on these properties, hACSCs -derived cardiomyocytes have the potential to be extremely useful in various in vitro applications and to provide the opportunity for cardiac cell replacement therapies. However, before this can become a reality, the molecular and functional characteristics of these cells need to be investigated in more detail. In the present study we differentiate hACSCs into cardiomyocyte-like cells. The fraction of spontaneously beating clusters obtained from the Cardiac Stem Cells averaged approximately 25% of the total number of Cardiac Clusters used. These cell clusters were isolated, dissociated into single-cell suspensions, and frozen for long-term storage. The cryopreserved cells could be successfully thawed and subcultured. Using Florence microscopy, we observed Z discs and tight junctions in the hACSC-derived cardiomyocytes, and by immunohistochemical analysis we detected expression of cardiac-specific markers (cTnI and cMHC). Also, utilizing BrdU labeling we could demonstrate that some of the hACSC-derived cardiomyocytes retain a proliferative capacity. The pharmacological stimulation of the cells resulted in responses indicative of functional adrenergic and muscarinic receptor coupling systems. Taken together, these results lend support to the notion that hACSCs can be used as a source for the procurement of cardiomyocytes for in vitro and in vivo applications.

### **Expression Dynamics and Evolution of Sperm PIWIL1, PIWIL2, and AGO2.**

*E. Crate<sup>1,2</sup>, R. Avula<sup>3</sup>, H. O'Neal<sup>2</sup>, A. Perkins<sup>3</sup>, E. Memilf<sup>2</sup>; <sup>1</sup>New College of Florida, Sarasota, FL, <sup>2</sup>Department of Animal and Dairy Sciences, Mississippi State University, Starkville, MS, <sup>3</sup>Computer Science and Engineering, Mississippi State University, Starkville, MS*

Early mammalian development is initiated by fertilization of the egg by the spermatozoon, and followed by dramatic reprogramming of gene expression during embryogenesis and beyond. Sperm provides half of the genome and other macromolecules, including coding and non-coding transcripts, into the oocyte to enable the formation of new organism, zygote. Research in our

laboratory and elsewhere showed that mammalian spermatozoa contain small non-coding RNAs, including piwi-interacting RNAs (piRNAs) and microRNAs (miRNAs). It is also known that spermatozoa lack ribosomal RNAs and that transcription and translation are largely absent in these cells. Although these short transcripts are known to play a vital role in genome protection and regulation of gene expression by RNA interference (RNAi), their functions in the sperm are not known. The objectives of this study were to: 1) analyze the expression profiles of specific binding proteins associated with piRNAs and miRNAs: PIWIL1, PIWIL2, and AGO2, in sperm from a high vs. a low fertility bull, and 2) determine conservation of the protein sequences among mouse, human, cow, dog, and opossum. To accomplish these objectives, we performed immunocytochemistry using bull sperm and clustal alignments to detect the piRNA and miRNA binding proteins and evolutionary conservation, respectively. Our results showed that PIWIL1, PIWIL2, and AGO2 were detectable in the sperm with varying cellular locations including sperm head and tail. In addition, all the three proteins are well conserved across the mammals examined. The degree of conservation was over 88% and 99% for PIWIL1 and 2, and AGO2 proteins, respectively. The results suggest that since the expression of these sncRNA binding proteins are present within the mature sperm cell; this can further implicate that the machinery for the transcriptional control of gene expression is present in the male gamete and that this may play roles in regulating gene expression at the onset of development. Furthermore, regulation of the gene expression by miRNAs, and protection of the genome by piRNAs appear to be a well- conserved mechanism across the mammals.

1555

#### Dissecting Auxin and *indeterminate gametophyte1 (ig1)* Signaling in Maize Embryo Sac Development.

A. M. Chettoor<sup>1</sup>, W. Nelson<sup>1</sup>, S. Subramaniam<sup>2</sup>, M. Evans<sup>1</sup>; <sup>1</sup>Department of Plant Biology, Carnegie Institution For Science, Stanford, CA, <sup>2</sup>Department of Plant and Microbial Biology, University of California Berkeley, Berkeley, CA

In plants, the female gametophyte produces two gametes, the egg and central cell, which are fertilized by the two male gametes in the process called double fertilization resulting in the embryo and endosperm of the seed. A detailed understanding of embryo sac development is central to better seed production. The female gametophytes of angiosperms have four cell types: the egg cell, synergids, central cell and antipodal cells arranged in the micropylar-chalazal axis. Cereal grasses possess proliferative antipodal cells which persist after fertilization, in contrast to Arabidopsis antipodal cells, which degenerate during embryo sac development. A number of maize mutants with altered antipodal cell morphology are being characterized. One of these, *indeterminate gametophyte1 (ig1)*, encodes a Lateral Organ Boundaries(LOB) domain protein with high similarity to Asymmetric Leaves2(AS2) of *Arabidopsis thaliana*. To decipher the mechanism of *ig1* regulation of embryo sac development, interactors of the LOB domain were identified in a yeast two- hybrid screen. Preliminary results identified DNA/chromatin modifiers and proteins involved in cell metabolism as potential interactors. RNA-Seq analysis of *ig1* mutant embryo sacs identified several differentially expressed genes, including several transcription factors. Detailed analysis of the two hybrid interactors and RNA-seq data, including future mutant analyses, could provide critical insights into female gametophyte development in plants.

To explore the role of phytohormone, auxin in maize embryo sacs, expression patterns of two fluorescent reporters in maize (a reporter for auxin levels (DR5::RFP) and auxin efflux carrier (PIN1::PIN1-YFP) were examined. In Maize, unlike in Arabidopsis DR5 expression is not present in the embryo sac before cellularization. However, in mature maize embryo sacs both DR5 and PIN1 expression are expressed strongly and specifically in the antipodals. Embryo sac enriched genes from RNA-seq data were consequently searched for cis Auxin Response

Elements (AuxRE) suggestive of these genes potentially regulated by auxin and compared to genes misregulated in *ig1* mutant embryo sacs to identify genes potentially regulated by both. Preliminary in-situ's with Maize Auxin Response Factors (ZmARF's) support presence of auxin in Maize antipodal cells. This raises the possibility that differences in auxin levels and patterns may be partially responsible for antipodal cell biology. Experiments that alter cell type specific auxin levels in the embryo sac are in progress to address this possibility.

1556

#### Expression and function of LYAR in male reproduction.

B. Lee<sup>1</sup>, C. Cho<sup>1</sup>; <sup>1</sup>Gwangju Institute of Science and Technology, Gwangju, Korea

Mammalian spermatogenesis is a complex process that involves an intrinsic genetic program consisting of germ cell-specific and -predominant genes. In the present study, we analyzed *Ly-1 reactive clone (Lyar)* gene in the mouse. *Lyar* is known to be expressed abundantly in the testis and encodes a nucleolar protein which contains a LYAR-type C2HC zinc finger motif and three copies of nuclear localization signals. We showed that *Lyar* is expressed predominantly in the testis and this expression is specific to germ cells in the testis. Protein analyses with an anti-LYAR antibody demonstrated that the LYAR protein is present in spermatocytes and spermatids, but not in sperm. To assess the functional role of LYAR *in vivo*, we have established a mouse model with the aid of gene trap mutagenesis approach. *Lyar* mutant mice were born live and developed normally. Male mutant mice lacking LYAR were fully fertile and spermatogenesis in the mutant testis was intact. Taken together, our study demonstrates that LYAR is strongly preferred in male germ cells, but has a dispensable role in spermatogenesis and fertility.

1557

#### Species Specificity of Energy Metabolisms and Mitochondrial Morphology in Fish Spermatozoa.

T. Harumi<sup>1</sup>, T. Andoh<sup>2</sup>, T. Ichikawa<sup>2</sup>, H. Matsubara<sup>3</sup>, Y. Hira<sup>1</sup>, Y. Hayashi<sup>4</sup>, R. Yanagimachi<sup>5</sup>; <sup>1</sup>Anatomy, Asahikawa Medical College, Asahikawa, Japan, <sup>2</sup>The Fisheries Research Agency, Yokohama & Kushiro, Japan, <sup>3</sup>Tokyo University of Agriculture, Abashiri, Japan, <sup>4</sup>Life Science, Asahikawa Medical College, Asahikawa, Japan, <sup>5</sup>Institute for Biogenesis Research, University of Hawaii, Honolulu, HI

Since fish spermatozoa are spawned and diluted in seawater, they have to swim through utilizing intracellular energy substrates to reach egg. To clarify any relation in sperm motility, energy sources and mitochondrial function and morphology, we compared these factors in spermatozoa freshly prepared from flounders such as Black flounder (*Liopsetta obscura*) and Barfin flounder (*Verasper moseri*), Pacific herring (*Clupea pallasii*). Spermatozoa of both flounders moved linearly, and turned their directions at the egg micropyle where they entered, while herring spermatozoa crawled into the micropyle in rotation movement. When diluted in seawater, spermatozoa of *L. obscura* swam vigorously followed by stopping the movement within one minute. *V. moseri* spermatozoa kept swimming for more than ten minutes. In *C. pallasii* spermatozoa, a very few sperms moved rarely in seawater, although they started vigorous swimming near the egg micropyle. Mitochondria produce the energy needed for biological functions mainly via the electron transport chain, concomitantly generating reactive oxygen species (ROS). Because ROS have the potential to cause cellular damage, cells defend against ROS through either enzymatic and/or non-enzymatic ROS eliminating systems. We also examined ROS eliminating mechanisms in these fish spermatozoa. Spermatozoa of *V. moseri* and *C. pallasii* showed high activities to degrade hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) added exogenously,

while the spermatozoa of a flounder, *L. obscura*, exceptionally showed low activity. Morphological observations revealed that *L. obscura* spermatozoa possesses small mitochondria with undeveloped cristae while *V. moseri* and *C. pallasii* possesses large mitochondria with developed cristae. These results, taken together, indicate that the sperm motility and energy metabolism in fish is coupled to its mitochondria morphology, varying from one species to another.

1558

**Effect of streptozotocin-induced diabetes on membrane integrity and acrosome reaction in mice spermatozoa.**

*M. Sánchez-Gutiérrez<sup>1</sup>, J. A. Izquierdo-Vega<sup>1</sup>, L. A. Rojas-Cruz<sup>1</sup>, D. García-Laguna<sup>1</sup>, C. Zúñiga-Pérez<sup>1</sup>, E. O. Madrigal-Santillán<sup>1</sup>, G. Betanzos-Cabrera<sup>1</sup>; <sup>1</sup>UAEH, Pachuca, Mexico*

Diabetes mellitus is a well-recognized cause of male sexual dysfunction and impairments of male fertility. This alteration includes endocrine disorders, neuropathy, deleterious effects on male reproductive function and increased oxidative stress. The aim of this study was to investigate the spermatozoa quality, the membrane integrity, acrosome reaction and testicular histology on mice diabetics during 60 days. Male CD1+ mice were divided into two groups of eight animals each: diabetic and control group. Animals were treated with a single injection of streptozotocin (150 mg/kg; ip), or buffer citrate. Blood glucose was estimated after one week and the animals with glucose levels  $\geq 250$  mg/dl were included in this study. Animals were kept with diabetes during two months before the experiments. We evaluated several parameters in spermatozoa from diabetic and not diabetic mice: i) standard quality analysis according to World Health Organization, ii) integrity of sperm membrane by hypoosmotic swelling test (HOS-T), iii) acrosome reaction by staining method using Coomassie Blue G-250 and iv) histology testicular using technical paraffin-embedded and stained with hematoxylin and eosin. Spermatozoa from diabetic mice exhibited a significant decrease in motility ( $p \leq 0.001$ ), concentration ( $p \leq 0.0042$ ), viability ( $p \leq 0.001$ ), a significant increase on alteration in membrane integrity ( $p \leq 0.001$ ), and a significant increase in the loss of acrosome ( $p \leq 0.001$ ), relative to spermatozoa from control group. Finally, the histoarchitecture in testis was visibly altered diabetic mice compared with control group. These observations suggest that subchronic diabetes causes an important alteration in the integrity of sperm membrane.

1559

**PI(4,5)P2 is required for chromatin reorganization during spermiogenesis.**

*L. Fabian<sup>1</sup>, J. A. Brill<sup>1</sup>; <sup>1</sup>Cell Biology, Hospital for Sick Kids, Toronto, ON, Canada*

Phosphoinositides (PIPs) regulate several aspects of *Drosophila* spermiogenesis, such as axoneme biogenesis, cell polarity and membrane trafficking. Here we show that PIPs are also required for nuclear morphogenesis, a process essential for male fertility and which requires interactions between nuclear membrane, chromatin and cytoskeleton. Nuclear morphogenesis includes dramatic changes in the shape and size of the sperm head and also in the state of chromatin condensation. These changes are associated with microtubule-dependent nuclear elongation, when the perinuclear microtubule cytoskeleton is reorganized to provide additional support to the elongating nucleus. Chromatin is reorganized by switching from a histone-based chromatin configuration, present in early round spermatid nuclei, to a protamine-based configuration, present in mature sperm nuclei. Spermatids in which levels of phosphatidylinositol 4,5-bisphosphate (PI(4,5)P2) have been reduced show profound defects in chromatin organization, lack of nuclear maturation, and male sterility. Posttranslational modification of histones is impaired and their removal is delayed. Protamines get incorporated into nuclei

despite histones not being completely removed. Transition proteins are not present in these spermatids. Localization of inner nuclear membrane proteins is defective, sumoylation is impaired, and repair of double-stranded DNA breaks is incomplete. Our present data suggest that normal levels of PI(4,5)P2 are required to coordinate interactions between the nuclear membrane and chromatin.

1560

**Spindle assembly checkpoint plays a role in DNA-damage-induced cell cycle arrest in *C. elegans* male germ line.**

K. Lawrence<sup>1</sup>, J. Engebrecht<sup>1</sup>; <sup>1</sup>MCB, University of California Davis, Davis, CA

Persistent DNA damage in germline stem cells leads to embryonic lethality, progeny inviability or germline tumors. Consequently, cells closely monitor genomic integrity and can delay their progress through the cell cycle so that repair precedes division. In *C. elegans*, genotoxic perturbations to proliferative cells in the distal tip of the gonad activate the DNA damage response (DDR) pathway, resulting in cell cycle arrest. When this arrest is in response to stalled replication forks induced by hydroxyurea (HU), it is characterized by enlarged nuclei and can be visualized cytologically.

We have found that while RNAi knockdown of several genes in the DDR pathway disrupts checkpoint output in hermaphrodites, the same treatment does not prevent HU-induced arrest in males, suggesting that not all components of the DDR are essential for male cell-cycle arrest in response to stalled replication forks.

We next investigated functional redundancy between the DDR and the spindle assembly checkpoint (SAC), which is most often associated with regulating kinetochore attachment to spindles during prometaphase/metaphase of mitosis and meiosis. RNAi knockdown of several SAC components alone did not affect HU-induced cell-cycle arrest in males; however, knockdown of both the DDR and SAC resulted in a failure to arrest in the presence of HU. This result suggests that males use two independent pathways to elicit arrest in response to stalled forks. Preliminary data from experiments utilizing cell cycle markers suggests that the SAC, like the DDR, mediates an S phase arrest not predictive of its expected role as an inhibitor of *cdc20* at metaphase. Future work aims to understand this novel role for SAC components and investigate the mechanisms used by the SAC to induce an S phase arrest in males.

1561

**Excess Consumption of Multiple Sugars Reduces Fertility in *Caenorhabditis elegans*: Roles for Hexosamine Signaling and Sex-Specificity.**

M. R. Liggett<sup>1</sup>, U. Ho<sup>1</sup>, M. A. Mondoux<sup>2</sup>; <sup>1</sup>These authors contributed equally to this work, Biology Department, College of the Holy Cross, Worcester, MA, <sup>2</sup>Biology Department, College of the Holy Cross, Worcester, MA

High sugar diets have been linked to several diseases: increased glucose intake correlates with obesity, diabetes, and cardiovascular disease, and increased galactose intake can lead to liver failure and neurotoxicity. The nematode worm *Caenorhabditis elegans* has a conserved insulin-signaling pathway and is thus a good model for the response to high sugar diets. Previous studies have shown that exposing hermaphrodite worms to high glucose conditions decreases fertility and lifespan (Lee *et al.* 2009, Mondoux *et al.* 2011). Among its many functions in the cell, glucose serves as the precursor for O-linked N-acetyl-glucosamine (O-GlcNAc), a post-translational protein modification. Mutants that lack the O-GlcNAc transferase, *ogt-1*, have decreased fertility and lifespan even at low glucose concentrations. We wanted to test whether the fertility response to sugar stress was sex-specific and/or glucose-specific.

We tested sex-specificity by mating hermaphrodites and males in the presence of glucose stress and found that the number of progeny and proportion of male progeny were reduced by ~20% compared to mating on control plates, indicating decreased male fertilization success. In order to determine the mechanism of this response, we performed a courtship ability assay and scored the location of males and their interactions with hermaphrodites. Interestingly, males on high glucose had no loss of courtship ability, indicating that their ability to find mates was not limited by glucose exposure. These results also showed a uniquely male sensitivity to glucose stress, as male fertilization success was compromised at concentrations that had no effect on hermaphrodite fertility.

We tested glucose specificity by assaying fertility in response to a high galactose diet. Glucose and galactose have the same molecular formula, and only differ in their spatial orientation, leading us to hypothesize that fertility levels would be similar for both sugars at the same concentration. However, we found that wild type *C. elegans* had no fertility defect at 333mM galactose, even though fertility is decreased 30% at that concentration of glucose. *C. elegans* was sensitive to galactose stress, as 500 mM galactose reduced fertility by 50% and caused a delay in reproductive timing. *ogt-1* mutant worms, in contrast, had extremely low fertility on 333mM galactose (< 10% fertility compared to wild-type); even lower than the published fertility levels on 333mM glucose.

Together, our data suggest that *C. elegans* is sensitive to multiple types of sugar stress but that different genetic backgrounds and sexes have different sensitivities to different sugars. Future experiments will test the role of germline apoptosis in both males and hermaphrodites and elucidate the role O-GlcNAc might play in this process.

1562

### **Sperm Parameters and Leydig cells function in adult rats are impaired by maternal obesity and overnutrition postnatal.**

M. E. Pinto<sup>1</sup>, V. Reame<sup>1</sup>, D. L. Ribeiro<sup>2</sup>, S. R. Taboga<sup>1</sup>, R. M. Góes<sup>1</sup>; <sup>1</sup>Biology, São Paulo State University/Ibilce, São José do Rio Preto, Brazil, <sup>2</sup>Federal University of Uberlândia, Uberlândia, Brazil

Sperm production and steroidogenic activity of Leydig cells are impaired by obesity in adult life. This investigation evaluates the effects of obesogenic environment (OE) during different periods of development on sperm parameters and Leydig cell function of adult rats. Wistar rats were subjected to a balanced feeding from gestation to adulthood (control group, 4% lipid in diet) or to OE during gestation (O1 group), from gestation to weaning (O2 group), from weaning to adulthood (O3 group), from breast-feeding to adulthood (O4 group) or from gestation to adulthood (O5 group). Obesity was induced to female rats before the pregnancy (group O1, O2 and O5) and also to offspring of groups O3, O4 and O5 by high-fat diet (20% saturated lipid) for 15 weeks. Animals were killed with 18-week-old and body weight, adiposity index and plasma leptin and testosterone were determined. It was performed the sperm counts in the testis and epididymal regions, the daily sperm production (DSP) and the transit time of spermatozoa in the epididymis. In addition, testes were subjected to immunohistochemistry and western blotting for androgen receptor (AR) and 17 $\beta$ -hydroxysteroid dehydrogenase (17 $\beta$ -HSD). All groups exposed to OE were obese at adulthood, as indicated by increase in body weight, adiposity index and plasma leptin. Obese groups presented a decrease in circulating testosterone. Furthermore, the number of spermatids in the testis and the DSP decreased 16% for group O1, 20% for groups O2 and O4, and 26% for groups O3 and O5. The number of sperm in the region caput/corpus epididymis decreased about 17% for groups O1, O2, O3 and O4, and 26% for

group O5. This reduction was 9% for group O1, 20% for groups O2, O3 and O4, and 27% for group O5 in the cauda; however, the transit time of spermatozoa through the caput/corpus and cauda of the epididymis was not affected. The number of Leydig cells AR- and 17 $\beta$ -HSD-positive was unaffected in obese rats but the content of these proteins in crude testis samples varied among obese groups. A low expression of 17 $\beta$ -HSD was detected to all obese groups. The OE during gestation/breast-feeding led to overexpression of AR whereas the others obese groups showed a reduction the AR content of testis in relation to control. In conclusion, the results observed in this study indicate that maternal obesity and overnutrition postnatal reduces the production and reserve of spermatozoa, as well as commits the function of Leydig cell in adult. This was probably due to decrease in circulating testosterone and reduction in AR and 17 $\beta$ -HSD expression. Financial Support: FAPESP.

1563

#### **A role for a sperm protease at fertilization.**

*L. S. Bates<sup>1</sup>, D. Carroll<sup>1</sup>; <sup>1</sup>Biological Sciences, Florida Institute of Technology, Melbourne, FL*

During fertilization, the sperm and egg membranes fuse and the zygote metabolism is activated. While many of the signaling molecules involved in fertilization have been discovered, little is known about the cell surface molecules that allow for sperm-egg fusion and egg activation. A number of proteases have been identified on the sperm acrosome and could potentially play a role in the initiation of fertilization. Among these are trypsin-like proteases (other than acrosin) whose function(s) have not been well established. A sperm acrosomal protease could participate in fertilization at several levels, functioning in: 1) the acrosome reaction that remodels the sperm surface to prepare it for fertilization; 2) penetration of the large jelly layer and/or the vitelline coat that surround the egg; 3) cleaving a receptor on the egg membrane, changing its conformation and initiating signaling pathways; or 4) remodeling an egg cell surface protein to generate a fusion protein to facilitate sperm-egg membrane fusion. The starfish represents a model system to test these ideas because of its amenability to in vitro fertilization following removal of either the egg jelly or the vitelline envelope, and it is possible to stimulate the acrosome-reaction in sperm separately from the eggs. To identify membrane proteins, the starfish eggs were biotinylated. Following fertilization, biotinylated fragments from cleaved cell surface proteins were recovered from sea water indicating that a protease does have a function. Next, to test possible protease functions at fertilization in the starfish, different egg preparations were fertilized in seawater with or without the presence of soybean trypsin inhibitor (SBTI) and scored for egg activation by vitelline envelope elevation. SBTI (1mg/ml, 2mg/ml, and 3mg/ml) inhibits fertilization envelope elevation in jelly-, and vitelline envelope-intact eggs. This suggests that the sperm protease is necessary for either the acrosome reaction and/or penetration of the egg jelly or vitelline envelope. Fertilization envelope elevation was also blocked when jelly-free eggs were treated with SBTI and fertilized with acrosome-reacted sperm, which strongly suggested that penetration of the vitelline envelope is dependent upon the sperm trypsin-like protease activity. When performing the SBTI experiment on jelly-free and vitelline-free (naked) eggs, they were observed after fertilization for cell division (as they do not have a vitelline envelope to elevate). At 2 hours after sperm were added, division was observed in naked eggs, suggesting the protease is needed for vitelline envelope penetration.

1564

**Zap70 and its downstream gene RanBP2 regulate meiotic cell cycle speed in oocytes.**

H-J. Kim<sup>1</sup>, H-S. Lee<sup>1</sup>, E-Y. Kim<sup>1</sup>, K-A. Lee<sup>1</sup>; <sup>1</sup>Department of Biomedical Science, CHA University, Seoul, Korea

Previously, we demonstrated that Zap70 (Zeta-chain-associated protein kinase) expressed in the mouse oocyte and played significant role in completion of meiosis. Aim of the present study was to determine the mechanisms of action of Zap70 during oocyte maturation by evaluating downstream signal networking after Zap70-RNAi.

To elucidate RNAi effects, Zap70 and RanBP2 dsRNA were microinjected into the GV (germinal vesicle) oocyte cytoplasm, and RNAi-treated oocytes were incubated in M16 medium containing IBMX (3-isobutyl-methyl-xanthine) for 8 hours followed by culture in the plain M16 for 8 hours. We examined maturational changes and the gene expression profiles by microarray analysis. The probe hybridization and data analysis were used by Affymetrix Gene Chip Mouse Genome 430 2.0 array and GenPlex 3.0 (ISTECH, Korea) software. Expression of Zap70 and RanBP2 during meiotic maturation was observed by immunofluorescence staining.

Immunofluorescence analysis showed that the Zap70 was localized in the GV cytoplasm and moved on to the chromosomes during *in vitro* oocyte maturation. Also, we found that GVBD in the Zap70-RNAi oocytes occurs 30 min faster than in control group. Zap70-RNAi resulted in arrest at MI stage with elongated spindles with prematurely divided chromosomes at 6~8 hr stages, that usually found in anaphase (12~16 hr). Among the genes regulated by Zap70-RNAi, we selected 10.7 folds down-regulated RanBP2 (Ran binding protein 2), since RanBP2 has been known to be involved in NEBD (Nuclear envelope breakdown). RanBP2 was localized on the nuclear envelope and its depletion by RNAi caused exactly similar results as found in the Zap70-RNAi oocytes.

We concluded that 1) the Zap70 is a crucial factor during oocyte maturation; especially for regulating the exact timing of meiosis, and 2) Zap70 function involves the role of RanBP2. These results are the first report regarding the function of Zap70 and RanBP2 in the oocyte maturation and regulation of meiotic cell cycle.

**Identification of germ cell genes expressed in F9 cell line.**

J. Kwon<sup>1</sup>, C. Cho<sup>1</sup>; <sup>1</sup>Life science, Gwangju Institute of Science and Technology, Gwangju, Korea

Mammalian spermatogenesis is a complex process involving the differentiation of spermatogonial stem cells into spermatozoa. During this process, spermatogonia-, spermatocytes-, and spermatid-specific genes are expressed in germ cells, following a precise spatial and temporal order. Because of the absence of permanent germ cell lines, the transcriptional and functional mechanisms have not been studied in depth for germ cell-specific genes. F9 cell line is a teratocarcinoma cell line, induced by ectopically implanting embryos into the testis. Several laboratories have used this cell line in promoter-report assays for germ cell-

specific genes. It is possible that F9 cell line can be used as a cell model for research of germ cell-specific gene expression. To identify germ cell genes expressed in F9 cell line, we used a microarray-based approach. We found that 1088 genes were co-expressed in male germ cells and F9 cells. The numbers of genes expressed in spermatogonia, spermatocytes and spermatid are 532, 353 and 203, respectively. To identify genes with testis-specific expression, we performed *in silico* analysis with the aid of UniGene database. Among 1088 genes, nine genes were predicted as testis-specific genes. We are performing further studies to validate testis-specific expression and stage-specific expression of those genes. We will investigate their promoter regions responsible for the testis- and germ cell-specific expression using F9 cell line.

#### Identification of a testis-specific KRAB gene in mice.

S. Jin<sup>1</sup>, C. Cho<sup>1</sup>; <sup>1</sup>Gwangju Institute of Science and Technology, Gwangju, Korea

C2H2 type-zinc fingers represent one of the largest families of transcription factor in mammals. One-third of them encode *Kruppel*-associated box (KRAB) domain which has a strong repressive activity in their N-terminal region. The KRAB domain is a conserved domain spanning about 40~75 amino acids. Structurally, it is composed of two subdomains, A and B boxes. KRAB containing zinc finger (KZNF) genes reside in large familial clusters, and many of them contain substantial numbers of lineage-specific genes. Most KZNF genes remain completely uncharacterized. To identify and characterize KZNF genes in the mouse genome, we performed *in silico* analysis and identified 191 KZNF genes. Based on tissue specificity, we focused to Mm.159188 gene which showed high specificity in testis. The Mm.159188 gene, also named as zinc finger protein 819 (Zfp819), consists of the KRAB domain and 14 zinc fingers. Tissue distribution analysis showed that the Mm.159188 gene is specifically transcribed in testis. Subcellular localization analysis revealed that GFP tagged-Mm.159188 protein is located in nucleus in NIH3T3 cells. Luciferase assay showed that the Mm.159188 has a repressive activity in transcription. Microarray analysis of cells overexpressing Mm.159188 identified 95 genes modulated more than 1.3-fold in expression level. Among them, 49 genes were down-regulated. Future analysis of these genes will elucidate the functional importance of the Mm.159188 gene in male germ cell development.

#### Molecular cell biology of spermatid coiling and release in *Drosophila melanogaster*.

P. K. Dubey<sup>1</sup>, K. Ray<sup>1</sup>; <sup>1</sup>Department of Biological sciences, Tata Institute of Fundamental Research, Mumbai, India

Spermatogenesis in *Drosophila* testis takes place within an enclosure formed by two somatic-origin cyst cells. During the final stages, mature spermatids coil up inside the cyst enclosure at the base of testis, and subsequently, they are released into the testis lumen. This process is known as spermiation. Till date, very few attempts were made to understand how the seemingly mature sperm, trapped in the cyst cell enclosure, come out. Earlier studies hypothesized that the spermatids would pass through head cyst cell and terminal epithelium interface during the release process. We observed that mature spermatids are, however, pulled from the head cyst cells before passaging through the sperm roller into the seminal vesicle, in live testis preparations. The process shares similarity with spermatid-release from Sertoli cells in mammalian testis. In addition, a directed screen using protein-trap lines, for their localization during late stages of spermatogenesis, helped to identify dynamic, Disc large (*Dlg1*)-enriched structures, containing other septate junction markers, around the elongated and coiled spermatids. Disruption of these junctions, by *Dlg1* knockdown in the cyst cells, caused

premature spermatid release, suggesting an essential role of septate junctions in regulating spermiation. These results will help to elucidate the molecular cell biology of sperm maturation and release in *Drosophila*, and identify its parallels in mammalian testes.

**The protein prenylation alteration in Sertoli cells is associated with adult infertility resulted from childhood Mumps infection.**

X. X. Wang<sup>1</sup>, B. Xue<sup>1</sup>, H. Tang<sup>2</sup>, X. Gao<sup>3</sup>, J. C. Li<sup>1</sup>; <sup>1</sup>MOE Key Laboratory of Model Animals for Disease Study, Model Animal Research Center and the School of Medicine, Nanjing University, Nanjing, China, <sup>2</sup>Institute of Biophysics, Chinese Academy of Sciences, Beijing, China, <sup>3</sup>MOE Key Laboratory of Model Animals for Disease Study, Model Animal Research Center, Nanjing University, Nanjing, China

**Abstract;** Mumps commonly affects children aged 5-9 years, often leading to mumps orchitis and resulting in permanent adult sterility in rare cases. However, the etiology of this long-term effect remains unclear. Mumps orchitis results in progressive degeneration of seminiferous epithelium and sometimes leads to Sertoli cell-only syndrome. Thus the left Sertoli cells may be critical to spermatogenesis recovery after orchitis healing. We found that the protein prenylation alteration in Sertoli cells during childhood might determine adulthood sterility. Mumps infection during childhood decreases the expression of geranylgeranyl diphosphate synthase 1 (GGPPS) in human testes. When we altered farnesylation/geranylgeranylation balance by specifically deleting GGPPS gene in Sertoli cell, Sertoli cell itself remained intact, while adjacent spermatogonium significantly decreased after the 5th postnatal day. The proinflammatory signaling pathways MAPK and NF- $\kappa$ B were constitutively activated because the farnesylation of H-Ras was enhanced. GGPPS<sup>-/-</sup> Sertoli cells synthesize an array of cytokines to stimulate spermatogonia apoptosis and chemokines to induce macrophage invasion into seminiferous tubules because the neonatal testes of mice had no BTB. Invaded macrophages further blocked spermatogonia development, thus resulting in a long-term effect on adult infertility. Our results suggest a novel mechanism by which mumps viral infection during human childhood results in adult infertility.

**Conclusions:** In summary, inactivating GGPPS in testicular Sertoli cell resulted in sustained activation of H-RAS proteins and spontaneous hyper-inflammation response in the early stage of testis development when there was no BTB formation between Sertoli cells of mice. Our results indicated that the protein prenylation in Sertoli cell was critical to regulate orchitis before puberty. This phenotype can mimic the assault against Sertoli cell during human childhood like mumps infection that would result in adulthood infertility.

**Relationship of testicular androgen receptor protein expression with in vitro fertilizability of epididymal sperm in mice.**

O. Suzuki<sup>1</sup>, M. Koura<sup>1</sup>, Y. Noguchi<sup>1</sup>, K. Uchio-Yamada<sup>1</sup>, J. Matsuda<sup>1</sup>; <sup>1</sup>Lab. Animal Models for Human Diseases, Natl Inst Biomed Innovation, Ibaraki, Japan

Strain differences in in vitro fertilizability still constitute a serious problem in mouse reproduction. We previously reported (Kawai et al., J Reprod Dev 52:561-568) that the in vitro fertilizability of sperm in five strains (mean $\pm$ SEM, n=5) was 31.3 $\pm$ 4.9%, 29.5 $\pm$ 3.2%, 47.8 $\pm$ 3.3%, 68.9 $\pm$ 3.8%, and 97.4 $\pm$ 4.3% in 129X1, C57BL/6, C3H, BALB/c (n=10), and DBA/2, respectively. To elucidate the molecular mechanism of strain difference in the in vitro fertilizability of mouse sperm, we examined the androgen receptor (AR) protein expression in testes of the five mouse strains.

Testes of five males per strain at 12 weeks of age were collected. Proteins from the testes were extracted using ReadyPrep protein extraction kit for Total Proteins (Bio-Rad). Quantitative Western blotting (QWB) using testicular protein extracts was conducted with anti-AR antibodies (Millipore, rabbit) and antibodies against glyceraldehyde-3-phosphate dehydrogenase (GAPDH, Millipore, mouse) as an internal control. Antibody-reacted bands were visualized with corresponding peroxidase-conjugated secondary antibodies (anti-Rabbit and anti-mouse IgG; Jackson ImmunoResearch) and chemiluminescent reagent (Pierce). Band intensities were quantified after image captures by a CCD-camera (LAS-3000, Fuji Film). AR protein expressions were obtained as AR/GAPDH ratios and statistically compared among strains by Kruskal-Wallis one way analysis of variance (ANOVA) on ranks (SigmaPlot 12, Systat software) because normality test (Shapiro-Wilk) was OK but equal equivalence test (Levene) failed. QWB showed significant strain difference in the AR protein expression ( $n=5$  per strain;  $p<0.05$ ). The expressions were  $0.498\pm 0.081$ ,  $0.526\pm 0.042$ ,  $0.834\pm 0.078$ ,  $0.950\pm 0.164$ ,  $1.356\pm 0.160$  in 129X1, C57BL/6, C3H, BALB/c, and DBA/2, respectively (Arbitrary units; mean $\pm$ SEM). Pairwise comparisons by Tukey test indicated significant differences ( $p<0.05$ ) between 129X1 and DBA/2, and between C57BL/6 and DBA/2. Linear regression analysis by ANOVA with average values between AR expression and in vitro fertilizability (SigmaPlot) showed significant association ( $p=0.002$ ) with  $R^2=0.974$ , suggesting that the differential AR expression in testes might cause strain difference in the in vitro fertilizability.

1570

#### Oocyte Growth Depends on Phosphorylation of Specific Serine Residues in the C-terminal Cytoplasmic Tail of Connexin43.

P. W. Dyce<sup>1,2</sup>, R. P. Norris<sup>3</sup>, P. D. Lampe<sup>3</sup>, G. M. Kidder<sup>1,2</sup>; <sup>1</sup>Physiology and Pharmacology, Western University, London, ON, Canada, <sup>2</sup>Children's Health Research Institute, London, ON, Canada, <sup>3</sup>Fred Hutchinson Cancer Research Center, Seattle, WA

Connexin43 (CX43) forms gap junction channels that metabolically couple the granulosa cells of developing ovarian follicles. Research with knockout mice has demonstrated a requirement for this connexin in supporting follicle and oocyte growth: CX43 null mutant follicles fail to develop beyond the primary stage on the C57BL/6 background due to failure of the granulosa cells to proliferate. We have used the CX43 null mutant mouse line and the recombinant-reaggregated ovary technique to examine the importance of specific CX43 phosphorylation sites in supporting oocyte growth. Serines at 255, 262, 279 and 282 are MAPK family substrates that become phosphorylated in response to EGF and other growth factors, causing a decrease in coupling levels. Mutant forms of CX43 were constructed with these serines replaced with amino acids that cannot be phosphorylated. These mutants, singly and in combination, were retrovirally transduced into CX43 null granulosa cells and combined with wildtype oocytes to make recombinant ovaries. The ovaries were grafted under the kidney capsules of immunocompromised female mice permitting follicle growth in vivo. Oocyte growth was retarded when the empty vector was introduced to CX43 null granulosa cells compared to granulosa cells infected with the CX43 wildtype (WT) control ( $35.47\pm 1.12$   $\mu\text{m}$  and  $61.34\pm 1.47$   $\mu\text{m}$  diameter respectively). CX43 with a single serine to alanine mutation at residue 255, or with a single serine to aspartic acid mutation at either residue 255 or 262, were able to rescue the null phenotype, restoring complete oocyte growth ( $60.43\pm 1.69$   $\mu\text{m}$ ,  $60.96\pm 1.22$   $\mu\text{m}$ , and  $62.11\pm 1.18$   $\mu\text{m}$  respectively). In contrast, CX43 with serine to alanine mutations at either residue 279 or 282 failed to permit a complete rescue, with follicle development largely limited to the early secondary stage and oocytes remaining significantly smaller than those in WT CX43 controls ( $34.84\pm 1.20$   $\mu\text{m}$  and  $43.49\pm 1.74$   $\mu\text{m}$  respectively). Mutating all four residues from serine to alanine caused complete arrest of folliculogenesis and retardation of oocyte growth in the context of our system ( $47.05\pm 1.63$   $\mu\text{m}$ ). Immunofluorescence analysis revealed that the mutant

molecules failing to rescue folliculogenesis were largely confined to intracellular sites, with few gap junctions visible. Using an *in vitro* EdU proliferation assay, we observed a decrease in proliferation in granulosa cells containing the mutated 279 and 282 construct compared to those receiving a non-mutated CX43 construct. These results indicate that CX43 phosphorylation is regulated by MAPK in granulosa cells and that this regulation is essential for supporting oocyte growth. The authors acknowledge Dan Li and Kevin J. Barr for technical assistance and the Canadian Institutes of Health Research and U.S. National Institutes of Health for funding.

**Interactions of 14-3-3 (YWHA) protein isoforms with CDC25B phosphatase in mouse oocytes.**

S. De<sup>1</sup>, A. Reese<sup>1</sup>, D. Kline<sup>1</sup>; <sup>1</sup>Biological Sciences, Kent State University, Kent, OH

Immature mammalian oocytes are arrested at prophase I of meiosis by an inhibitory phosphorylation on Cyclin-Dependent Kinase I (CDK1). Release from this meiotic arrest is dependent on dephosphorylation of CDK1 by M-phase inducer phosphatase 2 (CDC25B). Evidence suggests that phosphorylated CDC25B is bound to 14-3-3 (YWHA) proteins in the cytoplasm and rendered inactive. We previously reported expression of all seven mammalian isoforms of 14-3-3 in mouse oocytes and eggs. To examine the interactions of 14-3-3 isoforms with CDC25B in oocytes and eggs, we performed an *in situ* Proximity Ligation Assay (PLA; Duolink in cell Co-IP, Olink Bioscience) that can detect protein-protein interactions at the single molecule level and allows visualization of the actual intracellular sites of the interactions. We observed prominent interaction of all seven 14-3-3 isoforms with CDC25B throughout cytoplasm and nuclei of mouse oocytes, along with reduced interactions for each individual isoform in eggs compared to oocytes. Co-immunoprecipitation studies with extracts of mouse oocytes also demonstrated interaction of CDC25B with six 14-3-3 isoforms. These results suggest that any of the 14-3-3 isoforms may have the potential to hold CDC25B inactive in oocytes to maintain the meiotic arrest. In preliminary experiments to explore if interactions of 14-3-3 with other proteins are important for maintaining meiosis I arrest, we microinjected oocytes with 0.5µg/µL R18, a synthetic non-isoform specific 14-3-3-blocking peptide. Injected oocytes were incubated overnight in media containing a threshold concentration of dibutyryl cAMP (0.05mg/mL) which normally holds oocytes arrested through activation of Protein Kinase A (PKA) and phosphorylation of CDC25B and CDK1. We observed a marked increase in germinal vesicle breakdown (GVBD), compared to control oocytes. To investigate which specific isoform(s) of 14-3-3 is/are responsible for maintaining the meiotic arrest, we reduced the synthesis of each 14-3-3 isoform in mouse oocytes by intracytoplasmic microinjection of 0.1mM translation-blocking morpholino oligonucleotide against the corresponding isoform mRNA. Injected oocytes were held arrested at prophase I for 24 hours, and then incubated overnight in media containing the threshold concentration of dbcAMP. GVBD was observed in 70% of oocytes microinjected with morpholino against 14-3-3 eta, despite the presence of dbcAMP. Injection of morpholinos targeting other 14-3-3 isoforms caused little or no GVBD. Thus, reduction in 14-3-3 eta/CDC25B interaction releases the mouse oocyte from meiotic arrest. These results suggest that, while all 14-3-3 isoforms interact with CDC25B in mouse oocytes, 14-3-3 eta is essential for maintaining the prophase I meiotic arrest.

## Embryogenesis

1572

### eIF3m stabilizes the eIF3 complex and is essential for embryonic development and tissue homeostasis.

L. Zeng<sup>1</sup>, F. Wang<sup>1</sup>, Y. Wan<sup>1</sup>, X. Zhu<sup>1</sup>; <sup>1</sup>Chinese Academy of Sciences, Shanghai Inst Biochemistry/Cell Biology, Shanghai, China

eIF3, the largest eukaryotic initiation factor composed of approximately 13 subunits, plays a key role in protein biosynthesis and cell proliferation. How the different subunits contribute to its structural integrity and functions, however, is not fully understood. Here we show that eIF3m, a non-core subunit of eIF3 also known as GA17, is essential for mouse embryonic development and tissue functions. eIF3m null embryos were lethal at peri-implantation stage. The heterozygotes were normal, except for their diminished body weight. Compound heterozygotes or embryos with eIF3m deficiency in adipose tissue and the central nervous system were lethal at early embryonic stages as well. Acute ablation of eIF3m in the liver of adult mice led to rapidly decreased body weight and death in a week, correlated with severe decline of protein biogenesis. Its acute ablation in K-ras-expressing lung cells markedly repressed the K-ras-induced cancer formation in the mouse lung. Molecular analysis revealed that the eIF3m deficiency significantly impaired integrity of the eIF3 complex. Two of the subunits, to which eIF3m directly bound, were destabilized. Therefore, eIF3m is required for the structural integrity and the translation initiation functions of eIF3 fatal to the maintenance of cell viability.

1573

### The transcriptional co-factor Jab1 is essential for early mouse limb development *in vivo*.

L. Bashur<sup>1</sup>, D. Chen<sup>1</sup>, R. Pard<sup>2</sup>, S. Murakami<sup>1</sup>, G. Zhou<sup>1</sup>; <sup>1</sup>Orthopaedics, Case Western Reserve University, Cleveland, OH, <sup>2</sup>San Raffaele University, School of Medicine and Scientific Institute San Raffaele, Milano, Italy

The transcriptional cofactor Jab1 controls cell proliferation, apoptosis, and differentiation in many developmental processes by regulating the activity of numerous transcription factors. However, the physiological role of Jab1 in skeletal development is still poorly understood. We previously reported that the specific deletion of Jab1 in differentiating chondrocytes in mice leads to neonatal lethal chondrodysplasia with severe dwarfism. Jab1 mutant chondrocytes exhibited increased apoptosis and accelerated chondrocyte hypertrophy. Notably, there was a heightened expression of BMP signaling components and targets in Jab1 mutant chondrocytes, suggesting that Jab1 is a novel inhibitor of BMP signaling in differentiating chondrocytes *in vivo*. In this study, to determine the function of Jab1 in even earlier osteochondro progenitor cells (OPCs), we bred *Jab1<sup>fllox/fllox</sup>* mice with *Prx1-Cre* transgenes to delete *Jab1* specifically in limb buds. The *Jab1<sup>fllox/fllox</sup>; Prx1-Cre (cKO)* mutant mice displayed drastically shortened limbs starting at E13.5, strikingly mirroring the human skeletal disorder phocomelia. Phocomelia, a birth defect of severe limb truncation, is predominantly caused by the use of thalidomide, a potent teratogen, during early pregnancy. Children with such conditions are still being born today worldwide, especially in developing countries. Furthermore, thalidomide is being used to treat multiple myeloma, Crohn's disease, AIDS, and some cancers in the United States these days. Thus, even under strict guidelines, the thalidomide-induced phocomelia is still a real threat today. Recent studies in chicken models suggest that the etiology of phocomelia may lie in a defect in the survival and differentiation of OPCs. The molecular basis of phocomelia, however, is still poorly understood and the mouse model for this disease is also very much lacking. Thus,

the *Jab1 cKO* mice can serve as a novel model for phocomelia study. Indeed, the *Jab1 cKO* mutant limbs exhibited drastically reduced numbers of hypertrophic chondrocytes, disorganized chondrocyte columns, delayed primary ossification center formation and complete absence of secondary ossification center, and increased apoptosis during embryonic development. To determine the underlying mechanism for the severe short-limb defect in the *Jab1 cKO* mutants, we used a micromass culture of E11.5 *Jab1* mutant and wild-type limb mesenchyme cells to study chondrogenesis *ex vivo*. Alcian blue staining showed significantly decreased chondrogenesis in *Jab1* mutant cultures. Real time RT-PCR confirmed that the expression of chondrocyte differentiation markers, including *Sox9* and *Col2a1*, were significantly decreased in *Jab1* mutants. Western blot analysis indicated that FGF and BMP signalings were altered in *Jab1 cKO* mutants, suggesting that *Jab1* affects complex developmental cues during early limb development. Additionally, the deletion of *Jab1* in primary mouse osteoblastic precursors with *Ade-Cre* abolished overt osteoblast differentiation *ex vivo*. In conclusion, our study demonstrates that *Jab1* is a novel, essential regulator of early mouse limb development *in vivo* and the *Jab1 cKO* mutant mice in our study can serve as a powerful model for the development of novel therapeutics for phocomelia and other severe limb reduction defects in the future.

1574

**Pericentrin null mice exhibit features of primordial dwarfism, defects in centrosome organization and aberrant stem cell division.**

G. Zheng<sup>1</sup>, C-T. Chen<sup>1</sup>, S. Redick<sup>1</sup>, Q. Yu<sup>2</sup>, Y. Guo<sup>3</sup>, S. Akbarian<sup>3</sup>, C. Wise<sup>4</sup>, A. Jackson<sup>5</sup>, C. Lo<sup>2</sup>, S. Doxsey<sup>1</sup>; <sup>1</sup>Program in Molecular Medicine, Univ Mass Medical School, Worcester, MA, <sup>2</sup>Dept. Developmental Biology, Univ Pittsburgh, Pittsburgh, PA, <sup>3</sup>Dept. Neuroscience, Univ Mass Medical School, Worcester, MA, <sup>4</sup>Texas Scottish Rite Hospital for Children, Dallas, TX, <sup>5</sup>MRC, Edinburgh, Scotland

Majewski Osteodysplastic Primordial Dwarfism type II (MOPDII) is one of the primordial dwarfisms that are characterized by extreme intrauterine growth retardation that continues throughout adulthood. The etiology of MOPDII was recently linked to the centrosome gene pericentrin (PCNT) but the underlying mechanisms at cellular and molecular levels remain obscure. To address this, we developed PCNT-null mice that fully recapitulate major features of MOPDII, including small stature, microcephaly and cardiovascular defects. Cardiovascular defects include atrial and ventricular septal defects, mitral valve dysfunction, increased vascularization and hemorrhaging of brain vessels. At the cellular level, prominent phenotypes include supernumerary centrioles or centrosomes, and misoriented cell division plane in both stem and committed cells. The former could delay mitotic progression or cause mitotic catastrophe, and the later could account for premature differentiation divisions and/or mitotic exit *in vivo*. Both may contribute to the decrease in overall cell number and the smaller body size, as observed in humans. At the molecular level, PCNT deletion delocalizes a subset of centriole and centrosome proteins that is consistent with the cellular defects. We conclude that the disease phenotypes in both mice and humans harboring PCNT mutations can be attributed to compromised centrosomes. We propose that disrupted centrosomes, in turn, causes spindle disorganization and misoriented cell division, which contributes to primordial dwarfism.

1575

**The ciliary G protein-coupled receptor Gpr161 negatively regulates the sonic hedgehog pathway via cAMP signaling.**

S. Mukhopadhyay<sup>1</sup>, X. Wen<sup>1</sup>, N. Ratti<sup>1</sup>, A. Loktev<sup>1</sup>, L. Rangell<sup>1</sup>, S. J. Scales<sup>1</sup>, P. K. Jackson<sup>1</sup>;  
<sup>1</sup>Genentech, So San Francisco, CA

Graded signals, referred to as morphogens, provide positional information for organizing developing tissues; particularly, a gradient of Sonic Hedgehog (Shh) controls ventral patterning in the neural tube in vertebrates. The primary cilium is required for vertebrate Shh signaling. The intraflagellar transport (IFT) machinery is fundamental for assembly and maintenance of primary cilia. Thus, mutants encoding components of the IFT-B complex (implicated in anterograde IFT), as well as the IFT motors exhibit strongly decreased Shh signaling in the neural tube. Paradoxically, mutations in the ciliary IFT-A complex, which is implicated in retrograde IFT, cause increased Shh signaling. The opposing neural tube phenotypes of IFT-A from the other IFT mutants suggest that the IFT-A complex has functions in addition to its postulated role in retrograde IFT. Similar to the IFT-A mutants, mutations in the tubby-like protein *Tulp3*, also exhibit increased Shh signaling in the neural tube. We previously showed that the IFT-A complex binds to *Tulp3*, and recruits it to cilia. *Tulp3* in turn promotes trafficking of specific rhodopsin family G protein-coupled receptors (GPCRs) to cilia (Mukhopadhyay et al, *Genes Dev* 24, 2180-2193). The function of IFT-A/*Tulp3* in mediating GPCR trafficking to the cilia suggests the role of a novel GPCR in the Shh pathway. In order to identify GPCRs important in vertebrate Shh signaling, we performed a screen to identify candidate GPCRs that are ciliary and are expressed early during development. This led us to the discovery of an “orphan” GPCR, Gpr161 that is localized to the cilia. This receptor is expressed ubiquitously as early as E8.5, and is mostly concentrated in the developing nervous system in later stages. Furthermore, depletion of *Tulp3* and IFT-A prevents its ciliary localization. Most importantly, a null knockout mice model for this receptor results in embryonic lethality by E10.5 and phenocopies the *Tulp3*/IFT-A mutants by showing increased Shh signaling in the developing neural tube. These data suggest that Gpr161 functions as a negative regulator of the Shh pathway. The cAMP-activated protein kinase A (PKA) is pivotal in regulating the basal repression mechanism in Shh pathway by mediating the processing of Gli transcription factors into Gli repressors; however, the cAMP regulating pathways that mediate activation of PKA remain unknown. Interestingly, constitutive Gpr161 activity increases cAMP levels and represses Shh signaling by determining the processing of the Gli transcription factor Gli3 to its repressor form. Simultaneously, Shh signaling directs Gpr161 to be internalized from cilia preventing its activity. Thus, Gpr161 defines a new pathway coupling PKA activation to Shh signaling during neural tube morphogenesis.

1576

**Novel *Drosophila* long non-coding RNAs regulate transcription of the Hox gene *Sex combs reduced in cis and trans*.**

T. Pettini<sup>1</sup>, M. R. Ronshaugen<sup>1</sup>; <sup>1</sup>Faculty of Life Sciences, University of Manchester, Manchester, UK

Hox genes encode a conserved family of clustered transcription factors specifying segmental identity in all animals. The Hox intergenic regions exemplify a complex landscape containing many long range interactions between cis-regulatory domains and promoter elements that are responsible for establishing and maintaining proper Hox gene expression. Recently it has become clear that Hox cluster intergenic sequences exhibit extensive non-coding transcription, and that many of the classically defined ‘regulatory elements’ are themselves transcribed. Here,

we have identified and functionally characterized two new conserved ncRNAs in the fruit fly *Drosophila* upstream of the Hox gene *Sex combs reduced (Scr)*. Both ncRNAs are transcribed from genomic regions previously defined as 'Scr regulatory elements'. We use transgenic overexpression and knockdown to confirm that both ncRNA transcripts are required for proper activation of *Scr* expression and repression, via a 'tethered RNA' mechanism. Analysis of a naturally occurring GOF mutation establishes that ectopic transcription of the endogenous ncRNA is sufficient to activate *Scr* expression, and surprisingly that this ncRNA-mediated activation of *Scr* occurs in *trans*, between homologs. This work contributes to our mechanistic understanding of the role non-coding RNAs play in long range enhancer promoter interaction and transvection both within and between chromosomes.

1577

### **Lipid droplets control the maternal histone supply of *Drosophila* embryos.**

Z. Li<sup>1</sup>, K. Thiel<sup>2</sup>, P. J. Thul<sup>2,3</sup>, M. Beller<sup>2,3</sup>, R. Kühnlein<sup>4</sup>, M. A. Welte<sup>1</sup>; <sup>1</sup>Department of Biology, University of Rochester, Rochester, NY, <sup>2</sup>Department of Molecular Developmental Biology, Max Planck Institute for Biophysical Chemistry, Göttingen, Germany, <sup>3</sup>Institute for Mathematical Modeling of Biological Systems, Heinrich-Heine University, Düsseldorf, Germany, <sup>4</sup>Research Group Molecular Physiology, Max Planck Institute for Biophysical Chemistry, Göttingen, Germany

Histones are essential for chromatin packing, yet free histones not incorporated into chromatin are toxic. In most cells, multiple regulatory mechanisms prevent accumulation of excess histones; early *Drosophila* embryos, in contrast, contain a thousand-fold excess of histones over DNA. The function of these maternal histone deposits is unclear, in particular because these embryos also contain maternally provided histone messages. Excess histones H2A, H2B, and H2Av are bound to lipid droplets, ubiquitous fat storage organelles that are especially abundant in embryos. We had previously proposed that sequestration on lipid droplets allows safe transient storage of excess histones. The studies described here critically test this sequestration hypothesis. We find that histones are anchored to lipid droplets via the previously uncharacterized protein Jabba: Jabba localizes to droplets, co-immunoprecipitates with histones, and is necessary to recruit histones to droplets. *Jabba* mutants lack the maternal H2A, H2B, and H2Av deposits altogether; presumably, these excess histones are degraded unless sequestered on droplets. *Jabba* mutant embryos compensate for this histone deficit by translating maternal histone mRNAs. Mild disruption of histone expression has no discernable effect in a wild-type genetic background, but in the absence of Jabba results in defective mitoses and embryonic death. Our findings are of broad general importance because a growing number of proteins from other cellular compartments have been found to transiently associate with lipid droplets. Our studies provide the first insight into mechanism and functional relevance of such sequestration. We conclude that sequestration on lipid droplets allows embryos to build up extra-nuclear histones stores and provides histones for chromatin assembly during times of high demand. This work demonstrates a novel function of lipid droplets for development, as storage sites for unstable or detrimental proteins.

**Plasma membrane partitioning of syncytial blastoderm into individual cells is critical for tissue invagination during *Drosophila* ventral furrow formation.**

B. He<sup>1</sup>, O. Polyakov<sup>2</sup>, K. Doubrovinski<sup>1</sup>, E. Wieschaus<sup>1,3</sup>; <sup>1</sup>Department of Molecular Biology, Princeton University, Princeton, NJ, <sup>2</sup>Department of Physics, Princeton University, Princeton, NJ, <sup>3</sup>HHMI, Princeton, NJ

Epithelial morphogenesis is a fundamental mechanical process that generates changes in shape and motility utilizing the response of biomaterials to cellular forces. During *Drosophila* gastrulation, an apical actomyosin contractile network powers the internalization of mesoderm precursor cells to form a ventral furrow (VF) in the epithelial monolayer. In this process, the ventral cells first constrict their apex and elongate along the apical-basal axis, then are rapidly internalized into the embryo as they return back to their original length. It remains unclear how apically generated forces are transmitted across the entire apical-basal axis and how cells transition from lengthening to shortening to internalize VF. Here we apply particle tracking microrheology with injected fluorescent micro-beads to measure the movement of cytoplasm and plasma membrane within individual cells undergoing VF formation. We find that during the lengthening phase the apical cytoplasm responds as a viscous fluid to apical constriction, gradually elongating along the apical-basal direction, and thus accounting for much of the lengthening observed in the cell. Within a cell, the nucleus and the basal cytoplasm are displaced basally with no apparent mixing between compartments. Surprisingly, beads bound to the lateral plasma membrane showed a pattern of basal movement very similar to that of beads in the cytoplasm, as if the lateral membrane is flexible to apical-basal stretching and passively follows cytoplasm during lengthening. To address the role of the lateral membrane in VF formation, we generated mutant embryos that do not form cells prior to gastrulation, while the dorsal-ventral patterning, the developmental timing of gastrulation, and the apical myosin activity remain intact. In such “acellular” embryos, the movements of the cytoplasm and nuclei during the “lengthening phase” resemble those in wild type; however, the “shortening phase” is absent and the ventral tissue fails to internalize. We propose that the lengthening and shortening phases of VF formation have distinct requirements for the basolateral plasma membrane. While the viscous cytoplasm is sufficient to transmit force across a distance to drive cell elongation without the basolateral membrane, the membrane partition of common cytoplasm into individual cells is critical for shortening and tissue invagination.

**The role of miR-206 in *Xenopus laevis* somitogenesis.**

J. Ramirez<sup>1</sup>, H. Martinez<sup>1</sup>, T. Rosing<sup>1</sup>, D. Saw<sup>1</sup>, P. Saraf<sup>1</sup>, C. Nave<sup>1</sup>, J. Wright<sup>1</sup>, C. Domingo<sup>1</sup>; <sup>1</sup>Biology, San Francisco State University, San Francisco, CA

MicroRNAs (miRNAs) are highly conserved small non-coding RNA molecules that regulate gene expression post-transcriptionally in multicellular organisms. Each miRNA has a distinct and specific expression pattern and can target multiple messenger RNAs. miR-206 is part of the muscle-specific family of miRNAs (myomiRs) but it is the only miRNA expressed in skeletal muscle. Unlike other myomiRs, miR-206 is found exclusively in vertebrates and recent work has linked miR-206 to several diseases including muscle dystrophy. Here, we have characterized the importance of miR-206 in muscle formation using *Xenopus laevis* embryos. Similar to other studies, our *in situ* hybridization analysis shows that miR206 is found exclusively in muscle. Expression analysis using qRT-PCR shows that a morpholino directed against the mature form of miR-206 downregulates its expression without significantly affecting the expression of another myomiR, miR-133b. Embryos lacking miR-206 show abnormal muscle formation and an abnormal gap between the somites and notochord. Scanning electron microscopy results show

that this abnormal gap is comprised of extracellular matrix (ECM). Expression analysis of several ECM components surrounding the notochord and somites reveal their abnormal distribution during somite formation in miR-206 morphants. We hypothesize that the main role of miR-206 in *Xenopus laevis* is to regulate the deposition of matrix molecules during somite boundary formation. The abnormal formation of these intersegmental boundaries then interferes with the ability of muscle fibers to adapt the normal parallel alignment observed in wild-type embryos.

#### **Centrosome positioning via dynein-powered intracellular cargo transport.**

R. A. Longoria<sup>1</sup>, G. T. Shubeita<sup>1</sup>; <sup>1</sup>Center for Nonlinear Dynamics and Department of Physics, Institute for Cellular and Molecular Biology, The University of Texas at Austin, Austin, TX

Correct positioning of the centrosome is critical for the survival of the cell. For small and medium-sized cells, the force required to move the centrosome can arise from either microtubule pushing on the cortex, or cortically-attached dynein pulling on microtubules. However, in large cells, such as the fertilized *Xenopus laevis* embryo, where microtubules are too long to support pushing forces or they do not reach all boundaries before centrosome centering begins, a different force-generating mechanism must exist. Here, we present a centrosome positioning model in which the cytosolic drag experienced by cargos hauled by cytoplasmic dynein on the sperm aster microtubules can move the centrosome towards the cell's center. We find that small, fast cargos (diameter  $\sim 100\text{nm}$ , cargo velocity  $\sim 2\mu\text{m/s}$ ) are sufficient to move the centrosome in the geometry of the *Xenopus laevis* embryo within the experimentally observed length and time scales.

#### **Regulation of TRPM7 By 80K-H and Wnt Signaling During Early Embryonic Development.**

J. D. Overton<sup>1</sup>, C. Mezzacappa<sup>2</sup>, Y. Komiyama<sup>2</sup>, K. Nama<sup>2</sup>, R. Habas<sup>2</sup>, L. Runnels<sup>1</sup>; <sup>1</sup>Department of Pharmacology, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ, <sup>2</sup>Department of Biology, Temple University, Philadelphia, PA

TRPM7 is a bifunctional protein that contains both ion channel and kinase domains. TRPM7's channel is permeable to  $\text{Mg}^{2+}$ ,  $\text{Ca}^{2+}$ , and other divalent cations such as  $\text{Zn}^{2+}$ , while the function of the kinase has remained relatively elusive. Our studies have identified TRPM7 as an essential component of the non-canonical Wnt pathway regulating gastrulation, a pivotal process during early embryonic life that executes the emergence of the body plan and closure of the neural tube. The mechanism by which TRPM7 is regulated during early development is unknown. To gain insight into how the channel-kinase is controlled we conducted a yeast two hybrid screen using the COOH-terminus of TRPM7, which revealed 80K-H as a potential binding partner. Pulldown purification assays and immunoprecipitation experiments confirmed 80K-H as a bona fide TRPM7-interacting protein. Surprisingly, the strength of the interaction between 80K-H and TRPM7 was dependent upon growth factor stimulation. 80K-H has previously been shown to be involved in regulating TRPP2 protein expression. Our studies revealed that knockdown of 80K-H decreased TRPM7 protein expression, which can be prevented by application of MG132, a proteasome inhibitor. Depletion of 80K-H from *Xenopus laevis* embryos produced a gastrulation defect, which can be made more severe by the simultaneous depletion of 80K-H and TRPM7. These results uncover a novel role for 80K-H in early development and suggest a model in which 80K-H regulates TRPM7 during early embryonic development by regulating its expression level.

**Two isoforms of protein phosphatase 1 beta assemble the zebrafish myosin phosphatase.**

*V. Jayashankar<sup>1</sup>, D. C. Weiser<sup>1</sup>; <sup>1</sup>Biological Sciences, University of the Pacific, Stockton, CA*

The myosin phosphatase is a highly conserved regulator of actomyosin contractility. Zebrafish has emerged as an ideal model system to study the *in vivo* role of myosin phosphatase in controlling cell contractility, cell movement and epithelial biology. Most work in zebrafish has focused on the regulatory subunit of the myosin phosphatase called Mypt1. In this work, we examined the critical role of Protein Phosphatase 1, PP1, the catalytic subunit of the myosin phosphatase. We observed that two isoforms of PP1 $\beta$ , called PP1 Ba and PP1 Bb, are both expressed ubiquitously during early zebrafish development. Furthermore, we found that both isoforms can interact with Mypt1 and assemble an active myosin phosphatase complex *in vitro*. Expression of this complex results in dephosphorylation of the myosin regulatory light chain and large scale rearrangements of the actin cytoskeleton in cell culture. Morpholino antisense knockdown of either isoform results in a dose-dependent defect in morphogenetic cell movements during zebrafish gastrulation. Furthermore, co-injection of mRNA of either isoform can rescue the gastrulation phenotype indicating functional redundancy. Taken together, this work provides evidence that zebrafish express two isoforms of PP1 $\beta$  that both assemble the myosin phosphatase and are required in a dose-dependent manner to regulate morphogenetic cell movements during gastrulation. This work will provide valuable insight and tools for the study of the role of actomyosin contractility in epithelial biology, neural development and morphogenetic cell movement.

**Characterization of the mitochondrial transport complex in developing zebrafish.**

*B. M. Hollister<sup>1</sup>, E. Nickoloff<sup>1</sup>, D. C. Weiser<sup>2</sup>, S. Walsh<sup>1</sup>; <sup>1</sup>Department of Biology, Rollins College, Winter Park, FL, <sup>2</sup>Department of Biological Sciences, University of the Pacific, Stockton, CA*

Inside a cell, mitochondria exhibit dynamic locomotion and spatial rearrangement. This movement is necessary for a cell to maintain basic metabolic functions, and disruption of this motility often results in cell death. Miro is a mitochondrial outer membrane Rho GTPase essential for mitochondrial movement in diverse systems. In fruit flies and mammals, Miro interacts with a protein called Milton/Trak to link mitochondria to kinesin (KIF5) for trafficking along microtubules. We sought to characterize the Miro and Trak protein families in zebrafish. We confirmed that, like human Miro, the zebrafish Miro proteins (Rhot1a, Rhot1b, and Rhot2) localized to mitochondria in mammalian tissue culture cells by both biochemical fractionation and immunofluorescent colocalization. In addition, using whole mount *in situ* hybridization, we observed ubiquitous expression of all three mRNAs throughout development. By microinjecting three antisense morpholino oligonucleotides targeted to each of the mRNAs, we knocked down all three proteins in developing zebrafish embryos. The triple morphants demonstrated a dose-dependent defect in posterior body-axis elongation, while a single knockdown of each protein at the same dose produced no effect. At higher doses of a triple knockdown, embryos failed in gastrulation and died during epiboly. We are currently working to rescue the morphants with human Miro mRNA. Furthermore, in contrast to the two human Trak proteins, zebrafish Trak2, but not Trak1, localized to mitochondria when overexpressed in COS-7 cells. Given the low amino acid conservation between these two proteins, it is not surprising that these two zebrafish

proteins might have different cellular functions. Taken altogether, this research will lay the foundation for studies in the role of mitochondrial motility during vertebrate development.

**Optimizing Conditions for Preserving Sea Urchin Eggs.**

*N. Ehlert<sup>1</sup>, H. Musaev<sup>1</sup>, A. Azhar<sup>1</sup>, C. Priano<sup>1</sup>, L. Jayant<sup>1</sup>; <sup>1</sup>Science, Borough of Manhattan Community College, New York, NY*

This study is to optimize conditions for maintaining viable sea urchins eggs in the laboratory for extended periods of time so that they are more readily useful for research and for classroom experiments. After spawning, sea urchin eggs have an average shelf life of 24 to 36 hours. Previously, we have shown that 0.3 mM of empty liposomes and liposomal glutathione (L-GSH) at a concentration of 1.08 mg/mL glutathione can preserve the integrity of spawned sea urchin eggs for up to seven days. In addition, eggs incubated in these agents could be fertilized by fresh sperm for up to 24 hours. Although both L GSH and empty liposomes were shown to maintain the integrity of the eggs, the liposome concentration and the type of liposomes in each case was not directly comparable. The aim of the experiments outlined here is to determine optimal conditions using L GSH and empty liposomes at uniform concentrations. We will use (1) custom prepared empty HSPC-chol liposomes (98-103 nm diameter) at 0.3 mM and (2) custom prepared liposomal glutathione (L GSH) with HSPC-chol liposomes (98-103 nm diameter) at 0.3 mM of liposomes with a concentration of 1.08 mg/mL of GSH. Using these agents for incubation, eggs will be observed and counted each day for the duration that they remain intact. Viability will be confirmed by observing the elevation of a fertilization membrane following exposure to live sperm. In a separate experiment, we will also determine optimal incubation temperature for extended preservation.

1585

**Examining Protist Infestation of Harvested Sea Urchin Eggs.**

*A. E. Gonzalez<sup>1</sup>, Y. Mariana<sup>1</sup>, C. Priano<sup>1</sup>, L. Jayant<sup>1</sup>; <sup>1</sup>Science, Borough of Manhattan Community College, New York, NY*

Without treatment, harvested sea urchin eggs have a poor shelf life of less than 36 hours during which they become heavily infested with protists. Previously, we have shown that sea urchin eggs incubated in the presence of liposomal glutathione (L-GSH) and empty liposomes remained intact for up to seven days and could be fertilized for up to 24 hours. In addition, these agents protected against infestation of the eggs by protists. Preliminary results indicated that there was an inverse relationship between the concentration of L GSH or liposomes and the number of protists observed. We are continuing to investigate the role of these agents in controlling protist infestation of harvested sea urchin eggs. We will monitor and quantitate protist appearance and survival rates in the presence of various concentrations of both L GSH and empty liposomes. In addition, we will examine whether the observed protists are endogenous to sea urchin stocks or appear later as contaminants. Finally, we will identify the type or types of salt water protists that are isolated from our sea urchin egg cultures.

### Construction of a ubiquilin-2 interaction network affected in amyotrophic lateral sclerosis.

*K. M. Gilpin<sup>1</sup>, L. Chang<sup>1</sup>, M. J. Monteiro<sup>1</sup>; <sup>1</sup>University of Maryland, Baltimore, MD*

Amyotrophic lateral sclerosis (ALS) is a rapidly progressive debilitating disease that affects one in every 50,000 people. Like other neurodegenerative diseases, the mechanisms that cause ALS remain unresolved. However, recent evidence suggests a possible common link between mutations in different genes and the neuropathology seen in the disease. One such connection is the finding that mutations in ubiquilin-2 (ubqln-2) and in other ALS susceptibility genes are linked with ubqln neuropathology. Yet the underlying mechanisms of how mutations in ubqln-2 or ubqln pathology contribute to ALS pathogenesis are unclear. To understand how ubqln proteins are involved in ALS we are constructing a map of ubqln-2-interacting proteins. Ubqln-2 is one of four ubqln proteins expressed in humans. The proteins are ~600 amino acids long and contain conserved UBL and UBA domains that flank a more variable central domain. Each ubqln protein is distinguished by containing unique short inserts. Interestingly, the missense mutations in ubqln-2 that cause ALS map to one of these inserts that is rich in PXX repeats. We used almost the entire central domain of ubqln-2 and the segment containing the PXX repeats as baits to screen a human brain cDNA library using the yeast two-hybrid system. Through this screen we recovered several candidates that interacted strongly with each of the baits. Among the interactors were factors that function in RNA splicing, protein folding, protein translation and cell stress. Several of these factors function in pathways that have been implicated in ALS. The clones are being screened to determine whether they interact differently with wild type and ALS mutant (P497H, P497S, P506T, P509S, and P525S) ubqln-2 baits. Clones that display altered binding to the ALS mutants are excellent candidates for genes that might be disrupted in ALS pathogenesis. We will report on these findings and on the further characterization of the clones.

### Validating ubiquilin-1 overexpression as a therapy for Huntington's disease.

*N. I. Safren<sup>1</sup>, A. El Ayad<sup>2</sup>, L. Chang<sup>1</sup>, D. F. Boehning<sup>2</sup>, M. J. Monteiro<sup>1</sup>; <sup>1</sup>University of Maryland, Baltimore, MD, <sup>2</sup>University of Texas Medical Branch, Galveston, TX*

Huntington's disease (HD) is a debilitating neurodegenerative disorder caused by a polyglutamine expansion in huntingtin (htt) protein. The mechanism(s) by which mutant htt proteins cause disease remains unresolved. However, recent therapeutic strategies have focused on ways to either silence or clear mutant huntingtin. Ubiquilin-1, one of four ubiquilin isoforms in humans, contains conserved N- and C-terminal UBL and UBA domains, which flank a longer central domain that differs among the ubiquilin isoforms. This structure facilitates the function of the protein as a shuttle factor, binding polyubiquitinated proteins and delivering them to the proteasome for degradation. Moreover, ubiquilin-1 has been implicated in both endoplasmic reticulum-associated degradation and autophagy. We previously demonstrated that overexpression of ubiquilin-1 in cell and *C. elegans* models of HD reduces huntingtin aggregates and toxicity. Importantly, we found that ubiquilin-1 overexpression selectively enhances the clearance of mutant htt protein without affecting normal htt protein. Two key questions need to be addressed in order to further validate ubiquilin-1 as a therapeutic target for HD. First, does overexpression of ubiquilin-1 prevent or delay neurodegeneration in mouse models of HD? Second, can factors be found to modulate ubiquilin-1 expression? Toward the first goal we have generated transgenic mice that overexpress human ubiquilin-1 driven by the

neuron specific Thy1.2 promoter. Transgene integration was verified via PCR and Southern blotting, and ubiquilin-1 protein overexpression through immunoblotting. Immunoblotting revealed that one of these lines overexpresses ubiquilin protein as much as 1.8 fold in brain lysates. Interestingly, we also observed significantly reduced ubiquilin-1 levels in brain lysates of R6/2 HD model mice, as well as colocalization of ubiquilin-1 with huntingtin aggregates. We therefore crossed our ubiquilin-1 transgenic line with R6/2 mice in order to assess whether we could restore ubiquilin-1 levels and potentially delay pathology in these mice. We will report of the assessment of the motor phenotype, neuropathology, and survival of ubiquilin-1-R6/2 double transgenic mice. In further attempts to manipulate ubiquilin expression, we are studying factors that regulate ubiquilin-1 expression using luciferase reporter constructs and real-time PCR. Initial findings indicate that ER-stressors potently upregulate ubiquilin-1. The regulation of ubiquilin-2 in which mutations were found to cause amyotrophic lateral sclerosis is also being examined.

### **Cross-Talk Between Proteasomes and Lysosomes Determines the Fate of Amyloid Peptides in Pancreatic Cells.**

A. M. Jeremic<sup>1</sup>, S. Trikha<sup>1</sup>; <sup>1</sup>*Biological Sciences, The George Washington University, Washington, DC*

Self-assembly of the human pancreatic hormone amylin into toxic oligomers and aggregates is linked to the dysfunction of islet beta-cells and pathogenesis of type-2 Diabetes Mellitus (T2DM). The other aggregation-prone peptide  $\beta$ -amyloid, previously linked to pathology of Alzheimer's disease, was recently found, together with amylin aggregates, in the extracellular plaques of human islets, suggesting a common etiology of the two amyloid diseases. However, the trafficking mechanism and identity of degradation compartments involved in the clearance of these two misfolded amyloid peptides, and their causal roles in islet amyloid formation and T2DM remain poorly understood. Hence, in the current study, we investigated amylin and  $\beta$ -amyloid trafficking and degradation pathways in pancreatic rat insulinoma (RIN-m5F) and human islet cells, and explored the causal connection between amyloid peptide turnover and toxicity in these cells. Confocal microscopy analysis of fluorescently-labeled amyloid peptides and organelle/ trafficking markers revealed a common trafficking itinerary for amylin and  $\beta$ -amyloid in pancreatic cells. Dominant negative (DN) clathrin (AP180c) and dynamin (Dyn1/2K44A) constructs or low temperature (+4° C) markedly inhibited ( $\geq 90\%$ ) internalization of both peptides and completely inhibited entry of other proteins such as cholera toxin (CTX) and transferrin (Trf), indicating endocytosis as major mechanism in amylin and  $\beta$ -amyloid uptake by cells. Amylin and  $\beta$ -amyloid co-trafficked with CTX but not with Trf to juxtannuclear compartments indicating possible association with Golgi and/or lysosomes. Supporting this finding, high colocalization between amyloid peptides and lysosomes and their partial colocalization with autophagosomes in RIN-m5F and human islet cells were detected. Although amyloid peptides and Trf uptakes require clathrin, amylin and  $\beta$ -amyloid were absent from Trf-labeled endosomes, suggesting little association of amyloid peptides with recycling compartment under control conditions. Thus, degrading compartments appear to be a final common destination for both peptides. Interestingly, significant colocalization between amyloid peptides and 20S proteasome subunit was demonstrated in our studies. Inhibition of proteasome function using specific proteasome inhibitor lactacystin increased co-localization between amylin and lysosomes. Similarly, inhibition of lysosome proteolytic function with pepstatin and ammonium-chloride re-directed amylin to the proteasome. Increased accumulation of amyloid peptides in culture and apoptosis was observed by western blot and ELISA following inhibition of amylin degradation in lysosomes or proteasomes. Thus, our

studies indicate that the evolutionarily conserved endocytotic pathway regulates turnover and toxicity of amyloid peptides in pancreatic cells via two distinct but closely interacting proteolytic compartments, proteasomes and autolysosomes.

1589

**Alternative nucleotides to rescue the function of disease-causing mutant septins.**

A. Weems<sup>1</sup>, C. Musselman<sup>2</sup>, C. Coughlan<sup>1</sup>, C. Johnson<sup>1</sup>, T. Kutateladze<sup>2</sup>, M. A. McMurray<sup>1</sup>;  
<sup>1</sup>Cell and Developmental Biology, University of Colorado Anschutz Medical Campus, Aurora, CO, <sup>2</sup>Pharmacology, University of Colorado Anschutz Medical Campus, Aurora, CO

Septins are a family of GTP-binding proteins that form cortical filamentous arrays in a wide variety of eukaryotic cell types and play diverse roles in processes such as cytokinesis and the establishment of cell polarity/morphogenesis. Mutation or misregulation of septin-encoding genes has been linked to a panoply of human diseases, including cancer, neurodegeneration, and male infertility. Septin proteins typically co-assemble into rod-shaped hetero-oligomeric complexes composed of two molecules of each of three or four distinct polypeptides. Septin rods polymerize into filaments and associate with the plasma membrane and/or other elements of the cytoskeleton to regulate vesicle trafficking and membrane dynamics by functioning as scaffolds and/or membrane diffusion barriers. Despite significant progress in the last few years, how septin ultrastructure relates to septin function remains largely unknown, a problem whose importance has been highlighted by the identification of disease-associated septin mutations that appear to target higher-order assembly properties.

For example, whereas male infertility has been experimentally induced in transgenic mice using deletion alleles of specific septin genes, all of the septin mutations identified in infertile men cause substitutions at specific residues predicted to make important contacts either with GTP bound in the nucleotide-binding pocket, or between septin subunits in the context of septin filaments. Thus, surprisingly, naturally-occurring disease-causing mutations are not null alleles, and instead resemble the original septin mutants identified in Lee Hartwell's pioneering cell division cycle screen of temperature-sensitive mutants in *Saccharomyces cerevisiae*, several of which have been sequenced and determined to carry single nucleotide-binding-pocket mutations. Indeed, we discovered that one of the infertility-causing mutations (SEPT12 Asp197Asn) is identical to a temperature-sensitivity-inducing mutation isolated in the Hartwell screen (Cdc10 Asp182Asn). In septins and many other GTP-binding proteins, the Asp in the position corresponding to SEPT12 Asp197 or Cdc10 Asp182 contacts the base of the bound nucleotide. Remarkably, for many such proteins (most famously EF-Tu) substitution of this residue to Asn switches the nucleotide-binding specificity from GTP to xanthosine triphosphate (XTP), a nucleotide that is not typically produced *in vivo*. Experimental manipulations providing an intracellular source of XTP were able to rescue function of one such mutant protein, the *Drosophila* P element transposase (PMID: 9250688). Nucleotide binding by septins plays important roles in the folding of septin proteins and their assembly into complexes and filaments, suggesting that the functional defects of GTP-binding-defective septins might be overcome if another nucleotide could occupy the mutant septin's pocket. Our studies indicate that additional mutant septins bind other alternative nucleotides, and that generating these nucleotides *in vivo* rescues function. Thus, we propose a novel approach to remedy the dysfunction of nucleotide-binding-pocket septin mutants and thereby treat disorders arising from such mutations.

1590

### **FKBP14 is an essential gene that regulates Presenilin protein and Notch signaling in *Drosophila* development.**

J. M. Bonner<sup>1,2</sup>, D. van de Hoef<sup>1</sup>, G. Boulianne<sup>1,2</sup>; <sup>1</sup>Developmental and Stem Cell Biology, The Hospital for Sick Children, Toronto, ON, Canada, <sup>2</sup>Molecular Genetics, University of Toronto, Toronto, ON, Canada

Presenilins were identified as causative factors in Familial Alzheimer's Disease and also play an essential role in Notch signalling during development. We previously identified FKBP14, a member of the family of FK506-binding proteins (FKBPs), as a modifier of *presenilin* in *Drosophila*. FKBPs are highly conserved peptidyl-prolyl cis-trans isomerases that play integral roles in protein folding, assembly and trafficking. Although FKBPs have been implicated in a broad range of biological processes, they are non-essential in yeast and their role in the development of multicellular organisms remains unclear. We show that FKBP14 is an essential gene in *Drosophila* and that loss of FKBP14 gives rise to specific defects in eye, bristle and wing development. FKBP14 mutants genetically interact with components of the Notch pathway, indicating that these phenotypes are associated, at least in part, with dysregulation of Notch signaling. We show that while Notch trafficking to the membrane is unaffected in FKBP14 mutants, levels of Notch target genes are reduced, suggesting that FKBP14 acts downstream of Notch activation at the membrane. Consistent with this model, we find that Presenilin protein levels are significantly reduced in FKBP14 null mutants. We also find evidence of critical, apparently Notch-independent roles for FKBP14, including a requirement in cell viability. Altogether, our data demonstrate that FKBP14 plays an essential role in development, one aspect of which includes regulating members of the Notch signaling pathway.

1591

### **Influence of Bag2 cochaperone overexpression on the hyperphosphorylation of Tau.**

K. L. Farizatto<sup>1</sup>, D. C. Carrettiero<sup>2</sup>, M. F. Ferrari<sup>1</sup>; <sup>1</sup>Fisiopatologia Experimental, Universidade de San Paulo, San Paulo, Brazil, <sup>2</sup>Biossistema, Universidade Federal do ABC, Santo Andre, Brazil

Introduction: Tau inclusions are classic hallmarks of neurodegenerative diseases, including Alzheimer's diseases. Impairment of degradation pathway, besides protein misfolding altogether contribute to deficit in cellular homeostasis, such as: molecules traffic disturbance and synaptic deficit. The Bag2 cochaperone participates of protein triage and clearance through ubiquitin-independent degradation pathways. The goal of this study was to analyze the effect of Bag-2 overexpression on the hyperphosphorylated Tau (p-Tau). Methods: All the procedures were performed in accordance with the Institutional Guidelines for Animal Experimentation (CEA/IB-USP protocol 136 /2011). Hippocampal cell cultures were made using one-day old Lewis rat. Cultures were exposed to either 0.3; 0.5 or 0.7nM of rotenone for 48h, followed by Bag-2 transfection. Western blotting technique was employed to determine the total Tau and p-Tau levels. Films were analyzed by ImageJ software. Results are shown as mean  $\pm$  standard error. Two-way ANOVA was used for statistical analysis. N=3. Results: Levels of p-Tau decreased in the presence of Bag-2 overexpression as compared with Bag-2 absence in control and rotenone groups; DMSO (75.17 $\pm$  1.167 vs 99.00 $\pm$ 0.3333), 0.3nM (50.33 $\pm$  0.6667 vs 92.83 $\pm$ 0.5000), 0.5nM (63.67 $\pm$  0.3333 vs 111.5 $\pm$ 0.5000) and 0.7nM (55.17 $\pm$  1.167 vs 121.5 $\pm$ 0.1667). Bag-2 overexpression also increased the levels of total Tau when compared to cells in the absence of Bag2 at control and rotenone group; DMSO (5026 $\pm$ 28.50 vs 8778 $\pm$ 43.00) and 0.5nM (5612  $\pm$ 80.00 vs 8660 $\pm$ 207.5). Total Tau did not change in cultures exposed to 0.3 and 0.7nM of rotenone after Bag-2 overexpression. Discussion: Our findings revealed that Bag-2 overexpression was able to decreased p-Tau levels. In addition, the cochaperone may

increase the total Tau levels. The results presented herein reveal new venues of investigation regarding Bag-2 role in the neurodegenerative diseases involving the formation of neurofibrillary tangles. Financial Support: CAPES, FAPESP and CNPq.

1592

**Neuroprotection Against Beta-Amyloid Mediated by a Targeted Antioxidant.**

*C. R. Giordano<sup>1</sup>, L. J. Terlecky<sup>1</sup>, J. I. Koepke<sup>2</sup>, M. Shen<sup>1</sup>, P. A. Walton<sup>3</sup>, S. R. Terlecky<sup>1</sup>;*

*<sup>1</sup>Pharmacology, Wayne State University School of Medicine, Detroit, MI, <sup>2</sup>Biology, Edison State College, Naples, FL, <sup>3</sup>Anatomy and Cell Biology, University of Western Ontario, London, ON, Canada*

Alzheimer's disease is a progressive neurodegenerative disorder characterized, at least in part, by accumulation of amyloid  $\beta$ -protein ( $A\beta$ ) in the brain.  $A\beta$ , produced by proteolytic cleavage from the  $\beta$ -amyloid precursor protein, either assembles extracellularly into fibrils or remains as soluble globular oligomers, both of which appear capable of initiating the cellular and molecular reactions associated with the disease. How, mechanistically, fibrillar or soluble oligomeric amyloid induces neuronal toxicity remains an area of intense investigation. Affected neurons certainly experience oxidative stress, generate a number of pro-inflammatory cytokines, and appear to activate the endoplasmic reticulum-mediated unfolded protein response. Synaptic circuitry is compromised and patients eventually suffer neurological impairment.

The goal of this work was to document the neuroprotective effects of a cell-penetrating enzyme with powerful antioxidant and anti-inflammatory properties. To accomplish this,  $\beta$ -amyloid fibrils or soluble monomers were generated in vitro and used to treat primary rat hippocampal/cortical neuron co-cultures. We show that  $A\beta$  induces production of reactive oxygen species (ROS) in these cells, and viability is compromised. We also demonstrate that our targeted antioxidant, catalase-SKL (CAT-SKL) dramatically protects cells, reducing ROS levels and enhancing their survival. We are currently examining the production of a number of inflammatory cytokines (e.g. IL-6, IL-8, and TNF- $\alpha$ ) in response to  $A\beta$  and will similarly examine the effects of CAT-SKL.

The results obtained to date constitute the preliminary observations/proof-of-concept validation necessary for follow-up studies with appropriate Alzheimer's disease animal models in a preclinical setting.

1593

**The Role of the Interaction Between the ER and the Mitochondria in the Development of the Dementia of Alzheimer's Disease.**

*J. L. Holtzman<sup>1</sup>; <sup>1</sup>Pharmacology, University of Minnesota, Minneapolis, MN*

Studies from my laboratory have suggested that there is a decline with age in the capacity of the ER to catalyze the posttranslational processing of nascent proteins. This loss is associated with a decline with age in the content of the ER chaperones. Data from other laboratories indicate that declines in N-glycosylation may also play a role. Together these findings suggest that the dementia of Alzheimer's disease may be due to a decrease in the capacity of neurons to synthesize the synaptic, membrane proteins that are necessary for a functioning memory. It has also been thought that the decline in cognition may be secondary to a loss of mitochondrial function with age. Recent studies have indicated possible biochemical mechanisms whereby this decline may be related to our observed loss of ER function, since the ER plays a critical role in maintaining normal mitochondrial activity. The ER and mitochondria are connected through the Mitochondria Associated Membrane (MAM). This structure serves a number of critical functions including transporting phospholipids from the ER, where they are synthesized, into the mitochondria. It also regulates the fusion and fission of mitochondria. These processes are important because as the organism ages the mitochondrial proteins undergo oxidative damage.

During fusion and fission the damaged proteins are isolated to one of the daughter mitochondria that then undergo autophagy. The proteins which form the MAM and the autophagic vesicles are processed in the ER. Hence, declines in protein processing in the ER would compromise both of these systems. Furthermore, these findings provide a biochemical basis for the well recognized role of polymorphisms in apolipoprotein E (apoE) in the early development of Alzheimer's disease. The gene for apoE is 30 kb down stream from the gene for TOM40. TOM40 is a pore protein necessary for the transport of nascent proteins from the cytosol into the mitochondria. Furthermore, the apoE4 gene is tightly linked to a poly T polymorphism in intron 6 of TOM40. Individuals with this polymorphism have low mitochondrial function at all ages. I would postulate that these compromised mitochondria will be more susceptible to the age related decline in ER processing than the more robust mitochondria found in individuals with short poly T polymorphisms in intron 6.

**A prion-containing yeast cell can switch into agar-invasive growth while an isogenic non-prion strain cannot.**

*Y. P. Lee<sup>1</sup>, P. Patil<sup>1</sup>, H. A. Kessler<sup>1</sup>, D. S. Weil<sup>1</sup>, B-L. Dennis<sup>1</sup>, I. M. Evans<sup>1</sup>; <sup>1</sup>School of Life Sciences, Rochester Institute of Technology, Rochester, NY*

Yeast prions consist of infectious, self-propagating protein particles which act as epigenetic elements of inheritance. Yeast prions may provide an epigenetic mechanism for allowing inheritable diversity that promotes survival in fluctuating stressful environments by switching into pseudohyphal filamentous growth in order to stimulate migration to find new food sources.

Yeast cells enter different differentiation pathways according to nutrient availability and environmental conditions. Our hypothesis is that [PSI<sup>+</sup>], a prion-containing strain can switch to filamentous pseudohyphal growth under stressful conditions while a prion-negative [psi<sup>-</sup>] strain cannot.

Under nitrogen-limiting media conditions, [PSI<sup>+</sup>], a Sup35 prion-containing cell, enters filamentous growth and invades agar. [psi<sup>-</sup>], which contains Sup35 in its native functional form, is not invasive even when grown under the same nitrogen-limiting conditions. In order to check whether these strains are invasive/non-invasive under different stressful conditions, we tested the strains in different growth media using three different growth and invasion assays, two of which are novel and developed in our laboratory.

[PSI<sup>+</sup>] and [psi<sup>-</sup>] strains were tested for invasive growth using 1) an agar washing assay, 2) a test tube invasion assay, or 3) a confocal invasion assay. In all three assays carried out under stressful conditions, the [PSI<sup>+</sup>] prion-containing strain invaded the agar while the [psi<sup>-</sup>] strain did not. [PSI<sup>+</sup>] prion-containing strains are able to read through stop codons and this ability of [PSI<sup>+</sup>] may explain our results. The ability of [PSI<sup>+</sup>] to invade agar may allow it to survive in stressful conditions and is evidence that prion formation may sometimes result in the acquisition of traits that can be advantageous to the organism.

**Exposure to Sodium 4-phenylbutyrate Does Not Increase Grp78 Levels in *C. elegans* following E.R. Stress Treatment.**

*G. P. Le<sup>1</sup>, C-A. Gutekunst<sup>2</sup>, R. E. Gross<sup>2</sup>, F. Norflus<sup>1</sup>; <sup>1</sup>Natural Sciences, Clayton State University, Morrow, GA, <sup>2</sup>Department of Neurosurgery, Emory, Atlanta, GA*

Unfolded protein response (UPR) is the basic cellular process that underlies a wide range of diseases such as Parkinson's disease, prion disease, and other chronic metabolic diseases such as obesity and type 2 diabetes. In this research, *C. elegans* were exposed to cadmium chloride at concentrations of 3 mM and 7 mM and tunicamycin at concentrations of 3 µg/mL and

7 µg/mL. The worms were either grown on nutrient agar medium plates supplemented with sodium 4-phenylbutyrate (PBA) at a concentration of 3mM or on nutrient agar medium plates alone. After the experiment, all worms were lysed and the protein concentrations in each sample were determined using the Bradford assay. The same amount of protein was used for Western Blot analysis to determine the amount of Grp78 present in each sample. The initial findings suggested that PBA treatment did not increase Grp78 level.

**Allosteric control of the IRE1 $\alpha$  endoribonuclease using kinase inhibitors.**

*L. Wang<sup>1</sup>, G. Perera<sup>2</sup>, S. Hari<sup>2</sup>, B. Bhatarai<sup>3</sup>, B. Backes<sup>1</sup>, M. Seeliger<sup>4</sup>, S. Schurer<sup>3</sup>, S. Oakes<sup>5</sup>, F. Papa<sup>1</sup>, D. Maly<sup>2</sup>; <sup>1</sup>Medicine, UCSF, San Francisco, CA, <sup>2</sup>Chemistry, University of Washington, Seattle, WA, <sup>3</sup>Center for Computational Science, Miller School of Medicine, University of Miami, Miami, FL, <sup>4</sup>Pharmacological Sciences, Stony Brook University Medical school, Stony Brook, NY, <sup>5</sup>Pathology, UCSF, San Francisco, CA*

The unfolded protein response (UPR) is an evolutionarily conserved intracellular signaling pathway triggered when unfolded proteins accumulate in the endoplasmic reticulum (ER). Aberrant UPR contributes to cell degenerative disorders and the inappropriate survival of secretory cell tumors. To control the UPR's cell fate outcomes may provide new therapeutic options for these diseases. IRE1 $\alpha$  is an ER-transmembrane kinase/endoribonuclease (RNase) that senses unfolded proteins, oligomerizes, autophosphorylates, and initiates splicing of XBP1 mRNA, thus triggering the UPR. Although activation of IRE1 $\alpha$ 's RNase is normally dependent on kinase autophosphorylation, using chemical-genetic systems we had previously shown that a conformational change in the kinase domain triggered by ATP-competitive inhibitors bypasses autophosphorylation requirement in genetically modified versions of IRE1 $\alpha$  to allosterically activate IRE1 $\alpha$ 's RNase domain. Here we show that novel kinase inhibitors occupy the ATP-binding site of endogenous IRE1 $\alpha$ , to affect RNase activity from a distance. As dysregulation of the UPR has been implicated in a variety of cell degenerative and neoplastic disorders, small molecule control over endogenous IRE1 $\alpha$  should advance efforts to understand the UPR's role in pathophysiology and to develop drugs for ER stress-related diseases.

**Calreticulin and Calnexin, Ca<sup>2+</sup> Binding Chaperones in ER, Regulate Olfactory Sensory Animal Behavior.**

*K. Kalichamy<sup>1</sup>, J. Ahnn<sup>1</sup>, S-K. Lee<sup>1</sup>; <sup>1</sup>Dept. of Life Science, Hanyang University, Seoul, Korea*

Calreticulin and calnexin, molecular chaperone proteins, are Ca<sup>2+</sup> binding proteins residing in endoplasmic reticulum (ER). These proteins control Ca<sup>2+</sup> homeostasis and facilitate the proper folding of newly synthesized proteins in the lumen of ER. In order to study the function of calreticulin and calnexin in chemosensory behaviors, we investigated the behavioral phenotype of calreticulin (*crt-1*) and calnexin (*cnx-1*) mutants of *Caenorhabditis elegans*. Both *crt-1* and *cnx-1* mutants exhibited normal chemotaxis responding to AWC sensed odorants such as isoamyl alcohol, benzaldehyde and butanone. The *crt-1* mutants exhibited hyperadaptation to AWC sensed odors whereas *cnx-1* mutants failed to adapt, when compared with wildtype. These results imply that CNX-1 and CRT-1 may be involved in adaptation of AWC-mediated chemosensation. The expression of *str-2::GFP*, the neural developmental asymmetry indicator, in *crt-1* or *cnx-1* mutant background showed defects in the asymmetry of AWC neurons. We are further investigating how these ER resident proteins modulate to the chemosensory behavior and the underlying mechanism.

**Single Molecule Studies on Protein Unfolding and Polypeptide Translocation by an ATP-dependent Protease.**

R. A. Maillard<sup>1,2</sup>, G. Chisto<sup>2</sup>, M. Sen<sup>3</sup>, M. Righini<sup>1</sup>, C. M. Kaiser<sup>1,2</sup>, A. Martin<sup>1,4</sup>, C. J. Bustamante<sup>1,2,3,4,5</sup>, <sup>1</sup>California Institute for Quantitative Biosciences, University of California, Berkeley, CA, <sup>2</sup>Department of Physics, University of California, Berkeley, CA, <sup>3</sup>College of Chemistry, University of California, Berkeley, CA, <sup>4</sup>Department of Molecular and Cellular Biology, University of California, Berkeley, CA, <sup>5</sup>Howard Hughes Medical Institute, University of California, Berkeley, CA

The process of controlled protein degradation is critical for the maintenance of cellular homeostasis in all organisms. This task is strictly regulated and mainly performed by ATP-dependent proteases. These energy-dependent proteases have two components: a barrel-shaped peptidase with active sites sequestered deep in its cavity, and a hexameric, ring-shaped unfoldase that uses the energy of ATP hydrolysis to unfold protein substrates and translocate them into the associated peptidase. In this study, we developed a single-molecule optical tweezers assay to monitor in real time protein unfolding and polypeptide translocation by ClpXP, a model ATP-dependent protease from *Escherichia coli*. We conducted these experiments with the ClpX unfoldase alone, and in complex with the ClpP peptidase. Our results showed that upon ATP hydrolysis, ClpX generates mechanical force to unfold and translocate polypeptides through its central pore. Polypeptide translocation is interrupted by pauses that are found to be off the main translocation pathway. The translocation velocity of ClpX is force dependent, reaching a maximum of 8 nm/s (~80 aa/s) at near zero force and vanishing at around 20 pN. During translocation, ClpX takes 1, 2, or 3 nm steps, suggesting a fundamental step size of 1 nm and a certain degree of intersubunit coordination. In front of a folded substrate like GFP, ClpX either overcomes this mechanical barrier by unfolding it, or slips on the polypeptide before making another unfolding attempt. Binding of ClpP decreases the slip probability and enhances the unfolding efficiency of ClpX. The mechanical unfolding of GFP by ClpXP is cooperative and displays well-defined intermediate states. Because ClpXP shares its basic structural design with other ATP-dependent proteases, these studies provide important insight into the fundamental operating principles used by this group of enzymes.

**Plasma membrane to vacuole traffic mediates cell survival in glucose starvation and inhibits canonical macroautophagy.**

M. J. Lang<sup>1</sup>, J. Y. Martinez-Marquez<sup>1</sup>, L. Ganser<sup>1</sup>, D. Buelto<sup>2</sup>, M. C. Duncan<sup>1,2</sup>; <sup>1</sup>Biology, UNC-Chapel Hill, Chapel Hill, NC, <sup>2</sup>Curriculum of Genetics and Molecular Biology, UNC-Chapel Hill, Chapel Hill, NC

Starvation is a common event in the life of a cell. Facing starvation, the cell deploys highly conserved responses that modify cell behavior to survive. These responses frequently differ depending on the identity of the scarce nutrient or nutrients. It is thought that macroautophagy, a process by which the cell recycles its own cytoplasmic components, is an integral response to many types of starvation. Despite its critical role in many types of starvation, numerous observations suggest that there are additional alternative mechanisms to survive starvation. Here we report a new form of cell catabolism that occurs in response to glucose starvation in the yeast *Saccharomyces cerevisiae*. This process involves massive plasma membrane to

vacuole traffic. This process also actively inhibits the onset of macroautophagy via a TORC1 dependent pathway. We find that plasma membrane to vacuole traffic is necessary for cell survival, while macroautophagy is, in fact, dispensable. These results identify the plasma membrane to vacuole pathway as the mechanism for cell catabolism that directs cell survival in glucose starvation in yeast and thus expands the repertoire of response pathways available to a starving cell.

**LC3 constitutively associates with a high molecular weight complex in both the cytoplasm and nucleus.**

*L. J. Kraft<sup>1</sup>, B. Han<sup>2</sup>, A. J. Baucum<sup>2</sup>, T. A. Nguyen<sup>3</sup>, S. S. Vogel<sup>3</sup>, A. K. Kenworthy<sup>1,2,4</sup>; <sup>1</sup>Chemical and Physical Biology Program, Vanderbilt School of Medicine, Nashville, TN, <sup>2</sup>Molecular Physiology and Biophysics, Vanderbilt School of Medicine, Nashville, TN, <sup>3</sup>National Institute on Alcohol Abuse and Alcoholism, National Institutes of Health, Rockville, MD, <sup>4</sup>Cell and Developmental Biology, Vanderbilt School of Medicine, Nashville, TN*

LC3 is a key component of the autophagy pathway, where it functions in autophagosome formation and cargo recruitment. Recent proteomics analysis indicates LC3 and other members of the ATG8 family interact with 67 different proteins, many of which appear to bind to common sites on LC3. However, it is currently unknown how many proteins are bound to LC3 at a given time. In addition, it is unclear if cytoplasmic and nuclear forms of LC3 interact with similar or different proteins. Here, we report several independent lines of evidence that suggest LC3 is constitutively associated with a high molecular weight complex in both the cytoplasm and nucleus. First, confocal FRAP measurements indicate that Venus-LC3 diffuses significantly more slowly than predicted based on its molecular weight in both the cytoplasm and nucleus of living cells. Second, fluorescence correlation spectroscopy measurements of freshly prepared cell homogenates report the correlation time of Venus-LC3 is longer than that of Venus alone, again suggesting it is contained within a large complex. Third, both cytoplasmic and nuclear forms of endogenous LC3 and Venus-LC3 migrate as part of a high molecular weight complex in blue native gel electrophoresis. To test whether multiple copies of LC3 are contained within the same complex, we performed FRET analysis between Venus- and Cerulean-tagged LC3, homoFRET analysis of Venus-LC3, and brightness analysis of Venus-LC3. No FRET was detected between LC3 molecules in the cytoplasm or in cell homogenates, and the brightness of LC3 was consistent with approximately 1 Venus-LC3 per complex. However, a small level of FRET was measured between LC3 molecules in the nucleus, suggesting multiple copies of the protein may be present within the same complex. Experiments are currently underway to determine how the formation of these complexes is regulated as well as to identify other complex components. We suggest that the incorporation of LC3 into multi-protein complexes may represent a currently unrecognized mechanism for regulating autophagy.

1601

**Autophagy Inhibition by irreversible deconjugation of Atg8 proteins from membranes.**

*A. Choy<sup>1</sup>, J. Dancourt<sup>2</sup>, B. Mugo<sup>2</sup>, T. J. O'Connor<sup>3</sup>, R. R. Isberg<sup>3</sup>, T. J. Melia<sup>2</sup>, C. R. Roy<sup>1</sup>; <sup>1</sup>Department of Microbial Pathogenesis, Yale University School of Medicine, New Haven, CT, <sup>2</sup>Department of Cell Biology, Yale University School of Medicine, New Haven, CT, <sup>3</sup>Howard Hughes Medical Institute and Department of Molecular Biology and Microbiology, Tufts University School of Medicine, Boston, MA*

Eukaryotic cells use the autophagy pathway to defend against microbes that gain access to the cytosol or reside in pathogen-modified vacuoles. It remains unclear if pathogens have evolved specific mechanisms to manipulate autophagy. Here we demonstrate that the intracellular

pathogen *Legionella pneumophila* interferes with autophagy using the bacterial effector protein RavZ, which is an enzyme that directly uncouples Atg8 proteins attached to phosphatidylethanolamine on autophagosome membranes. RavZ hydrolyzes the amide bond between the carboxyl-terminal glycine residue and an adjacent aromatic residue in Atg8 proteins. The result is an Atg8 protein that is no longer a substrate for reconjugation by Atg7 and Atg3. Thus, one mechanism by which intracellular pathogens inhibit autophagy is to irreversibly inactivate Atg8 proteins on the early phagophore membrane.

1602

### Phosphorylation and proteolysis-dependent regulation of Acinus stability modulates autophagy and resistance to starvation stress.

N. Nandi<sup>1</sup>, L. K. Dickel<sup>1</sup>, H. Kramer<sup>1</sup>; <sup>1</sup>Neuroscience, UT Southwestern, Dallas, TX

Acinus is a conserved nuclear protein that has been implicated in the regulation of cell death and autophagy. We have previously shown that loss-of-function mutants of *Drosophila* Acinus (*dAcn*) interfere with autophagosome maturation in the larval fatbody, whereas elevated levels of *dAcn* induce autophagy downstream of mTor (1). Therefore we were interested in defining the mechanisms that regulate the dynamic, cell-type-specific changes in *dAcn* protein levels. In a targeted RNAi screen, we identified the Caspase-3 homolog Dcp-1 as a protease regulating *dAcn* stability. Loss of Dcp-1 stabilized *dAcn* and increased *dAcn*-dependent autophagy. Furthermore, a mutation in a conserved Caspase-3 cleavage site (*dAcn*<sup>D527A</sup>) stabilized *dAcn* and enhanced autophagy. In fed and starved larvae, fat bodies expressing the *dAcn*<sup>D527A</sup> mutant - instead of wild-type *dAcn* - showed robustly enhanced autophagy as detected by a 3MA-dependent accumulation of lysotracker and an increase in Atg8 staining. The Dcp-1-mediated cleavage of *dAcn* appears to be regulated by phosphorylation. We identified two conserved potential phosphorylation sites in the C-terminus of *dAcn*. To explore their role we generated flies in which - instead of wild-type *dAcn* - either a phospho-mimetic (*dAcn*<sup>S641,731D</sup>) or a phospho-inert (*dAcn*<sup>S641,731D</sup>) mutant was expressed under control of the endogenous *dAcn* promoter. Proteolysis of the phospho-mimetic *dAcn*<sup>S641,731D</sup> protein was reduced and these flies exhibited enhanced autophagy similar to flies expressing the Caspase-3 cleavage-resistant *dAcn*<sup>D527A</sup> mutant. By contrast, the *dAcn*<sup>S641,731A</sup> mutant was destabilized and autophagy was reduced even after starvation. This regulation of *dAcn* stability is important on the organismal level, as increased induction of autophagy paralleled an increased resistance to starvation stress: flies expressing the stabilized *dAcn*<sup>S641,731D</sup> or *dAcn*<sup>D527A</sup> mutants lived significantly longer compared to a wild-type *dAcn* control, whereas flies expressing the destabilized *dAcn*<sup>S641,731A</sup> protein died faster. These results are consistent with a model in which phosphorylation of serines 641 and 731 counteract DCP-1-mediated cleavage of Acinus. In turn, elevated levels of *dAcn* protein play a critical role in regulating developmental decisions and promoting survival of animals exposed to starvation stress.

### Dynamic Live Cell-based Assays for Autophagy.

C. S. Chen<sup>1</sup>, L. Armstrong<sup>2</sup>, T. Gaige<sup>1</sup>, P. J. Hung<sup>1</sup>; <sup>1</sup>EMD Millipore - CellASIC, Hayward, CA, <sup>2</sup>EMD Millipore, Temecula, CA

Autophagy is a complex physiologic cellular process essential for cell survival under stressed conditions. Probing into the pathway has offered novel targets for new drug development for cancer and neuronal diseases. By performing live-cell imaging on cells transduced with the autophagosome marker LC3 genetically fused to green fluorescent protein (GFP), the

autophagy process can be visualized on a fluorescent microscope. However, the dynamics of the lysosomal degradation phase of the autophagy process are less easily assessed than the preceding autophagosome formation phase. To better profile the effects of molecules acting on the whole autophagy pathway, a dynamic live cell-based assay has been developed to monitor both the rate of autophagosome formation and the decay for different autophagy-related perturbations. In this study, we interrogated GFP-LC3 CHO reporter cells with multiple reagents at the designated time points and visualized the autophagy process by fluorescence microscopy. In order to observe the dynamics of the autophagy process, we also exploited a commercially available microfluidic live cell imaging platform that has temperature and gaseous microenvironment control along with a solution switching capability.

The dynamic assay was composed of four continuous phases: (1) a standard culture phase where the native background fluorescent signal was recorded; (2) a stressed phase where a stressor was applied to induce autophagy; (3) a lysosome inhibition (with stressor) phase where the rate of autophagosome formation was recorded by enumeration with the Cell Profiler software; and finally (4) a recovery phase where culture medium was perfused continuously to return the cells from autophagy while monitoring the degradation rate of autophagosomes. To validate the dynamic cell-based assay, we applied known stressors such as starvation with EBSS, as well as a model inducer Rapamycin at various concentrations. The results have successfully shown that the entire dynamic profiling of these stressors for autophagy is feasible through the established live-cell imaging system on a fluorescent microscope. Through software analysis, we also observed that the complete lysosome degradation in the GFP-LC3 CHO reporter cells occurred linearly within 180 minutes after the recovery growth medium was added. Here we describe an autophagy assay that provides the quantitative information of the study of both autophagosome formation and the lysosome degradation machinery, which may facilitate the characterization of existing targets and discovery of new targets for drug development for multiple autophagy-related diseases.

1604

**The clearance of protein aggregates: Elucidating a role for small heat shock proteins versus selective macroautophagy.**

*E. Eenjes<sup>1</sup>, H. Kampinga<sup>2</sup>, A. Yamamoto<sup>1</sup>; <sup>1</sup>Neurology, Columbia University, New York, NY, <sup>2</sup>Cell biology, University of Groningen, Groningen, Netherlands*

Macroautophagy is the cellular pathway by which the lysosome eliminates cytosolic proteins through fusion with a de novo synthesized organelle known as the autophagosome. The ability of cargo to be targeted for degradation can rely on autophagic receptors and selectivity adaptors, which may be required for the degradation of some cargo, but not for macroautophagic degradation as a whole. For example, the selective degradation of aggregated proteins relies on the selectivity adaptor, Alfy (autophagy linked FYVE protein), which acts as a molecular scaffold between its cargo and the key macroautophagic protein Atg5. Overexpression of Alfy decreases the presence of cytoplasmic protein aggregates and can be cytoprotective against toxic aggregates in vivo. One of the key questions about Alfy, however, is how it recognizes aggregated proteins; Alfy is a nuclear protein that shuttles to the cytosol in the presence of aggregation. Similarly, it has recently been shown that the small heat shock protein (sHSP), HSPB7 also modulates protein aggregation in a manner similar to Alfy: its overexpression diminishes aggregation and is cytoprotective in vivo. Moreover, it has been suggested that unlike classic sHSPs, HSPB7 relies on the macroautophagic machinery to exert its functions, although how remains unclear. In this study, we test the hypothesis that HSPB7 contributes towards Alfy-mediated selective macroautophagy to promote the degradation of toxic protein aggregates. Using fragments of the huntingtin protein with an expanded

polyglutamine (polyQ) repeat as a model aggregation-protein protein, we use a combination of biochemical (segregation of detergent soluble and insoluble proteins) and cell biological methods to examine the role of Alfy and HSPB7 on polyQ protein. First, we confirmed previous published data showing that overexpression of Alfy in a stable polyQ cell line and co-transfection of HSPB7 with polyQ constructs leads to diminished protein aggregation. Next, when investigating the role of stable expression versus transient transfection of polyQ proteins, we found that unlike Alfy, HSPB7 failed to reduce the amount of detergent insoluble proteins under conditions of stable expression, suggesting that HSPB7 cannot eliminate preformed inclusions, and works independently of Alfy. This was further confirmed when the anti-aggregation activity of HSPB7 was maintained in Alfy knockout MEFs. These findings indicate that distinct pathways may be used by the cell to reduce protein aggregation and promote cytoprotection.

1605

### **Recycle or Destroy? The Duplicitous Roles of Autophagy in Cadmium-induced Apoptosis in *Saccharomyces cerevisiae***

P-J. Chin<sup>1</sup>, J. Houghton<sup>1</sup>;<sup>1</sup>Biology, Gerogia State University, Atlanta, GA

Autophagy, or self-eating, is a conserved cellular stress response that gives rise to the controlled breakdown of unwanted cytosolic material, enhancing the potential for cellular survival. As such, it can be considered to be a protective mechanism. The process begins with the formation of membrane vesicles, or preautophagosome structures (PAS), which engulf the cytosolic contents to be digested. The PAS then mature in to so-called autophagosomes, which are double-membrane structures that ultimately fuse with the lysosome to facilitate the further degradation and recycling of their contents. Autophagy can be induced by variety of cellular stressors, such as nutrient deprivation, accumulation of dysfunctional proteins or exposure to heavy metals. The overly simplified view of autophagy as being a mechanism to conserve cellular function has been challenged, of late, as autophagic activity has been correlated, in a number of different cells, with the augmentation of programmed cellular demise, or apoptosis. Herein, we confirm that the autophagic process is indeed necessary for the induction of the caspase-dependent apoptotic response in *S. cerevisiae* to the presence of the heavy metal, cadmium. We demonstrate further that the initial phase of autophagy is crucial in determining whether autophagy or apoptosis predominate. We also show that the timing of the autophagic induction is a key factor in deciding which role it plays in cell survival: in that induction of autophagy prior to exposure of the cell to cadmium serves to negate the apoptotic response, while the independent induction of autophagy after caspase induction serves only to facilitate the apoptotic potential of the cell.

1606

### **The Role of the NAADP/Two Pore Channel 2 (TPC2)/Ca<sup>2+</sup> Signaling in the Maturation of Autophagosome.**

Y. Lu<sup>1</sup>, H-C. Lee<sup>1</sup>, G. Churchill<sup>2</sup>, J. Yue<sup>1</sup>; <sup>1</sup>University of Hong Kong, Hong Kong, China,<sup>2</sup>University of Oxford, Oxford, London, England

Autophagy, an evolutionarily conserved lysosomal degradation pathway, has been implicated in a wide variety of cellular processes, and the underlying mechanisms have been extensively studied. Yet, the fusion between autophagosome and lysosome is poorly understood. Nicotinic acid adenine dinucleotide phosphate (NAADP), an endogenous Ca<sup>2+</sup> mobilizing nucleotide, mobilizes Ca<sup>2+</sup> from acidic organelles, e.g. lysosome, through two pore channel 2 (TPC2). Here

we reported that overexpression of TPC2 in HeLa cells, which lack the expression of endogenous TPC2, inhibited the fusion between autophagosome and lysosome by raising lysosomal pH, whereas overexpression of a TPC2 inactive mutant failed to inhibit the fusion. Transient treatment of the cells expressing the wildtype, not mutant, TPC2 with a cell permeant NAADP analogue further inhibited the fusion. Interestingly, autophagy occurs during the in vitro neural differentiation of mouse embryonic stem (ES) cells initiated by the monolayer culture, and the expression of endogenous TPC2 was markedly decreased during the initial ES cell entry into neural progenitors. Consistently, TPC2 knockdown or overexpression in mouse ES cells promoted or inhibited the fusion between autophagosome and lysosome during the in vitro neural differentiation, respectively. Correspondingly, TPC2 knockdown or overexpression in ES cells accelerated or delayed mouse ES cells entry into neural lineages, respectively. Taken together, our results indicated that the NAADP/TPC2/Ca<sup>2+</sup> signaling inhibited the maturation of autophagosome to antagonize the neural differentiation of mouse ES cells. The development of novel agonists or antagonists of TPC2 based on NAADP might be a good approach to control the maturation processes of autophagosome.

1607

**The autophagy lipidation enzyme, Atg3, is a membrane curvature sensor.**

S. Nath<sup>1</sup>, J. Dancourt<sup>1</sup>, G. Puente<sup>1</sup>, A. Yamamoto<sup>2</sup>, B. Antonny<sup>3</sup>, T. J. Melia<sup>1</sup>; <sup>1</sup>Cell Biology, Yale School of Medicine, New Haven, CT, <sup>2</sup>Neurology, Columbia University, New York, NY, <sup>3</sup>Institut de Pharmacologie Moléculaire et Cellulaire, CNRS & University de Nice, Nice, France

Although a wide variety of autophagy-related proteins can target the cup-like autophagosomal isolation membrane, once the autophagosome closes only lipidated Atg8 proteins remain associated with the outer surface. It is not yet known what features of the isolation membrane distinguish it from the mature autophagosome, but one possibility is that the highly curved rim of the cup is an important marker for transiently-associated components of the autophagic machinery. Here we use a fully reconstituted in vitro assay of protein lipidation to establish several first principles in the ubiquitin-like lipidation of Atg8. We show that the E2-like enzyme, Atg3, is a membrane hydrophobicity sensor and requires extensive exposure of the membrane hydrophobic core to facilitate Atg3 function. This detection depends upon an amino-terminal ALPS-like amphipathic helix similar to motifs found on other proteins targeting highly curved intracellular membranes. Indeed, in vitro Atg3 function is dramatically increased on membranes exhibiting strident curvature. By tuning the amphipathicity and hydrophobicity of the ALPS motif, we can promote or inhibit LC3 lipidation both in vitro and in rescue experiments in Atg3 knockout MEFs, implying a physiologic role for this sensing. The need for extensive hydrophobic membrane exposure suggests that Atg3 is designed to work at highly-curved membranes perhaps including the limiting edge of the growing phagophore.

1608

**Parkin regulates the clearance of misfolded proteins by the aggresome-autophagy pathway.**

C. Yung<sup>1</sup>, L-S. Chin<sup>1</sup>, L. Li<sup>1</sup>; <sup>1</sup>Pharmacology, Emory University, Atlanta, GA

Parkinson disease (PD) and many other human diseases (e.g., cystic fibrosis and Alzheimer disease) are often referred to as “protein misfolding diseases” because their pathogenesis involves protein misfolding and aggregation. The accumulation of misfolded proteins in these diseases is likely due to a chronic imbalance in the generation and clearance of misfolded proteins, and it suggests that failure of cells to cope with excess misfolded proteins may be a common pathological mechanism linking these clinically distinct diseases. Recent evidence

indicates that the aggresome-autophagy pathway plays a cytoprotective role by mediating selective clearance of misfolded and aggregated proteins under conditions of proteotoxic stress. The molecular mechanisms that regulate the aggresome-autophagy pathway remain poorly understood. We have shown that the PD-linked E3 ubiquitin-protein ligase parkin selectively binds and catalyzes K63-linked polyubiquitination of misfolded DJ-1 but not wild-type DJ-1. Furthermore, our study reveals that the K63-linked polyubiquitination serves as a signal for targeting misfolded DJ-1 to the aggresome-autophagy pathway. We have identified another misfolded protein (MFP) that is specifically recognized and ubiquitinated by parkin. We find that parkin overexpression promotes clearance of MFP by the aggresome-autophagy pathway and protects cells against MFP-induced toxicity. Our findings support a general role of parkin-mediated K63-linked polyubiquitination in regulating misfolded protein clearance by the aggresome-autophagy pathway.

1609

**Microbial detection controls defective ribosomal proteins degradation by autophagy and subsequent endogenous MHC II-restricted presentation in dendritic cells.**

*P. D. Pierre<sup>1</sup>, T. Wenger<sup>1</sup>, V. Camosseto<sup>1</sup>, S. Terawaki<sup>1</sup>, E. Gatti<sup>1</sup>; <sup>1</sup>CIML, marseille, France*

Dendritic cells (DCs) are antigen presenting cells with the unique capacity to initiate primary immune responses. DCs have a remarkable pattern of differentiation (maturation) that exhibits highly specific mechanisms to control antigen presentation in response to microbial stimuli. In particular, expression, transport and loading of MHC class I and II molecules are strongly activated during DC maturation. MHC class I molecules present to CD8+ cytotoxic T cells peptides mostly derived from defective cytosolic proteins (DRiPS), which are ubiquitinated and degraded by the proteasome. Here, we show that newly synthesized defective proteins are also targeted to autophagosomes and degraded. Upon DC maturation, autophagy is inhibited leading to the accumulation of these DRiPs in large cytosolic structures. Interestingly, these Dendritic cell Aggresome Like Induced Structures (DALIS) are transient, and require both translation inhibition and proteasome activity for their disappearance. Thus, autophagy affects the efficiency of the classical proteasome-mediated antigen processing by competing for a fraction of the same DRiPs substrates. Autophagy was estimated to reduce the level MHC I presentation by 20%. We also demonstrate, that this pathway is used by DCs to present endogenous proteins on the MHC II molecules and that immature cells have the capacity of presenting peptides derived from the same endogenous antigens both on the MHC I and MHC II. Upon microbial activation MHC II presentation of the endogenous antigens is lost, while the MHC I antigens source changes from newly synthesized proteins to other undefined sources. Moreover, we demonstrate that several cytokines can revert this process and induce alternative pathways for the autophagic processing of antigens as well as different immunological functions. This phenomenon is likely to be important for regulating MHC class I and II presentation and the establishment of tolerogenic or immunostimulatory conditions during the necessary functional switch of DC maturation and CD4+ T cells licensing

**The Functional Analysis of Autophagy Using a New Class of Lysosome-Specific Fluorescent Indicators.**

*Q. Zhao<sup>1</sup>, J. Liao<sup>1</sup>, Z. Diwu<sup>1</sup>; <sup>1</sup>AAT Bioquest, Sunnyvale, CA*

Lysosomes are cellular organelles which contain acid hydrolase enzymes to break up waste materials and cellular debris. Lysosomes digest excess or worn-out organelles, food particles, and engulfed viruses or bacteria from phagocytosis, endocytosis, and autophagy. Autophagy is

a process that degrades damaged organelles, cell membranes and proteins. The failure of autophagy is thought to be one of the main reasons for the accumulation of cell damage and aging.

We report the functional analysis of autophagy using a new class of lysosome-selective fluorescent indicators (called LysoBrite). These newly developed fluorescent lysosome indicators are well retained in cells with minimum cell cytotoxicity. These hydrophobic compounds easily permeate into intact cells, and become trapped in lysosomes after passing through the cell membranes. Their fluorescence is significantly enhanced upon entering lysosomes.

We demonstrated these new lysosome dyes are a set of valuable tools for monitoring autophagy in live cells. The signal intensity, photostability, cellular retention, as well as cell cytotoxicity of these new lysosome indicators were evaluated in HeLa and Jurkat cells with fluorescence microscopy and flow cytometry. The LysoBrite dyes has significantly improved signal intensity that can be used for tracking more than 6 passages of HeLa cells, and the indicators stay in lysosomes for more than 20 days in Jurkat cells. Furthermore, there is no fading observed even after a 2 minute exposure time. The cells show no cytotoxicity effect after exposure to the dyes over 24 hours.

In summary, LysoBrite dyes have extremely high photostability as well as excellent cellular retention, making them useful for a variety of applications, including cell adhesion, chemotaxis, multidrug resistance, cell viability, apoptosis and cytotoxicity. The dye is suitable for proliferating and non-proliferating cells, and can be used for both suspension and adherent cells.

## Oncogenes and Tumor Suppressors II

### Development of mouse brain tumor models derived from neural stem cells expressing activated ALK.

*N. Onishi<sup>1</sup>, O. Sampetean<sup>1</sup>, E. Sugihara<sup>1</sup>, H. Saya<sup>1</sup>; <sup>1</sup>Division of Gene Regulation, Institute for Advanced Medical Research, Keio University School of Medicine, Tokyo, Japan*

Neural Stem Cells (NSCs), having self-renewal and multipotent ability, are considered one of the cells-of-origin of glioblastoma multiforme (GBM). Although NSCs can be enriched in neurosphere floating culture with serum-free media containing EGF/FGF as a classical method, neurosphere is composed of not only NSCs but also differentiated and apoptotic cells. Therefore, we utilize the method for efficient derivation of NSCs with long-term self-renewal and differentiate capacity in adherent culture. Using this method, we cultured the genetically modified NSCs. Anaplastic lymphoma kinase (ALK) is a receptor tyrosine kinase first identified in a chromosomal translocation associated with anaplastic large cell lymphomas. Subsequently, new ALK translocations were found in a fraction of non-small-cell lung cancers and in other solid tumors. The function of full-length ALK is involved in neuronal cell differentiation, regeneration and synapse formation. Recently, gene amplification and mutations of full-length ALK were identified in neuroblastoma. Furthermore, many of the GBM samples and cell lines were observed to have overexpression of ALK. Although constitutive activation of ALK signaling results in cell transformation, little is known about the tumorigenic mechanisms induced by activated ALK. We have established a stable mouse model of brain tumor transplanting the genetically modified NSCs. The NSCs derived from *Ink4a/Arf* KO mice transduced with

constitutively active mutants of ALK (F1174L, R1275Q), identified in neuroblastoma, rapidly formed highly proliferative and invasive brain tumors. Histological characteristics of these tumors resembled human GBM phenotype demonstrating necrosis, perivascular cuffing and giant cell formation. Immunostaining analysis revealed that the tumors have astrocytic differentiation and highly proliferative characteristics. In addition, *WT* mice NSCs transduced with ALK R1275Q, but not F1174L, formed brain tumors same as *Ink4a/Arf* KO mice NSCs. On the basis these findings, we propose a specific regulation of tumorigenic signaling induced by activated ALK.

1612

### **The Role of MXD3 in Human Precursor B cell Acute Lymphoblastic Leukemia.**

G. Barisone<sup>1</sup>, N. Satake<sup>2</sup>, C. Lewis<sup>3</sup>, K. Lam<sup>4</sup>, J. Nolte<sup>5</sup>, E. Diaz<sup>1</sup>; <sup>1</sup>Pharmacology, UC Davis, Davis, CA, <sup>2</sup>Pediatrics, UC Davis, Sacramento, CA, <sup>3</sup>University of Iowa, Iowa, IA, <sup>4</sup>Biochemistry and Molecular Biology, UC Davis, Sacramento, CA, <sup>5</sup>Stem Cell Program and Institute for Regenerative Cures, UC Davis, Sacramento, CA

MXD3 is a transcription factor previously shown in our lab to be a novel member of the Hh pathway (Yun, Rust, Ishimaru, Diaz, *Mol Bio Cell*, 2007). We have previously shown that MXD3 is expressed in medulloblastoma and that its knockdown reduces proliferation of human medulloblastoma cell lines (Barisone et al., *PLoS*, 2012). In the current study, we investigated a possible role for MXD3 in precursor B (preB) acute lymphoblastic leukemia (ALL) cell proliferation. Using qRT-PCR we observed 13 to 35 times higher levels of MXD3 mRNA expression in 8 primary preB ALL samples, as well as in the preB ALL cell lines Reh and JM1, than in mobilized peripheral blood mononuclear cells from healthy donors, mouse bone marrow and spleen. Immunoblot analysis with anti-MXD3 monoclonal antibodies confirmed that the protein was present in the ALL samples but not in normal cells. We investigated the role of MXD3 in cell proliferation and survival by silencing MXD3 in the Reh cell line. We used lentiviral delivery to knockdown MXD3 using an RNA interference approach. Upon transduction by the viral vector, MXD3 knockdown was confirmed at both the RNA and protein level. Within 48 hours, MXD3 protein levels were reduced >90% in cells infected with the shMXD3 virus but not with the control virus. MXD3 knockdown resulted in decreased proliferation in Reh cells, supporting our hypothesis that it may be involved in the maintenance of ALL. To understand the role of MXD3 in leukemia cells, we analyzed cell cycle progression and apoptosis levels after knockdown using flow cytometry. We observed no significant differences in the G0/G1, S or G2/M populations between experimental and control samples. However, samples where MXD3 had been knocked down showed higher levels of apoptosis when compared to controls. Our results suggest that MXD3 is important for preB ALL cell proliferation, possibly by acting as an anti-apoptotic factor. Therefore, MXD3 is a potential candidate for targeted therapies against preB ALL.

1613

### **The protooncprotein TCL1 activates the endoplasmic reticulum stress response to promote leukemic progression in mice.**

C. Kriss<sup>1</sup>, J. Pinilla-Ibarz<sup>1</sup>, A. Mailloux<sup>1</sup>, J. Powers<sup>1</sup>, C-H. A. Tang<sup>1</sup>, C. Kang<sup>1</sup>, N. Zanes<sup>2</sup>, P. Epling-Burnette<sup>1</sup>, E. Sotomayor<sup>1</sup>, C. Croce<sup>2</sup>, J. Del Valle<sup>1</sup>, C-C. A. Hu<sup>1</sup>; <sup>1</sup>H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL, <sup>2</sup>The Ohio State University School of Medicine, Columbus, OH

T cell leukemia/lymphoma-1 (TCL1) protein is expressed in approximately 90% of human B-cell chronic lymphocytic leukemia (B-CLL) samples. Transgenic expression of TCL1 in murine B

cells (E $\mu$ -TCL1) results in mouse CLL. Much still needs to be explored to understand how the expression of this 14-kDa TCL1 protein leads to leukemia. Here we show that TCL1 can associate with X-box binding protein 1 (XBP-1), and transcriptionally upregulate the expression of several endoplasmic reticulum (ER) chaperones, which include glucose-regulated protein 78 (GRP78/BiP), GRP94 and protein disulfide isomerase. Highly elevated expression of XBP-1 in TCL1-overexpressing mouse CLL cells causes dysregulated expression of paired box protein 5 (Pax5), interferon regulatory factor 4 (IRF4), B lymphocyte-induced maturation protein 1 (Blimp-1), and activation-induced cytidine deaminase (AID). To establish that XBP-1 supports the growth of TCL1-overexpressing CLL cells in mice, we developed an inhibitor that specifically targets the ribonuclease activity of the ER-resident transmembrane kinase-endoribonuclease inositol-requiring enzyme 1 (IRE-1), which is responsible for the splicing of XBP-1 mRNA and the expression of the functional XBP-1 protein. Inhibitor-treated B cells mimic the phenotypes of B cells deleted with the XBP-1 gene, as evidenced by the upregulated expression of IRE-1 and a specific inhibitory effect on the expression of secretory IgM but not membrane-bound IgM in these B cells. This inhibitor also does not affect general protein synthesis and trafficking in B cells. When we blocked the IRE-1/XBP-1 pathway using the inhibitor, we observed apoptosis and significantly stalled growth of CLL cells in vitro and in mice. This inhibitor does not affect naïve B cells because these cells do not express XBP-1. Our studies reveal an important role of TCL1 in activating the ER stress response in support for malignant progression of CLL.

1614

**The T-cell acute lymphoblastic leukemia-associated rpl10-R98S mutation prevents the release of the nuclear export adapter Nmd3 in yeast.**

S. Patchett<sup>1</sup>, K. De Keersmaecker<sup>2,3</sup>, Z. K. Atak<sup>3</sup>, N. Li<sup>4</sup>, T. Girard<sup>2</sup>, E. Geerdens<sup>2</sup>, G. Hulselmans<sup>2</sup>, E. Clappier<sup>5</sup>, B. Cauwelier<sup>6</sup>, J. Cloos<sup>7</sup>, J. Soulier<sup>5</sup>, A. Uyttebroeck<sup>8</sup>, P. Vandenberghe<sup>3</sup>, S. Aerts<sup>3</sup>, J. Cools<sup>2</sup>, A. W. Johnson<sup>1</sup>; <sup>1</sup>UT Austin, Austin, TX, <sup>2</sup>VIB, Leuven, Belgium, <sup>3</sup>KU Leuven, Leuven, Belgium, <sup>4</sup>BGI Europe, Copenhagen, Denmark, <sup>5</sup>Hôpital Saint-Louis, Paris, France, <sup>6</sup>AZ St-Jan, Brugge, Belgium, <sup>7</sup>VU Medical Center, Amsterdam, Netherlands, <sup>8</sup>University Hospitals Leuven, Leuven, Belgium

T-cell acute lymphoblastic leukemia (T-ALL) is an aggressive neoplastic disorder that is caused by accumulation of multiple oncogenic lesions in developing T-cells. Major driver mutations in T-ALL include hyperactivity of the NOTCH1 pathway, activation of JAK/STAT signaling, overexpression of a set of transcription factors, and loss of cell cycle control. Whole exome sequencing of 67 T-ALL samples identified mutations in large ribosomal subunit proteins in 13.3% of pediatric samples with mutation of arginine 98 to serine in RPL10 occurring in 9.5% of patients. These results identify mutation of the RPL10 as a new driver of T-ALL. R98 is highly conserved in eukaryotic Rpl10 and is found at the base of a  $\beta$ -hairpin that supports the P-site loop of Rpl10. We have recently shown that mutations in the P-site loop of Rpl10 (eg rpl10-S104D) cause a failure in the cytoplasmic maturation of the 60S subunits by blocking the release of the anti-association factor Tif6 from the subunit. As a consequence, the export adapter Nmd3 also fails to be released. The phenotypes of rpl10-S104D are similar to those of loss of Sdo1, the protein associated with Shwachman-Diamond syndrome. The T-ALL-associated rpl10-R98S mutation similarly blocks the release of both Tif6 and Nmd3. However, rpl10-S104D and sdo1<sup>#8710</sup>; can be suppressed by mutations in TIF6, but not in NMD3. In contrast, rpl10-R98S is strongly suppressed by mutations in NMD3 but not in TIF6, identifying release of Nmd3 as the step that is specifically impaired in the rpl10-R98S mutant. These results suggest related underlying defects in ribosome maturation in both Shwachman-Diamond syndrome and cases of T-ALL in which RPL10 is mutated.

1615

**Tumor cells derived from different cells of origin show distinct therapeutic sensitivities in Myc-induced lymphoid tumor model.**

E. Sugihara<sup>1</sup>, H. Saya<sup>1</sup>; <sup>1</sup>Division of Gene Regulation, Institute for Advanced Medical Research, Keio University, Tokyo, Japan

Understanding the cell of origin of tumors is important not only for elucidating detailed mechanisms of tumorigenesis but also for characterizing the context in which tumor cells develop, both of which provide valuable information that can inform preventive therapy and therapeutic strategies in the clinical setting. However **the factors determining the cell of origin and difference of therapeutic outcome between tumor cells derived from distinct cells of origin remain unclear.**

In this study, **a mouse model of precursor-B acute lymphoblastic leukemia/lymphoma (pre-B ALL/LBL) was established by retroviral transduction of *N-Myc* oncogenes into mouse bone marrow immature cells.** To identify the cell of origin of this tumor, we fractionated *N-Myc*-transduced hematopoietic stem cells (HSCs), lymphoid progenitors, myeloid progenitors and committed progenitor B cells, and then transplanted into recipient mice in a limiting dilution manner. As a result, HSCs showed the highest susceptibility to pre-B ALL/LBL versus lymphoid progenitors, myeloid progenitors. Although *N-Myc* was unable to induce any tumor directly from committed B cells, *N-Myc* was able to induce tumor directly from those cells in the absence of *Ink4a* and *Arf* (*CDKN2A*) genes whose expression is normally maintained at low levels for endowing of self-renewal capacity to HSCs. Furthermore, since *Arf* was expressed higher in progenitor B cells than *Ink4a* and *N-Myc* could induce pre-B ALL/LBL directly from *Arf* single deficient progenitor B cells, ***Arf* might play a predominant role in determining the cell of origin.**

Next, we compared proliferation and drug sensitivities in tumor cells derived from distinct cells of origin. Tumor cells derived from *Ink4a/Arf*<sup>-/-</sup> progenitor B cells exhibited faster growth and were more resistant to an anti-cancer drug Ara-C (Cytarabine) treatment than those derived from wild-type (*Ink4a/Arf*<sup>+/+</sup>) HSCs in vivo and in vitro. Given that *Arf* functions as an inhibitor of Mdm2, the E3 ubiquitin ligase for the tumor suppressor p53, we tried to treat the Mdm2 inhibitor Nutlin-3 to both cells. As a result, Nutlin-3 restored p53 and thereby induced massive apoptosis in tumor cells derived from *Ink4a/Arf*<sup>-/-</sup> cells but not in those derived from wild-type (*Ink4a/Arf*<sup>+/+</sup>) HSCs due to p53 mutations. Furthermore, Nutlin-3 significantly induced apoptosis in human B-ALL cell lines with wild-type *p53* and lacking *Ink4a* and *Arf* expression. Therefore, **Mdm2 inhibition might be a promising therapeutic approach to the treatment of *Ink4a/Arf* deficient B-ALL that is frequently found in Ph<sup>+</sup> ALL and relapsed ALL.**

Collectively these findings suggest that ***Ink4a* and *Arf*, especially *Arf*, are critical determining factors of the cell of origin of pre-B ALL/LBL**, and that **tumor cells derived from distinct cells of origin showed different drug sensitivities to Ara-C and Nutlin-3**, which provides a novel insight into preventive therapy and different therapeutic approaches depending on genetic background of tumor cells.

1616

***Drosophila* Ard1 RNA interference knockdown causes massive cell death.**

*P. A. Martin*<sup>1</sup>, *A. Scholes*<sup>1</sup>, *J. Ahlander*<sup>1</sup>; <sup>1</sup>*Department of Natural Sciences, Northeastern State University, Tahlequah, OK*

Cancer treatment and prevention is a vital part of biomedical research today considering the millions of those who suffer from a wide variety of cancers. N-acetylation is a major form of protein regulation in humans, where most of this activity is carried out by NatA, an N $\alpha$ -acetyltransferase complex. The catalytic subunit of NatA, Ard1, has been shown to be highly overexpressed in certain forms of cancer, such as liver cancer, colon cancer, and lung cancer. We believe that Ard1 regulates programmed cell death and may contribute to cancer progression. *Drosophila* lines were crossed to allow knockdown of Ard1 via RNA interference in the cells of the larval wing disc. Cell death was observed using fluorescent acridine orange staining. The knockdown of Ard1 in the wing resulted in large scale cell death. Since Ard1 is a highly conserved gene between species, using *Drosophila* as a model organism is an ideal way to unfold the mystery behind the function of Ard1. Considering Ard1 is highly overexpressed in many cancers, understanding how Ard1 functions could be a key element in the prevention and cure to those cancers.

1617

**The genetic interaction of *Drosophila* Ard1 with DIAP1 suggests that Ard1 regulates apoptosis.**

*A. N. Scholes*<sup>1</sup>, *P. Martin*<sup>1</sup>, *J. Ahlander*<sup>1</sup>; <sup>1</sup>*Department of Natural Sciences, Northeastern State University, Tahlequah, OK*

Cancer is a widespread problem, and estimated 1.6 million people are diagnosed with cancer every year. Ard1 is the catalytic subunit of the NatA complex, an N $\alpha$ -terminal acetyltransferase. Ard1 is expressed in most tissues, but the Ard1 protein has been found to be overexpressed in a wide range of cancer lines. Our present study investigates how the Ard1 plays a role in cell survival in *Drosophila*. Genetic crosses were used to show that RNAi knockdown of Ard1 in the eye causes a small eye phenotype. Expression of DIAP1, a caspase inhibitor, rescued the Ard1 knockdown phenotype. This genetic interaction suggests that Ard1 is a regulator of apoptosis. Our research into the function of Ard1 and the role it plays in cell survival may help to advance our understanding of cancer genetics.

1618

**BCAS2 is essential for *Drosophila* viability and functions in pre-mRNA splicing.**

*C-W. Huang*<sup>1</sup>, *P-H. Chen*<sup>1</sup>, *S-L. Chen*<sup>1</sup>; <sup>1</sup>*National Taiwan University/College of Medicine, Taipei, Taiwan*

Here, we demonstrate that dBCAS2 (CG4980, human Breast Carcinoma Amplified Sequence 2 ortholog) is essential for the viability of *Drosophila melanogaster*. We find that whole-body and tissue specifically silencing dBCAS2 leads to larval lethality, wing deformities and impaired splicing. More importantly, overexpression of hBCAS2 rescues these defects. Furthermore, the C-terminal coiled-coil domain of hBCAS2 directly binds to CDC5L and recruits hPrp19/PLRG1 to form a core complex for splicing in mammalian cells; and can restore wing damage induced by silenced dBCAS2 in flies. In summary, *Drosophila* and human BCAS2 share similar function in RNA splicing, which affect cell growth viability

1619

**Synthetic Lethality with Raf-Transformation and Dysregulated Intracellular pH.**

B. K. Grillo-Hill<sup>1</sup>, M. Jimenez-Vidal<sup>1</sup>, D. Barber<sup>1</sup>; <sup>1</sup>Cell and Tissue Biology Dept, UC San Francisco, San Francisco, CA

Constitutively increased intracellular pH (pHi) is a hallmark of cancer cells, regardless of genetic lesion or tissue of origin. Increased pHi is thought to facilitate adaptive behaviors of cancer cells, suggesting pHi reduction as a therapeutic approach to limit cancer progression. However, this has not been experimentally confirmed *in situ*. Using *Drosophila melanogaster*, we genetically deleted *Dnhe2*, the homolog of the mammalian plasma membrane Na<sup>+</sup>-H<sup>+</sup> exchanger NHE1 that extrudes protons to increase pHi. *Dnhe2*<sup>null</sup> mutations are semi-lethal; fewer than 10% of homozygous flies survive to adulthood, although those that survive appear morphologically normal. Expression of oncogenic Raf in the eye (*GMR-Raf*) causes externally rough adult eyes and sections reveal dysplasia with missing or extra photoreceptors and orientation defects. We predicted that removing *Dnhe2* would limit Raf-induced dysplasia. Unexpectedly, loss of *Dnhe2* with *GMR-Raf* expression resulted in necrosis, with a profound loss of retinal organization and cellular structure. The cell death appears to be progressive in nature as there is no evidence of cell death in pupal eyes, suggesting an onset very late in eye development. *GMR-Raf* expression induces cell morphology defects that are evident in late pupal eyes, but cell-cell junctions and cell fate markers are present, even in the absence of *Dnhe2*. To investigate effects of dysregulated pHi on proliferation, we analyzed *Dnhe2*<sup>null</sup> third instar imaginal eye discs and found reduced proliferation compared with wild type. *GMR-Raf* induced expanded proliferation of retinal cells, and removing *Dnhe2* in *GMR-Raf* flies reduced the over-proliferation, yielding levels similar to wild type. These results suggest that Raf-induced proliferative signals require *Dnhe2* activity and increased pHi. These results led to the prediction that Raf-transformed cells lacking *Dnhe2* abnormally accumulate protons, decreasing pHi. To test this prediction, we generated transgenic flies with a genetically encoded fluorescent biosensor to measure pHi *in situ*. Wild type and *Dnhe2*<sup>null</sup> *Drosophila* retinal tissue exhibited a pHi of ~7.1 while Raf expression increases pHi to 7.4. Deletion of *Dnhe2* with Raf expression progressively decreased pHi to 6.8 in late pupal eyes, which is consistent with increased cell death. Our data suggest that dysregulated pHi via loss of *Dnhe2* acts as a synthetic lethal in transformed but not normal cells, which suggests inhibition of proton efflux may induce the selective death of transformed cells.

1620

**Loss of PTP-PEST enhances STAT3 activation downstream of integrins and cytokine receptors and promotes tumor growth, invasion, and metastasis in colon cancer.**

R. Espejo<sup>1</sup>, Y. Jeng<sup>1</sup>, C. Johnson<sup>1</sup>, J. R. Carmical<sup>2</sup>, C. Chao<sup>1,3</sup>, S. K. Sastry<sup>1,2</sup>; <sup>1</sup>UTMB Cancer Center, University of Texas Medical Branch, Galveston, TX, <sup>2</sup>Biochemistry and Molecular Biology, University of Texas Medical Branch, Galveston, TX, <sup>3</sup>Surgery, University of Texas Medical Branch, Galveston, TX

The transcription factor STAT3 is hyperactivated by phosphorylation on Y705 in over 75% of metastatic colon cancers and is associated with EMT, cancer stem cells, survival and chemoresistance. The mechanisms of STAT3 inactivation are not well-defined. Here, we identified the protein tyrosine phosphatase, PTP-PEST, as a novel negative regulator of STAT3 in colon carcinoma cells. Using lentiviral shRNA silencing of PTP-PEST in KM12C and HCT116 colon carcinoma cells, we show that PTP-PEST knockdown enhances activation of STAT3. Whereas STAT3 was activated by cell attachment to collagen in control cells expressing non-targeting shRNA, PTP-PEST knockdown resulted in constitutive activation of STAT3 in an anchorage-independent manner. STAT3 also exhibited elevated and sustained activation in

response to IL-6 stimulation in PTP-PEST knockdown cells, which was further enhanced in the presence of collagen. PTP-PEST knockdown cells also showed enhanced chemotaxis to IL-6 and increased activation of Rac1, an upstream activator of STAT3, in response to IL-6 and collagen and expression of STAT3 target genes, MMP2 and mcl-1, was elevated. In vitro assays showed that silencing of PTP-PEST does not affect proliferation, but does enhance anchorage-independent and tumorsphere growth, matrigel invasion, and resistance to 5-fluorouracil in 3-D cultures. Subcutaneous injection of PTP-PEST knockdown cells showed enhanced tumor size while intrasplenic injection showed enhanced metastatic potential as assessed by quantitative PCR for human DNA content in mouse liver. Finally, reduced PTP-PEST expression correlates with metastasis in clinical specimens from colon cancer patients. Taken together, these findings suggest that down-regulation of PTP-PEST in colon cancer may promote metastasis through enhanced activation of STAT3.

1621

### **The Effect of StarD13 on Colorectal Cancer Proliferation and Invasion.**

*A. Nasrallah<sup>1</sup>, M. El-Sibai<sup>1</sup>; <sup>1</sup>Natural sciences, Lebanese American University, Beirut, Lebanon*

Colon cancer, also considered as colorectal cancer or bowel cancer, is the cancer of the epithelial cells lining the colon. There are many risk factors and many prophylactic measurements against this cancer. 95% of colon cancer is known as adenocarcinoma, mainly divided into different stages according to invasiveness and metastatic ability of the tumor. Many mutations are acquired, leading to this malignancy. Mainly, these occur in entities that greatly alter and affect the cell cycle, cell signaling pathways, cell movement, which all involve the action of Rho GTPases. The protein of our interest is DLC2, also known as StarD13 or START-GAP2, a GAP for Rho and Cdc42. Literature states that this protein is considered a tumor-suppressor in hepatocellular carcinoma. Previous work in our lab proved StarD13 to be a tumor suppressor in brain tumor and in breast cancer. In this work, we studied the role of StarD13 in colon cancer.

When overexpressed, StarD13 led to a decrease in cell proliferation in colon cancer cells. This was measured by WST MTT kits. Knocking down StarD13 using StarD13 siRNA led to an increase in cell proliferation. This showed that, similarly to its role in astrocytoma and breast cancer, StarD13 seems to be a tumor suppressor in colon cancer as well. We were also interested in examining the role of StarD13 in cell motility. StarD13 knock down resulted in an inhibition of cell motility, as seen by time lapse microscopy. This might be due to the inhibition of Rho, thus Rac-dependant focal complexes are not formed nor detached for the cells to move forward. future work is still needed to determine the exact mechanism of inhibition.

1622

### **Identification of an E3 Ubiquitin Ligase as a Novel PDZ-containing Target of Oncogenic Human Papillomavirus E6 proteins.**

*M. Thomas<sup>1</sup>, L. Banks<sup>1</sup>; <sup>1</sup>I.C.G.E.B., Trieste, Italy*

High-risk human papillomaviruses (HPVs) are the causative agents of several malignancies, including cervical, anal, penile and head-and-neck cancers. The E6 oncoprotein of the high-risk HPV types has a PDZ-binding motif (PBM) at its extreme carboxy terminus, which is not found in the E6 proteins of the low-risk, non-cancer-causing HPV types. Thus the PDZ-binding activities of the high-risk E6 proteins are thought to contribute to the malignant potential of the virus. High-risk E6 proteins have been shown to direct the proteasomal degradation of a number of their cellular target proteins through interaction with cellular ubiquitin-protein ligases, such as E6AP (also known as UBE3A) or EDD. Their cellular targets include the tumour suppressor,

p53, as well as a number of PDZ-containing proteins, including Dlg, hScrib, and the MAGI proteins.

In this report we identify PDZRN3 as a new PDZ domain-containing target of high-risk HPV E6 proteins. PDZRN3 is a PDZ-containing ubiquitin-protein ligase, whose ligase activity occurs through a RING domain. This is in contrast to E6AP and EDD, both of which function through a HECT domain. PDZRN3 is found as two isoforms PDZRN3A and B, both of which are targeted by high-risk HPV E6s. We have found that PDZRN3 levels are strongly reduced in the presence of high-risk E6 protein, and that this reduction is dependent upon the PBM of E6.

Given that PDZRN3 has been shown to inhibit canonical Wnt- $\beta$ -catenin signaling, it is possible that the E6-induced reduction in PDZRN3 contributes to its oncogenic potential. Studies are in progress to investigate the role of this interaction in HPV-transformed cervical tumour-derived cells.

1623

### **Prevalence of human papillomavirus (HPV) infection in oral cancer.**

*M. Seo<sup>1</sup>, H. Kim<sup>1</sup>, M. Eo<sup>1</sup>, J. Kang<sup>1</sup>, J. Oh<sup>1</sup>, H. Myoung<sup>1</sup>, S. Kim<sup>1</sup>; <sup>1</sup>Oral and Maxillofacial Surgery, School of Dentistry Seoul National University, Seoul, Korea*

High-risk human papillomavirus (HPV) is the main source of cervical cancer, accounting for nearly 100% of all cases. Recently, the association of HPV with oropharyngeal cancer has been established, but the relationship between HPV and oral cancer is not yet known. A prognosis of HPV-positive cancer is known to be better than that of HPV-negative cancer. The purpose of this study was to determine the incidence and types of HPV-positive oral cancer in Korea using a HPV DNA chip and immunohistochemical analysis with HPV6, HPV11, HPV16 L1 and HPV18 E6 monoclonal antibodies.

106 patients who were previously diagnosed with invasive cancer of the oral cavity for HPV detection were examined. A DNA chip (MY-HPV chip kit, Mygene Co., Korea) was used for detecting low risk (6, 11, 34, 40, 42, 43, 44) and high-risk (16, 18, 31, 33, 35, 39, 45, 51, 52, 54, 56, 58) HPV types. Specimens used for HPV detection were extracted from the main mass during surgery and were tested for HPV typing using a DNA chip. First, DNA isolation was performed from the specimens using DNA extraction buffer via centrifugation. DNA amplification was performed by polymerase chain reaction (PCR) using primers, B-globin primer for the control group, Taq polymerase, template DNA, four types of deoxynucleotides (dNTP), and buffer solution. The second PCR product was mixed with hybridization buffer for hybridization. After chip scanning, we analyzed the result.

Immunohistochemical examination was performed with formalin-fixed, paraffin-embedded tissue of normal and cancer specimens. HPV 6, HPV 11, HPV 16 L1, and HPV 18 E6 monoclonal antibody was diluted in 1:300, incubated with samples and visualized by incubating with diaminobenzidine. Counter staining was performed with Mayer's hematoxylin, and we analyzed the result.

Of the 106 oral cancer patients in this study, histopathologic results showed squamous cell carcinoma, mucoepidermoid carcinoma, cystadenocarcinoma, and leiomyosarcoma. Among HPV-positive cancer patients, 1 patient was high-risk HPV type 16 positive, 1 patient as both high-risk HPV type 16 and low risk HPV type 6 positive, 3 patients were low risk HPV type 6 positive, and 2 patients were unknown type HPV positive. Different sites in the oral cavity were involved including tongue, palate, buccal mucosa, and mandibular body. Of the 7 patients who were HPV positive, 4 cancers were located on the tongue and 3 were on the lower gingiva.

Our study showed that the incidence of HPV infection in oral cancer was very low, and HPV type 16 in high risk HPV types and HPV type 6 in low risk HPV types were the most frequently detected HPV types in Korean oral cancer patients. "This research was supported by grant no 03-2012-0028 from the SNUHD Research Fund."

Tumor hypoxia is associated with disease progression and treatment failure, but the hypoxia signaling mechanism is not fully understood. Here, we show that KLHL20, a Cullin3 (Cul3) substrate adaptor induced by HIF-1, coordinates with the actions of CDK1/2 and Pin1 to mediate hypoxia-induced PML proteasomal degradation. Furthermore, this PML destruction pathway participates in a feedback mechanism to maximize HIF-1 $\alpha$  induction, thereby potentiating multiple tumor hypoxia responses, including metabolic reprogramming, epithelial-mesenchymal transition, migration, tumor growth, angiogenesis, and chemoresistance. In human prostate cancer, overexpression of HIF-1 $\alpha$ , KLHL20, and Pin1 correlates with PML down-regulation, and hyperactivation of the PML destruction pathway is associated with disease progression. Our study indicates that the KLHL20-mediated PML degradation and HIF-1 $\alpha$  autoregulation play key roles in tumor progression.

### **Profiling differential microRNA expression in African American and Caucasian Prostate Samples.**

S. Theodore<sup>1</sup>, M. Davis<sup>2</sup>, J. Rhim<sup>3</sup>, T. Turner<sup>1</sup>, C. Yates<sup>1</sup>; <sup>1</sup>Tuskegee University, Tuskegee, AL, <sup>2</sup>University of Georgia, Athens, GA, <sup>3</sup>Uniformed Services, University of the Health Sciences, Bethesda, MD

Purpose: African American men have almost twice the incidence and death rates related to prostate cancer compared to Caucasian men. Several studies have suggested that some of these differences may be attributed to the elevated expression of different genes. Recently, a new class of genetic regulators has emerged known as microRNAs. Many reports have found microRNAs to be implicated in cell growth, cell differentiation and the onset of many diseases including prostate cancer. To date, many studies have investigated differences of gene expression in Africa Americans and Caucasians, but no comprehensive analysis of microRNA differences between races has been investigated. Thus, we sought to investigate whether microRNAs are differentially expressed in African American and Caucasian prostate samples.

Methods: We analyzed the expression of over 300 microRNAs in 11 African American and Caucasian cell lines utilizing Affymetrix Microarray Chip. Validations of the most significant miRNAs were done by qRT-PCR. Characterization of the miRNA was carried out by performing MTT assay, Flow Cytometry, Western Blot, and Immunofluorescence.

Results: We identified 15 microRNAs that were differentially expressed between the African American and Caucasian cell lines. Further validations led to the identification of miR-152 which is significantly expressed among both groups. MiR-152 is responsible for inhibiting DNA methyltransferase 1. Our results showed that miR-152 reduced cellular proliferation in PC-3, DU-145 and LNCaP prostate cancer cell lines. In addition, miR-152 inhibited DNMT1 expression as well as initiated G2-M cell cycle arrest.

Conclusion: These results suggest that microRNAs may play a role in the advance progression seen in prostate cancer in African Americans. Ongoing research will validate these findings in normal-tumor paired African American and Caucasian tissue samples. Research supported by G12 RR03059-21A1(NIH/RCMI), and CA118623 (NIH/NCI).

**Finasteride alters microRNAs expression in tumoral prostatic cells.**

*F. K. Delella<sup>1</sup>, A. Moroz<sup>1</sup>, A. E. Martins<sup>1</sup>, G. J. Garcia<sup>1</sup>, R. F. Carvalho<sup>1</sup>, E. Deffune<sup>2</sup>, S. L. Felisbino<sup>1</sup>; <sup>1</sup>Department of Morphology, Univ Estadual Paulista, UNESP, Botucatu, Brazil, <sup>2</sup>Blood Transfusion Center, Univ Estadual Paulista, UNESP, Botucatu, Brazil*

Prostate cancer (PCa) continues to be one of the most prevalent cancers in men of western countries and studies have shown that many microRNAs are differentially expressed and deregulated in PCa, acting as oncogenes or tumor suppressors. Androgen deprivation is an effective therapeutic approach for advanced PCa and finasteride (an inhibitor of type 2 5- $\alpha$  reductase) had been suggested to act as a PCa chemopreventive agent, but its prescription is still controversial between urologists. Considering that microRNAs play a major role on PCa progression and the current discussion about the safety use of finasteride, we investigated microRNAs 16, 205 (tumor suppressor genes) and 21, 125b, 141, 221 and 222 (oncogenes) expression in normal prostatic epithelial cells (RWPE-1) and in androgen-dependent prostatic cancer cells (LNCaP) treated with finasteride. Cells were cultivated in specific media supplemented with 10  $\mu$ M of finasteride dissolved in 0.1% DMSO or with 0.1% DMSO only (control group). After 1, 5 and 10 days of finasteride exposure, total RNA was isolated using TRIzol. The relative microRNA expression levels of target and housekeeping (U6) genes were quantified using real-time PCR analysis with an Applied Biosystems 7300 Real-Time PCR System. The data analysis showed that 125b, 141, 221 and 222 microRNAs are up regulated in LNCaP cells treated with finasteride. The fold change increase was time-dependent to all microRNAs up regulated, being higher at day-10 of treatment. miR-16, miR-205 and miR-21 expression was not altered in LNCaP cells. By contrast, finasteride did not alter microRNAs expression in RWPE-1 cells. The increased expression of the oncomirs 125b, 141 (both involved in the evolution of PCa), and 221 and 222 (both involved in the progression of PCa to androgen independent stage) induced by finasteride treatment in LNCaP cells can contribute to the malignancy and decrease the response of these cells to antiandrogenic therapy. Concomitantly, no change in oncomirs expression of normal cells corroborates with previous studies that point finasteride as a potential chemopreventive against PCa. In summary, our study provides a significant contribution to the molecular mechanisms behind finasteride effects on prostatic cancer cells and encourages its analysis on in vivo models of PCa.

**Characterization of the Roles of Vitamin D and Androgens on CYP24A1 Expression in Prostate Cancer Cells.**

V. C. Echemdu<sup>1,2</sup>, S. K. Lewis<sup>2,3</sup>, J. Adda<sup>2</sup>, S. Mukherjee<sup>2</sup>, D. J. Lamb<sup>2,3,4</sup>; <sup>1</sup>Department of Biology, Prairie View A&M University, Prairie View, TX, <sup>2</sup>Scott Department of Urology, Baylor College of Medicine, Houston, TX, <sup>3</sup>Center for Reproductive Medicine, Baylor College of Medicine, Houston, TX, <sup>4</sup>Department of Molecular and Cellular Biology, Baylor College of Medicine, Houston, TX

The second leading cause of cancer death in males in the US involves the growth of a malignant tumor in the prostate. CYP24A1 is associated with prostate cancer metastasis. This gene product is a multi-catalytic CYP24 enzyme that metabolizes vitamin D<sup>3</sup>. The expression of CYP24A1 is stimulated by vitamin D<sup>3</sup>. Human studies in the Lamb lab indicate that CYP24A1 expression increases in advance staged cancer. Although vitamin D is known to have anti-proliferative effects on tumors, CYP24A1 is a classical vitamin D-stimulated gene. Androgen is thought to have biphasic effects on CYP24A1 expression—at low doses promoting while high doses inhibiting tumor growth. Vitamin D3 and androgen together have a synergistic anti-proliferative effect on androgen-dependent prostate cancer cell growth. The primary objective of this project is to understand the synergistic, growth inhibitory actions of vitamin D and androgen in prostate cancer cells and to study the independent and combined roles of androgen and vitamin D in the regulation of CYP24A1 expression in androgen-dependent and – independent prostate cancer cells. I hypothesize that ligand activated androgen receptor acts as a dominant inhibitor or repressor of CYP24A1 expression in LNCaP prostate cancer cells.

In order to determine the actions of vitamin D and androgen on CYP24A1 expression, LNCaP and C42 cells were subjected to a series of treatments involving vitamin D, R1881, and different combinations of both. Immunoprecipitation with CYP24A1 revealed the presence of a 37 KDa band when immuno-blotting with CYP24A1 antibody. No band was present when immuno-blotting with either AR (androgen receptor) or VDR (vitamin D receptor) antibodies. Immunoprecipitation with AR revealed the presence of a 110 KDa band when immuno-blotting with AR antibody. No band was detected when immuno-blotting with CYP24A1. Interestingly, immuno-blotting with VDR antibody revealed a possible protein-protein interaction with AR. I conclude from these results that AR does not form a complex with CYP24A1. By means of real-time qPCR, our objective was to understand the fold effect of androgen and vitamin D on AR, VDR, and CYP24A1. In C42 cells, vitamin D induced a 23-fold increase in CYP24A1 expression. These results were not observed in LNCaP cells.

To determine mechanisms of transcriptional regulation of CYP24A1 I first interrogated the proximal promoter regions of CYP24 for the presence of cis-acting elements indicative of androgen receptor trans-acting factors. Future studies will focus on transcriptional mechanisms underlying the synergistic interactions of androgen and vitamin D and on biphasic actions of androgen on CYP24A1 expression. These studies aim to identify important pathways that lead to prostate cancer progression, which may be used to improve proper treatment and diagnoses, such as preventing androgen castration resistance in advanced prostate cancer.

**The Y-located TSPY proto-oncogene amplifies its expression in prostate cancer cells through a positive feedback loop.**

*T. Kido<sup>1</sup>, Y-F. C. Lau<sup>1</sup>; <sup>1</sup>Department of Medicine, VA Medical Center, University of California San Francisco, San Francisco, CA*

The testis-specific protein Y-encoded (TSPY) gene is the proto-oncogene for the gonadoblastoma locus on the Y-chromosome (GBY). It is present in the genome of XY sex-reversed patients and predisposes their dysgenetic gonads to gonadoblastoma development. It is also abundantly expressed in other testicular germ cell tumors and numerous types of somatic cancers, including hepatocellular carcinoma, melanoma and prostate cancer. TSPY accelerates cell cycle progression, particularly the G2/M stage, and contributes to oncogenesis by promoting abnormal cell proliferation. Besides its effects on cell cycle, TSPY could exert oncogenic actions via other mechanisms. In the present study, we demonstrated that an exogenously transfected TSPY transgene could enhance the expression of the endogenous TSPY gene in LNCaP cells. Similar transfection analysis showed that it could significantly enhance the activities of luciferase-reporter harboring first exon sequence of TSPY gene. Consistently, chromatin immunoprecipitation and promoter tiling microarray (ChIP-Chip) analysis showed that TSPY could bind to the first exon sequence of the endogenous TSPY genes. Using a Gal4DBD-TSPY fusion protein expression plasmid and a Gal4UAS-luciferase reporter plasmid in a mammalian one-hybrid system, we demonstrated that Gal4DBD-TSPY strongly activated the Gal4UAS-luciferase reporter, while TSPY alone did not. Hence, TSPY could play an important role as a transactivator, capable of amplifying its expression in a positive feedback manner in prostate cancer cells and accelerate its oncogenic actions in affected cells and tissues.

**Chemical genetics *ex vivo* reveals that Lkb1 regulates organogenesis and oncogenesis along AMPK-dependent and -independent pathways.**

*B. Lo<sup>1</sup>, G. Strasser<sup>1</sup>, I. Mellman<sup>1</sup>; <sup>1</sup>Genentech, South San Francisco, CA*

The tumor suppressor Lkb1 is a regulator of cellular energy, proliferation, and polarity, yet the mechanism by which it controls tissue morphogenesis or cancer remains poorly defined. We generated mice harboring a mutant Lkb1 knock-in allele that allows for rapid inhibition of Lkb1 kinase. By culturing embryonic tissues, we show that acute loss of kinase activity perturbs epithelial morphogenesis without a loss in apical-basal polarity. In pancreas, cystic structures developed rapidly following Lkb1 inhibition. In lung, inhibition resulted in epithelial cell-autonomous defects in branching morphogenesis. While the lung phenotype was rescued by bypassing Lkb1 inhibition using an activator of the Lkb1 target AMP kinase, pancreatic cyst development was independent of AMP kinase signaling. The pancreatic phenotype and alterations in gene expression resembled pre-cancerous lesions also induced by expression of mutant K-Ras together with p16/p19 deletion. These observations demonstrate combining the culture of embryonic tissues with chemical inhibition provides a powerful approach to both unraveling developmental programs and evaluating new approaches to cancer therapy.

### A Molecular Signature of Tubulogenesis in Pancreatic Cancer and Oncogenic Role of ASPM.

K. K. Tsai<sup>1</sup>, W-Y. Wang<sup>1</sup>, T-Y. Wang<sup>1</sup>, C-R. Li<sup>2</sup>, J. J. Su<sup>1</sup>, T-S. Chan<sup>3</sup>, M. Lee<sup>4</sup>; <sup>1</sup>National Institute of Cancer Research, National Health Research Institutes, Tainan, Taiwan, <sup>2</sup>Department of Nursing, Chung Shan Medical University, Taichung, Taiwan, <sup>3</sup>Department of Internal Medicine, Taipei Medical University Wang Fang Hospital, Taipei, Taiwan, <sup>4</sup>Department of Computer Science, Kun Shan University, Tainan, Taiwan

Pancreatic ductal adenocarcinoma (PDAC) is a devastating malignancy and only a small subpopulation of the patients with PDAC present with resectable tumors. Unfortunately, the diseases invariably recur following surgery and it is thus imperative to identify patients with risk of early relapse as they may benefit from aggressive neoadjuvant or adjuvant therapy. Disruption of tissue microarchitectures represents an early step of pancreatic tumorigenesis and the degree of which has been used for the histopathological grading of PDAC. We here performed comparative genomic analysis of pancreatic tubules generated in a three-dimensional organotypic culture system which recapitulated the differentiated morphology and exocrine functions of a human pancreatic ductal epithelial tissue. We identified a pancreatic tubulogenesis-specific gene profile and applied it to several independent cohorts of patients with PDAC. We found that the patients with tumors expressing this profile, which we designated “tubule-like” PDAC, fared remarkably well following surgery. Based on this profile we established a 28-gene “tubulogenesis signature” that has strong and robust prognostic value across multiple independent cohorts (total n = 128). We identified from this signature a microcephaly- and stem cell-related gene ASPM as a novel prognostic marker in PDAC. Follow-on functional studies using organotypic cultures and orthotopic tumor xenograft models established the role of ASPM in the malignant progression of PDAC. Thus, by exploiting the genomic program associated with pancreatic tubulogenesis we identified tubule-like PDAC and related molecular markers that significantly enhance prognostic prediction of human PDAC (Supported by grant CA-100-PP-19 from National Health Research Institutes and grant DOH101-TD-C-111-004 from Department of Health of Taiwan for K. Tsai).

### Association between Expression of ERCC1, XPA and 8092C>A of ERCC1, 5'UTR of XPA Polymorphisms and Clinical Response to Cisplatin-Based Chemotherapy and Survival in Patients with Non-Seminomatous Testicular Germ Cell Tumors.

J. Mendoza<sup>1</sup>, C. Hernández<sup>1</sup>, J. Martínez<sup>1</sup>, D. Pérez-Montiel<sup>1</sup>, C. Castro<sup>1</sup>, E. Fabián-Morales<sup>1</sup>, M. Santibáñez<sup>1</sup>, R. González-Barrios<sup>1</sup>, E. Soto-Reyes<sup>1</sup>, J. Díaz-Chávez<sup>1</sup>, L. Oñate<sup>1</sup>, M. Jiménez<sup>1</sup>, M. Núñez<sup>2</sup>, R. Dyer<sup>2</sup>, L. A. Herrera<sup>1</sup>; <sup>1</sup>National Cancer Institute, Mexico City, Mexico, <sup>2</sup>Instituto Nacional de Enfermedades Neoplásicas, Lima, Peru

**Purpose:** To explore role of expression of ERCC1 and XPA in cancer cell lines and its association to cisplatin-sensitivity (CPS); and to define the association of expression of ERCC1 and XPA, and single nucleotide polymorphisms 8092C>A and 5'UTR, respectively, with CPS and overall survival (OS) in patients with non-seminomatous testicular germ cell tumors (TGCT) treated with bleomycin, etoposide, cisplatin (BEP). **Methods:** ERCC1 and XPA cisplatin-treated expression and DNA damage was tested in cancer cell lines. ERCC1 and XPA expression was analyzed in fresh samples of non-seminomatous TGCT from patients chemo-naïve to BEP. Genomic DNA was extracted from paraffin-embedded samples of patients with non-seminomatous TGCT treated with BEP were included; 8092C>A ERCC1 and 5'UTR XPA polymorphisms were defined; immunohistochemistry for ERCC1 expression was done. **Results:**

The *ERCC1* expression was increased in non-CPS cancer cell lines and increased further after cisplatin treatment. Increased  $\gamma$ H2AX was observed in non-sensitive cancer cell lines after cisplatin treatment compared with testicular germ cell tumor cell line. Increased expression of *ERCC1* in non-CPS patients was found, but not *XPA*. Polymorphisms were not associated to CPS or OS, neither with clinical-pathological variables. Expression of *ERCC1* in TGCT patients was associated to CPS ( $p=0.011$ ) but not to OS ( $p=0.231$ ). **Conclusions:** Diminished expression of *ERCC1* is associated to CPS, as well as the presence of *ERCC1* is associated with non-CPS. This study proposes the use of *ERCC1* as a possible marker of clinical response to cisplatin based chemotherapy in patients with non-seminomatous testicular germ cell tumors. **Acknowledgements:** This work was supported by CONACYT 83959 and PAPIIT IN213311-3.

### Role of Shc1 protein during 8-Cl-cAMP induced growth inhibition of cancer cells.

K. Choi<sup>1</sup>, Y. Cho<sup>1</sup>, J. Park<sup>1</sup>, S. Hong<sup>1</sup>; <sup>1</sup>Seoul National University, Seoul, Korea

8-Cl-cAMP, which induces differentiation, growth inhibition and apoptosis in various cancer cells, has been investigated as a putative anti-cancer drug. The Shc1 protein is an adapter protein that is known to be involved in the signaling of numerous cell surface receptors such as growth factor receptors, antigen receptors, cytokine receptors and hormone receptors. Shc1 protein is expressed as three isoforms (46, 52 and 66 kDa) and the hyper-phosphorylation of Shc1 proteins were shown in many different types of tumor cells. We were able to show that the phosphorylation of Shc1 protein was decreased during 8-Cl-cAMP induced cancer cell growth inhibition. ABT702 (an adenosine kinase inhibitor) pre-treatment could restore the decreased phosphorylation of Shc1 protein by 8-Cl-cAMP treatment. Furthermore, whereas Compound C (an AMPK inhibitor) and SB203580 (a p38 MAPK inhibitor) did not block the 8-Cl-cAMP-induced decrease of Shc1 phosphorylation, AMPK and p38 MAPK were phosphorylated by introducing Shc1-targeted siRNA. These results suggest that reduced level of Shc1 phosphorylation acted upon the phosphorylation of AMPK and p38 MAPK during 8-Cl-cAMP-induced growth inhibition.

## Tumor Invasion and Metastasis II

1634

### Palladin expression modulates RhoG activation, migration and invasion of breast cancer cells.

A. Valdivia<sup>1,2</sup>, S. Goicoechea<sup>1,2</sup>, H-A. Brauer<sup>2</sup>, C. Anders<sup>3</sup>, R. Garcia-Mata<sup>1,2</sup>, C. Otey<sup>2,3</sup>, H. J. Kim<sup>3,4</sup>; <sup>1</sup>Biological Sciences, University of Toledo, Toledo, OH, <sup>2</sup>Cell Biology and Physiology, University of North Carolina at Chapel Hill, Chapel Hill, NC, <sup>3</sup>Lineberger Comprehensive Cancer Center, University of North Carolina at Chapel Hill, Chapel Hill, NC, <sup>4</sup>Surgery, University of North Carolina at Chapel Hill, Chapel Hill, NC

Metastasis is the leading cause of death related to cancer. Breast cancer patients are particularly susceptible to metastasis, with survival rates decreasing from 98.3% for local tumors to 23.3% for distant tumors. Our previous results showed that palladin levels in breast cancer patients are higher in malignant tissues than in normal breast samples. In addition, highly invasive breast cancer cell lines express higher levels of palladin than non-invasive cell types. Rho GTPases control many aspects of the metastatic process including cell migration, cell adhesion, cell cycle progression, gene expression and cell polarity. Thus, the aim of our study was to evaluate the role of palladin in GTPase activation, and cell migration and invasion. In our experimental model, we used three cell lines that differ in their levels of palladin expression and

invasive potential. We overexpressed palladin in the non-invasive MCF7 cell line and we generated palladin stable knock-down cell lines for invasive MDA-MB-231 and for the highly metastatic MDA-MB-231-BR. Our results showed that palladin expression is correlated with high levels of active RhoG. This increase in active RhoG was also dependent on the levels of palladin overexpression. In addition, palladin knockdown lines showed a decrease in cell migration and invasion when compared with control lines.

These results suggest that palladin plays an important role in RhoG activation, and thus high palladin expression levels may contribute to the invasive motility of metastatic breast cancer cells. Further analyses are necessary to determine the molecular mechanisms implicated in these events.

**The integrin  $\alpha$ V  $\beta$ 3 alters cellular biomechanical properties during cancer cell invasion.**

C. T. Mierke<sup>1</sup>;

<sup>1</sup>Biological Physics and Soft Matter Physics, University of Leipzig, Leipzig, Germany

The process of cancer cell invasion through the extracellular matrix (ECM) of connective tissue plays a prominent role in tumor progression and is based fundamentally on biomechanics. Cancer cell invasion usually requires cell adhesion to the ECM through the cell-matrix adhesion receptors integrins. The expression of the  $\alpha$  $\beta$ 3 integrin is increased in several tumor types and is consistently associated with increased metastasis formation in patients. The hypothesis was that the  $\alpha$  $\beta$ 3 integrin expression increases the invasiveness of cancer cells through increased cellular stiffness, and reduced cytoskeletal remodeling dynamics. Here, the invasion of cancer cells with different  $\alpha$  $\beta$ 3 integrin expression levels into loose and dense 3D-ECMs has been studied. Using a cell sorter, two subcell lines expressing either high or low amounts of  $\alpha$  $\beta$ 3 integrins ( $\alpha$  $\beta$ 3<sup>high</sup> or  $\alpha$  $\beta$ 3<sup>low</sup> cells, respectively) have been isolated from parental MDA-MB-231 breast cancer cells.  $\alpha$  $\beta$ 3<sup>high</sup> cells showed a threefold increased cell invasion compared to  $\alpha$  $\beta$ 3<sup>low</sup> cells. Similar results were obtained for A375 melanoma, 786-O kidney and T24 bladder carcinoma cells, and cells in which the  $\beta$ 3 integrin subunit was knocked down using specific siRNA. To investigate whether contractile forces are essential for  $\alpha$  $\beta$ 3 integrin-mediated increased cellular stiffness and subsequently enhanced cancer cell invasion, invasion assays were performed in the presence of myosin light chain kinase inhibitor ML-7 and Rho kinase inhibitor Y27632. Indeed, cancer cell invasiveness was reduced after addition of ML-7 and Y27632 in  $\alpha$  $\beta$ 3<sup>high</sup> cells but not in  $\alpha$  $\beta$ 3<sup>low</sup> cells. Moreover, after addition calyculin A, an increase in pre-stress in  $\alpha$  $\beta$ 3<sup>low</sup> cells was observed, which enhanced cellular invasiveness. In addition, inhibition of the Src kinase, STAT3 or Rac1 strongly reduced the invasiveness of  $\alpha$  $\beta$ 3<sup>high</sup> cells, whereas the invasiveness of  $\beta$ 3 knock-down cells and  $\alpha$  $\beta$ 3<sup>low</sup> cells was not altered. In summary, these results suggest that the  $\alpha$  $\beta$ 3 integrin enhances cancer cell invasion through increased cellular stiffness, which enables the cells to generate and transmit contractile forces to overcome the steric hindrance of 3D-ECMs.

1636

**Tumor necrosis factor- $\alpha$  converting enzyme (TACE) mediates TGF- $\beta$  dependent shedding of epithin.**

Y. Cho<sup>1</sup>, H. Lee<sup>1</sup>, B. Park<sup>1</sup>, H. Shin<sup>1</sup>, M. Kim<sup>2</sup>, D. Park<sup>1</sup>; <sup>1</sup>School of Biological Sciences, Seoul National University, Seoul 151-742, Korea, <sup>2</sup>Department of Biological Sciences, Inha University, Incheon 402-751, Korea

Epithin, a type II transmembrane serine protease, is broadly expressed in epithelial and carcinoma cells. It is known that epithin plays critical roles in cancer metastasis as well as in normal epithelial functions such as epidermal differentiation and barrier formation. Previously, we have reported that epithin undergoes ectodomain shedding in response to phorbol myristate acetate (PMA) stimulation. However, the endogenous ligands that induce epithin shedding and the responsible sheddase have not been characterized well. In this study, it is shown that TGF- $\beta$  induces epithin shedding strongly in thymic epithelial cell, 427.1.86 and tumor necrosis factor- $\alpha$ -converting enzyme (TACE) mediates this shedding. TGF- $\beta$  induced epithin shedding was greatly reduced by the treatment of TACE inhibitor, TAPI-0 and also by the inhibition of TACE expression with TACE siRNA. TGF- $\beta$  treatment also induces translocation of intracellular pool of TACE to the membrane where epithin is located. These findings suggest that TGF- $\beta$  induces epithin shedding by the translocation of epithin sheddase, TACE, to the membrane.

1637

**The hemopexin domain of matrix metalloproteinase-9 binds  $\alpha 4\beta 1$  integrin in B-cell chronic lymphocytic leukemia cells. Biochemical and functional characterization.**

E. Ugarte-Berzal<sup>1</sup>, E. Bailon<sup>1</sup>, I. Amigo-Jimenez<sup>1</sup>, G. Rivas<sup>1</sup>, J. A. Garcia-Marco<sup>2</sup>, A. Garcia-Pardo<sup>1</sup>; <sup>1</sup>Centro de Investigaciones Biológicas, CSIC, Madrid, Spain, <sup>2</sup>Hospital Universitario Puerta de Hierro, Madrid, Spain

We previously showed that pro-matrix metalloproteinase-9 (prommp-9) binds to b chronic lymphocytic leukemia (b-cll) cells and contributes to b-cll progression by regulating cell migration and survival (Redondo-Muñoz et al, Blood 2008; Cancer Cell 2010). Induction of cell survival involves a non-proteolytic mechanism and the prommp-9 hemopexin domain (pex9). To help design specific inhibitors of prommp-9-cell binding, we have characterized b-cll cell interaction with the isolated pex9. B-cll cells bound soluble and immobilized gst-pex9, but not gst, and binding was mediated by  $\alpha 4\beta 1$  integrin. The ability to recognize pex9 was observed in all 20 primary samples studied, irrespectively of their clinical stage or prognostic marker phenotype. By preparing truncated forms of gst-pex9 containing structural blades b1b2 or b3b4, we identified b3b4 as the primary  $\alpha 4\beta 1$  integrin-interacting region within pex9. Overlapping synthetic peptides spanning b3b4 were then tested in functional assays. Peptide p3 (fpgvpldthdvfqyrekayfc), a sequence present in b4 or smaller versions of this sequence (peptides p3a/p3b), inhibited b-cll cell adhesion to gst-pex9 or prommp-9, with ic50 values of 138 and 279  $\mu$ molar, respectively. Mutating the two aspartate residues to alanine rendered the peptides inactive. An anti-p3 antibody also inhibited adhesion to gst-pex9 and prommp-9. Gst-pex9, gst-b3b4 and p3/p3a/p3b peptides inhibited b-cll cell transendothelial migration, while the mutated peptide did not. B-cll cell incubation with gst-pex9 induced intracellular survival signals, namely lyn phosphorylation and mcl-1 upregulation and this was also prevented by the p3 peptides. The p3 sequence may therefore constitute an excellent target to prevent prommp-9 contribution to b-cll pathogenesis. Functionally, adhesion of b-cll cells to gst-pex9 increased vegf production, suggesting a direct regulation of angiogenesis by pex9. We are currently studying whether binding of pex9 (or mmp-9) provides resistance of b-cll cells to therapeutic drugs. Our results expand the role of non-catalytic effects of mmp-9 in b-cll and support the

contribution of mmp-9 to b-*c*ll pathogenesis. Supported by grants saf2009-07035 and rd06/0020/0011, ministerio de ciencia e innovación, Madrid, Spain.

**EGF receptor activates the ADP-ribosylation factor 1 to promote invasion of breast cancer cells.**

*S. A. Schlienger<sup>1</sup>, S. Campbell<sup>1</sup>, A. Claing<sup>1</sup>; <sup>1</sup>Department of Pharmacology, Université de Montréal, Montreal, QC, Canada*

Cell invasion is a process tightly regulated by multiple signalling proteins such as plasma membrane receptors, adaptors and small GTP-binding proteins. During cancer progression, transformed cells migrate and invade surrounding tissues to form metastasis. Expression of small GTPases and their regulatory factors is frequently modulated in human cancers. Recently, the ADP-ribosylation factor (ARF) family of GTP-binding proteins have been associated with cancer progression. We have shown that the GTPase ARF1 is overexpressed in highly invasive cancer cells and that EGF stimulation can activate this ARF isoform to regulate migration. Here, we report that modulation of ARF1 expression levels and activity markedly impaired the ability of invasive breast cancer cells to degrade the extracellular and invade its surrounding. Our results indicate that ARF1 impacts shedding of membrane derived microvesicles and metalloprotease activity. ARF1 is required for basal secretion and activation of MMP-9, but not MMP-2. This study therefore shows that ARF1 is a molecular switch regulating key events important for cellular invasion.

1639

**XRCC3/RAD51C Downregulation Induces Invasiveness in Pre-invasive and Invasive Breast Cancer and Bystander Cells via Cyclophilin A.**

*A. Marz<sup>1</sup>, S. Saini<sup>1</sup>, A. Miller<sup>1</sup>, T. Park<sup>1</sup>, C. Alvarado<sup>1</sup>, C. Dumur<sup>2</sup>; <sup>1</sup>Radiation Oncology, Virginia Commonwealth University, Richmond, VA, <sup>2</sup>Pathology, Virginia Commonwealth University, Richmond, VA*

Ectopic overexpression of the homologous recombinational repair protein XRCC3 has been shown to increase breast cell invasiveness. This raises the question of whether XRCC3 is a positive modulator of invasion or an overexpression dominant negative effector which acts by sequestering its partner RAD51C in a non-functional complex when overexpressed. To address this question, and to determine if downregulation of XRCC3 levels has therapeutic implications in reducing invasion and metastasis, we used siRNAs against XRCC3 and RAD51C to transiently downregulate the XRCC3-RAD51C complex in an ER/PR/HER2 negative basal-like human cell line model of pre-invasive to invasive transition in breast cancer. We find that XRCC3 and RAD51C downregulation enhances cell invasiveness. XRCC3 downregulation increases FAK activation on Y397 and signaling via Y861. The FAK effect is abolished when cells are treated with EGF or TGFbeta suggesting that XRCC3 is upstream of these growth factors. Global gene expression analysis shows that XRCC3 downregulation most significantly alters a network of proteins involved in cell movement, including a large number of secreted factors. Consistent with this, conditioned medium collected from XRCC3-downregulated cells has a paracrine enhancement effect on the invasion of naïve pre-invasive and invasive cells. Mass spectrometric analysis reveals that secreted cyclophilin A (CYPA) is upregulated by XRCC3-siRNA. The addition of nanomolar concentrations of recombinant CYPA to XRCC3-wild-type cells enhances invasiveness, suggesting that CYPA is downstream of XRCC3 and is sufficient to induce bystander cell invasiveness. Inhibiting CYPA using cyclosporine A inhibits cell invasiveness at concentrations that do not affect cell proliferation. In addition, using cyclosporine A to block CYPA in the conditioned medium from XRCC3 siRNA treated cells is

sufficient to diminish the ability of this conditioned medium to induce invasiveness in bystander cells. We conclude that XRCC3 is a negative modulator of cell invasiveness working with RAD51C upstream of cell adhesion, growth factor, and paracrine effectors, such as CYPA. These results support the novel idea that DNA repair stress induced by the misregulation of repair proteins could affect the breast tumor microenvironment by altering bystander cell invasion.

1640

**CRN2 (coronin 1C, coronin 3) promotes invasion of tumor cells.**

A. Ziemann<sup>1</sup>, S. Hess<sup>2</sup>, R. Bhuwania<sup>3</sup>, A. A. Noegel<sup>1</sup>, C. S. Clemen<sup>1</sup>; <sup>1</sup>Institute of Biochemistry I, University of Cologne, Cologne, Germany, <sup>2</sup>Institute of Zoology, University of Cologne, Cologne, Germany, <sup>3</sup>Department of Medical Microbiology, Virology and Hygiene, University Hospital Hamburg-Eppendorf, Hamburg, Germany

Spreading of tumor cells from the solid tumor to the surrounding tissue is a critical process in cancer progression. Movement of tumor cells relies on the dynamic remodeling of the actin cytoskeleton regulated by actin binding proteins. One of these actin binding proteins is the WD40-repeat domain protein CRN2, which is involved in cellular processes like protrusion formation, secretion, migration and invasion. Its expression correlates with the malignant phenotype of diffuse gliomas as well as with initiation of pulmonary metastasis of hepatocellular carcinoma cells. Moreover, CRN2 binds to F-actin via its N-terminal  $\beta$ -propeller as well as its C-terminal coiled-coil domain resulting in F-actin bundling and an inhibition of actin polymerization. The CRN2–F-actin interaction is negatively regulated by CK2 dependent phosphorylation at serine 463. This work aimed at a more profound understanding of the CRN2 functions in migration and invasion of tumor cells. We generated stably transduced human U373 glioblastoma cell lines with a knock-down of CRN2 or an over-expression of CRN2 variants. These cells were employed in organotypic brain slice cultures serving as a more physiological model of tumor cell invasion. We could show that CRN2 over-expression increases invasion, whereas CRN2 knock-down decreases invasion of glioblastoma cells into the brain tissue. Additionally invasion is reduced in cells expressing S463D phosphomimetic CRN2 compared to cells expressing the S463A phosphoresistent CRN2. Immunofluorescence studies showed an altered co-localization of CRN2 and F-actin in rod shaped cell extensions in glioblastoma cells expressing the phosphomimetic CRN2 mutant. Our results support the hypothesis that CRN2 plays an important role in actin cytoskeleton dynamics of invasive tumor cells and that phosphorylation at serine 463 modulates this process.

1642

**SGEF is overexpressed in glioblastoma and mediates tumor cell invasion and survival.**

S. P. Fortin<sup>1,2</sup>, I. T. Mathews<sup>2</sup>, J. Rollo<sup>2</sup>, M. H. Symons<sup>3</sup>, J. N. Sarkaria<sup>4</sup>, N. L. Tran<sup>1,2</sup>; <sup>1</sup>University of Arizona, Tucson, AZ, <sup>2</sup>Translational Genomics Research Institute, Phoenix, AZ, <sup>3</sup>The Feinstein Institute, Manhasset, NY, <sup>4</sup>Mayo Clinic, Rochester, MN

Glioblastoma (GB) is the highest grade and most common form of primary adult brain tumors. GB tumors are characterized by a poorly defined mass due to a highly invasive cell population attributed with having a decreased sensitivity to radiation and chemotherapy with temozolomide (TMZ). Importantly, current therapies for GB do not target invading cells. Thus, the identification and characterization of genes important for cell motility could direct the development of therapies targeting invading cells in an effort to confer an increased sensitivity to radiation and TMZ. We have previously shown that several guanine nucleotide exchange factors (GEFs) for Rho family small GTPases are overexpressed in GB tumors and play important roles in glioma invasion. Here we report a role for SGEF, a RhoG specific GEF, in

mediating glioma invasion and survival. A genome-wide determination of NF- $\kappa$ B-controlled genes in TMZ-resistant primary GB tumor grafts (GB14-TMZ-R) revealed an increased occupancy of NF- $\kappa$ B on the SGEF gene promoter region via ChIP-on-chip analysis as compared to non-TMZ-resistant GB tumor grafts (GB14), and SGEF mRNA and protein expression were found to be inducible under the pro-survival and pro-invasive TWEAK-Fn14 cytokine-receptor signaling axis in an NF- $\kappa$ B dependent manner. Moreover, the resistant line GB14-TMZ-R migrated at an increased rate compared to non-TMZ-resistant GB14. In addition, among human tumor specimens, SGEF mRNA expression is increased in high grade gliomas and levels of SGEF expression in GB tumors inversely correlate with patient survival. Laser capture microdissection of GB tumors showed that SGEF mRNA expression is increased at the invasive tumor rim relative to tumor core, and depletion of SGEF expression by shRNA decreases *in vitro* glioma cell migration and *ex vivo* glioma cell invasion without affecting cell proliferation. In addition, depletion of SGEF sensitizes glioma cells to TMZ-induced apoptosis and impairs colony formation following TMZ insult. Understanding the role of SGEF in promoting cell motility and chemotherapeutic resistance may direct the development of novel targeted therapeutics for invasive GB cells.

### **Recruitment and Regulation of Glycolysis in Cancer by Phosphofruktokinase-1.**

B. A. Webb<sup>1</sup>, D. L. Barber<sup>1</sup>; <sup>1</sup>Cell and Tissue Biology, University of California, San Francisco, San Francisco, CA

Increased aerobic glycolysis and increased cell motility are two hallmarks of metastatic cancer cells. Metastatic cells are highly polarized, suggesting glycolytic enzymes in cancer cells could be spatially regulated. Phosphofruktokinase-1 (PFK-1) is the first rate-limiting step in glycolysis, and we hypothesized that it may be spatially and temporally regulated. We found that PFK-1 is dynamically recruited from the cytosol to the lamellipodia during cell motility. In response to growth factors, endogenous PFK-1 is enriched at the distal margin of lamellipodia of MTLn3 mammary carcinoma cells and CCL39 lung fibroblasts. Other members of the glycolytic metabolon that have increased expression in cancers, including pyruvate kinase isoform PKM2 and lactate dehydrogenase A, show a similar recruitment and co-localize with PFK-1 at lamellipodia. PFK-1 does not co-localize with mitochondria, which are excluded from lamellipodia. We generated an MTLn3 cell line expressing GFP-tagged PFK-1 and used live-cell imaging to show that GFP-PFK-1 is dynamically recruited to the lamellipodia and that enrichment of GFP-PFK-1 in lamellipodia occurs after the extension of the membrane. Polymerization of metabolic enzymes is an area of renewed interest because has been shown to regulate metabolic flux. We asked if PFK-1 can form filaments by electron microscopy and light scattering analysis. In the absence of substrate, recombinant PFK-1 is tetrameric and occasionally forms short filaments. The addition of substrate rapidly induces the formation of higher longer filaments that coincides with increased catalytic activity. A mutant, His199Tyr, which is inactive but retains the tetrameric structure, does not form filaments upon the addition of substrate. Further, ectopically expressed PFK-1 His199Tyr is not enriched in the lamellipodia. To examine the role of PFK-1 in increased glycolytic flux observed in cancer, we generated several cancer-specific mutations of PFK-1. Although these mutations were located in distinct areas of PFK-1, several of these mutations confer a ~2-fold increase in PFK-1 activity. Our data indicate a structural and functional coupling between metabolic adaptation and increased pH<sub>i</sub> in cancer cells and further suggest molecular mechanisms that may provide novel targets for pharmaceutical intervention. Further, the dynamic recruitment and enrichment of glycolytic enzymes at the distal margin of lamellipodia that lack mitochondria suggest the intriguing possibility of localized energy production for membrane protrusion and cell migration.

1644

**Anaphylatoxin C5a enhances human cancer cell motility and invasiveness via aberrantly expressed C5a-receptor (CD88).**

*T. Imamura<sup>1</sup>, Y. Murakami<sup>2</sup>, Y. Wada<sup>2</sup>, Y. Kawano<sup>2</sup>, H. Nitta<sup>3</sup>; <sup>1</sup>Department of Molecular Pathology, Faculty of Life Sciences, Kumamoto University, Kumamoto, Japan, <sup>2</sup>Department of Urology, Faculty of Life Sciences, Kumamoto University, Kumamoto, Japan, <sup>3</sup>Department of Gastroenterological Surgery, Faculty of Life Sciences, Kumamoto University, Kumamoto, Japan*

The anaphylatoxin C5a is a chemoattractant that induces leukocyte migration via C5a receptor (C5aR). There is emerging evidence that C5a is generated in the cancer microenvironment. We analyzed C5aR expression in human cancer specimens, and sought direct influence of C5a-C5aR axis on cancer cells.

Immunohistochemical staining for human cancer tissues revealed that C5aR was aberrantly expressed in various cancer cells but not in noncancerous epithelial cells except renal tubular cells. The C5aR-positive ratio varied in origins of cancer cells. C5aR was expressed on the cell surface in the cancer cell lines examined. In order to analyze the biological effects of C5aR expression in cancer cells under C5a stimuli, C5aR-negative HuCCT1 cells derived from bile duct carcinoma, in which C5aR expression ratio was the highest, were transfected with C5aR cDNA to establish stably C5aR-expressing HuCCT1 cells. C5a triggered cytoskeletal rearrangement in C5aR-expressing HuCCT1 cells, which was visualized by immunofluorescence staining of F-actin. Time lapse analysis showed that C5a enhanced cell motility 3-fold. C5a also enhanced cell invasiveness 13-fold in Matrigel chamber assay. However, such enhancing effect of C5a was not observed in C5aR-negative control cancer cells. Cancer cell invasion was still enhanced in the absence of C5a concentration gradient and even after the removal of C5a stimulation, suggesting that random cell locomotion plays an important role in C5a-triggered cancer cell invasion. C5a increased the release of matrix metalloproteinases (MMPs) from cancer cells by 2 to 11-fold, and inhibition of MMP activity with GM 6001 abolished the C5a enhancing effect on cancer cell invasion. Compared with C5aR-negative control cells, C5aR-expressing HuCCT1 cells spread 1.8-fold more broadly when implanted in nude mouse skin only when stimulated with C5a.

These results illustrate a novel activity of C5a-C5aR axis that promotes cancer cell invasion through motility activation and MMP release. Targeting this signaling pathway may provide a useful therapeutic option for cancer treatment.

1645

**Down regulation of Cell Proliferation and ROCK-1 Protein Expression in Metastatic Breast Cancer Cells in Response to Treatment with Melatonin and Y27632.**

*T. F. Borin<sup>1</sup>, V. A. Fabri<sup>1</sup>, V. B. Coimbra<sup>1</sup>, B. V. Jardim<sup>2</sup>, J. R. Lopes<sup>2</sup>, G. B. Gelalet<sup>2</sup>, G. R. Martins<sup>1</sup>, L. C. Ferreira<sup>2</sup>, M. G. Moschetta<sup>1</sup>, C. Leone<sup>2</sup>, N. N. Gonçalves<sup>1</sup>, L. B. Maschio<sup>1</sup>, J. G. Oliveira<sup>3</sup>, D. A. Zuccari<sup>1,2</sup>; <sup>1</sup>Biologia Molecular, Faculdade de medicina de são José do rio preto, São José do Rio Preto, Brazil, <sup>2</sup>Genética, Universidade estadual paulista "Julio de Mesquita Filho", São José do Rio Preto, Brazil, <sup>3</sup>Pós-graduação, Universidade do sagrado coração, Bauru, Brazil*

Breast cancer affects more women than any other cancer in the world with a high mortality rate mainly related to late diagnosis and the occurrence of metastases. In vitro and in vivo experiments have shown that increased expression of the Rho kinase protein (ROCK-1) is related with tumor growth and metastasis, whereas this molecule signaling inhibition results in significant down regulation of tumor metastasis. Melatonin has several oncostatic and anti-metastatic properties, but its mechanism of action is not fully understood. The aim of this study

was to investigate the protein expression of ROCK-1 in metastatic breast cancer cells and its correlation with the potential oncostatic and oncoprotector effects of melatonin. A metastatic breast cancer cell line (MDA-MB-231) was divided into 4 groups: group I as control and with no treatment, group II treated with melatonin, group III treated with the ROCK-1 inhibitor, Y27632, and group IV treated with melatonin and Y27632. The protein expression of ROCK-1 and the proliferation marker Ki67 were verified by immunocytochemistry, and quantified by optical densitometry. Melatonin concentration of 2 mM ( $p < 0.01$ ), 5 mM ( $p < 0.001$ ) and 10mM ( $p < 0.001$ ) significantly decreased the viability of MDA-MB-231 cells after 24 hours of incubation. Different concentrations of Y27632 were also evaluated and only the dose of 10 $\mu$ M was able to reduce cell viability significantly ( $p < 0.05$ ). 10mM of melatonin and 10 $\mu$ M of Y27632, associated or not, significantly decreased the protein expression of ROCK-1 and the number of cells per cm<sup>2</sup>. These drugs, when associated significantly decreased Ki67 immunocytochemical labeling. This results were validated by a migration/invasion assay. In conclusion, melatonin and Y27632 are effective drugs to down regulate in vitro metastatic breast cancer, confirming their effects of decreasing cell viability and reducing the protein expression of ROCK-1 and Ki67 in these cells. Melatonin, in particular, appears to be more efficient when associated with ROCK-1 inhibitor. Financial support: FAPESP

**Lysophosphatidic acid induces reactive oxygen species generation through protein kinase C in PC-3 prostate cancer cells.**

C-C. Lin<sup>1</sup>, Y-C. Lin<sup>1</sup>, H. Lee<sup>1</sup>; <sup>1</sup>Institute of Zoology, National Taiwan University, Taipei, Taiwan

Prostate cancer is one of the most frequently diagnosed cancers in males. PC-3 cell is a popular cell model for investigating late prostate cancer behavior and finding a useful treatment toward it. Lysophosphatidic acid (LPA) is a lysophospholipid regulates multiple cell processes including proliferation, migration and other aggressive cell behaviors in cancer. In our previous study, we demonstrated that LPA enhances VEGF-C expression in PC-3 cell through activating the generation of reactive oxygen species (ROS), which is known important in the development of many different cancers. Using flow cytometry, we measured the relative ROS levels in PC-3 cells. LPA triggers ROS generation within ten minutes. This ROS production can be suppressed by antioxidant, N-acetylcysteine. By using LPA<sub>1/3</sub> antagonist Ki16425, we confirmed that LPA induced ROS is mediated through LPA<sub>1/3</sub>-dependent pathway. Moreover, pretreatment with PKC inhibitors can block the ROS generation by LPA treatment. Overall, we first demonstrated that LPA induces ROS generation in a PKC dependent manner in PC-3 prostate cancer cell line.

**Sodium butyrate induced cellular senescence and inhibited invasion of cancer cells with distinct mechanism.**

K. Itoh<sup>1</sup>, H. Nakagawa<sup>2</sup>, K. Yoshioka<sup>1</sup>; <sup>1</sup>Biology, Osaka Medical Center for Cancer and Cardiovascular Diseases, Osaka, Japan, <sup>2</sup>Nozaki Tokushukai Hospital, Daito-City, Osaka, Japan

Sodium butyrate (SB) -C-4 saturated fatty acid present in the human bowel membrane in quite high concentration (2 mM) as food metabolites. Here, we focused on the role of SB on cancer cell growth, motility and invasion. SB inhibited the cellular growth, motility and invasiveness in a dose-dependent fashion in both human fibrosarcoma (HT1080) and glioblastoma (A172) cell lines. SB also affected the morphology of the HT1080 and the A172 cells, namely spread out with marked stress fibers bridging focal adhesions. Phosphorylation levels of focal adhesion kinase (Y577 and Y397 sites) were increased but that of myosin light chain (S19 site) was not

altered. All of these biological effects of SB were reversible, and recovered after withdrawal. In addition, HT1080 cells and A172 cells treated with SB showed positivity for senescence-associated beta-gal (SA-beta gal) staining with elevated expression levels of p53 and p21 proteins in a time and dose-dependent manner. By contrast, mRNA level of p21 was sharply declined after the treatment with SB. Knocking down of p21 protein expression by siRNA reversed both the growth inhibition and positivity for SA-beta gal staining but not the inhibition of invasiveness. Further, proteasome inhibitor, MG-132 decreased the cellular growth and inhibited motility and invasiveness of the HT1080 and A172 cells, and showed similar all these biological effects of SB. Finally, intrathecal administration of SB effectively inhibited the invasion of rat mammary cancer cells (Walker256) into the brain and elongated the animal survival in vivo. Collectively, SB inhibited growth with induced cellular senescence, inhibited invasion by distinct mechanism, and thus would be a good candidate for anti-invasive therapy without severe adverse effects.

1648

**Capsaicin suppresses the migration and invasion of cholangiocarcinoma cell by downregulation of matrix metalloproteinase-9 expression via AMPK activation.**

G-R. Lee<sup>1</sup>, D-J. Yoon<sup>2</sup>, N-H. Park<sup>1</sup>, I-S. Han<sup>2</sup>; <sup>1</sup>Medical Science, University of Ulsan, Ulsan, Korea, <sup>2</sup>Biological Sciences, University of Ulsan, Ulsan, Korea

Cholangiocarcinoma is one of the most difficult malignancies for cure. An important prognostic factor for cholangiocarcinoma is metastasis, which precludes curative surgical resection. The development of metastasis requires the movement and invasion of cancer cells from the primary tumor into the surrounding tissue. Recent evidence indicates that capsaicin has depression effects on cancer cell migration and invasion. Thus, we investigated the molecular mechanism of capsaicin-induced anti-migration and anti-invasion effects in HuCCT1 cells. The results of invasion, migration and gelatin zymography assay showed that the treatment of capsaicin significantly suppressed tumor migration and invasion. We further found that capsaicin reduced the PMA-induced expression of MMP-9 and MMP-2 but did not alter TIMP-1 and TIMP-2 levels in immunoblot and RT-qPCR analyses. Interestingly, capsaicin elevated the accumulation of NAD<sup>+</sup> by AMPK activation in intracellular and enhanced SIRT1 activity in nucleus. In addition, capsaicin inhibited NF- $\kappa$ B activity by the deacetylation of the p65 subunit of NF-kB through SIRT1 activation. These results suggest that capsaicin suppressed PMA-induced up-regulation of MMP9 by inhibition of the MMP9 transcription factor NF-kB through AMPK-NAD<sup>+</sup>-SIRT1 signaling cascade, and contributes to cholangiocarcinoma cell metastasis.

1649

**Native type IV collagen induces an epithelial to mesenchymal transition-like process in mammary epithelial cells MCF10A.**

R. Espinosa-Neira<sup>1</sup>, E. P. Salazar<sup>1</sup>; <sup>1</sup>Departamento de Biología Celular, Centro de Investigación y de Estudios Avanzados IPN, Mexico D.F., Mexico

Basement membrane (BM) is a complex network of interacting proteins, including type IV collagen (Col IV) that acts as a scaffold that stabilizes the physical structures of tissues and regulates cellular processes. In the mammary gland, BM is a continuous deposit that separates epithelial cells from stroma, and its degradation is related with an increased potential for invasion and metastasis. Epithelial to mesenchymal transition (EMT) is a process by which epithelial cells are transdifferentiated to one mesenchymal state, and is a normal process during embryonic development, tissue remodeling and wound healing, as well as it has been implicated during cancer progression. In breast cancer cells, native Col V induces migration and gelatinases secretion. However, the role of native Col IV on the EMT process in human

mammary epithelial cells remains to be investigated. In this study, we demonstrate that native Col IV induces down-regulation of E-cadherin expression, accompanied with an increase of Snail1, Snail2 and Sip1 transcripts. Native Col IV also induces an increase in N-cadherin and vimentin expression, an increase of MMP-2 secretion, the activation of FAK and NFκB and cell migration and invasion in MCF10A cells. In summary, these findings demonstrate, for the first time, that native Col IV induces an EMT-like process in MCF10A human mammary non-tumorigenic epithelial cells.

1650

**The Synthetic Triterpenoid Acetylenic Tricyclic Bis-(Cyano Enone) Affects the Cytoskeleton in Cell Migration and Epithelial-to-Mesenchymal Transition.**

*E. Chan<sup>1</sup>, J. Di Guglielmo<sup>1</sup>; <sup>1</sup>Physiology & Pharmacology, Western University, London, ON, Canada*

During metastasis tumor cells undergo an epithelial to mesenchymal transition (EMT), where cell-cell junctions dissolve and actin stress fibers are formed. This transition unmask the migratory and invasive potential of the tumor cells to migrate to distant organs to establish secondary tumors. Cell migration is initiated by the asymmetrical localization of polarity proteins towards the leading edge, this stimulates the reorganization and polymerization of the microtubule and actin, which form protrusions in the plasma membrane to drive the cell forwards. Our lab has identified the synthetic triterpenoid, CDDO-Im, as a potent inhibitor of cell migration by inhibiting the polymerization of branched actin and disrupting the organization of the microtubule network (To et al., J Biol Chem. 2008, 2010). Recently, TBE-31 has been developed, which is a smaller 3 ring compound that contains the same active functional groups as CDDO-Im. Thus our hypothesis is that TBE-31 will also effectively inhibit the polymerization of actin and disorganize the microtubule network to inhibit cell migration and epithelial to mesenchymal transitions. TBE-31 was found to displace the polarity proteins from the leading edge of migrating cells, causing Rat2 fibroblasts to form multiple protrusions in multiple directions. The microtubule network became disorganized and the polymerization rates for tubulin and actin were decreased. These effects are believed to allow submicromolar concentrations TBE-31 to inhibit fibroblast migration by as much as 60%. Finally, the reorganization of actin and formation of stress fibers normally associated with EMT was also inhibited by TBE-31. In conclusion, TBE-31 disrupts the cytoskeleton, inhibits cell migration and preliminary data suggest TBE-31 may also hinder EMT.

1651

**Cranberry flavonols affect human prostate cancer cell growth via cell cycle arrest by modulating expression of cell cycle regulators.**

*R. Hurta<sup>1</sup>, J. Kim<sup>2</sup>, K. Patel<sup>3</sup>, C. Neto<sup>3</sup>; <sup>1</sup>U.P.E.I., Charlottetown, PE, Canada, <sup>2</sup>U.P.E.I., Charlottetown, Canada, <sup>3</sup>UMass-Dartmouth, North Dartmouth, MA*

Previously, we have demonstrated that an American cranberry (*V. macrocarpon*) extract can inhibit human prostate cancer cell growth via cell cycle arrest by modulating the expression of cell cycle regulators. This present study was designed to identify the phytochemicals present in cranberry responsible for the alterations in cell cycle regulators which occurred in response to cranberry. This current study examined the effects of a flavonol-enriched fraction (FL) from cranberry on the behavior of DU145 human prostate cancer cells in vitro. FL was characterized to contain quercetin and myricetin glycosides. FL (50 µg/mL) decreased cellular viability by ~15% post 6 hours of treatment. FL (post 6h. exposure) increased the proportion of cells in G2-M and decreased the proportion of cells in G1. These alterations in cell cycle were associated with

changes in cell cycle regulatory proteins and other cell cycle associated activities. FL (6h.treatment) decreased the protein expression levels of cyclin A & cyclin B1 and increased the expression of cyclin D1 & cyclin E. FL treatment resulted in a decrease in the protein expression levels of CDK2 & CDK4. Increased p21, p27, and p16 protein expression levels were evident in response to FL treatment, whereas a decrease in pRb p130 protein expression levels occurred with no readily apparent alteration in the levels of pRbp107 protein. These findings demonstrate that one of the classes of phytochemicals responsible for the cranberry mediated alterations in cell cycle protein expression levels are the flavonols. These findings also demonstrate that phytochemical extracts from the American cranberry (*V. macrocarpon*) can affect the behavior of human prostate cancer cells in vitro and further supports the potential health benefits associated with cranberries. [N.C.I.C.- Canadian Cancer Society, P.E.I. Health Research Program, The Cranberry Institute (Wisconsin Cranberry Board) & Telus MRFD Prostate Cancer Fund (PEI Division) funded]

**Cell and Molecular Processes Critical in Metastasis of Breast Cancer Cells are Inhibited by Specific Components of Pomegranate Juice.**

A. Rocha<sup>1</sup>, L. Wang<sup>1</sup>, M. Martins-Green<sup>1</sup>; <sup>1</sup>Cell Biology & Neuroscience, UC Riverside, Riverside, CA

Breast cancer is the most common cancer and the second leading cause of cancer death and morbidity among women in the western world. Pomegranate juice (PJ) and a combination of three of its specific components have been shown to inhibit processes involved in prostate cancer metastasis. If this also proves to be true for breast cancer cells, these natural treatments will be promising agents against breast cancer that can serve as potentially effective and nontoxic alternatives or adjuncts to the use of conventional selective estrogen receptor modulators (SERMs) for breast cancer prevention and treatment. To test this possibility, we have used 2 breast cancer cell lines, MDA-MB-231 cells (ER-) and MCF7 (ER+), and the non-neoplastic cell line MCF10A. We show that, in addition to decreasing growth of breast cancer cells, PJ or a combination of its components Luteolin (L) plus Ellagic Acid (E) plus Punicic Acid (P) increase cancer cell adhesion and decrease cancer cell migration but do not affect normal cells. These treatments also inhibit chemotaxis of the cancer cells to SDF1 $\alpha$ ; a chemokine that attracts breast cancer cells to the bone. We hypothesize that PJ and L+E+P stimulate expression of genes that increase adhesion and inhibit genes that stimulate cell migration and chemotaxis to SDF1 $\alpha$ ; Using qPCR, we confirmed these proposed effects on gene expression and in addition we found that a gene important in epithelial-to-mesenchymal transitions is decreased. We also found that pro-inflammatory cytokines/chemokines are significantly reduced by these treatments, thereby having the potential to decrease inflammation and its impact on cancer progression. Discovery that PJ and L+E+P are inhibitory of metastatic processes in breast cancer cells in addition to prostate cancer cells indicates that they are very likely to be an effective treatment to inhibit cancer progression in general.

**2-D DIGE and siRNA to find new cancer targets.**

S. Grimsby<sup>1</sup>, S. Sandahl<sup>1</sup>, M. Winkvist<sup>1</sup>, A. Jorsback<sup>1</sup>, U. Engström<sup>2</sup>, R. Sundar<sup>3</sup>, M. Landström<sup>3</sup>; <sup>1</sup>GE Healthcare Lifesciences, Uppsala, Sweden, <sup>2</sup>Ludwig Institute of cancer research, Uppsala, Sweden, <sup>3</sup>Umeå Universitet, Umeå, Sweden

siRNA is a powerful tool in loss-of-function studies which generates valuable information on target validation. siRNA is highly selective and suppress gene expression in a sequence-

specific manner. These features have made it a key tool in signal transduction - a cornerstone in cancer biology. 2-D DIGE (two dimensional differential gel electrophoresis) is a fluorescence based technology with the capacity to separate thousands of proteins in one single run, with high reproducibility. This makes it a valuable tool for differential expression analyses. In this study two powerful methods, siRNA and 2-D DIGE, were combined to investigate a well-known signaling pathway, pivotal in cancer biology. Silencing of the target protein made it possible not only to identify a large number of proteins that were differentially regulated but also to resolve the time dependency of protein regulation. Thus the combined use of siRNA and 2-D DIGE made it possible to find potentially new targets in the signaling pathway.

## Cancer Stem Cells

### IL-6 modulates cisplatin resistance involving stem cells in HNSCC.

*C. Nor<sup>1,2,3,4,5</sup>, Z. Zhang<sup>1</sup>, K. A. Meiers<sup>1</sup>, R. Roesler<sup>2,3,4,5</sup>, J. E. Nor<sup>1,6,7</sup>; <sup>1</sup>CRSE, University of Michigan School of Dentistry, Ann Arbor, MI, <sup>2</sup>Cancer Research Laboratory, University Hospital Research Center (CPE-HCPA), Porto Alegre, Brazil, <sup>3</sup>Federal University of Rio Grande do Sul, Porto Alegre, Brazil, <sup>4</sup>National Institute for Translational Medicine (INCT-TM), Porto Alegre, Brazil, <sup>5</sup>Laboratory of Neuropharmacology and Neural Tumor Biology, Department of Pharmacology, Institute for Basic Health Sciences, Federal University of Rio Grande do Sul. Rua Sarmento Leite, 500 (ICBS, Campus Centro/UFRGS), Porto Alegre, Brazil, <sup>6</sup>Dept. of Biomedical Engineering, University of Michigan College of Engineering, Ann Arbor, MI, <sup>7</sup>Dept. of Otolaryngology, University of Michigan School of Medicine, Ann Arbor, MI*

Cisplatin is one of the most effective drug in the management of patients with advanced head and neck squamous cell carcinoma (HNSCC). However, patients frequently develop resistance to cisplatin through mechanisms that are not fully understood. Here, we hypothesized that endothelial cell-initiated signaling contributes to cisplatin resistance in HNSCC. We observed that IL-6 secreted by primary human dermal microvascular endothelial cells (HDMEC) induce STAT3 and ERK phosphorylation in HNSCC. UM-SCC-22B cells exposed to 0-50 ng/ml IL-6 and 0-2  $\mu$ M Cisplatin were analyzed by western blot for STAT3, phospho-STAT3, ERK and phospho-ERK. STAT3 phosphorylation was enhanced in cells treated with IL-6, and remained unaffected by treatment with cisplatin. In contrast, ERK phosphorylation was induced by IL-6 alone, but was inhibited when cells were exposed to Cisplatin. However, ERK phosphorylation was seen when IL6 50 ng/mL was combined to Cisplatin. Accordingly to the Stem Cell Hypothesis, the slow growing cancer stem cells can scape from conventional therapy and as tumor-initiating cells establish local recurrences and distant metastases. We also looked at the stem cells proportion in HNSCC. We observed an increased percentage of ALDH+CD44+ cells when UM-SCC-22B cells were exposed to Cisplatin combined with 20 and 50 ng/ml IL-6 by flow cytometry. Sphere formation was enhanced when single ALDH+CD44+ cells were submitted to low attachment plates in appropriate medium and treated with Cisplatin and IL-6 together. The same regimen seems not affect ALDH-CD44- cells. By western blot we observed higher levels of Bmi-1 expression in cells treated with IL-6 in addition to Cisplatin and we also observed that IL-6R antibody can decrease the expression of this protein. Taken together these results suggest that endothelial cell-secreted IL-6 plays a role in the development of cisplatin resistance involving stem cells in HNSCC and IL-6 receptor can be evaluated as a new molecular target for the development of adjuvant therapy.

**Human glioblastoma cancer stem cells are sensitive to doxorubicin and temozolomide.**

*E. S. Villodre<sup>1</sup>, P. C. Lopez<sup>1</sup>, G. Lenz<sup>1</sup>; <sup>1</sup>Biophysics, Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil*

Gliomas are aggressive brain tumors and the cell line U87 produces tumor-spheres enriched in cancer stem cells (CSCs) that are important for the establishment and maintenance of tumor mass. CSCs are more resistant to radio and chemotherapies than differentiated cells. Temozolomide (Tmz) is a DNA methylating agent and doxorubicin (Doxo) is a topoisomerase inhibitor. Our objective was to evaluate the effects of these drugs on CSCs derived from human glioblastoma.

We performed sphere formation assay to quantify the number of spheres, flow cytometry to measure the percentage of Oct4 and Nanog positive cells and beta-galactosidase senescence assay .

Using DMEM/FBS, Doxo 1 and 10 nM reduced the number of spheres (54.7 in control versus 2.5 and 1.8, respectively) and induced cell senescence in the cell line U87 after 7 days. Doxo 10 nM decreased the number of Nanog and Oct4 positive cells while Doxo 1 nM had no effect. Tmz 5 µM decreased the number of spheres (to 54.7 in control versus 30.4) and the CSCs markers. Using serum free medium, we observed that all treatments reduced the sphere formation after 7 days (224 in control and 110, 125 and 41 after treatment with Tmz, Doxo 1 nM and 10 nM, respectively).

Our results indicate that low doses of Doxo reduce the proportion of CSCs in glioma cultures as well as induces cell senescence. Tmz had a similar effect except that did not induce cell senescence. The response obtained using sublethal doses is an important condition to therapeutic approach, which could lead to a reduction on side effects.

**Sphere culture of murine lung cancer cell lines are enriched with cancer-initiating cells (CICs).**

*B. J. Morrison<sup>1</sup>, J. C. Steel<sup>1</sup>, J. C. Morris<sup>1</sup>; <sup>1</sup>Department of Internal Medicine, University of Cincinnati, Cincinnati, OH*

**Background:** CICs are hypothesized to represent a unique cell population essential for the growth and maintenance of tumor. Most *in vivo* studies of CICs utilize human tumor xenografts in immunodeficient mice. These models provide limited information on the interaction of CICs with the host immune system. We hypothesize that assessing the tumorigenicity of CICs in immunocompetent syngeneic animal models will be a more meaningful approach than in immunocompromised animal models, particularly in the ability to accurately define the frequency of CICs in a cell line.

**Methods:** We studied the sphere forming capacity of 13 murine lung cancer cell lines. Additionally, we examined TC-1 and Lewis lung carcinoma (LLC) cells using sphere culture and a series of phenotypic and functional assays in an effort to isolate CICs. Furthermore, we compared CIC frequency of sphere-derived cells enriched for CICs compared to “differentiated” tumor cells in syngeneic and immunocompromised animals.

**Results:** TC-1 and a highly metastatic variant of LLC (HM-LLC) tumorspheres exhibited some characteristics associated with CICs. TC-1 tumorspheres were not enriched for expression of CD133 or CD44, putative CIC markers, nor did they demonstrate Hoechst 33342 side-

population staining or Aldefluor activity compared to adherent cells. In tumorsphere culture these cells exhibited self-renewal and long-term symmetric division capacity, expressed Oct-4, and demonstrated greater tumorigenicity in syngeneic animals compared to adherent cells. HM-LLC readily formed tumorspheres. Sphere-derived cells exhibited increased Oct-4, CD133, and CD44 expression, demonstrated a Hoechst 33342 side-population, and Aldefluor activity compared to adherent cells or a low metastatic subclone of LLC (LM-LLC). In syngeneic mice, HM-LLC sphere-derived cells required fewer cells to initiate tumorigenesis compared to adherent or LM-LLC cells. In immunocompromised mice, less than 500 TC-1 cells and less than 1,000 LLC cells were required to initiate a tumor.

**Conclusions:** We suggest that no single phenotypic marker can identify CICs in murine lung cancer cell lines. Tumorsphere culture may provide an alternative approach to enrich for murine lung CICs. Results of CIC frequency in immunocompromised animals become less meaningful as this interaction is not taken into account. We propose that assessing tumorigenicity of murine lung CICs in syngeneic mice better models the interaction of CICs with the host immune system, a critical component of tumor biology.

1657

#### **Inhibitory effects of phylligenin on the proliferation of cultured rat neural progenitor cells.**

*S. Lee<sup>1</sup>, H. Go<sup>1</sup>, Y-J. Jeong<sup>2</sup>, H. Shin<sup>2</sup>, S-Y. Han<sup>2</sup>; <sup>1</sup>School of Medicine, Konkuk University, Seoul, Korea, <sup>2</sup>College of Pharmacy, Gyeongsang National University, Jinju, Korea*

Neural progenitor cells (NPCs) differentiate into astrocytes, neurons and oligodendrocytes, which is controlled by various factors in brain. Recent evidences suggest that small molecules modulating the proliferation and differentiation of NPCs may have therapeutic value as well as use of chemical probes. Phylligenin is a lignan with anti-inflammatory activity that is isolated from the fruits of *Forsythia koreana*. We investigated effects of phylligenin on proliferation and differentiation of NPCs. Treatment of phylligenin decreased the number of proliferating NSCs in culture without effects on the differentiation and survival of neural cells such as neurons and astrocytes. To examine the mechanism of the decreased NSCs number, we performed FACS analysis. Proliferation of NSCs was decreased via G1-S transition block by phylligenin treatment. The anti-proliferative effect of phylligenin was mediated by the increase of p21 level. However, phylligenin did not induce apoptosis of NSCs as determined by TUNEL assay and PARP cleavage. We also found that viability of glioma cell lines such as C6 and U87MG glioma cells, but not that of primary neuron and astrocyte, was inhibited by phylligenin. These results suggest that phylligenin selectively inhibit proliferation of rapidly growing cells such as neural stem cells and glioma cells. Given that the possible role of brain tumor stem cells in the pathology of brain cancers, the inhibitory effects of phylligenin might be useful in the development of new therapeutic agents against brain cancers.

#### **Focal Adhesion Kinase Maintains Luminal Progenitor and Basal Mammary Stem Cell Activities with Differential Requirement of Tyrosine Kinase Function.**

*M. Luo<sup>1</sup>, X. Zhao<sup>1</sup>, S. Liu<sup>2</sup>, M. Wicha<sup>2</sup>, J-L. Guan<sup>1</sup>; <sup>1</sup>Department of Internal Medicine, Division of Molecular Medicine and Genetics, University of Michigan, Ann Arbor, MI, <sup>2</sup>Department of Internal Medicine, Division of Hematology and Oncology, University of Michigan, Ann Arbor, MI*

Mammary stem cells (MaSCs) and progenitor cells are important for mammary gland development and maintenance, and also serve as potential cell origins of mammary cancer stem cells (MaCSCs). However, the signaling mechanisms regulating these cells and how they

contribute to tumorigenesis are not well understood. Here, we show that conditional deletion of focal adhesion kinase (FAK) in mammary epithelial cells (MaECs) during early embryonic stage significantly decreased the content of luminal progenitors (LPs) and basal MaSCs, and reduced their colony-forming and regenerative potential in a cell-autonomous manner. Further rescue experiments and creation of FAK kinase-defective (MFCKD) knockin mice unveiled that loss of FAK kinase activity in MaECs specifically impairs the proliferation of LPs and functional alveologenesis/milk production, but kinase-independent function of FAK is sufficient to support ductal invasion and basal MaSC activity. Such deficiency in LPs of MFCKD mice significantly suppressed tumorigenesis and formation of MaCSCs in a mouse breast cancer model derived from LPs. Lastly, we demonstrated that, in contrast to the universal inhibitory effect of FAK knockdown, FAK kinase blockers preferentially inhibited proliferation and tumorsphere formation of LP-, but not MaSC-like (claudin-low) human breast cancer cells. Together, these studies demonstrated intrinsic role of FAK and its kinase-dependent and -independent actions in regulation of LPs and basal MaSCs, and suggest that targeting distinct FAK function alone, or in combination, may serve as tailored therapeutic approaches for breast cancer heterogeneity.

1659

**Neoblast Response to Carcinogen Induced Malignancy in Planarians: A Preliminary Study.**

J. Pic<sup>1</sup>, G. Varghese<sup>1</sup>, C. Pierce<sup>1</sup>, R. Abdullah<sup>1</sup>, J. G. Golfinos<sup>2</sup>, M. Chacko<sup>1</sup>, E. B. Voura<sup>1,2</sup>;  
<sup>1</sup>Dominican College, Orangeburg, NY, <sup>2</sup>New York University Langone Medical Center, New York, NY

Current thinking considers cancer a stem cell disease. But how these cells affect tumor growth, and whether cancer stem cells are native to tumors or home in on them are still open questions. To learn more about how stem cells react to carcinogens and to the presence of a growing tumor we turned to the planarian species *Dugesia dorotocephala*. Planarians have an exceptional regenerative capacity owing to their ready supply of undifferentiated stem cells or neoblasts. Furthermore, research has shown that various carcinogens can induce tumor growth in the planarian, and that these lesions can be histologically similar to those found in patients. We used a two-week exposure to a mixture of TPA and cadmium sulfate to stimulate tumorigenesis in the planarian. BrdU was used to examine the activity of mitotic or neoblastic cells in planarians exposed to the carcinogens. An analysis of the actin ultrastructure was used to study the overall cellular response of the organism to a growing tumor and to gauge the possible motility of the neoblasts. Work testing the migratory response of cells from tissue grafts of healthy worms to carcinogen exposed or tumor-bearing worms was also begun. This study will set the stage for developing an understanding of how stem cells react to and affect tumor growth.

**Crosstalk between matrix metallo-proteinases and chemokines during prostate cancer stem cells mediated metastasis.**

S. Rentala<sup>1</sup>, L. Mangamoor<sup>2</sup>, P. Yalavarthy<sup>3</sup>; <sup>1</sup>Department of Biotechnology, Gandhi Institute of Technology and Management University, Visakhapatnam, India, <sup>2</sup>Department of Biotechnology, Jawaharlal Nehru Technological University, Hyderabad, India, <sup>3</sup>Department of Zoology, Kakatiya University, Warangal, India

Although prostate cancer is now the most commonly diagnosed cancer in men, the etiology of this disease remains unclear. Recent efforts to identify and characterize prostate cancer stem cells (PCSCs) also support this hypothesis. Human prostate cancer cell sub-population that is,

PCSCs with the highest *in vitro* proliferative potential is negative for androgen receptor (AR) expression. This population also possesses CD44<sup>+</sup>α<sub>2</sub>β<sub>1</sub><sup>hi</sup>CD133<sup>+</sup> and predominantly expresses the basal cell cytokeratins. Our study explored the ability of CD133-positive and CD44-positive cells (CD44<sup>+</sup>CD133<sup>+</sup>) to differentiate into prostate cancer epithelial cells bearing CD57, androgen receptor and prostate specific antigen (PSA). Prostate cancer stem cells expressed chemokines and their receptors, such as SDF1- α and CXCR4 (n=6). *In vitro* and *in vivo* investigations into the expression of matrix metalloproteinases (MMPs) showed the expression high levels of MMP-2 and MMP-9, whereas MMP-7 and MMP-13 were expressed in moderate levels, at both the levels of mRNA and proteins in prostate cancer tissue derived CD44<sup>+</sup>α<sub>2</sub>β<sub>1</sub><sup>hi</sup>CD133<sup>+</sup> cells. Matrigel invasion assay and chemotaxis assay confirmed the role of above MMPs and chemokines during migration and differentiation of prostate cancer stem cells. *In vivo* metastasis models (n=6) and immuno-histochemical analysis showed the correlation between MMPs and chemokines during migration and differentiation of prostate cancer stem cells mediated metastasis.

1661

### **Restricting Brain Tumor-Initiating Cell Motility By Rewiring Cell-Matrix Mechanosensing.**

S. Y. Wong<sup>1,2</sup>, T. A. Ulrich<sup>1,2</sup>, J. L. MacKay<sup>3</sup>, L. P. Deleyrolle<sup>4,5</sup>, B. A. Reynolds<sup>4,5</sup>, S. Kumar<sup>1,2</sup>;

<sup>1</sup>UC Berkeley-UCSF Graduate Group in Bioengineering, Berkeley, CA, <sup>2</sup>Bioengineering, University of California, Berkeley, Berkeley, CA, <sup>3</sup>Chemical and Biomolecular Engineering, University of California, Berkeley, Berkeley, CA, <sup>4</sup>McKnight Brain Institute, University of Florida, Gainesville, FL, <sup>5</sup>Queensland Brain Institute, University of Queensland, Brisbane, Australia

Glioblastoma multiforme (GBM) is the most aggressive primary brain tumor and is characterized by poor survival even in the setting of surgery, radiation, and chemotherapy. While GBM tumors are very heterogeneous, recent work has shown that a specific subpopulation of tumor cells - so-called "brain tumor-initiating cells" (BTICs, also called brain tumor stem cells) - is particularly resistant to conventional treatments, is uniquely capable of initiating new GBM-like tumors following transplantation, and may directly participate in the invasive process. Thus, there is tremendous interest in identifying microenvironmental factors that regulate BTIC self-renewal and motility. Specifically, studies have shown that Rho family GTPases can influence brain tumor progression, but results from these studies have been contradictory. Here, we investigate the sensitivity of BTICs to extracellular matrix (ECM) mechanics and the role of Rho GTPases in regulating this sensitivity.

We cultured BTIC lines on laminin-coated polyacrylamide ECMs ranging in stiffness from 80 Pa to 119 kPa. We found no significant differences in spreading area, random motility speed, or proliferation as a function of ECM stiffness. Remarkably, all BTIC lines proliferated robustly, underwent rapid mesenchymal motility, and developed vinculin-positive adhesions on extremely soft ECMs (~ 80 Pa) normally regarded as non-permissive for spreading, adhesion maturation, and migration. Lentiviral transduction of BTICs with a constitutively active (CA) mutant of Rho GTPase strongly restored mechanosensitivity abrogating BTIC spreading and migration on soft ECMs of comparable stiffness to brain tissue. Administration of myosin II inhibitor blebbistatin offset CA RhoA-mediated mechanosensitivity and restored BTIC spreading and migration on soft ECMs. AFM measurements suggest that BTICs are very soft on both stiff and soft ECMs, thus failing to exhibit normal tensional homeostasis. These findings are consistent with a model in which BTICs evade the anti-tumorigenic effects of soft ECMs but may be rendered susceptible through activation of RhoA-dependent cell contractility.

These results provide the first evidence that BTICs can uniquely resist mechanical suppression of motility and other culture behaviors relevant to tumor spread, in the same way they can resist

radio- and chemotherapy. In addition, motility on ECMs of stiffness comparable to brain tissue may be restricted by forcing activation of myosin-dependent contractility, implying that proteins in this pathway may represent a novel set of therapeutic targets.

1662

**In vitro and in vivo interaction of cdk6 and Eya2 indicate potential crosstalk between cell cycle and developmental pathways.**

*M. J. Grosse<sup>1</sup>, D. Kohrt<sup>1</sup>, J. Cray<sup>1</sup>, P. W. Hinds<sup>2</sup>; <sup>1</sup>Department of Biology, Connecticut College, New London, CT, <sup>2</sup>Department of Radiation Oncology, Molecular Oncology Research Institute, Tufts-New England Medical Center, Boston, MA*

We have identified a novel association of the developmentally significant protein, Eya2, with cyclin dependent kinase (cdk) 6. The protein-protein interaction was first identified in a yeast two-hybrid analysis of a human fetal brain library. Subsequent results confirm the association of cdk6 and Eya2 in GST binding assays and co-immunoprecipitations. GST binding assays demonstrated that Six4, a cofactor of Eya2, competes with cdk6 for Eya2 binding. Co-immunoprecipitation of transfected cell lysates and native immunoprecipitations also demonstrate binding of cdk6 and Eya2. Functional outcomes of this interaction are under investigation. Given that Eya and Six proteins are known to impact (breast) tumor cell invasiveness, we propose that the cdk6/Eya2 interaction affects fundamental properties of the cancer cell and may also function in normal development of the (mammary) epithelium.

**Novel EGFR Pathways with Fast Kinetics Similar to a Neuron are Conserved in a Broad Variety of Cancer-Types.**

*F. Azizi<sup>1</sup>, E. J. Tisdale<sup>1</sup>, C. R. Artalejo<sup>1</sup>; <sup>1</sup>Pharmacology, Wayne State University School of Medicine, Detroit, MI*

The epidermal growth factor receptor (EGFR) is a tyrosine kinase receptor and overexpression of EGFR (high-EGFR) is associated with an aggressive cancer phenotype, poor clinical prognosis, and high rates of recurrences and/or metastasis. Although a variety of cancer therapies exist, all treatments damage normal cells. Therefore, it is important to identify cancer-specific targets for future therapeutic intervention. The objective of this study was to directly measure in “real-time” EGFR membrane trafficking in epithelial cells (high-EGFR versus low-EGFR) from a broad variety of cancer-types by using membrane capacitance (Cm) measurements of cell surface area. Capacitance techniques have been used to track exocytosis and the subsequent endocytosis in neurons and endocrine cells. Our results show that EGFR-stimulation of high-EGFR cancer cells causes extremely fast changes in Cm measurements that have time-constants in the order of a few msec-secs, which is temporally consistent with the rate of the fast steps in exocytosis and endocytosis observed in endocrine cells as well as synaptic terminals. Importantly, these EGFR responses are absent in normal and non-malignant cells (low-normal EGFR levels). Moreover, these cancer-specific EGFR pathways have alternative and kinetically distinct modes of endocytosis depending on the frequency of stimulation. These EGFR responses could never be detected by the techniques and protocols routinely employed to study EGFR internalization. In this study we have obtained proof of concept for the use of the Cm measurements in cancer research: cancer-cell lines are not “professional” secretory cells and Cm measurements have never been evaluated in cancer-

cells nor explored in a cancer-relevant context. To that end, in the current study we have verified that the capacitance technique is a widely applicable method to directly visualize in cancer cells the unprecedented EGFR membrane incorporation and EGFR endocytosis that occurs in response to EGFR-stimulation. Based on our results, we propose that malignant cancers behave with a level of sophistication comparable to neurons with ultra-rapid responses to satisfy their high functional demands. Additionally, the fact that these EGFR responses are present only in malignant cancer cells suggests that a component(s) of these new pathways could be a potential target(s) for universal cancer-specific therapy. Understanding the details of the EGFR-processes in cancer versus noncancer cells will enable major advances in our knowledge of the molecular and cellular basis of EGFR contribution to cancer (supported by NIH GM68813).

### **Role of tumor pericytes in regulating myeloid-derived suppressor cells (MDSC).**

J. Hong<sup>1</sup>, G. Genove<sup>1</sup>; <sup>1</sup>Dept of Medical Biochemistry and Biophysics, Karolinska Institute, Stockholm, Sweden

Myeloid-derived suppressor cells (MDSC) are a heterogeneous population which defined as Gr1<sup>+</sup>/CD11b<sup>+</sup> cells and dramatically expand in many pathological conditions, inflammation, autoimmune disease, infection and cancer. Recently it has been highly reported that MDSC might have a critical role on tumor malignancy by modulating tumor immunity and tumor microenvironment. However, it still remains elusive how MDSC infiltrate through tumor vessels. Previously, we have reported that pericyte deficient mice model, *pdgfb* retention motif knock out mice, *pdgfb*<sup>ret/ret</sup> have less pericyte coverage in tumor vessels. In this study, we found that MDSC expansion was associated with pericyte coverage in tumor vessels. In both syngeneic mouse tumor models, LLC and B16 melanoma, pericyte deficient *pdgfb*<sup>ret/ret</sup> tumorigenic mice has an increased MDSC expansion in blood and tumor as compared to control. Naïve MDSC in non-tumorigenic mice were also assessed in various organs, brain, lung, pancreas and skin, but the level of naïve mdsc was not associated with pericyte deficiency, which means that only tumorigenic MDSC expansion is correlated with pericyte deficiency in tumors. Furthermore, one of MDSC-recruiting cytokines, IL6, was also highly upregulated in blood of *pdgfb*<sup>ret/ret</sup> tumorigenic mice, but the level of other candidate cytokines, IL1b, GM-CSF, G-CSF and VEGF-A was not changed. These results were confirmed by using B16-PDGF-BB tumor model, which have paracrine PDGF-BB production and recover from pericyte depletion near tumor vessel in pericyte deficient *pdgfb*<sup>ret/ret</sup> tumorigenic mice. Taken together, these findings suggest that tumor pericytes regulate the recruitment of MDSC into tumor by modulating the cytokine release through tumor vessels.

1665

### **Visualizing the hypoxia selectivity of cobalt(III) prodrugs in tumor spheroids.**

B. J. Kim<sup>1</sup>, T. W. Hambley<sup>1</sup>, N. S. Bryce<sup>1</sup>; <sup>1</sup>School of Chemistry, The University of Sydney, Camperdown, Australia

Despite the clinical success of many chemotherapeutic agents, anticancer drugs are still limited by their lack of specificity which results in indiscriminate toxicity to both healthy and cancerous cells, and inadequate penetration into tumors. As a result, cancer patients experience side effects such as nephrotoxicity, emetogenesis and neurotoxicity. In an effort to improve the efficacy of anticancer drugs, tumor activated prodrugs have been designed whereby an inactive agent is degraded or metabolized at the tumor site to form the active cytotoxic species.

Cobalt(III) prodrugs have been previously investigated as chaperones for the selective delivery of cytotoxins to solid tumors.

To determine whether cobalt complexes are releasing fluorescent cytotoxic ligands in hypoxic regions, a concatamer of the hypoxia response element (HRE) from the human VEGF gene were cloned upstream of a minimal CMV promoter. DLD-1 colon carcinoma cells were genetically modified to respond to hypoxic stress in two and three-dimensional cell culture by turning on the expression of a fluorescent protein, EosFP. This study used tumor spheroids as an in vitro model to investigate hypoxia selectivity of the cobalt complexes, by correlating the fluorescence of the drug with the green fluorescent protein using confocal microscopy. The distance from which the green fluorescent proteins are expressed in the tumor spheroid is approximately 70  $\mu\text{m}$  from the edge, this is comparable to the hypoxic regions of the immunolabelled mouse biopsies reported in literature [1]. Therefore, tumor spheroids are exemplary models for hypoxia. Co-localisation of the blue fluorescent cytotoxic ligands and the green fluorescent protein has shown that the cobalt(III) complexes are partially hypoxia selective.

#### **The N-terminal Projection Domain of the Microtubule Associated Protein Tau Inhibits TNF $\alpha$ signaling.**

*S. Debnath<sup>1</sup>, P. Hannon<sup>2</sup>, K. Toropova<sup>2</sup>, N. N. Rodriguez<sup>2</sup>, A. Alonso<sup>3</sup>, J. E. Fata<sup>3</sup>; <sup>1</sup>Ph.D program in Biochemistry, The City University of New York, New York, NY, <sup>2</sup>Biology, The College of Staten Island, The City University of New York, New York, NY, <sup>3</sup>Biochemistry, Biology, The College of Staten Island, The City University of New York, New York, NY*

Tumor Necrosis Factor-alpha (TNF $\alpha$ ) is a multifunctional pro-inflammatory cytokine implicated in inducing both tumor promotion and tumor inhibition. This paradoxical effect can be partly explained by the fact that TNF $\alpha$  acts as a regulator of both proliferation and apoptosis; however the mechanisms and factors associated with how or whether a tumor cell responds to a microenvironment rich in TNF $\alpha$  have not been fully resolved. Here we provide evidence that the microtubule associate protein Tau inhibits TNF $\alpha$  signaling through its N-terminal domain and implicate it as a novel regulator of the cellular response to this key cytokine. Our findings indicate that over-expression of Tau in the human breast cancer cell lines MCF7, SkBr3 and in the pheochromocytoma cell line PC12 suppresses TNF $\alpha$  induced apoptosis evident in the control cells. TNF $\alpha$  induced cell apoptosis in control cells is triggered as early as 6 hrs post-treatment with hallmark features of cell shrinkage, membrane blebbing, disruption of tubulin architecture and caspase-3 activation. While over-expression of wild type full length Tau isoform in these cell lines, completely abrogates all TNF $\alpha$  associated apoptotic phenotypes. Aside from inhibiting TNF $\alpha$  induced apoptosis, Tau over-expression also interferes with TNF $\alpha$  induced NF $\kappa$ B activation. This is evident by a significant decrease in NF $\kappa$ B nuclear translocation in Tau over-expressed cells compared to controls. Suppression of TNF $\alpha$  signaling by Tau is not associated with its tubulin interaction since a truncated N-terminal projection domain lacking all microtubule binding domains still provides resistance to TNF $\alpha$  induced apoptosis and NF $\kappa$ B activation. These findings lead us to conclude that the functional domain of Tau that regulates TNF $\alpha$  response lies within its N-terminal region and current mechanistic studies indicate this region inhibits TNF $\alpha$  receptor clustering, which is needed for signaling. Our data provide direct evidence that the N-terminal domain of the microtubule associated protein Tau can inhibit TNF $\alpha$

signaling in tumor cells. These findings indicate a novel function for Tau and add to our knowledge of how a tumor cell responds to TNF $\alpha$  signaling.

1667

**Extracellular matrix fiber alignment by stromal syndecan-1 requires  $\beta$ 3 integrin activity and syndecan-1 ectodomain and heparan sulfate chains.**

*N. Yang<sup>1</sup>, A. Friedl<sup>1</sup>; <sup>1</sup>University of Wisconsin-Madison, Madison, WI*

The cell surface proteoglycan syndecan-1 (Sdc1) is frequently induced in the stromal fibroblasts of invasive breast carcinomas. We have recently identified a correlation between stromal Sdc1 expression and extracellular matrix (ECM) fiber alignment, both *In vivo* (in human breast carcinoma samples) and *in vitro*. Bioactive, cell-free 3D ECMs derived from Sdc1-positive human mammary fibroblasts (HMF), termed ECM-Sdc1, showed an organized, aligned fiber architecture, which contrasted markedly with the random fiber arrangement seen in the ECM of Sdc1-negative HMFs (ECM-mock). We further demonstrated that ECM fiber alignment is responsible for the enhanced directional migration and invasion of breast carcinoma cells when seeded into the fibroblast-free ECM-Sdc1.

To decipher the molecular mechanisms responsible for the formation of an invasion-permissive ECM, a series of Sdc1 mutants were introduced into HMF. These include a heparan sulfate (HS) – deficient, a partial extracellular domain (ectodomain) deletion, a cytoplasmic domain (CD) deletion and a transmembrane domain (TMD) substitution mutant. We found that the ectodomain and HS chains of Sdc1 are required for the full activity of Sdc1 in regulating ECM alignment, while TDM and CD are dispensable.

Integrins are key players in the assembly of fibronectin-rich ECM and Sdc1 has been shown to be an important regulator of integrin activity. Therefore, we investigated the role of integrins in Sdc1-mediated ECM fiber alignment. We found that expression silencing of the integrin  $\beta$ 3 subunit by siRNA largely abolished the aligned ECM fiber architecture induced by Sdc1. Given the integrin subunit repertoire of HMF, this finding suggests that integrin  $\alpha$  $\beta$ 3 is responsible for Sdc1-dependent ECM fiber alignment and consequently the invasion-permissive properties of the ECM. Activation of the  $\alpha$  $\beta$ 3 integrin by  $\beta$ 3 clasp peptide increases ECM fiber alignment in the absence of Sdc1, further supporting this model. Understanding the mechanisms governing ECM organization may lead to the development of novel stroma-targeted therapy for breast cancer.

1668

**The interplay of growth and migration of cancer cells in tumor growth dynamics and invasion.**

*A. M. Jimenez Valencia<sup>1,2,3</sup>, O. N. Yagutcu<sup>4</sup>, M-H. Lee<sup>1,2</sup>, P-H. Wu<sup>1,2</sup>, S. Nutting<sup>1</sup>, S. Tan<sup>1</sup>, S. X. Sun<sup>3,4</sup>, D. Wirtz<sup>1,2,3</sup>; <sup>1</sup>Chemical and Biomolecular Engineering, Johns Hopkins University, Baltimore, MD, <sup>2</sup>Physical Science-Oncology Center, Johns Hopkins University, Baltimore, MD, <sup>3</sup>Institute for NanoBio Technology, Johns Hopkins University, Baltimore, MD, <sup>4</sup>Mechanical Engineering, Johns Hopkins University, Baltimore, MD*

Tumors are a complex arrangement of tissues made up of several components, including dense masses of cancer cells and re-organized extracellular matrix (ECM). Recent studies have revealed the crucial role that extracellular matrix components have on single cancer cell behavior, but how the interaction of ECM components affects the growth dynamics of an entire tumor is not fully understood. Here, we use human derived fibrosarcoma cell aggregates in

combination with live cell imaging, cryo-stat sectioning, immunostaining, and confocal imaging to study changes in cell aggregate size, proliferation, and spatial distribution within 3 dimensional (3D) matrices. We coupled our experimental observations with a continuous approximation model to predict cell aggregate growth and cell density distribution and determine how cell interactions play a significant role in this dynamic growth. Using this model, we investigate the distinct contributions from cell migration, proliferation, cell-matrix interactions, and matrix remodeling to the aggregate progression. Coupling 3D experiments with mathematical modeling could have applications in predicting patient prognosis and in improving drug screening designs.

1669

**Tumoral soluble factors secreted by breast cancer cell lines induce the expression of adhesion molecules in endothelial cells.**

*J. Mejia-Rangel<sup>1</sup>, P. Gariglio<sup>1</sup>, A. Zentella-Dehesa<sup>2</sup>; <sup>1</sup>Genetica y Biologia Molecular, Cinvestav, Mexico D.F., Mexico, <sup>2</sup>Medicina Genomica y Toxicologia Ambiental, IIB-UNAM, Mexico D.F., Mexico*

In the last decade, it has been recognized that the tumor associated endothelial cells express a phenotype different to that expressed by normal endothelial cells. This phenotype appears to be determined by the tumoral microenvironment. The endothelial cells are part of the tumor microenvironment and also play an important role in metastasis including angiogenesis as well as intra- and extra-vascularization. These processes involve the direct interactions between cancer and endothelial cells and require the expression of cell adhesion molecules (selectins, lectins, Ig and integrins) on the endothelial surface and ligands on the cancer cells (glycoproteins, Ig and integrins). The objective of the present study was to determine the expression of adhesion molecules induced by tumoral soluble factors (TSF) secreted by breast cancer cell lines with high (ZR75.30) or low (MCF-7) metastatic potential in human umbilical vein endothelial cells (HUVECs). For this purpose we cultured primary endothelial cells from umbilical cords and evaluate its purity using the expression of von Willebrand Factor as an endothelial marker. We also used a bioplex system to determine the molecules present in the TSFs, finding that the ZR75.30-TSF was enriched with chemokines and growth factors such as: VEGF, IL-8 and G-CSF. These factors have been identified in vivo and in vitro as contributors to progression and metastasis. We also tested the effect of the TSFs on endothelial phenotype, using TNF treatment as a control for the endothelial activated phenotype characterized by the expression of cell adhesion molecules (CAMs: E-Selectin, ICAM-1 and VCAM-1) and an increase in cell adhesion. We found that ZR75.30-TSF induced the expression of the three CAMs at the mRNA and protein levels and also lead to a pro-adhesive phenotype as show by the adhesion assay, while the MCF-7-TSF had no effect on the expression of CAMs nor on cell adhesion.

1670

**Clinicopathological significance and hormonal regulation of ADAMTS-1 in ovarian cancer.**

*M. Lima<sup>1</sup>, A. Turri<sup>1</sup>, T. A. Silva<sup>1</sup>, S. Nonogaki<sup>2</sup>, C. A. Toledo<sup>2</sup>, M. Buim<sup>2</sup>, F. A. Soares<sup>2</sup>, R. G. Jaeger<sup>1</sup>, V. M. Freitas<sup>1</sup>; <sup>1</sup>Department of Cell and Developmental Biology, Institute of Biomedical Sciences, University of Sao Paulo, Sao Paulo, Brazil, <sup>2</sup>Department of Pathology, Hospital A.C. Camargo, Sao Paulo, Brazil*

In ovarian cancer alterations in the extracellular environment are critical for tumor initiation, progression and intra-peritoneal dissemination. Extracellular matrix (ECM) remodeling would influence ovarian cancer behavior. ADAMTS (a disintegrin and metalloprotease with thrombospondin motifs) is a family of secreted matrix metalloproteases, playing a role on

biological processes such as inflammation, angiogenesis and development of urogenital system. Despite suggestive role of ADAMTS in tumor invasion and metastasis, effects played by these molecules in cancer progression are still controversial. Here we analyzed the effect of ADAMTS-1 influencing ovary cancer. Forty-eight human ovary tumors (10 benign, 9 borderline and 29 malignant) were retrieved from the files of the Department of Pathology, Hospital A. C. Camargo, Sao Paulo, Brazil. Tumors were classified according to the WHO Histological Typing of Tumors of the Breast and Female Genital Organs. Clinical stage was determined according to the UICC TNM (tumor, nodes, metastasis) staging system. Immunohistochemistry assessed the presence of ADAMTS-1 in these tumors. ADAMTS-1 substrates, such as proteoglycans versican, aggrecan and brevican, were also analyzed. In addition, immunostaining of TIMP-3, ADAMTS-1 potent inhibitor, was carried out. Immunohistochemistry differences were analyzed by measurements of stained areas normalized per nuclei area. Expression of ADAMTS-1 and TIMP-3 was significantly higher in ovary malignant tumors compared to benign and borderline tumors. ADAMTS substrates brevican, aggrecan and versican expression showed no differences among benign, borderline and malignant ovary tumors. ADAMTS-1 and TIMP-3 are highly expressed in malignant tumors. We may assume that inhibitor levels compensate enzyme effects, thus reducing substrate breakdown and resulting in maintenance of proteoglycan levels in malignant tumors. To further explore the role of ADAMTS-1 in ovary tumor biology, we investigated the role of well-known ovary cancer modulators, such as steroid hormones, in ADAMTS-1 expression. The cell lines NIH-OVCAR-3 (more differentiated) and ES-2 (less differentiated) were treated with different concentrations of progesterone, estrogen or testosterone. ADAMTS levels (mRNA) were analyzed by qPCR. In less differentiated ES-2 cells, ADAMTS-1 mRNA levels increased after treatment with hormones estrogen and testosterone. No differences were found in ADAMTS-1 levels were found in more differentiated NIH-OVCAR-3 cells treated by these hormones. We conclude that ADAMTS-1 protein expression increases in ovary malignant tumors, being regulated by steroid hormones estrogen and testosterone. Supported by FAPESP (2010/07699-1)

### **Laminin-induced quiescence of breast epithelial cells is mediated by rapid decrease of nuclear actin.**

A. Bruni-Cardoso<sup>1</sup>, M. J. Bissell<sup>1</sup>; <sup>1</sup>Cancer & DNA Damage Responses Department, Lawrence Berkeley National Laboratory, Berkeley, CA

Cell quiescence is a central aspect of tissue specificity and its loss is one of the crucial steps in cancer progression. Whereas growth has been subject of much investigation, we still do not know how cells within the tissues become quiescent. We showed previously that signals from the extracellular matrix (ECM), in particular from laminin-111(LN1), lead to quiescence in mouse mammary epithelial cells preceded by a substantial decrease in nuclear actin (N-actin). Inhibition of this drop in the nucleus prevents quiescence. Here we investigated quiescence, a crucial event for organ homeostasis using HMT-3522, a human breast cancer progression series. We show that that LN1 treatment in HMT-3522-nonmalignant cells (referred to as S1) causes a rapid drop of N-actin levels (~30% by 30 minutes) and this is followed by a decrease in RNA Polymerase II activity (~60% by 2 hours) and cell proliferation (~60% by 4 hours). Interestingly, in HMT-3522-malignant cells (referred to as T4-2), the same treatment does not deplete N-actin nor does it induce changes in transcriptional activity and proliferation indicating that the mechanism(s) that controls quiescence induced by LN1 (and mediated by N-actin decrease) have gone awry in cancer cells. These data point to a new link between the ECM and the nucleus, and to a new explanation for why nonmalignant and malignant cells respond differently to growth and quiescence cues from the ECM, and suggest a new pathway to target for breast cancer therapy and possibly also other organs.

**Laminin-derived peptide C16 regulates gene expression and protein levels of cancer-related molecules in breast cancer cells.**R. G. Jaeger<sup>1</sup>, E. S. Santos<sup>2</sup>, B. Smuczek<sup>1</sup>, M. Paiva<sup>1</sup>, J. J. Pinheiro<sup>3</sup>, V. M. Freitas<sup>1</sup>;<sup>1</sup>Department of Cell and Developmental Biology, Institute of Biomedical Sciences, University of Sao Paulo, Sao Paulo, Brazil, <sup>2</sup>Department of Clinical Analysis, Faculty of Pharmaceutical Sciences, University of Sao Paulo at Ribeirao Preto, Ribeirao Preto, Sao Paulo, Brazil,<sup>3</sup>Department of Pathology, School of Dentistry, Federal University of Para, Belem, Para, Brazil

Human breast cancer constitutes worldwide health care problem. A complex pattern of molecular alterations is involved in tumorigenesis, conferring to transformed cells a higher proliferative potential, evasion to apoptosis, sustained angiogenesis, and capacity to invade the surrounding tissue and metastasize. Extracellular matrix molecules play important role influencing malignant behavior. An increasing number of evidences have shown that peptides derived from laminin cleavage are involved in tumor progression. We are particularly interested in peptide C16, derived from laminin-111 gamma-1 chain. This peptide increases cell migration, enhances metastasis, and promotes angiogenesis. These findings prompted us to investigate whether C16 would regulate gene expression of metastatic breast cancer cells (MDA-MB-231). Cells were treated with C16 (100 microgram/ml) for 24 hours. Cells treated by scrambled peptide C16SX served as controls. After treatment, gene expression was analyzed by microarray. Total RNA was extracted; biotin-labeled cDNA was generated and hybridized to Human Gene 1.0 ST Array (Affymetrix). GeneChips were stained and scanned. Expression Console software converted fluorescence intensities into numerical values. C16 induced differential expression of cancer-related genes (validated by real-time qPCR), such as FGFR3, SPOCK1 and GPNMB. FGFR3 encodes a tyrosine kinase receptor, which regulates various biological processes, including cell migration and angiogenesis. GPNMB encodes a transmembrane glycoprotein involved in angiogenesis and promotion of migration, invasion and bone metastasis of breast cancer cells. SPOCK1 encodes a proteoglycan (spock-1 or testican-1) associated with cell adhesion and increased migration. The importance of these molecules in tumor biology has prompted us to analyze whether C16 would modulate expression levels. MDA-MB-231 cells were treated overnight by either C16 (100micrograms/ml) or C16SX. Immunoblot showed that C16 increased the expression of GPNMB and SPOCK-1 compared to controls. We conclude that laminin-derived peptide C16 regulates gene expression and protein levels of cancer-related molecules in breast cancer cells. Support: FAPESP (2008/55847-0; 2009/04114-5)

**Externally applied forces can phenotypically revert malignant breast epithelial structures.**G. Venugopalan<sup>1</sup>, K. Tanner<sup>2,3</sup>, W. Orellana<sup>2,3</sup>, C. D. Reber<sup>1</sup>, M. J. Bissell<sup>2</sup>, D. A. Fletcher<sup>1,4</sup>;<sup>1</sup>Bioengineering, University of California-Berkeley, Berkeley, CA, <sup>2</sup>Life Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA, <sup>3</sup>Center for Cancer Research, National Cancer Institute, National Institutes of Health, Bethesda, MD, <sup>4</sup>Physical Biosciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA

Single breast epithelial cells embedded in three-dimensional laminin-rich extracellular matrix gels grow to form highly-organized, growth-arrested acini. Malignant cells form larger, disorganized structures, but they can be 'phenotypically reverted' into acini by treatment with pharmacological reverting agents (1). While extracellular matrix stiffness has been shown to be important in acinar morphogenesis (2), the role of external forces remains unclear. Here, we investigate the effects of external compression on acinar morphogenesis. Using an elastic chamber to transiently apply compression, we found that compressed malignant cells formed

growth-arrested, polarized acini complete with lumen, rather than the disorganized structures observed in uncompressed gels. This 'phenotypic reversion' of malignant cells under compression occurred without the use of exogenous pharmacological agents, but was eliminated by blocking E-Cadherin function. Recently, it was discovered that epithelial cells undergo coherent rotation during acinar development that ultimately controls multicellular architecture (3). This coherence was lost in the malignant phenotype but reestablished during 'phenotypic reversion' of malignant cells. In this study, time lapse microscopy of malignant cells under compression revealed that external forces induce rotation of the cells, leading to organized acini. Our findings suggest that external forces can modulate coherent rotation and cell-cell adhesion, thereby reprogramming malignant cells to re-enter the correct morphogenetic program.

**Aging-related changes make mammary epithelia more vulnerable to cancer: a story of altered stem cells.**

*J. C. Garbe<sup>1</sup>, F. Pepin<sup>1</sup>, F. Pelissier<sup>1</sup>, K. Sputova<sup>1</sup>, O. W. Petersen<sup>2</sup>, M. Park<sup>3</sup>, A. D. Borowsky<sup>4</sup>, M. R. Stampfer<sup>1</sup>, M. A. LaBarge<sup>1</sup>; <sup>1</sup>Life Science Division, Lawrence Berkeley National Laboratory, Berkeley, CA, <sup>2</sup>Structural Cell Biology, Panum Institute, Copenhagen, Denmark, <sup>3</sup>Department of Biochemistry, McGill University, Montreal, --, Canada, <sup>4</sup>Department of Pathology, University of California Davis, Davis, CA*

Women over 50 years of age account for 75% of new breast cancer diagnoses, and the majority of these tumors are of a luminal subtype. Although age-associated changes, including endocrine profiles and alterations within the breast microenvironment, increase cancer risk, an understanding of the molecular mechanisms that underlie these observations is lacking. We generated a large collection of normal human mammary epithelial cell strains from women aged 16 to 91 years, derived from primary tissues, to investigate the molecular changes that occur in aging breast cells. We found that in uncultured epithelial cells and in finite-lifespan cultured cells, aging is associated with a reduction of myoepithelial cells and an increase in luminal cells that acquire phenotypes that are usually observed exclusively in myoepithelial cells in women under 30. Changes to the luminal lineage resulted from age-dependent expansion of defective multipotent progenitors that gave rise to incompletely differentiated luminal or myoepithelial cells. The aging process therefore results in both a shift in the balance of luminal/myoepithelial lineages and to changes in the functional spectrum of multipotent progenitors, which together increase the potential for malignant transformation. Together, our findings provide a cellular basis to explain the observed vulnerability to breast cancer that increases with age.

**Proteomic Study of Prostate Cancer Derived Extracellular Microvesicles for Identification of Novel Therapeutic Targets.**

*G. Polanco<sup>1</sup>, E. A. Arigi<sup>1</sup>, M. B. Cox<sup>1</sup>, I. C. Almeida<sup>1</sup>; <sup>1</sup>The Border Biomedical Research Center, Department of Biological Sciences, University of Texas at El Paso, El Paso, TX*

Extracellular microvesicles (EMVs) contain material such as proteins that can be transferred from one cell to another, and interact with recipient cells by binding to adhesion receptors or fusing with the plasma membrane. They can be categorized into two populations: Microparticles (MPs, ≥100nm) which bud off the plasma membrane, and exosomes (≤100nm) which are formed

within the cell in multivesicular bodies. In prostate cancer, the second leading cause of cancer related death in men, EMVs have been shown to alter the tumor microenvironment by increasing motility and apoptotic resistance. Because EMVs may play a role in this disease, it is important to survey their content to identify potential players that can then be therapeutically targeted. The present study uses LC-MS/MS approaches to survey proteins present in EMVs derived from LNCaP prostate cancer cells. We first established a protocol for isolation of MPs and exosomes, confirmed effective by nanoparticle tracking and TEM analyses. Using 1D LC-MS/MS we identified 47 proteins in MPs with  $\geq 90\%$  protein identification probability in three or more of the five technical replicates. Among those proteins, HSP90 (a component of the unliganded androgen receptor complex) was identified and its presence was corroborated by western blot. Other proteins detected include unconventional myosin-VI (which is important in maintaining malignant properties of prostate cancer), apoptosis inhibitor programmed cell death 6-interacting protein isoform 2, and  $\alpha$ -catenin (which regulates prostate cancer cell proliferation by reducing  $\beta$ -catenin transcriptional activity and cyclin D1 levels). In addition,  $\alpha$ -catenin plays an important role in prostate cancer because it regulates  $\beta$ -catenin, which in complex with protein FKBP52 plays an important role in androgen receptor signaling. The same proteomic approach will be employed in the analysis of several other prostate cancer cells, including 22RV1 and FKBP52KD. Our goal is to identify potential therapeutic targets for the prevention of late stage prostate cancer.

**Autophagy plays a major role in mediating hypoxia tolerance to the CTL-mediated lysis.**

M. Z. Noman<sup>\*1</sup>, B. Janji<sup>\*2</sup>, K. Van Moer<sup>2</sup>, S. Pierson<sup>2</sup>, S. Buart<sup>1</sup>, G. Berchem<sup>2</sup>, P. Romero<sup>3</sup>, F. Mami-Chouaib<sup>1</sup>, S. Chouaib<sup>1</sup>; <sup>1</sup>Inserm U753, Institut de Cancérologie Gustave Roussy, Villejuif, France, <sup>2</sup>Department of Oncology, Public Research Center For Health, Luxembourg City, Luxembourg, <sup>3</sup>Ludwig Center for Cancer Research, University of Lausanne, Lausanne, Switzerland

Hypoxic tumor microenvironment has attracted much attention as a major contributor in tumor escape from immune surveillance. In this study, we showed that hypoxia-induced resistance of lung tumor cells to Cytolytic T Lymphocyte (CTL)-mediated lysis is associated with STAT3 phosphorylation (pSTAT3) on tyrosine-705 residue and autophagy induction in target cells. Interestingly, targeting autophagy significantly decreases pSTAT3 level in hypoxic tumor cells and restores their susceptibility to CTL-mediated lysis. We investigated the mechanism by which autophagy controls pSTAT3 level in hypoxic tumor cells. We showed that the decrease in the pSTAT3 level following autophagy inhibition is related to an acceleration of its degradation by the ubiquitin proteasome system in a p62/SQSTM1 dependent manner. Our results strongly argue for a role of autophagy in mediating hypoxia tolerance to the immune system. This argument was further supported by our results showing that inhibition of autophagy improves CTL-mediated tumor cell lysis in vivo. Knowing the efficiency of the vaccination with Tyrosinase-Related Protein-2 (TRP2) peptide in inducing tumor cell-specific CTLs response, we used this vaccination strategy in combination with autophagy inhibitor hydroxychloroquine (HCQ) in vivo. Our results showed an abrogation of tumor growth in B16-F10 tumor-bearing mice which were vaccinated and treated with HCQ compared to either treatment alone (vaccination or HCQ-treatment). Overall, this study establishes a novel functional link between hypoxia-induced autophagy and the regulation of antigen-specific T-cell lysis, and points to the critical role of autophagy in cancer immunotherapy. \*Contributed equally to this work.

**Acinus Formation and Phenotypic Reversion Result from a Functioning Interaction Between Cells and the Basement Membrane in an Agent Based Model.**

S. Becker-Weimann<sup>1</sup>, J. Tang<sup>1</sup>, J. Kumar<sup>1</sup>, M. J. Bissell<sup>1</sup>, S. V. Costes<sup>1</sup>; <sup>1</sup>Life Sciences, Lawrence Berkeley National Laboratory, Berkeley, CA

When healthy mammary epithelial S1 cells from the human HMT-3522 cancer progression series are grown in a 3-dimensional laminin-rich gel, they form hollow spheres which resemble the milk-secreting structural units in breast tissue ('acini'). Their malignant counterpart - the T4-2 cells - do not form organized structures under the same conditions. The basement membrane (BM) and downstream signaling within the cells have been identified as crucial participants in this process: Manipulation of the signaling between the cells and the BM can induce the formation of acinus-like structures even in malignant T4-2 cells ('phenotypic reversion'). Whereas many molecular components involved in this process have been identified, a comprehensive connection of cellular and extracellular properties with acinus formation has not been established. Here, we present a model of acinus formation based on the interaction between the cells and the BM: 1. growth control by the BM regulates the size, 2. cell adhesion provides the spherical shape, and 3. anchorage-dependence leads to formation of the lumen. An agent-based model using these properties can reproduce phenotypes observed in cell culture under different conditions including acinus formation, full and partial phenotypic reversion. The phenotypic characteristics of the obtained multicellular structures correlates with the presence or loss of the three properties. When applying the same conditions of the agent-based model for an extended period of time in order to simulate cancer formation, we observe three distinct types of aberrant growth that not only differ in their cause and appearance, but also in their response to different treatments. In particular, we find that a loss of cell-adhesion alone can lead to aberrant growth that displays very poor response to treatment. This model reveals a link between molecular processes in cells and their micro-environment and the appearance and responsiveness of the multicellular structure that might explain differences in prognosis and help to steer the development of drugs for specific cancer subtypes.

**Inhibition of Glioma Cancer Cell Proliferation by High Crystallined Serum Coated Carbon Nanostructures.**

D. Lee<sup>1</sup>, J. Choi<sup>1</sup>, J. Jeong<sup>1</sup>, Y. Lee<sup>1</sup>, J. Yoo<sup>1</sup>, D. Woo<sup>1</sup>, D. Khang<sup>1</sup>, S. Kang<sup>1</sup>; <sup>1</sup>Gyeongsang National University, Jinju, Korea

The majority of previous nano toxicity evaluations on carbon nanostructured materials focused the cellular response by altering conventional physiochemical surface properties, such as size and chemistry (functionalization). This study, however, demonstrated that the surface crystallinity of carbon nanostructures is an additional independent factor that should be considered for the inhibition of cancer proliferation without mitigating reactive oxygen species (ROS). In addition, cytotoxic evaluation of both proliferating cancer cells and fully differentiated nerve cells (i.e. non-proliferative) showed selective cytotoxicity: single walled and highly crystalline carbon nanostructures aggressively inhibited the proliferation of glioma cancer cells, but no notable cytotoxicity effects were observed on differentiated nerve cells. Although single wall carbon nanotubes tend to trigger ROS as a manner of potent triggering of pro-inflammatory responses, obtained results demonstrate that highly crystalline carbon structures can be utilized as a selective anti-proliferative agent against brain tumor cells without increasing ROS level and without significant cytotoxic effects to adjacent nerve cells.

1679

**Study cell-cell communications across nano-passages.**

*P.-Y. Chi<sup>1,2,3</sup>, C.-H. Lee<sup>4,5</sup>, C.-F. Chou<sup>3,4</sup>; <sup>1</sup>Nano Science and Technology, Taiwan International Graduate Program, Academia Sinica, Taipei, Taiwan, <sup>2</sup>Department of Engineering and System Science, National Tsing Hua University, Hsinchu, Taiwan, <sup>3</sup>Institute of Physics, Academia Sinica, Taipei, Taiwan, <sup>4</sup>Research Center for Applied Science, Academia Sinica, Taipei, Taiwan, <sup>5</sup>Institute of Biophotonics, National Yang-Ming University, Taipei, Taiwan*

The interactions between cancer cells and nearby tissues are crucial for tumor development and metastasis. The traditional way to study the communications between different types of cells is by co-culturing them in a culture dish. In this way, cell communications take place in all directions without well-defined temporal starting points and the cell-cell contacts are established at any contact point. It is difficult to obtain clear data for analyses in such experiments.

In this work we introduce a microfluidic nano-slit device for studying the contact communication between cancer cells and fibroblasts. This device confines cell-cell contacts in predictable locations and enables easier observation of the temporal sequence of the communication events between the two types of cells. The microfluidic chip has parallel incubation channels connected by transversal slits of vertical dimension in the range of 100-500 nm. The slits prevent cells from crossing between the incubation channels while allowing them to easily communicate across the slits by chemical signals as well as by direct contacts, such as membrane nanotubes. Cell communications from all slits can be synchronized by mechanically controlled valves of the slits. Because our device confines the cell communications within a thin slit, all the contact communication events are kept in the focal plane of a high-numerical-aperture objective lens for long-term observation. Moreover, we make nano-slits of various lengths to study cell-cell communications over various length scales.

By using this nano-slit device, we observed the growth of membrane nanotubes across the slit from a lung cancer cell into the incubation channel of the fibroblasts. The protrusion rate of nanotubes was estimated to be ~4  $\mu\text{m}/\text{min}$ . We also observed the transportation of microvesicles along the membrane nanotubes from a fibroblast to a cancer cell. The transport speed of these microvesicles was ~0.5  $\mu\text{m}/\text{min}$ . The dynamical observations provide important information for the time scales of contact communications between cancer cells and the stromal fibroblasts. We are also trying to identify the substances inside these microvesicles. In addition, potential motor proteins transporting the microvesicles in the membrane nanotubes will also be checked.

**Generation of a protein gradient within a bacterial cell by the cell division regulator MipZ.**

*D. Kiekebusch<sup>1,2,3</sup>, K. A. Michie<sup>4</sup>, L.-O. Essen<sup>5</sup>, J. Löwe<sup>4</sup>, M. Thanbichler<sup>1,2,3</sup>; <sup>1</sup>Max Planck Institute for Terrestrial Microbiology, Marburg, Germany, <sup>2</sup>Department of Biology, Philipps University, Marburg, Germany, <sup>3</sup>Loewe Center for Synthetic Microbiology, Marburg, Germany, <sup>4</sup>Mrc Laboratory of Molecular Biology, Cambridge, United Kingdom, <sup>5</sup>Structural Biochemistry, Department of Chemistry, Philipps University, Marburg, Germany*

Intracellular protein gradients are critical for the organization of eukaryotic cells, being involved in embryogenesis, morphogenesis of the mitotic spindle or cell size homeostasis. In contrast,

gradient-forming systems have long been assumed to be absent from prokaryotic organisms due to high diffusion rates of cytoplasmic proteins and the small dimensions of a bacterial cell. However, a bipolar gradient of the P-loop ATPase MipZ was found to be required for proper division site placement in the differentiating bacterium *Caulobacter crescentus*. Based on the crystal structures of the apo and ATP-bound protein and by means of mutant variants of MipZ, we dissected the role of nucleotide binding and hydrolysis in MipZ function and present a model for the establishment of the MipZ steady-state concentration gradient. Its formation is found to rely on a nucleotide-regulated alternation of MipZ between a monomeric and dimeric form. MipZ monomers interact with the polarly localized chromosome segregation protein ParB resulting in recruitment of MipZ to the polar regions. Our results suggest that the polar ParB complexes locally stimulate the formation of ATP-bound MipZ dimers. Moreover, dimers are retained near the cell poles through association with chromosomal DNA. Due to their intrinsic ATPase activity, dimers eventually dissociate into freely diffusible monomers that undergo spontaneous nucleotide exchange and are recaptured by ParB. The MipZ gradient can thus be envisioned as an asymmetric distribution of dimers that are released from a polar pool and slowly diffuse towards mid-cell. Given the marked differences in the interaction networks and diffusion rates of monomers and dimers, ATP hydrolysis promotes oscillation of MipZ between the polar ParB complexes and pole-distal regions of the nucleoid. The MipZ gradient thus represents the steady-state distribution of molecules in a highly dynamic system, providing a general mechanism for the establishment of protein gradients within the confined space of the bacterial cytoplasm.

1681

**A mutation in *C. crescentus* MreB results in a variable width phenotype, revealing distinct MreB- and FtsZ-dependent modes of cell elongation.**

L. K. Harris<sup>1</sup>, N. A. Dye<sup>1</sup>, J. A. Theriot<sup>1</sup>; <sup>1</sup>Biochemistry, Stanford University, Stanford, CA

The bacterial actin homolog MreB is a morphogenetic protein that contributes to cell width control. A point mutation in *Caulobacter crescentus* MreB was investigated which confers a variable width phenotype, where cells can develop thin extensions at one or both poles and a wider region in the middle. Fluorescently-labeled mutant MreB localizes preferentially to thin regions of cells, without affecting canonical polar markers, suggesting that thin sections do not represent extended poles. Additionally, localization of the peptidoglycan machinery is not dramatically altered in these cells. Reports that FtsZ can direct the insertion of lateral cell wall independent of MreB led us to hypothesize that, in this mutant, growth in the wide regions is due to an FtsZ-dependent mechanism, while growth in the thin regions is due to an MreB-dependent mechanism. To test this hypothesis, we depleted cells of FtsZ and observed that addition in wide regions was halted while addition in thin regions continued. This supports a model where there are two distinct modes of growth: MreB- and FtsZ-directed cell elongation. Normally, both modes work synergistically but, in this mutant, MreB preferentially localizes to peripheral thin sections, leading to a functional separation of the two modes of cell elongation.

1682

**Structure of the magnetosome actin MamK.**

J. Kollman<sup>1</sup>, E. Ozyamak<sup>2</sup>, A. Komeil<sup>2</sup>; <sup>1</sup>Dept. of Anatomy & Cell Biology, McGill University, Montreal, QC, Canada, <sup>2</sup>Dept. of Plant and Microbial Biology, UC Berkeley, Berkeley, CA

Bacterial actins, in contrast to their eukaryotic homologs, are diverse in both sequence and function. Although bacterial actins share a common fold of the monomer, they assemble filaments with a surprising degree of variation in both their dynamic behaviors and filament architectures. The bacterial actin MamK is involved in the proper organization of a unique

membrane-bound organelle, the magnetosome, essential for magnetotaxis in a phylogenetically diverse group of bacteria. MamK is required to align magnetosomes along the long axis of the cell, where they serve essentially as a compass needle. MamK forms dynamic filaments *in vivo*, and these dynamics are dependent on other magnetosome-specific proteins. To better understand the mechanisms of magnetosome alignment by MamK and the basis for its dynamics we have determined the structure of MamK filaments by cryo-electron microscopy. Like actin and most bacterial actins, MamK forms a two-stranded filament. However, it is unique in that the two strands are in register, rather than staggered as in actin. This unusual arrangement suggests large-scale changes have been made in the cross-strand contacts, which may prove to be the primary driver of variation in bacterial actin filament structures. Thus, the structure of MamK serves as a framework for understanding its function in magnetotactic bacteria, as well as extending our understanding of the diversity of bacterial actins in general.

1683

### **Polymerization and Nucleotide Regulation of a Spindle-forming Bacteriophage Tubulin, PhuZ.**

J. A. Kraemer<sup>1</sup>, M. L. Erb<sup>2</sup>, E. A. Zehr<sup>1</sup>, J. Pogliano<sup>2</sup>, D. A. Agard<sup>1</sup>; <sup>1</sup>University of California, San Francisco, San Francisco, CA, <sup>2</sup>University of California, San Diego, La Jolla, CA

Tubulins are essential for the reproduction of many eukaryotic viruses, but bacteriophage are generally assumed not to require such cytoskeletal elements. Here we show a divergent tubulin-like protein, PhuZ, encoded by bacteriophage 201φ2-1, assembles a dynamic spindle that positions phage DNA at the center of the cell. This is the first example of a prokaryotic spindle that performs a function analogous to the microtubule based spindles of eukaryotes. We solved the structure of full length PhuZ-GDP to 1.67 Å resolution, and found an extended C-terminus that we show to be critical for polymerization. Longitudinal packing in the crystal lattice appears to mimic packing observed by EM of *in vitro* formed filaments indicating how interactions between the C-terminus and the following monomer drive polymerization. We have solved structures of non-polymerizing, tail deletion mutants with GDP as well as with GTP soaked in, revealing no change in conformation. Additionally, we characterize the behavior of PhuZ filaments in limiting GTP and in the presence of excess GDP. Our findings reveal a previously unknown role for tubulins in viral function and provide important insights into the structural basis for polymer formation.

1684

### **Division site placement in *E. coli*: Dissecting functional domains of MinE.**

Y-L. Chiang<sup>1</sup>, Y-C. Chang<sup>2</sup>, H-M. Mak<sup>3</sup>, M. Zheng<sup>3</sup>, I-S. Hwang<sup>1,4</sup>, Y-L. Shih<sup>3,5</sup>; <sup>1</sup>Department of Material Science and Engineering, National Tsing Hua University, Hsinchu, Taiwan, <sup>2</sup>Institute of Cellular and Organismic Biology, Academia Sinica, Taipei, Taiwan, <sup>3</sup>Institute of Biological Chemistry, Academia Sinica, Taipei, Taiwan, <sup>4</sup>Institute of Physics, Academia Sinica, Taipei, Taiwan, <sup>5</sup>Institute of Biochemical Sciences, National Taiwan University, Taipei, Taiwan

The Min system of *E. coli* mediates placement of the division septum at midcell. MinD and MinE form a dynamic oscillator to partition the division inhibitor MinC towards the poles to blocks aberrant polar division. MinE forms a ring-like structure at the receding edge of the MinD polar zone during oscillation, which arrests growth of the MinD polar zone passing midcell and switches into the shrinkage phase. This phenomenon underlies intricate interplays between the Min proteins and the membrane. In this study, we investigated self-assembly properties of MinE *in vitro* that may underlie the MinE-ring formation. Our results demonstrated that the N-terminal domain of MinE self-associated into protein fibrils consisted of multiple protofilaments. The

organization of protofilaments changed upon association with the membrane. Since the same N-terminal region is responsible for MinD interaction, the two functions are likely to take place at different time points or in different MinE molecules. The filamentous structure of full-length MinE showed spatial preference on the membrane, suggesting the C-terminal domain provides positional information for membrane localization. Taken together, we provided direct evidence for self-assembly of MinE and the function of the MinE C-terminal domain.

**Outer membrane composition and dynamics in *Escherichia coli*.**

V. J. Kern<sup>1</sup>, E. Trepagnier<sup>1</sup>, J. Theriot<sup>1,2</sup>; <sup>1</sup>Biochemistry, Stanford University, Stanford, CA, <sup>2</sup>Microbiology and Immunology, Stanford University, Stanford, CA

The Gram-negative outer membrane (OM) of *E. coli* is a heterogenous bilayer comprising various proteins, lipids and polysaccharides. These OM components are often virulence determinants that facilitate motility, confer toxicity, mediate invasion, etc. Thus, a detailed understanding of the secretion and in situ dynamics of these features with respect to the cell envelope may offer novel targets for the development of future antimicrobials. In particular, the ability to track specific labeled components with high resolution over short time periods, as well as OM constituent partitioning over extended generational periods, will yield critical insights into the mechanisms governing OM biogenesis. However, many OM components are derived from essential pathways or are themselves essential, severely limiting classical genetic approaches. Others are products of complex biosynthetic or post-translational modification systems which precludes many of the standard labeling technologies (*i.e.* the inability to secrete *gfp*-chimeras from the cytoplasm). Here, we describe labeling technologies developed for compatibility with imaging the compositional dynamics of OM constituents of live cells. In one approach, we use a genetically-encoded polypeptide tag (*ybbR*) incorporated into a specific OM protein (LamB) which is covalently labeled with derivatized coenzyme A by action of the Sfp synthase. Preliminary data suggests new OM material is inserted as discrete puncta distributed along the cell cylinder rather than polar regions. Additionally, we describe the development of bacteriophage-derived proteins into recombinant, feature-specific markers for components of the *E. coli* OM. Not only will this approach permit specific, simultaneous observation of proteins and lipopolysaccharides, but can also be adapted to spatiotemporal dynamic studies of these major envelope features. We anticipate that these multiplexed labels will yield a more comprehensive understanding of OM biogenesis and maintenance.

1686

**In vivo investigation of DNA replication in *Escherichia coli* using single-molecule fluorescence microscopy.**

C. Moolman<sup>1</sup>, S. Tiruvadi Krishnan<sup>1</sup>, L. Jimenez van Hoorn<sup>1</sup>, S. Hage<sup>1</sup>, R. Reyes-Lamothe<sup>2</sup>, D. Sherratt<sup>2</sup>, N. Dekker<sup>1</sup>; <sup>1</sup>BionanoScience, Delft University of Technology, Delft, Netherlands, <sup>2</sup>Department of Biochemistry, University of Oxford, Oxford, United Kingdom

An *Escherichia coli* cell contains a circular chromosomal DNA that is duplicated in a bidirectional manner during cell division. DNA polymerase III proteins, along with helper proteins, form a replisome complex that duplicates the DNA. Recent studies have shown that two individual replisomes initiate replication and duplicate the chromosomal DNA independently of one another. Our current knowledge of DNA replication in *E. coli*, specifically its mechanism of termination, has mainly been obtained from in vitro experiments. However, the processes that occur in living cells may differ considerably from those of the in vitro environment and can have

a significant influence on dynamics of protein function. Interestingly, it is now possible to monitor single-molecule processes in vivo using fluorescence microscopy by tagging the native proteins with fluorescent proteins. We employ single-molecule fluorescence microscopy to track the individual replisomes and investigate their dynamics during the process of DNA replication in live cells. The single-molecule sensitivity in such experiments can provide additional information to the results obtained from previous studies done by ensemble-averaging techniques. In this poster we discuss our live-cell imaging techniques, the strain creation and characterization methods employed, the experiment methodology, and the latest results obtained at the single-molecule level.

**How the rate of osmotic downshift affects *E. coli* survival: a study of mechanosensitive channel function.**

*M. Bialecka-Fornal*<sup>1</sup>, *H. Lee*<sup>2</sup>, *R. Phillips*<sup>1</sup>; <sup>1</sup>*Biochemistry & Molecular Biophysics, Caltech, Pasadena, CA*, <sup>2</sup>*Applied Physics, Caltech, Pasadena, CA*

Bacteria have developed a wide variety of defense mechanisms that allow them to survive in fast changing environmental conditions. One such adaptation is the presence of mechanosensitive (MS) channels in the inner membrane which act as an osmotic valve preventing membrane rupture during osmotic downshift. Our understanding of the in vivo osmotic response of these channels has largely been based upon plating/colony-counting assays. In this work we use microscopy based techniques with single-cell level resolution to investigate the impact of the rate of osmotic downshift on the survival rate of various *E. coli* mutants, where combinations of MS channels have been deleted. In our measurements, we determine how specific MS channels types (e.g. YbdG and MscL) contribute to the survival rate and try to find the minimal number of MscL needed for survival after osmotic shock.

**Localized cell death focuses mechanical forces during 3D patterning in a biofilm.**

*M. Asally*<sup>1</sup>, *M. Kittisopikul*<sup>1,2</sup>, *P. Rué*<sup>3</sup>, *Y. Du*<sup>4</sup>, *Z. Hu*<sup>4</sup>, *T. Çağatay*<sup>2</sup>, *A. Robinson*<sup>2</sup>, *H. Lu*<sup>4</sup>, *J. Garcia-Ojalvo*<sup>3</sup>, *G. M. Süel*<sup>1</sup>; <sup>1</sup>*University of California, San Diego, La Jolla, CA*, <sup>2</sup>*University of Texas Southwestern, Dallas, TX*, <sup>3</sup>*Universitat Pompeu Fabra, Barcelona, Spain*, <sup>4</sup>*University of Texas at Dallas, Richardson, TX*

Self-organization of cells into structures during development is a fundamental process that occurs in many different biological systems. Over the last decades, a number of studies have shown that bacterial communities like biofilms can also exhibit extensive spatio-temporal organization, similarly to multi-cellular organisms. Unlike laboratory domesticated bacterial strains, native bacteria form biofilms typically with complex and intriguing three-dimensional (3D) wrinkle patterns. Investigating wrinkled biofilms of gram-positive bacteria *Bacillus subtilis*, we discovered a dynamic pattern of localized cell death that emerges during biofilm formation. We quantitatively and simultaneously measured cell death, movement and mechanical properties to analyze wild-type and gene deletion mutant biofilm development. The results suggest that localized cell death provides an outlet for lateral compressive forces, thereby promoting vertical mechanical buckling and 3D wrinkle formation. Guided by the principles that emerged from our findings, we were able to generate arbitrary patterns of wrinkles within a biofilm. The formation of 3D structures facilitated by cell death may underlie self-organization in other developmental systems, and could enable engineering of macroscopic structures from cell populations in a future.

**Crystal Structure of *Streptococcus pyogenes* Csn2 protein, a component of CRISPR-mediated bacterial immune system.***Y. Koo<sup>1</sup>, D-K. Jung<sup>1</sup>, E. Bae<sup>1</sup>; <sup>1</sup>Seoul National University, Seoul, Korea*

Clustered regularly interspaced short palindromic repeats (CRISPR) and CRISPR-associated (Cas) proteins constitute a microbial immune system against invading genetic elements, such as plasmids and phages. Csn2 is a Cas protein found in subtype II-A CRISPR-Cas systems, and was suggested to function in the adaptation process, during which parts of foreign nucleic acids are integrated into the host microbial genome to enable immunity against future invasion. Here, we report a crystal structure of *Streptococcus pyogenes* Csn2. The structure revealed previously unseen calcium-dependent conformational changes in its tertiary and quaternary structure. This supports the proposed double-stranded DNA-binding function of *S. pyogenes* Csn2.

1690

**Elucidating phototaxis mechanism to engineer coordinated communities of cyanobacteria.***A. Chandra<sup>1,2</sup>, D. Bhaya<sup>2</sup>, K. C. Huang<sup>1</sup>; <sup>1</sup>Bioengineering, Stanford University, Stanford, CA, <sup>2</sup>Plant Science, Carnegie Institution for Science, Stanford University, Stanford, CA*

Many unicellular photosynthetic organisms such as cyanobacteria display oriented movement with respect to light (phototaxis), thus harnessing light energy for carbon fixation. By coupling metabolism and behavior, phototaxis allows a cell to quickly adapt to changing environmental conditions, governing the active migration of cells in response to shifting light gradients and contributing to community spatial organization. Cyanobacteria play a crucial ecological role in primary production and global biogeochemical cycling of nutrients, and have been targeted as possible biofuel sources using synthetic biology.

The phototaxis response can be categorized into three subsystems: a light-sensing module such as photoreceptors or photopigments, an intracellular regulatory signaling module, and a motility module organized around multi-functional TFP. Several photoreceptors have been characterized and are now workhorses for optogenetics, though cyanobacteria employ other light-sensing modes that have yet to be characterized. Access to a diverse collection of mutants in each of the three modules can be used to reveal the minimal set of molecular players.

In recent years, bacteriology has undergone a paradigm shift from reductionist “single-cell” biology toward the investigation of the complexity of interacting communities. We will elucidate the mechanisms underlying cyanobacterial phototaxis at the level of individual cells, allowing us to engineer coordinated communities with complex spatiotemporal movement. We will utilize an interdisciplinary genetics, microscopy, and biophysical modeling approach for:

- 1) Genetic identification of novel signaling elements that couple positive and negative phototaxis to regulate cell decision-making capabilities
- 2) Characterization of the localization and dynamics of the type-IV pilus (TFP) machinery in individual cyanobacteria and in multi-cellular communities

Experimental data will be utilized to develop quantitative models of cyanobacterial phototaxis that can identify key variables responsible for the spatial structure of multi-cellular communities and cellular decision-making. In the future, organized communities of a mixture of species could be used to perform synthetic or syntrophic functions and to model behavior in ecologically

relevant environments. This study has potential applications in the design of synthetic invasive, immunogenic biological devices and engineered environmental remediation communities.

1692

**Quantitation of cell wall and outer membrane growth that indicates how to robustly build rod-like bacteria.**

*T. Ursell<sup>1</sup>, K. C. Huang<sup>1</sup>; <sup>1</sup>Bioengineering, Stanford University, Stanford, CA*

In both Gram-negative and Gram-positive bacteria, a host of enzymes, collectively termed PBPs, regulate the reproducible and robust construction of the cell wall, whose mechanical integrity is crucial for viability under osmotic stress. Antibiotics that target these enzymes and their corresponding scaffolding proteins, disrupt cell wall construction, ultimately leading to mechanical failure of the cell. In this work, we use a combination of cell wall and outer membrane-specific fluorescent labeling, high resolution time-lapse microscopy, and computational image processing to characterize where, and with what dynamics, cell wall and outer membrane growth occurs in *E. coli*. These measurements allow us to partially uncover the interplay between cell shape and dynamic localization of proteins implicated in cell wall construction. Our results suggest that the presence of the cytoskeletal protein MreB is necessary for localized bursts in growth across the cell surface. We also find strong evidence that the necessary orchestration in growth between the cell wall and outer membrane is achieved by spatio-temporal coupling of the growth in each layer. We tested mechanistic models of outer membrane growth, and independently verified that it grows in uniformly random bursts on the bacterial cell surface, similar to the cell wall. Finally, quantitative tracking of cell wall growth is an effective method for the characterization of cell wall mechanical failure, and subsequent death, that results from treatment with beta-lactams or other upstream antibiotics. These techniques make new regimes available for studying the detailed dynamics of cell wall-associated proteins and their disturbance by antibiotics.

1693

**Entropy-Driven Translocation of Disordered Proteins Through the Gram-Positive Cell Wall.**

*D. K. Halladin<sup>1</sup>, K. C. Huang<sup>1</sup>, A. Gopinathan<sup>2</sup>, J. A. Theriot<sup>1</sup>; <sup>1</sup>Stanford University, Stanford, CA, <sup>2</sup>UC Merced, Merced, CA*

Surface proteins mediate interactions between cells and their environment. In Gram-positive bacteria, proteins exposed on the cell surface must navigate tens of nanometers from their sites of secretion at the membrane through the bacterial cell wall. This problem is compounded for proteins that remain anchored to the bacterial membrane, such as the *Listeria monocytogenes* actin nucleation-promoting factor ActA, which contains a transmembrane domain near the carboxy-terminus, but interacts with host cell cytoplasmic factors at the amino-terminus. We have developed a physical model indicating that the entropic constraint imposed by a small periplasmic space could drive the translocation of an intrinsically disordered protein across a barrier with a thickness and porosity similar to the Gram-positive cell wall. We demonstrate experimentally that protein translocation depends on both the dimensions of the cell envelope and the length of the disordered protein. In addition, we show that disordered regions from nuclear pore complex proteins translocate in an entropy-dependent manner through the cell wall of *L. monocytogenes* and *Staphylococcus aureus*. These observations imply that purely physical forces can explain the translocation of certain Gram-positive surface proteins. Bioinformatic analyses suggest that entropic translocation is utilized by a variety of Gram-positive bacteria.

1694

**The serine protease MamE acts as a checkpoint control protein during the development of the magnetosome organelles of magnetotactic bacteria.**

*E. Ozyamak*<sup>1</sup>, *A. Komeili*<sup>1</sup>; <sup>1</sup>*Plant & Microbial Biology, UC Berkeley, Berkeley, CA*

Research over the last decades or so has revealed that bacteria are not devoid of subcellular organization and that fine-tuned cellular processes govern their growth and development. Some bacteria even contain subcellular compartments that are reminiscent of eukaryotic organelles. One such organism is the aquatic bacterium *Magnetospirillum magneticum* AMB-1, which is capable of forming organelles called magnetosomes. These lipid-bounded compartments encase magnetic nano-particles that passively align the bacteria to the geo-magnetic field and make its search for optimal growth conditions more efficient. A select number of highly specialized proteins are involved in the formation of magnetosomes performing roles such as membrane remodeling, protein sorting, ion transport and mineral formation. In our group we have used several approaches to identify these factors and define the mechanisms by which they act to form an active magnetosome compartment. MamE, an HtrA protein homologue, appears to have roles in both protein sorting and biomineralization. Both in eukaryotes and bacteria HtrA proteins are highly regulated proteases that are essential for maintaining protein homeostasis after protein misfolding and aggregation. We have shown that MamE recruits proteins to the magnetosome independent of its protease activity and that its proteolytic activity is instead required for biomineralization of magnetic particles. Surprisingly, we have found that MamE acts on itself resulting in a subpopulation of the protein being processed into two distinct fragments *in vivo*. This autoproteolysis appears to be regulated since it only occurs at a specific stage in the development of the organelle and depends on appropriate environmental cues. We have thus hypothesized that MamE functions as a checkpoint control protein to link the quality of the environment to the biomineralization of magnetic particles. We are currently employing *in vivo* and *in vitro* approaches to further understand MamE function at the molecular level. Investigation of MamE function will provide missing information about control of organelle development in bacteria and add new knowledge about the regulation of HtrA proteases.

1695

**YfiA is necessary and sufficient for dimerization and inactivation of ribosomes in *Lactococcus lactis*.**

*P. Puri*<sup>1</sup>, *T. H. Eckhardt*<sup>2</sup>, *L. E. Franken*<sup>3</sup>, *F. Fusetti*<sup>4</sup>, *M. C. Stuart*<sup>3</sup>, *E. J. Boekema*<sup>3</sup>, *J. Kok*<sup>2</sup>, *O. P. Kuipers*<sup>2</sup>, *B. Poolman*<sup>1,4</sup>; <sup>1</sup>*Membrane Enzymology, University of Groningen, Groningen, Netherlands*, <sup>2</sup>*Molecular genetics, University of Groningen, Groningen, Netherlands*, <sup>3</sup>*Electron Microscopy, University of Groningen, Groningen, Netherlands*, <sup>4</sup>*Netherlands Proteomics Centre, Groningen, Netherlands*

When *E. coli* cells enter stationary phase the 70S ribosome dimerizes to form 100S structures, which represent the hibernation state of these translationally-inactive ribosomes. In *E. coli* the protein YfiA is known to inhibit translation, while the proteins RMF and HPF are involved in dimerizing the 70S ribosomes. The dimerization interface is between the two 30S subunits and induced by a conformational change upon binding of RMF. The binding site for RMF overlaps with for anti Shine Dalgarno sequence on the 16S rRNA and thereby inhibits translation. We have explored the formation of ribosome dimers in the Gram-positive bacterium *Lactococcus lactis*. An open reading frame annotated as *yfiA* is present in the genome of *Lactococcus lactis*, and the YfiA protein shares 34% sequence identity with orthologue of *E. coli*. In contrast to *E. coli*, *L. lactis* does not have homologues of *rmf* and *hpf*. Strikingly, a *Lactococcus lactis* strain lacking *yfiA* gene does not show ribosome dimerization; the dimerisation can be restored by

controlled in trans expression of *yfiA*. MS analysis of ribosome dimer fractions confirms that analogues of RMF and HPF are not present in *L. lactis* and that YfiA is necessary and sufficient for dimerization of ribosomes. YfiA from *L. lactis* differs from the *E. coli* orthologue by having an 72 amino acid extension, which most likely takes over the role of RMF and/or HPF and induces the dimerization interphase. Electron Microscopy experiments have been performed to characterize the ribosome dimers in *Lactococcus lactis*.

1696

**Studying the positioning of replicating phage DNA by the divergent tubulin PhuZ at the single cell level.**

M. L. Erb<sup>1</sup>, J. Coker<sup>1</sup>, K. Nguyen<sup>1</sup>, H. Wang<sup>1</sup>, J. Pogliano<sup>1</sup>; <sup>1</sup>Biological Sciences, University of California, San Diego, La Jolla, CA

Bacteriophage were generally assumed not to require a filament-forming cytoskeleton during lytic growth. We have discovered a number of bacteriophage that encode highly divergent tubulin like proteins (PhuZ). We have shown that the PhuZ protein from the extremely large Pseudomonas phage 201[phi]2-1 assembles a dynamic spindle that positions replicating phage DNA during lytic growth. By developing a single infection assay to directly visualize phage DNA and PhuZ assembly in time-lapse microscopy, we have now defined some of the key steps in the phage life cycle. After injection of phage DNA, the host chromosome is degraded. The phage DNA then replicates in a single nucleoid which is positioned at midcell by PhuZ polymers. Phage DNA becomes encapsidated in viral particles which assemble in a spherical structure surrounding the centrally located phage nucleoid.

1697

**Proteolysis autoregulates RNA helicase expression in response to abiotic stress.**

O. S. Tarassova<sup>1</sup>, G. W. Owtrim<sup>1</sup>; <sup>1</sup>Biological Sciences, University of Alberta, Edmonton, AB, Canada

Bacteria respond to constantly changing environment by inducing expression of the specific proteins essential for adaptation to external stresses. Cyanobacterial RNA helicase, CrhR, is one of such proteins, whose levels are regulated in response to changes in temperature, light intensity, salt concentration or any other changes that alter redox status of the electron transport chain in the cell. RNA helicases are ubiquitous enzymes that are present in all domains of life. Their function is to modify RNA secondary structure, which subsequently can regulate RNA metabolism and gene expression. CrhR is unique RNA helicase that is capable of catalyzing ATP-stimulated RNA unwinding, annealing and also RNA strand exchange (Chamot *et.al.*, 2004). A basal level of CrhR protein is observed at 30°C, which is significantly increased at 20°C. This differential expression of cyanobacterial helicase with its ability to perform several functions indicates its important role in adjusting cell physiology to rapidly changing environmental condition such as temperature. However, the pathways controlling RNA helicase expression have not been well characterized. Here we describe experiments indicating that CrhR protein abundance is regulated by a temperature-controlled proteolytic mechanism that is CrhR-dependent. A series of *in vitro* experiments were conducted in which protein extracts from warm and cold grown wild type and mutant cells were mixed in all possible combinations and a time course of CrhR abundance was followed by western analysis. The results indicate that active proteolytic degradation machinery is present only in wild type cells at 30°C. Functional CrhR RNA helicase activity is required for either the presence or activity of the proteolytic machinery, as CrhR degradation is not observed in the *crhR* mutant. *In vivo* experiments with cells engineered to express CrhR constitutively in addition to endogenous CrhR indicate that

proteolysis is mostly functional in the first two hours upon the shift to 30°C. Following the degradation of the most of CrhR protein at 30°C its low level is further maintained by temperature regulated promoter. The data indicate that the proteolytic degradation of CrhR protein is autoregulatory, temperature dependent and essential to immediately reduce levels of CrhR protein at 30°C. Our data provide insights into the pathways that are involved in the regulation of RNA helicase expression. The results also have important implications with respect to the molecular mechanisms utilized by microorganisms to respond to abiotic stresses.

1698

### **Characterization of Foodborne Pathogens Bacteria Profiles.**

J. Y. Gardner<sup>1</sup>, J-M. Dimandja<sup>2</sup>; <sup>1</sup>Natural Sciences, Clayton State University, Morrow, GA, <sup>2</sup>Chemistry, Spelman College, Atlanta, GA

The cellular fatty acid profiles of eight strains of Bacillus, Staphylococcus, and Enterobacteriaceae (Escherichia coli, and Salmonella) were analyzed by comprehensive two-dimensional gas chromatography/time-of-flight mass spectrometry (GCxGC/TOF MS). A novel template method was developed to standardize the raw GCxGC retention data through the use of a chemical indexing mixture. Analyte retention coordinates were normalized in the primary dimension with respect to a series of n-alkanes (Kovats index) and in the secondary dimension with respect to a series of aromatic hydrocarbons (Lee index). Fatty acid profiles extracted from the templates were compared by multidimensional scaling (MDS) and principal component analysis (PCA). Differences in the profiles of Gram positive and Gram negative bacteria were observed, and a series of heterogeneous mixtures comprised of different fractions (containing one Gram positive and one Gram negative bacteria strains) were also distinguished from their homogeneous constituents.

## **Imaging Technologies, Single Molecule Imaging, and Super-Resolution I**

1699

### **Two-color, 3D super-resolution imaging of bacterial protein ultrastructures with the double-helix point-spread function microscope.**

A. Gahlmann<sup>1</sup>, J. L. Ptacin<sup>1</sup>, G. Grover<sup>2</sup>, R. Piestun<sup>2</sup>, L. Shapiro<sup>1</sup>, W. E. Moerner<sup>1</sup>; <sup>1</sup>Stanford University, Stanford, CA, <sup>2</sup>University of Colorado Boulder, Boulder, CO

We have implemented a two-color 3D imaging approach for visualizing and colocalizing different protein ultrastructures in bacteria with a precision beyond the optical diffraction limit. Our experiment makes use of the recently introduced double-helix point-spread-function (DH-PSF) microscope and single-molecule photoblinking, which allows quantitative 3D super-resolution imaging of fluorescently tagged proteins throughout a ~2 μm axial depth of field. We apply the multicolor version of the DH-PSF methodology using genetically encoded fluorescent protein fusions in live *Caulobacter crescentus* cells and visualize the subcellular organization of critical cell-cycle dependent proteins, such as PopZ, at the cell pole. Fluorescent emission from two fluorophores is collected in two separate detection channels with negligible cross-talk between them, thus providing clear fluorophore identification. Quantitative overlay of the super-resolved 3D reconstructions obtained in these two detection channels is made possible by computational 3D image registration during post-processing. We show that the precision in distance measurements between any imaged fluorescent proteins within the same cell is chiefly limited by the localization precision of the individual single-molecule fluorophores themselves. This allows us to probe the relative subcellular organization within the bacterial cell, i.e. the size and

shape of neighboring protein ultrastructures. Furthermore, by sampling the cell surface using the PAINT technique, we can position the cell-internal fluorescent protein localizations with respect to the 3D spatial context of the cell's outer boundary.

1700

**Resolving structural features in biological and biomedical imaging with STED super-resolution microscopy.**

*L. Lau<sup>1</sup>, Y. L. Lee<sup>2</sup>, S. J. Sahl<sup>1</sup>, L. E. Weiss<sup>1</sup>, T. Stearns<sup>2</sup>, W. E. Moerner<sup>1</sup>; <sup>1</sup>Chemistry, Stanford University, Stanford, CA, <sup>2</sup>Biology, Stanford University, Stanford, CA*

Super-resolution optical microscopy is a rapidly emerging method that is creating multiple opportunities for biological imaging beyond the visible diffraction limit of ~250 nm. We have built a Stimulated Emission Depletion (STED) super-resolution microscope to image cells and tissue with 50-80 nm full-width-at-half-maximum resolution. Utilizing the sectioning ability of STED to reject out-of-focus fluorescence, we have probed planar cell polarity protein complexes tens of  $\mu\text{m}$  deep in intact *Drosophila* tissue at ~80 nm resolution (Proc. SPIE 7910:7910N-1-8).

The influence of labeling density in super-resolution microscopy studies is more critical than in diffraction-limited imaging. We have quantified labeling density effects in STED immunofluorescence imaging using the centriole as a model system (Biophys. J. 102(12):2926-2935). A key component of the microtubule organizing center in eukaryotic cells, the centriole is one diffraction limit in diameter and possesses a 9-fold radial symmetry. To our knowledge, no specific centriole component had been identified with this symmetry. We employed optimized immunolabeling to reveal that a particular centriole distal appendage protein, Cep164, localizes as 9 clusters spaced in a ring of ~350 nm diameter. The labeling density influenced the observed cluster number, size and brightness. As opposed to the averaged structure obtained from electron microscopy, the ability to simultaneously observe many single centrioles with optimized labeling allowed measurement of the distributions of behavior.

A hallmark of Huntington's Disease is the aggregation of mutant (polyQ-expanded) huntingtin (Htt) protein in neurons. Understanding the morphology of these aggregates may provide insight into the neurodegenerative mechanism. We have characterized a range of structures including inclusion bodies, fibers and perinuclear aggregates by STED microscopy of fluorescently labeled Htt-Exon1 in a neuronal cell-culture model. We found that individual fibers can be ~1-2  $\mu\text{m}$  long and ~100 nm wide, while inclusion bodies often are up to ~10  $\mu\text{m}$  in size. This work provides a detailed catalog of huntingtin structures for further investigations inside cells.

Our STED measurements are consistent with results from ensemble measurements by electron microscopy while avoiding the complex sample preparation required by the latter. This work shows that STED microscopy is an excellent tool for elucidating structural features in a variety of biological and biomedical applications.

### Enzymatic activation of nitro-aryl fluorogens in live bacterial cells for Enzymatic Turnover Activated Localization Microscopy beyond the diffraction limit.

M. K. Lee<sup>1</sup>, J. Williams<sup>2</sup>, R. Twieg<sup>2</sup>, J. Rao<sup>3</sup>, W. E. Moerner<sup>1</sup>; <sup>1</sup>Chemistry, Stanford University, Stanford, CA, <sup>2</sup>Chemistry and Biochemistry, Kent State University, Kent, OH, <sup>3</sup>Radiology, Stanford University, Stanford, CA

Many recently developed super-resolution (SR) microscopies (e.g., PALM, FPALM, STORM) based on single-molecule (SM) fluorescence require the conversion of a dark fluorogen into a bright emitter. This process allows the experimenter to control fluorophore concentration, enabling sparse sets of single-molecule fluorophores to be successively imaged and localized with spatial resolution 5-10 times smaller than the diffraction limit of  $\approx 200$  nm for visible wavelengths. This work uses a new strategy to control fluorescence emission for SR imaging: the enzymatic activation of a small-molecule and cell-permeable fluorogen, or Enzymatic Turnover Activated Localization Microscopy (ETALM), and demonstrates its use in live bacterial cells. Previous work using fluorogenic substrates enabled detailed SM enzymology studies, but without extracting subdiffraction information. Our study combines synthesis, bulk spectroscopic measurements, and microscopy (both *in vitro* on a surface and *in vivo* in cells). Synthesis of model compounds and optical spectroscopy identify a hydroxyl-amino derivative as the product fluorophore, which is bright and detectable on the single-molecule level for fluorogens attached to a surface. The fluorescent hydroxyl-amino derivative emits an average of  $1.7 \times 10^6$  photons per SM in the aqueous surroundings of poly(vinyl alcohol). Solution kinetic analysis shows Michaelis-Menten rate dependence upon both NADH and the fluorogen concentrations as expected with fit parameters  $k_{\text{cat}}$  of  $224 \pm 40$  s<sup>-1</sup> and  $K_M^{\text{NADH}}$  of  $13 \pm 3$   $\mu\text{M}$  and a  $K_M^{\text{fluorogen}}$  of  $4.9 \pm 1$   $\mu\text{M}$ . The generation of low concentrations of single-molecule emitters by enzymatic turnovers is used to extract subdiffraction information about localizations of both fluorophores and nitroreductase enzymes in *B. subtilis* with an average of  $17.9 \pm 0.3$  nm statistical localization precision. Together, this work shows that ETALM is a complementary mechanism to activate SM fluorescence to image beyond the diffraction limit in biological systems.

1702

### Noninvasive Imaging of Three-Dimensional Dynamics in Thickly Fluorescent Specimens Beyond the Diffraction Limit.

L. Gao<sup>1</sup>, L. Shao<sup>1</sup>, C. D. Higgins<sup>2</sup>, J. S. Poulton<sup>2</sup>, M. Peifer<sup>2</sup>, M. W. Davidson<sup>3</sup>, X. Wu<sup>4</sup>, B. Goldstein<sup>2</sup>, E. Betzig<sup>1</sup>; <sup>1</sup>HHMI and Janelia Farm Research Campus, Ashburn, VA, <sup>2</sup>Biology Department, University of North Carolina at Chapel Hill, Chapel Hill, NC, <sup>3</sup>National High Magnetic Field Laboratory and Department of Biological Science, Florida State University, Tallahassee, FL, <sup>4</sup>NHLBI, National Institutes of Health, Bethesda, MD

Understanding of cell activities often requires live fluorescence imaging with high spatial and temporal resolution. However, 4-D (space and time) fluorescence imaging is challenging, due to tradeoffs between spatial resolution, temporal resolution, photobleaching and photodamage. Here, we report a 4-D fluorescence imaging technique with spatial resolution beyond the diffraction limit and temporal resolution at the level of seconds per 3D volume which induces minimal photobleaching and sample damage. The method (Bessel SR-SIM) combines ultra-thin planar illumination produced by scanned Bessel beams with super-resolution structured illumination microscopy. We demonstrate high speed super-resolution Bessel SR-SIM from single cell to multicellular length scales, including: cell membrane and actin cytoskeleton dynamics in cancer cells, fibroblasts, and *D. discoideum*, *in vivo* karyotyping and tracking of mitotic mammalian cell kinetochores and chromosomes from prophase to anaphase; and development within *C. elegans* and *Drosophila* embryos. Furthermore, by combining Bessel SR-

SIM with two-photon excitation, the imaging capability can be extended to large multicellular samples such as *C. elegans* larval worms and the adult brain of *Drosophila*. In comparison with widely adopted spinning-disk confocal imaging and other live super-resolution imaging techniques on samples at different scales, Bessel SR-SIM shows significant advantages in balancing spatial resolution, imaging speed, photobleaching and sample damage, especially on thickly fluorescent specimens.

1703

**Probing neural circuitry in the retina with molecular specificity through serial section reconstruction and stochastic optical reconstruction microscopy (STORM).**

Y. Sigal<sup>1,2</sup>, C. Speer<sup>1,2</sup>, H. Babcock<sup>1</sup>, X. Zhuang<sup>1,2</sup>; <sup>1</sup>Department of Chemistry and Chemical Biology, Harvard University, Cambridge, MA, <sup>2</sup>HHMI, Cambridge, MA

One of the main challenges in biology is to understand how the molecular structure and function detected at the micro-scale leads to an observed phenotype at the cellular and higher order macro-scales. While conventional light microscopy allows for both molecular specificity and comparative studies using several spectrally separated probes, its use is precluded in the investigation of most molecular scale interactions due to the technique's resolution barrier imposed by the diffraction limit of light. Conversely, serial section electron microscopy allows for nanometer resolution throughout a sample volume, but is limited in its power to probe molecular interactions due to its monochromatic nature. Within the past decade, several super-resolution fluorescence microscopy techniques, including stochastic optical reconstruction microscopy (STORM), have succeeded in circumventing the diffraction limit of light microscopy, thereby allowing for the unprecedented visualization of molecular organization in a wide range of systems from bacterial chromosomes to neuronal synapses. Here, we combine STORM with ultra-thin serial section reconstruction across hundreds of sections of neuronal tissue to achieve truly volumetric imaging at a molecular scale with four spectrally distinct probes. By utilizing the transgenic YFP-H mouse line, which labels a sparse population of ganglion cells within the retina, in combination with membrane markers necessary for proper serial section alignment, we demonstrate nearly complete reconstructions of the dendritic arbors of retinal ganglion cells (~100µm in diameter) and their cell bodies with a lateral resolution of 20-30nm and an axial resolution dictated by our section thickness (50-70nm). By also probing against targets of both the presynaptic cytomatrix (Bassoon, Munc13, ELKS, and Piccolo) and the postsynaptic density (Gephyrin) within these reconstructions, we are able to investigate the distribution and organization of both excitatory and inhibitory synapses within the volume as a whole, as well as identify those synapses which are specifically associated with the YFP+ neuron of interest. Through this combination of ultra-structural information and molecular specificity, we are able to probe both structure and function over four orders of magnitude and begin to explore how the organization and integration of these competing signals leads to the emergence of an observed functional output at the level of the entire neuron.

1704

**Probing the Nuclear Pore Complex Architecture by Super-Resolution Microscopy.**

R. Kasper<sup>1</sup>, J. Hu<sup>1</sup>, W. Zhang<sup>1</sup>, B. Huang<sup>1,2</sup>; <sup>1</sup>Pharmaceutical Chemistry, UCSF, San Francisco, CA, <sup>2</sup>Biochemistry and Biophysics, UCSF, San Francisco, CA

The nuclear pore complex (NPC) is the exclusive gateway for transport between the nucleus and the cytoplasm, including both proteins and RNAs. As a giant macromolecular complex (~1000 Å in size), the NPC represents a great challenge to current structural biology methods. Here we demonstrate that super-resolution microscopy can resolve individual nucleoporins

(nups) in the yeast NPC, which provides structural insights into the architecture of the NPC in situ. Specifically, we use stochastic optical reconstruction microscopy (STORM), which localizes individual fluorescent molecules in a structure by stochastically switching them between a fluorescent and a dark state. STORM has demonstrated a three-dimensional localization precision of ~20 nm.

A key challenge for precisely determining nup positions is to label them specifically in a cell with bright fluorescent dyes. To address this issue, we have explored the enzymatic approach, by fusing the target nups to a small enzyme which can covalently link to a fluorescently labelled small molecule substrate. Among the available enzymatic tags, we have discovered that the widely used SNAP-tag interferes with the attached cyanine dye, reducing the fluorescence signal as well as increasing photobleaching. We have identified HALO-tag as a complimentary approach.

The enzymatic approach allowed us to label and image single nucleoporins in fixed yeast cells and to measure the radial positions of 10 nups in the NPC. We believe that this approach can be generally applicable to many other molecular complexes, especially those difficult to be purified and/or reconstituted *in vitro*.

### **Ultra-High Resolution Imaging Reveals Formation and Preponderance of neuronal SNARE/Munc18 Complexes in situ.**

A. Pertsinidis<sup>1</sup>, K. Mukherjee<sup>2</sup>, M. Sharma<sup>2</sup>, Z. Pang<sup>2</sup>, S. Park<sup>3</sup>, Y. Zhang<sup>3</sup>, A. Brunger<sup>2</sup>, T. Südhof<sup>2</sup>, S. Chu<sup>4</sup>; <sup>1</sup>Memorial Sloan-Kettering Cancer Center, New York, NY, <sup>2</sup>Stanford University, Stanford, CA, <sup>3</sup>University of California, Berkeley, Berkeley, CA, <sup>4</sup>U. S. Department of Energy, Washington, DC

Membrane fusion is mediated by complexes formed by SNAP-receptor (SNARE) and Sec1/Munc18-like (SM) proteins, however the precise modes of molecular interactions between SM and SNARE proteins and when and how these complexes assemble inside the cell is presently unclear. Here we describe an improved fluorescence nanoscopy technique that can achieve effective resolutions of up to 7.5 nm FWHM (3.2 nm localization precision), limited only by stochastic photon emission from single molecules. We use this technique to dissect for the first time inside a cell, the spatial relationships and molecular interactions between the essential components of the membrane fusion machinery, the neuronal SM protein Munc18-1 and SNARE proteins syntaxin-1 and SNAP-25. Strikingly, we observed nano-scale clusters consisting of syntaxin-1 and SNAP-25 that contained pools of associated Munc18-1. Rescue experiments with syntaxin-1 mutants revealed that Munc18-1 recruitment to the plasma membrane depends on the Munc18-1 binding N-terminal peptide of syntaxin-1, and occurs through interactions with the open conformation of syntaxin-1 that is permissive to SNARE-complex assembly. Extensive complimentary biochemical experiments further corroborate our imaging results. Our data provide unexpected insights into the spatial organization and association of Munc18-1, SNAP-25 and syntaxin-1 on the neuronal plasma membrane, and suggest that recruitment of an SM protein to an on-pathway tri-partite SM - syntaxin - SNAP-25 complex could be a general mechanism for setting the stage for SNARE-mediated membrane fusion reactions. Our high-resolution imaging approach provides a framework for investigating interactions between the fusion machinery and other sub-cellular systems in situ.

### Techniques for reducing background fluorescence for single molecule imaging of processive myosins: linear Zero Mode Waveguides (ZMW) and Convex Lens Induced Confinement (CLIC).

M. W. Elting<sup>1,2</sup>, S. R. Leslie<sup>3,4</sup>, L. S. Churchman<sup>5</sup>, J. Korlach<sup>6</sup>, C. McFaul<sup>3</sup>, J. S. Leith<sup>3</sup>, M. J. Levene<sup>7</sup>, A. E. Cohen<sup>4,8</sup>, J. A. Spudich<sup>2</sup>; <sup>1</sup>Applied Physics, Stanford University, Stanford, CA, <sup>2</sup>Biochemistry, Stanford University, Stanford, CA, <sup>3</sup>Physics, McGill University, Montreal, QC, Canada, <sup>4</sup>Chemistry & Chemical Biology, Harvard University, Cambridge, MA, <sup>5</sup>Genetics, Harvard Medical School, Boston, MA, <sup>6</sup>Pacific Biosciences, Menlo Park, CA, <sup>7</sup>Biomedical Engineering, Yale University, New Haven, CT, <sup>8</sup>Physics, Harvard University, Cambridge, MA

It is often the case that enzymatically useful concentrations of fluorescent species cause a high enough background that it is difficult to resolve single fluorescent molecules. For example, with total internal reflection fluorescence (TIRF) microscopy, single molecules can only be detected in the presence of an approximately 100 nM concentration of fluorophores, whereas many biological interactions require significantly higher concentrations. We present the application of two techniques, linear Zero Mode Waveguides (ZMW) and Convex Lens Induced Confinement (CLIC) for increasing that concentration in studies of processive myosins V and VI. Both techniques limit the excitation volume to a region significantly closer to the coverslip surface than is possible with TIRF. ZMWs use small holes in an aluminum film to confine laser excitation to a region very close to the coverslip surface [1]. We demonstrate a rectangular ZMW geometry that allows the observation of long (~1 micron) processive runs of myosin molecules. We show that actin can be inserted into linear ZMWs by polymerizing filaments inside the waveguides, and that myosin V will walk processively along these actin filaments. CLIC mechanically confines fluorescent molecules to a thin region between two glass surfaces [2]. We demonstrate a new version of this technique that produces confinement within a flow cell device, allowing for easier implementation and smaller sample volumes. We show that myosin VI can walk processively on actin in the CLIC device at a high degree of mechanical confinement (<50 nm). It is likely that these techniques will have many wider applications to observing enzymatic reactions with other single molecule systems, such as other processive motors, including myosins, kinesin, and dynein. An important future application of these technologies is in imaging single fluorescently labeled nucleotide molecules interacting with motors as they undergo processive motion in order to probe chemomechanical coupling and mechanisms of gating. Increasing the possible concentration of fluorescently labeled nucleotide would be a very valuable tool for such experiments.

### High-resolution protein localization in yeast using correlative super-resolution and electron microscopy.

J. Caplan<sup>1</sup>, C. Young<sup>1</sup>, S. Modla<sup>1</sup>, A. Ell<sup>2</sup>, K. Czymmek<sup>1</sup>; <sup>1</sup>University of Delaware, Newark, DE, <sup>2</sup>BioScience Division, Carl Zeiss Microscopy GmbH, Oberkochen, Germany

Specific recognition signals that govern quality control within the secretory pathway provide a basic framework for determining trafficking mechanisms of recombinantly expressed GPCRs. Using high-resolution correlative microscopy approaches, we have investigated processes that regulate the heterologous expression of two human adenosine receptors, hA2aR and hA3R, and engineered chimeras of these two receptors in yeast, *Saccharomyces cerevisiae*. To

improve functional production (i.e. ligand-binding yields indicative of active receptors) of GPCRs, we assessed protein structure/function through rational engineered chimeras. By implementing DNA recombination strategies combined with high-resolution imaging techniques, we have determined the intracellular localization of heterologous GPCRs in yeast compared to endogenous organelle markers at high spatial resolution using the super-resolution techniques Structured Illumination Microscopy (SIM), Fluorescence-Photoactivation Localization Microscopy, (F-PALM) and direct stochastic optical reconstruction microscopy (dSTORM). Specifically, we investigated discrete subpopulations of tagged proteins using correlative transmission electron microscopy and scanning electron microscopy with dSTORM (AlexaFluor® 488 and AlexaFluor® 633) and F-PALM (photoconvertible GFP variant mEos2). We will describe optimized protocols using cryo-fixation of high-pressure frozen freeze-substituted yeast cells followed by various epoxy and lowicryl resin infiltration regimen. The goal of this work was to obtain the best morphological preservation at the electron microscopy level while at the same time maintaining optimal fluorescence signal for super-resolution imaging, thus facilitating the identification of sub-cellular organelles and compartments where fusion proteins localized.

#### **Color-shifting FRET sensor for detection of phagocytic phase of apoptosis.**

*C. L. Minchew<sup>1,2</sup>, V. V. Didenko<sup>1,2</sup>; <sup>1</sup>Neurosurgery and Molecular & Cellular Biology, Baylor College of Medicine, Houston, TX, <sup>2</sup>Michael E. DeBakey Veterans Administration Medical Center, Houston, TX*

Apoptotic cell clearance is a collaborative cellular event where the corpses of cells which committed suicide are rapidly eliminated by phagocytosis. This phagocytic reaction is critical for normal apoptosis completion. Its disturbance can promote self-immunization, inflammation and the release of viral or tumor DNA. Therefore it is essential to have a specific assay capable of detecting such an engulfment. To solve this problem, we developed the first FRET sensor which selectively detects apoptotic cell engulfment in cell suspensions and cultures. The sensor signals its detection of apoptotic cell engulfment by shifting color of its fluorescence within minutes after addition to cells.

The new assay is useful in studies where detection and quantification of apoptotic clearance is essential, such as cancers, inflammation, infection and auto-immune disorders.

#### **Imaging protein-protein interaction within neurons *in situ* through FRET quantification of GFP lifetime.**

*N. Sharifai<sup>1</sup>, H. Samarajeewa<sup>1</sup>, S. Deng<sup>1</sup>, M. Boulina<sup>1</sup>, A. Chiba<sup>1</sup>; <sup>1</sup>University of Miami, Coral Gables, FL*

Molecular signaling results from direct associations of proteins, which in turn are highly sensitive to their immediate molecular environment of a given cell as well as to various surroundings of the organisms. In the past decade, the networks of interacting proteins have been systematically catalogued with yeast-two-hybrid and co-affinity purification analyses. These assays address exclusively protein associations and are amenable to high-throughput screens. They are, however, designed to yield molecularly amplified digital output with little information on restrictions in time and space imposed from the dynamic yet complex contexts of living organisms. Moreover, conducted in an either non-native or isolated unicellular environment, positive and negative protein interactions demonstrated might not reflect those that would occur in the native cellular environment within intact animals. In contrast, the iSPIN project takes a

novel approach to characterizing the protein-protein associations through direct visualization *in vivo* (see [www.ispinproject.org](http://www.ispinproject.org)). The project adopts distance-dependent Förster resonance energy transfer (FRET) as its quantification principle. It also combines the molecular genetics to systematically tag diverse proteins with genetically encoded green fluorescent protein (GFP). Positive evidence for the nanometer-scale association by signal partner proteins can be captured *in vivo* using a diffraction-limited fluorescent microscope that is capable of FRET quantification. Compatible with live imaging within multicellular model organisms such as *Drosophila*, the iSPIN project is capable of evaluating the influence of native molecular environment from specific cellular contexts on the protein-protein interaction networks throughout the dynamic development of animals under normal and medically relevant conditions. Here, we describe the fluorescent lifetime imaging microscope (FLIM) tuned specifically for quantifying GFP lifetime in three-dimensional (3D) biological samples and present a proof-of-concept demonstration of nanometer-scale physical association occurring between two known signal partner proteins, Cdc42 (cell division control protein 42 homolog) and WASp (Wiskott–Aldrich Syndrome protein), within the molecular environment of intact neurons in the model organism. We propose that FRET quantification of GFP lifetime could serve as a basis for characterizing dynamic interactions among these and other proteins directly within native molecular environment *in situ*.

#### Measuring actin flow in cell protrusion in 3D.

C-L. Chiu<sup>1</sup>, J. S. Aguilar<sup>1</sup>, M. A. Digman<sup>1</sup>, E. Gratton<sup>1</sup>; <sup>1</sup>University of California, Irvine, Irvine, CA

Cells generate forces through the cytoskeleton that are transmitted to the extracellular matrix via cell adhesion in order to adhere and migrate. Though cellular force generation has been studied in detail in 2D environment, less is known about cytoskeleton dynamics of cells embedded in natural 3D matrices. Fluorescent Speckle Microscopy (FSM) has been used to capture high-resolution images of actin turnover dynamics within live cells in 2D. However, this method is not applicable when cells are in 3D environment due to lower resolution and signal level.

In this work we developed a new method to capture actin flow in 3D with high spatial-temporal resolution. nSPIRO and correlation spectroscopy techniques were combined to show the directional flow of actin in 3D live cell. MDA-MB-231 cells with actin-GFP expression were cultured in type I collagen. The laser bin was oscillating back and forth at nearby two cross sections on cell protrusion, while scanning in orbit manner at each plane. The orbit radius was modulated in order to detect actin flow in the center of the protrusion. The intensity profiles from two positions were then cross-correlated.

We found that actin in cell protrusion in 3D is relatively stable. Most of the measurement showed no correlation of two positions while some showed directional flow near protrusion surface. The actin flow rate of cell protrusion in 3D measured using this method is in the order of seconds, which is comparable to 2D results using FSM. With this method, we are able to visualize and quantify actin flow in 3D without the need of special speckle vectors and with high spatial-temporal resolution.

1711

**Using a novel genetic tag compatible with electron microscopy to determine ultrastructural localization of ciliopathy associated proteins.**

*D. E. Landis<sup>1</sup>, D. Moore<sup>2</sup>, S. J. Henke<sup>1</sup>, B. Yoder<sup>2</sup>; <sup>1</sup>Genetics and Genomic Sciences, University of Alabama at Birmingham, Birmingham, AL, <sup>2</sup>Cell Biology, University of Alabama at Birmingham, Birmingham, AL*

Primary cilia are a microtubule based organelle that function in a sensory capacity and can be found on almost all cell types. This organelle is important for a copious amount of critical signaling events during many developmental processes. Ciliopathies are diseases caused by the dysfunction of primary cilia and result in severe developmental defects. Many ciliopathy proteins localize to a region at the base of the cilium called the transition zone (TZ). The TZ is thought to be important for the establishment of the cilium as a unique signaling center due to its ability to control protein access to the cilium, possibly via the unique structures of this region. Some of the proteins that cause ciliopathies such as Nephronphthisis and Meckel Gruber Syndrome are known to localize to the TZ and form two distinct yet genetically interacting complexes. Loss of these proteins in *C. elegans* has shown ectopic entry into the cilium of non-ciliary proteins indicating a breakdown of the specialized ciliary barrier. Based on the loss of critical architectural components in TZ mutants it is hypothesized ciliopathy proteins comprise these important structures. Ultrastructural localization of TZ ciliopathy proteins and their contribution to these structures will be determined using *C. elegans* and mammalian cells expressing Nephronphthisis and Meckel Gruber associated proteins tagged with a novel genetic tag (miniSOG), visible through electron microscopy. This will expand our understanding of where these proteins are localized and the role they play in ciliary gating, disease, and developmental processes.

1712

**A hybrid confocal & atomic force microscope for probing biophysical properties of migrating cells.**

*D. Manoussaki<sup>1,2</sup>, W. Shin<sup>3</sup>, N. C. Gavara<sup>4</sup>, R. S. Chadwick<sup>1</sup>, C. Waterman<sup>3</sup>; <sup>1</sup>NIDCD, National Institutes of Health, Bethesda, MD, <sup>2</sup>Technical University of Crete, Hania, Greece, <sup>3</sup>NHLBI, National Institutes of Health, Bethesda, MD, <sup>4</sup>Faculty of Physics, Universitaet Goettingen, Goettingen, Germany*

Directed cell motility plays a central role in a variety of biological processes including development, wound healing, inflammation, and metastasis. The process of cell crawling is highly complex, and occurs with spatiotemporal coordination between components of the cell molecular machinery. In order to better understand the biophysical mechanism of cell protrusion, we have built a hybrid AFM / confocal microscope that allows us to image the cytoskeleton of individual migrating cells and at the same time measure cell mechanical properties during lamellipodial extension or retraction.

We apply contact AFM techniques in conjunction with the recently developed Bottom Effect Cone Correction to the Sneddon model for estimating the Young's modulus in different regions of crawling or retracting cells, and in particular in very thin regions such as the cell lamellipodium. Moreover, we use non-contact frequency modulated atomic force microscopy to calculate cellular stiffness and viscosity. Stiffness measurements on transfected PtK-1 cells reveal that the cell stiffens as it retracts while the lamellipodium is softest during the extension phase. Measurements on cells transfected with fluorescent constructs allow us to focus our measurements on specific cell structures, such as focal adhesions or stress fibers.

1713

**Time-resolved nanometer scale AFM imaging of antimicrobial peptide activity on live *Escherichia coli* cells.**A. Slade<sup>1</sup>, J. H. Kindt<sup>1</sup>, S. C. Minne<sup>1</sup>; <sup>1</sup>*Bruker Nano Inc., Santa Barbara, CA*

Understanding drug-membrane interactions is crucial to drug research and development. Bacterial membranes have a much more complex structure than mammalian cell membranes. As such, knowledge of bacterial membrane composition and organization, as well as characterization of the molecular-level responses to drug interactions, is critical to the development and assessment of effective drug formulations. Cellular drug responses involve highly dynamic processes. However, the ability to image live cells with nanometer resolution on timescales relevant to dynamic cellular events has proven challenging. The ability of atomic force microscopy (AFM) to obtain three-dimensional topography images of biological molecules with nanometer resolution and under near-physiological conditions remains unmatched by other imaging techniques. However, with traditional AFM systems, the typically longer image acquisition times required to obtain a single high-resolution image (~minutes) has limited the ability to investigate dynamic biological processes. While recent years have shown significant progress in the development of high-speed atomic force microscopy (HS-AFM), the nature of the instrumentation that has been developed has several drawbacks in specimen size, requiring small scan sizes and flat sample surfaces. As such, the majority of biologically-related HS-AFM studies have concentrated on imaging single biomolecules with little focus on using HS-AFM to examine cellular processes. With the rapidly growing antibiotics crisis, antimicrobial peptides (AmP) are increasingly being investigated as therapeutic alternatives. Key to their success is an understanding of the mechanisms by which AmPs interact with the cell membrane and facilitate cellular death. Using HS-AFM, we have obtained the first high-resolution time sequence images of the native structure of a bacterial outer membrane, obtained directly on the surface of live *Escherichia coli* cells. The increased time resolution of HS-AFM allowed us to observe dynamic changes in the nanoscale structure of the outer membrane in direct response to the AmP CM15, at timescales relevant to the mechanism of AmP-induced cell death. The results of these HS-AFM studies have provided the first opportunity to resolve the dynamics of AmP-mediated cell death in a native cell membrane environment in real-time and with nanoscale resolution.

1714

**RNA sampling and analysis with single living cells using Atomic Force Microscopy.**M. Tom-Moy<sup>1</sup>, K. Bernick<sup>1</sup>, A. Sridhar<sup>1</sup>, K. Pekrun<sup>1</sup>, A. Yamada<sup>1</sup>; <sup>1</sup>*Agilent Laboratories, Agilent Technologies, Santa Clara, CA*

The ability to sample specific biological molecules from individual, live cells without disruption of their cellular environment presents new opportunities in cell biology measurements. In order to achieve this sampling, we have adapted a combined AFM and fluorescence microscope to visualize and manipulate single, living cells for the extraction of cellular material such as RNA, protein and protein-RNA complexes. Using an AFM probe functionalized with streptavidin on an Agilent 6000 AFM, we have extracted beta-actin mRNA from a single living rat fibroblast. Beta-actin mRNA was visualized by biotinylated Cy5-labeled oligonucleotide-based FISH probes, introduced into living cells by cell penetrating peptides. Live cell imaging of these cells confirmed that probes successfully hybridized to target RNA first at 4 hours with optimal signal at 24 hours. The AFM probe was inserted 2 micrometers into the cell for 5 minutes before being retracted. Cell membrane puncture by the AFM tip was confirmed by using the force-curve feature of the AFM. After collection of the RNA inside the living cells, the retracted tip was washed extensively and analyzed by PCR for the presence of beta actin mRNA signal. Specific controls confirmed the positive PCR signal for beta actin RNA was from the single cell that the

probe penetrated and not from other external sources such as the media, other cells, or non-specific binding to the AFM tip. We are currently extending this method to the detection of various genes in other cell types, such as stem cells and induced pluripotent cells. The ability to measure gene expression in single cells, as we show here, will provide a more accurate representation of cells in a population, permitting a more complete picture of the expression networks that underlie cell and tissue function.

## New Technologies for Cell Biology II

### Visualization and analysis of fluorescent labels in energy filtered TEM.

*M. Thaler<sup>1</sup>, M. Pfannmöller<sup>2</sup>, I. Angert<sup>1</sup>, G. Benner<sup>1</sup>, I. V. Röder<sup>2</sup>, I. U. Wacker<sup>3</sup>, R. R. Schröder<sup>2</sup>; <sup>1</sup>Carl Zeiss Microscopy GmbH, Oberkochen, Germany, <sup>2</sup>CellNetworks, BioQuant, Heidelberg University, Heidelberg, Germany, <sup>3</sup>Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany*

Precise localization of functional proteins in tissue and cellular samples is frequently used for biological and medical applications. For localisation a variety of specific fluorescent markers is available in light microscopy. Linking fluorescent light microscopical information to high resolution, ultrastructural data obtained by transmission electron microscopy (TEM) is a demanding task and the identification of labeled molecules at nanometer scale is still a challenge.

Energy filtered TEM (EFTEM) offers both: high spatial resolution and additional analytical imaging modalities for distinguishing materials by their spectral characteristics of electronic interactions. In EFTEM electron energy loss spectra (EELS) can be recorded as 3D image data and thus it is possible to visualize and localize different materials by their specific excitations of valance electrons.

We show that fluorescent labels such as quantum dots (Qdots) can be localized and identified by analyzing their characteristic energy loss in the low energy region (bandgap and plasmon excitations) using EFTEM. This method has the potential to visualize functional labels: It allows collecting spectral information with spectral energies from 1 - 3.5 eV energy-loss corresponding to light-optical absorptions, to the UV optical range (> 3.5 eV) up to plasmonic interactions (up to 30eV). Using both a Carl Zeiss LIBRA 200<sup>®</sup> MC equipped with an aberration corrected in-column omega filter, a monochromated electron source (CEOS, Heidelberg) and a Carl Zeiss LIBRA 120<sup>®</sup> PLUS energy filtered images from 0 eV to 30 eV energy-loss were acquired. Spectra were extracted from the 3D EFTEM data cube for each image pixel and classified via Multivariate Statistical Analysis (MSA) [1]. Data and a comparison of results for different acceleration voltages are presented. Ultrathin sections of muscle tissue labeled with Qdots were studied. We were able to distinguish Qdots and heterochromatin based on their specific energy loss signals.

Results from our experiments and previously published data indicate that the described method can be used to visualize Qdots in EFTEM by characteristic energy losses in the low loss region. We conclude that Qdots have the potential for multimodal analysis in the field of correlative microscopy. The possibility of directly detecting Qdots and fluorescent markers in EFTEM allows a combination of functional and ultrastructural studies by using a single instrument.

The project is supported by the German Federal Ministry for Education and Research (grant no. FKZ: 13N11403).

**A simple imaging-based method to characterize protein-protein interactions *in vivo*.**

O. Gallego<sup>1</sup>, T. Specht<sup>2</sup>, T. Brach<sup>2</sup>, A. Kumar<sup>2</sup>, A-C. Gavin<sup>2</sup>, M. Kaksonen<sup>2</sup>; <sup>1</sup>IRB, Barcelona, Spain, <sup>2</sup>EMBL, Heidelberg, Germany

Over the last decades there has been an explosion of new methodologies to study protein complexes. However, most of the approaches currently used are based on *in vitro* assays (e.g. NMR, X-ray, EM, ITC etc). *In vivo* studies are often limited to stable complexes or they cannot be used to quantitatively characterize the properties of the complex. Additionally, these approaches are often performed in a context far from the normal physiology of the target proteins (e.g. yeast two-hybrid method). Methods such as FRET or FCCS allow a more quantitative analysis of protein-protein interactions (PPIs) at conditions closer to normal physiology, but are technically challenging and therefore difficult to apply to high-throughput studies.

Here we present PICT (“PICT is Imaging of Complexes after Translocation”), an approach that provides a very simple readout for the analysis of direct and indirect PPIs in living cells, including transient interactions. This approach is based on the rapamycin-induced heterodimerization of the FRB and FKBP domains. The FKBP domain is fused to an anchor protein that has a distinct and stable localization. The protein of interest (“bait”) is fused to the FRB domain. Prey proteins, tagged with GFP, will co-translocate with the bait to the anchor sites upon addition of rapamycin if they interact with the bait. Consequently, PPIs are encoded as a change in localization of GFP-tagged prey proteins.

We show the potential of PICT by analysing different protein complexes in the yeast *Saccharomyces cerevisiae*. For example, we characterized the PPIs within the Ste5-Ste11-Ste50 complex of the pheromone-activated Mitogen-activated protein kinase (MAPK) cascade. We also combined PICT and FRAP methods to quantitate the transient interaction between the endocytic proteins Syp1 and Ede1.

In summary, PICT is a novel approach to study PPIs *in vivo*, follow their behaviour upon different perturbations and facilitate their characterization with additional methods such as FRAP. Importantly, due to its simple microscopic readout, PICT can be easily automatized for high-throughput screens.

1717

**High-throughput real-time analysis of fluctuation in cell oxygenation using a fluorescent intracellular oxygen-sensitive probe.**

B. Conkle<sup>1</sup>, J. Hynes<sup>1</sup>, C. Carey<sup>1</sup>, K. Morton<sup>2</sup>; <sup>1</sup>Luxcel BioSciences Ltd, Cork, Ireland, <sup>2</sup>Nuffield Dept of Obstetrics and Gynaecology, University of Oxford, Oxford, United Kingdom

Tissue and cell oxygenation is of critical importance to a large variety of disease states and adaptive responses and as researchers strive for more biologically relevant *in vitro* models, the ability to both control and monitor this parameter is of growing importance. Here we describe a novel plate-reader based method of monitoring cell oxygenation using an intracellular oxygen-sensitive probe and apply the method to both 2D and 3D cultures generating real-time oxygenation profiles in oxygen scale. The data generated using a plate reader equipped with an atmospheric control unit reveals that significant differences can exist between the oxygen concentration that pertains at the cell monolayer and the applied ambient oxygen concentration,

and that this difference is dependent on both the applied oxygen concentration, cell confluence and the basal metabolic activity of the test cells. Data is also presented illustrating that the degree of monolayer hypoxia can be modulated by altering the oxygen permeability of the test plate thereby allowing more precise control of cell oxygenation. The impact of metabolic stimulation and inhibition is also examined as is the potential for multiplexing with additional informative endpoints such as fluorometric assessments of mitochondrial membrane potential, reactive oxygen species and glycolytic flux measurements thereby providing a more complete measure of monolayer hypoxia as well as a real-time measure of the metabolic implications of stress imposed.

1718

**Measuring Barrier Tissue Integrity with the Organic Electrochemical Transistor.**

*L. H. Jimison<sup>1</sup>, S. Tria<sup>1</sup>, M. Bongo<sup>1</sup>, G. G. Malliaras<sup>1</sup>, R. M. Owens<sup>1</sup>; <sup>1</sup>Bioelectronics, Ecole des Mines de St. Etienne, Gardanne, France*

The ability to measure paracellular transport provides a wealth of information about barrier tissue function, and disruption or malfunction of the structures involved in transport through barrier tissue is often indicative of toxicity or disease. The use of barrier tissue models in combination with different measurement technologies has hitherto been hampered by invasive, expensive, slow to respond and difficult to implement methods.

To respond to this challenge, we have integrated the organic electrochemical transistor (OECT) with both epithelial and endothelial cells to model both the gastrointestinal barrier tissue layer, and the blood brain barrier respectively, as a means of assessing barrier tissue function. The ability of organic electronic materials to interface with biological systems has been much vaunted of late, with examples showing the elegant use of these materials to deliver neurotransmitters in vivo, control cell adhesion and migration and measure neuronal activity in vivo. With the unique ability of organic electronic materials to conduct both electronic and ionic carriers, they act as an ideal platform for the integration of electronic and biological systems. The OECT has been recently employed as a sensor for DNA, enzymes and cell attachment. The OECT is particularly suited for sensing due to inherent amplification of signal provided by the transistor.

In this study we demonstrate the ability to measure minute variations in paracellular ionic flux induced by toxic compounds in real time, with unprecedented temporal resolution and extreme sensitivity. Addition of concentrations down to 1 mM hydrogen peroxide, in complex cell media, to Caco-2 epithelial cell layers, was detected within 30 seconds. Our results are validated by comparison with existing methods used to evaluate barrier tissue layers, including immunofluorescence of tight junction proteins, a permeability assay using a fluorescent tracer (Lucifer Yellow) and a commercially available TER measurement system (Cellzscope, Nanoanalytics).

The integration of commercially available cell culture filters with the OECT demonstrates a sensing device in a format that is compatible with low cost manufacturing techniques, of great importance for high throughput screening. This work constitutes an elegant example of harnessing the power of engineering for relevant research in biological sciences. Future development of this technology will have implications for toxicology, drug development, reduction of animal use by enabling in vitro models, infectious disease diagnostics and basic research on the molecular biology and electrophysiology of barrier function.

1719

**Long-term simultaneous dual measurement of electrophysiological properties and mechanical responses of cardiomyocytes using on-chip extracellular field potential recording and real-time optical image analysis.**

*T. Kaneko<sup>1</sup>, F. Nomura<sup>1</sup>, T. Hamada<sup>1</sup>, A. Hattori<sup>1</sup>, K. Yasuda<sup>1</sup>; <sup>1</sup>Department of Biomedical Information, Institute of Biomaterials and Bioengineering, Tokyo Medical and Dental University, Tokyo, Japan*

Quantitative evaluation of mechanophysiological responses in cardiomyocytes has becoming more important to acquire more precise prediction of cardiotoxicity, especially relationships between mechano-chemical coupling in their electrophysiological responses during their adaptation process is one of the important topics of remodeling of cardiomyocyte networks in heart. Hence, for the evaluation of correlation between mechanophysiological effects and electrophysiological effects of drugs, we have developed an on-chip simultaneous dual measurement system that records the extracellular field potentials and the contractile motions in lined-up cardiomyocyte network with non-invasive/destructive measurement for long-term experiment. Cardiomyocytes were seeded in rectangular microchambers fabricated on the multi electrode array (MEA) chip for the field potential recording. To detect contractility of cardiomyocytes, the cells were labeled with the polystyrene beads attached on the surface of target cells and the motions of beads were acquired and analyzed using a newly developed wider depth of field optics equipped with 1/100 s high-speed digital camera. Electrophysiological properties [interspike intervals and field potential durations (FPDs)] and mechanophysiological properties [displacements, velocities, and direction of displacements of beads] were obtained simultaneously using real time processing system module. In the presence of verapamil, typical L-type calcium channel blocker, beating rate of cardiomyocytes decreased accompanying with shortening of FPD and its fluctuation increase, and contractility was weakened significantly with its fluctuation increase. Correlation of fluctuations of the FPD and force generation (the direction of displacement) was also examined and observed, and confirmed that the increase of both of fluctuation reflects the increase of inhomogeneity of tension generation of cardiomyocytes in the network according to the increase of uncertainty of electrophysiological responses. The results indicate that the fluctuation of force generation should also become an effective biomarker of cardiotoxicity risk more correctly in drug development, also might be used for the clarification of mechanisms especially for the adaptation process of cardiomyocytes from the viewpoint of spatiotemporal mechanoelectrophysiology.

1720

**Surface Modification of a Reconfigurable Co-Culture Device to Assess the Effect of Substrate Stiffness and Cell-Cell Interactions.**

*N. Rao<sup>1</sup>, G. Grover<sup>1</sup>, S. Evans<sup>1</sup>, L. Vincent<sup>1</sup>, Y. Choi<sup>1</sup>, K. Spencer<sup>2</sup>, E. Hu<sup>2</sup>, A. Engler<sup>1</sup>, K. L. Christman<sup>1</sup>; <sup>1</sup>Bioengineering, UC: San Diego, La Jolla, CA, <sup>2</sup>Biomedical Engineering, UC: Irvine, Irvine, CA*

Co-culture technology allows one to understand how one cell type affects another. There is a need to improve existing technologies to allow researchers to better understand what factors affect cell behavior, particularly for stem cell differentiation. Recently, a novel reconfigurable co-culture device was developed which allows a user to study physical cell-cell interactions and paracrine effects in an organized fashion. This device is an interlocking pair of silicon combs that allow the user to study organized co-culture in either “contact” or “gap” configurations (Hui, E et al. PNAS 2007). Our lab has shown that this tool is powerful, particularly for determining how mature cells affect progenitor cell differentiation (Rao et al., Biomedical Microdevices, accepted). Stem cell fate can be driven by the presence of other cell types and also by

changing the stiffness of the substrate that these stem cells feel. As a result, by adding a tunable surface stiffness to the device we show a synergistic effect when co-culturing at a specific stiffness. The surface of the device was treated for covalent attachment of polyacrylamide using slightly modified protocols (Tse et al. PNAS, 2007). Device pairs were locked in contact mode. Acrylamide, bisacrylamide and initiator were well mixed, added to the surface, and allowed to spread evenly with consistent height using coverslips. PA was photo polymerized by UV light for 10 minutes. AFM measurements were carried out by established methods (Engler et al. Cell 2006). Sulfo-Sanpah was used to attach 10 $\mu$ g/mL fibronectin. Adipose derived stem cells (ASCs) were used to test the ability of this technology to demonstrate that both co-culture and substrate serves synergistically to drive a myogenic lineage. Cells were seeded on individual comb halves, adhered, and placed together in a gap configuration. ASCs were cultured with ASCs or C2C12s on either the silicon combs or the combs coated with a 11kPA PA gels (4 groups total). The cultures were then stained with MyoD (an early myogenic marker), or ASC RNA was isolated, and qPCR normalized to GapDH was performed. MyoD was detected in all cultures except group 1. Myogenin was consistently upregulated on 11 kPA and in co-culture with C2C12s compared to other cultures. Likewise, Desmin showed increased gene expression in this group compared to ASCs on gel only or ASCs co-cultured with C2C12s on silicon ( $p < 0.05$ ). By using ASCs as proof of concept, we have demonstrated that we can develop a novel technology that can parse out whether substrate stiffness, cell-cell contact, and cell-cell paracrine effects cause changes in differentiation.

#### **Monolayer Stress Microscopy: Uncovering inter- and intra-cellular forces in cell sheets.**

*D. T. Tambe<sup>1</sup>, X. Trepal<sup>2</sup>, J. P. Butler<sup>1</sup>, J. J. Fredberg<sup>1</sup>; <sup>1</sup>Environmental Health, Harvard School of Public Health, Boston, MA, <sup>2</sup>University of Barcelona, Barcelona, Spain*

In wound healing, tissue growth, and certain cancers, the epithelial or endothelial monolayer sheet expands. Within the expanding monolayer sheet, motion of the individual cell is strongly guided by physical forces imposed by adjacent cells. This process is called plithotaxis and was discovered using Monolayer Stress Microscopy (MSM). MSM rests upon certain simplifying assumptions concerning boundary conditions and cell material properties, however. To assess their validity and quantify associated artifacts, we relaxed these assumptions and then used rigorous numerical and experimental analysis. For several commonly used experimental monolayer systems, we show that the simplifying assumptions lead to errors that are quite small. Moreover, characteristic features of intercellular stresses that underlie plithotaxis are largely unaffected. Finally, stresses due to out-of-plane tractions have little effect upon in-plane stresses. Taken together, these findings define the broad limits of applicability of Monolayer Stress Microscopy.

1722

#### **Polyacrylamide scaffolds for studying cellular responses to substrate stiffness in three dimensions.**

*Y-H. Lee<sup>1</sup>, S. M. Irulappan<sup>1</sup>, J-R. Huang<sup>2</sup>, K-H. Lin<sup>1</sup>; <sup>1</sup>Physics, Academia Sinica, Taipei, Taiwan, <sup>2</sup>Physics, National Taiwan Normal University, Taipei, Taiwan*

Recent developments in two-dimensional (2D) culture substrates with tunable stiffness and patterned adhesion ligands have demonstrated that biochemical and mechanical cues regulate the biological functions of living cells. We have extended these cell culture platforms into three dimensions (3D), as in complex biological systems, by producing highly ordered scaffolds of polyacrylamide coated with extracellular matrix proteins. We characterized important

parameters for ordered polyacrylamide scaffolds of tunable stiffness. We then grew individual fibroblasts in the identical pores of our scaffolds, examining cellular morphological, cytoskeletal, and adhesion properties. In a 3D scaffold, these cells sensed the surrounding stiffness as a value between the stiffness of bulk polyacrylamide and a scaffold. Many cells exhibited features similar to those of cells cultured in conventional 3D matrices. The cells were often elongated, with actin filaments concentrated at the cortical region and only forming thin stress fibres. We also observed the surprising phenotype of thick stress fibres similar to fibres detected in a 2D system, but these fibres did not occur ventrally. The rich variety of morphologies and anchoring strategies assumed by cells growing on our tunable 3D polyacrylamide scaffolds demonstrate the richness of cell-microenvironment interactions when cell adhesions are not confined to 2D surfaces.

1723

### High content profiling of cellular invasion in 3D cell culture models.

*G. Burgstaller<sup>1</sup>, B. Oherle<sup>1</sup>, O. Eickelberg<sup>1</sup>; <sup>1</sup>Comprehensive Pneumology Center, Helmholtz Zentrum Muenchen, Munich, Germany*

To-date, most invasion or migration assays use a modified Boyden chamber-like design to assess migration as single-cell or scratch assays on coated or uncoated planar plastic surfaces. Here, we describe an easy-to-use, 96-well, microplate-based, high-content, three-dimensional (3D) cell culture assay capable of assessing live kinetics and molecular signatures of cellular invasion. This assay will help to investigate aberrant motility processes of cells harvested from diseases like fibrosis, metastatic cancers, or chronic inflammatory states. Additionally, our technique is suitable for high-throughput pharmacological screening of novel compounds regulating invasive and migratory pathways, and is applicable to a wide spectrum of cells from different origins. Thus, we were able to demonstrate significant effects on the invasion capacity by comparing the adenocarcinomic human alveolar basal epithelial cell-line A549 (invasion of 1% of seeded cells) to the lung fibroblast cell-line Mlg 2908 (invasion of 9% of seeded cells). Treatment of Mlg 2908 fibroblasts with epidermal growth factor (EGF) even augmented the invasiveness of these cells (invasion of 18% of seeded cells). These results were further corroborated by live-cell imaging of invading fibroblasts. We could also monitor and measure significant changes in cell shape, cell surface area, cell volume and cell sphericity. By using DNA microarrays and qRT-PCR we observed a highly significant deregulation of various genes and proteins involved in migration in 3D collagen embedded fibroblasts. Furthermore, our method is easily expandable, as using a 3D collagen gel of different elastic moduli or adding additional ECM components like hydroxyproline or elastin might increase the versatility in the readout.

1724

### 3D Angiogenesis Assay with Concurrent Imaging and Multiplexed Biomarker Identification.

*C. S. Chen<sup>1</sup>, W-R. Lie<sup>2</sup>, P. J. Hung<sup>1</sup>; <sup>1</sup>EMD Millipore - CellASIC, Hayward, CA, <sup>2</sup>EMD Millipore, St Charles, MO*

It has been shown that angiogenesis is an important player in carcinogenesis and cancer cell metastasis, and thus is a promising target for anti-cancer drugs. Increasing evidence has shown that the conventional 2D tube formation assay on endothelial cells is inadequate to demonstrate clinical relevancy. In this study, we have adopted a commercially available microfluidic device which integrated 3D cell culture and continuous perfusion of reagents into a high throughput/content screening compatible format to develop a more physiologic-relevant angiogenesis assay. Since the reagents are continuously perfused through the 3D cultured

cells, this assay utilizes both imaging on the cell bodies as well as sampling of the flow-through volumes concurrently to correlate 3D sprout formation with multiplexed secreted biomarker identification to enable multi-facet profiling of the angiogenesis process. Using human umbilical vein endothelial cells (HUVEC) cultured in both 3D fibrin gel and traditional 2D format, the cells were exposed to various concentrations of known inducer PMA and inhibitor suramin, with regular culture medium as the control. Imaging of the sprout formation in 3D was conducted every 24 hours, with 50 $\mu$ L of the flow through volume collected at the same time for multiplexed biomarker identification with Luminex assay in order to quantify the secretion of Angiopoietin-2, Endothelin-1, Endoglin, FGF-1, IL-8, HB-EGF, PLGF, and VEGF-C. We observed that when grown in the absence of fibrin gel, the cells assumed a monolayer morphology with no noticeable angiogenesis activity, while in the fibrin gel, HUVEC exposed to pro-angiogenic factors for 24 hours arrested growth and exhibited sprouting behavior characteristic of angiogenesis, also evident by the biomarker assay. Sprouts were readily visualized under phase contrast imaging on an inverted microscope. Here, we have established a unique long-term perfusion 3D angiogenesis assay also with the co-culture potential that may improve drug screening and biological insight into this fundamental process.

1725

**Micro-devices for imaging of cells and model organisms.**A. Groisman<sup>1</sup>, E. Gutierrez<sup>1</sup>; <sup>1</sup>UC San Diego, La Jolla, CA

The imaging of model organisms and cells presents a variety of challenges. Long-term, high-resolution imaging of non-adherent cells (yeast, lymphocytes, oocytes) requires some degree of confinement and protection of cells from unwanted displacement by flow of the surrounding medium that may result from convection, motion of the microscope stage, or medium exchange. *C. elegans* worms are difficult to image, because they are constitutively motile and grow nearly 100-fold during their development. Zebrafish embryos are difficult to position with an optimal orientation because of their irregular shapes. Here we present different micro-devices for imaging of yeast, primary lymphocytes, *C. elegans* eggs and larval worms, and zebrafish embryos. Devices for yeast, *C. elegans* eggs, and lymphocytes have arrays of micro-wells at the bottoms of larger wells, which are accessible to pipetting. Yeast are mixed with low-melting agarose that solidifies in thin layers in micro-wells, both immobilizing yeast cells for high-resolution imaging and making them accessible to rapid and easy medium exchange. *C. elegans* worms carrying permeable eggs are loaded into a large well, where the worms are cut with a scalpel releasing the eggs. The eggs are then moved into micro-wells, where they are mechanically protected from flow. Therefore, the permeabilized eggs remain motionless, while the medium is exchanged (by aspirating the old medium and dispensing a new one), and can be imaged at a high-resolution. Primary human CD4<sup>+</sup> T lymphocytes loaded with a pipette into small wells settle by the gravity into finger-like micro-channels, where their motion is restricted to nearly one-dimensional manifolds. The device is used to image the expression of fluorescent proteins caused by HIV-infection at a single-cell resolution over a 2-3 day interval at several different conditions in parallel. Micro-well devices for zebrafish embryos enable well-defined orientation of the embryos for prolonged high-resolution imaging of specific parts of their body. Finally, a microfluidic device enables longitudinal imaging of larval and adult *C. elegans* worms with periodic complete immobilization for collecting stacks of high-resolution confocal images in different regions of interest.

1726

**Innovative "Confocal SEM" 3D microscopy in a biological context.**

*C. Mathisen<sup>1</sup>, B. Lich<sup>1</sup>, F. Bourhorbel<sup>1</sup>, B. Humbel<sup>2</sup>, C. Lousser<sup>2</sup>; <sup>1</sup>FEI Company, Eindhoven, Netherlands, <sup>2</sup>University Lausanne, Lausanne, Switzerland*

Over the last decade electron microscopy techniques have evolved from delivering 2D to 3D information with a main focus on the architecture of organelles on a subcellular level. These techniques have yielded important new insights in intracellular architecture and connectivity of organelles.

However, understanding complex biological systems requires knowing how this high resolution 3D Electron microscopy data correlates with the situation in-vitro, or even better in-vivo, in a relevant biological system.

To obtain more complete and meaningful information about the biological processes within a cell developments have taken place to combine light microscopy data with electron microscopy data.

The main challenge we face today is not only the acquisition and the presentation of the data (the amounts of data are vast) but also the extraction of valuable information from this data. In the field of image processing the first important steps towards automated segmentation are made. The success of automatic segmentation algorithms will be a critical next step in the near future of large volume 3D electron microscopy data acquisition. What has recently become clear is that the quality of both automated and manual segmentations are very dependent on the raw data quality that comes directly from the EM. In TEM, as well as in SEM, the data quality in the image plane (X,Y) is typically good enough for 2D segmentation, but when moving into the 3rd dimension the data quality in the Z plane is determined by tilt limitations in the TEM when tomography is used. In an automated SEM approach the data quality is limited to the smallest section that can be cut before the next image is acquired. Hence both in SEM approaches as well as in TEM approaches, data quality is mainly limited in the Z-plane. Here we explore the possibility to obtain isotropic 3D electron-imaging information down to the membrane level.

In this work we will present two practical parts: first we elaborate on how light and electron microscopy domains are correlated in an easy and intuitive way to determine the area for high resolution 3D data acquisition; second we elaborate on how an innovative technique is used to collect the required high resolution 3D in this particular specimen location. We use multi-energy SEM image acquisition and deconvolution techniques to reveal the sub-surface 3D structure in a biological relevant area, hence obtaining the highly desired isotropic data quality.

**Endogenous protein tagging for fluorescence studies and identification of protein-protein interactions by High Throughput.**

*I. Poser<sup>1</sup>, N. Berger<sup>2</sup>, A. W. Bird<sup>1</sup>, M. Sarov<sup>1</sup>, A. Pozniakovsky<sup>1</sup>, M. Leuschner<sup>1</sup>, A. Ssykor<sup>1</sup>, M. Pham<sup>1</sup>, M. Y. Hein<sup>3</sup>, M. Seiler<sup>4</sup>, J. Doerr<sup>5</sup>, O. Bruestle<sup>5</sup>, F. Buchholz<sup>2</sup>, M. Mann<sup>3</sup>, A. A. Hyman<sup>1</sup>; <sup>1</sup>MPI-CBG, Dresden, Germany, <sup>2</sup>TU Dresden, Dresden, Germany, <sup>3</sup>MPI of Biochemistry, Martinsried, Germany, <sup>4</sup>EMBL, Heidelberg, Germany, <sup>5</sup>University Bonn, Bonn, Germany*

Tagged proteins represent a powerful tool to study cell signaling cascades, protein-protein interactions and disease-related mechanisms in eukaryotic cells. Until now, it has been time-consuming and laborious to generate fluorescence-tagged cell lines that stably express tagged genes at or near physiological levels.

Here we present a powerful pipeline that enables us to tag nearly every gene of interest in a fast and reliable manner using bacterial artificial chromosomes (BACs). The most important

advantages of using BACs are that cell-type specific processing, regulation, and splicing of the gene of interest are maintained within the stable cell line. This is typically not included when using cDNAs. Furthermore, BACs containing a tagged target gene can be transfected into multiple human and mouse cell lines including tumor cell lines, embryonic stem cells and human neural stem cells.

The resulting stable transgenic cell lines then enable molecular characterization of for example unknown genes that have been identified in RNAi and proteomic screens. The lines expressing the tagged protein can be used in a variety of applications e.g. in fluorescence studies, by mass spectrometry to identify protein-protein interactions, and rescue experiments to monitor the specificity of an RNAi treatment (Ref.).

To increase the throughput of our pipeline we are currently building a customized automated cell culture robot that will enable us to increase our transfection ability by about 5 times. With this improved pipeline we plan to further increase our valuable resource of stable transgenic BAC cell lines, currently standing at 3000 lines.

#### **Expanding applications of BioID: A new screen for candidate protein interactions.**

*D. I. Kim<sup>1</sup>, B. Kc<sup>1</sup>, M. Greenfield<sup>1</sup>, G. Isaya<sup>2</sup>, K. J. Roux<sup>1</sup>; <sup>1</sup>Children's Health Research, Sanford Research/USD, Sioux Falls, SD, <sup>2</sup>Mayo Clinic College of Medicine, Rochester, MN*

Identification of protein-protein interactions is critical to the study of cell biology. Current methods to screen for these protein interactions, such as yeast-2-hybrid or complex purification, can present certain limitations. As a result, investigators often expend resources pursuing false-positives and/or miss relevant interactions. In attempt to overcome some of these limitations and provide an alternative approach to screen for protein interactions we have generated a method that is fundamentally different. Called BioID for proximity-dependent biotin identification, this method is based on fusion of a promiscuous biotin ligase to a protein of interest. When expressed in the presence of excess biotin, the BioID-fusion protein biotinylates vicinal proteins in live cells. This biotinylation permits the selective isolation and identification of these proteins. The net effect is an ability to generate a history of protein proximity in live cells that can be used as a screen for biologically relevant candidate protein interactions. Our initial use of BioID was with the A-type lamins, constituents of the nuclear lamina. Here we report new applications of BioID in different subcellular compartments and/or with a variety of proteins. We have utilized BioID with an integral membrane protein, oriented either towards the cytoplasmic/nuclear compartment or within the endoplasmic reticulum. BioID has also successfully been used in the mitochondrial matrix and applied to well-defined stable protein complexes of the nuclear pore complex. These studies considerably expand the applications of BioID and have refined our understanding of this new method.

1729

**Integration of Automated Live Cell Perturbation and Quantitative Time-Lapse Imaging via a Multi-Well Microfluidic Perfusion System.**

*J. Graham<sup>1</sup>, P. Lee<sup>2</sup>, P. Hung<sup>2</sup>, T. Gaige<sup>2</sup>, K. Ongena<sup>1</sup>, S. Gil<sup>1</sup>, B. Kopaciewicz<sup>1</sup>, T. Galitski<sup>1</sup>, A. J. Ball<sup>1</sup>; <sup>1</sup>Science & Technology, EMD Millipore, Danvers, MA, <sup>2</sup>CellASIC, Hayward, CA*

Dynamic live cell assays offer better understanding of cellular behavior, however control and monitoring of living cells is limited by the technical challenge of performing precise perturbations without interfering with the microenvironment and/or removing cells from the analysis platform. CellASIC has recently developed microfluidics-based systems for perfusion-based microenvironment control and live cell analysis, integrating temperature, gas, cell loading and fluid control. This study integrated CellASIC's ONIX system with automated time-lapse microscopy and quantitative image analysis to create a state of the art platform for dynamic live cell analysis. All cell loading, culture and drug treatment steps were automated via the CellASIC ONIX system; thus cell culture and perturbation could be performed while the plate was on an automated microscope stage. We used HeLa cells expressing Cdt1-Germinin fluorescent ubiquitination-based indicator (FUCCI) fusion proteins as dynamic cell cycle sensors to perform quantitative analysis of the kinetics of cell cycle progression in asynchronous controls and cells synchronized by thymidine block (S-phase); and serum removal (G0/G1 block). Using the FUCCI system cells in G1 display red fluorescence; green in S, G2 and M phases; during G1/S transition both red and green are observed. Thus, dynamic cellular color change from red-to-yellow-to-green represents progression through the cell cycle. Automated time lapse brightfield and fluorescence images were acquired for up to 96 hours for multiple stage positions. For quantitative analysis of cell images, open-source CellProfiler software was used to perform cell segmentation and quantify object counts and intensities. We demonstrate that with this system, cell loading, culture and drug treatments are readily automatable, enabling multi-well cell perturbation and multi-well time-lapse imaging of cells in situ without the need to remove the plate from the microscope stage. Using CellProfiler software we quantified % of cells at each cell cycle phase over time in asynchronous and synchronized cell populations, enabling dynamic tracking of cell cycle progression, arrest, and release in response to each perturbation. This study provides proof of concept that integration of the CellASIC microfluidics platform with automated microscopy and image analysis enables programmable cell loading, perturbation and analysis over time in a physiologically relevant microenvironment, facilitating novel assay designs and hands-free execution. By integrating and automating precise cellular environment control and quantitative imaging a wide range of advanced cell biology applications become possible, enabling significantly improved research tools to investigate the complex and dynamic behaviors of living cells.

1730

### Optogenetic Protein Clustering Allows Modular and Tunable Control of Diverse Signaling Cascades in Living Cells.

L. J. Bugaj<sup>1,2</sup>, A. Choks<sup>2</sup>, C. Mesuda<sup>3</sup>, R. Kane<sup>4</sup>, D. V. Schaffer<sup>1,2,3,5,6</sup>; <sup>1</sup>UC Berkeley-UCSF Graduate Program in Bioengineering, UC Berkeley, Berkeley, CA, <sup>2</sup>Department of Bioengineering, UC Berkeley, Berkeley, CA, <sup>3</sup>Department of Chemical and Biomolecular Engineering, UC Berkeley, Berkeley, CA, <sup>4</sup>Department of Chemical and Biological Engineering, Rensselaer Polytechnic Institute, Troy, NY, <sup>5</sup>Helen Wills Neuroscience Institute, UC Berkeley, Berkeley, CA, <sup>6</sup>California Institute for Quantitative Biosciences, UC Berkeley, Berkeley, CA

Protein clustering is known to play an important role in cellular signal transduction for diverse classes of proteins, but its study is made difficult by a lack of effective methods to modulate a protein's oligomeric state within a living cell. The best current tools require the addition of an exogenous molecule to multimerize a transgene product, but these approaches suffer from poor spatial control and lack the capability for dynamic regulation. Optogenetic techniques have in recent years demonstrated the ability to modulate protein activity with spatiotemporal precision, though these methods have been limited to individually engineered proteins or protein dimers. In this work, we present a genetically encoded photoactivatable protein capable of clustering in a light dependent manner, and we demonstrate its utility in activating a diverse set of signaling pathways with high spatiotemporal resolution.

Cryptochrome2 (Cry2) is a light sensitive protein that has been reported to form light-dependent, oligomeric "photobodies". We have demonstrated for the first time that these photobodies can be formed inducibly, reversibly, and tunably in mammalian cells in response to blue light. We first established the utility of this capability by photoactivating the  $\beta$ -catenin pathway, and as a result can achieve a higher transcriptional response than obtained even with the natural ligand Wnt3a. We also used Cry2 clustering to robustly and dynamically activate the Rac1 and RhoA pathways with light. While Rac1 oligomerization has been reported to increase enzymatic activity in *in vitro* assays, notably this is the first report of activating Rac1 in living cells through inducible oligomerization. Furthermore, in creating a photo-activatable RhoA, to our knowledge this is the first demonstration of clustering as a mode of activation for this well-studied protein.

Light-induced clustering of target proteins may allow biological researchers to pattern signaling activity onto cells and tissues with unprecedented ease, and may allow systems biologists to interrogate  $\beta$ -catenin, Rac1, and RhoA signaling network responses to quantitatively controlled and time-varying signaling inputs. More generally, the ability to abstract Cry2-mCherry as a "plug-and-play" clustering module will enable scientists to rapidly expand the optogenetic toolbox and, provided that at least one node of a signaling network involves clustering, endow numerous other signaling pathways with photocontrol.

1731

### Biochemical approach combined with immunometric tools to enable tracking metal uptake fluctuations in bacteria.

A. B<sup>1</sup>; <sup>1</sup>Technical University of Lodz, Lodz, Poland

A lot of attention has been drawn in the recent years to devising novel tools for quantitative analysis of chemicals associated with bacterial metabolism. Metal ions, often with toxic properties, are amongst these constituents that heavily affect viability of cells. Bacteria evolved intricate mechanisms of feedback, where specific protein transporters eject excessive amounts of contaminant out of the cell. The fluctuations are to restore balance before life processes suffer dent. To measure how strong adaptive aptitude of cells is we can track changes in their

microenvironment. While traditional analysis would involve costly equipment and people trained to operate it, alternative routes has been under investigation and expanding rapidly. Having studied successful cases, where elements such as mercury, cadmium or led were subject to determination, our laboratory has started a project thought to enable analysis of nickel in complex matrices, like food extracts or expansion media. Trace nickel does enrich bacterial media as an ingredient of yeast extract as well as a product of micro-corrosion in lab tools and equipment made of metal. A biosensor was composed of antibodies isolated from sera of rabbits immunized with protein complex bovine serum albumin-nickel and protein-chelate conjugate bovine serum albumin-dimethylglyoxime-nickel. Applied onto immobilized nickel-EDTA antigen and followed by anti-rabbit enzymatically labeled secondary antibody, the biosensor was shown to have potential in metal determination in the range of micrograms per milliliter. With our immunoassay being a biochemical test that checks for the presence and concentration, we can surpass conventional means of analyses for the benefit of conducting real-time reliable examinations at relatively low cost. The project is innovative as to date there is scarce literature on that type of detection with nickel as a central point to the research and none considers its prospective use in evaluation of bacterial fitness.

1732

### **Cyclic Di-Nucleotide Detection: The Development of RNA Sensors for Bacterial Second Messengers.**

C. A. Kellenberger<sup>1</sup>, X. Wang<sup>2</sup>, J. Sales-Lee<sup>1</sup>, M. C. Hammond<sup>1,2</sup>; <sup>1</sup>Chemistry, University of California, Berkeley, Berkeley, CA, <sup>2</sup>Molecular & Cell Biology, University of California, Berkeley, Berkeley, CA

Cyclic di-nucleotides have recently emerged as an important class of second messengers in bacteria. In particular, c-di-GMP has been shown to regulate diverse cellular processes, such as biofilm formation, virulence, and cell cycle progression. Here we present a simple gel mobility shift assay that allows for quantitation of c-di-GMP from cell extracts. Furthermore, we have exciting preliminary results on the development of an *in vivo* fluorescent biosensor for c-di-GMP based on the Spinach aptamer. The ability to quantitate c-di-GMP both *in vitro* and *in vivo* will assist ongoing efforts to elucidate the signaling pathways regulating this second messenger.

1733

### **Monitoring Alterations in RNA Levels of Living Cells Using a Novel RNA Detection Technology.**

D. Weldon<sup>1</sup>, A. Ko<sup>1</sup>, Y. Williams<sup>1</sup>, E. Wells<sup>1</sup>, L. White<sup>1</sup>, M. Hsu<sup>1</sup>, G. Johnston<sup>1</sup>; <sup>1</sup>EMD Millipore, Temecula, CA

The ability to determine the expression level of a given gene and more importantly to monitor changes in its expression due to stimulation or inhibition allows researchers to elucidate the complex regulatory networks inside of living cells. Unfortunately, current technologies require fixation, transfection, or cell lysis in order to determine RNA expression levels. These techniques alone can alter gene expression making monitoring a specific RNA problematic.

The ideal solution should be non-toxic, transfection free, allow for detection of the RNA target of interest, and then leave the cell unharmed and unchanged. Only then would the detection be based on normal cellular activity and not artifacts created solely by the detection method. Since the cells would remain unharmed they could be used for downstream experimentation following their original profiling.

We have developed an innovative technology that enables researchers to specifically detect RNA in living cells, while at the same time reducing the numerous hands-on steps and pain points associated with traditional RNA-based assays. It will allow the researcher the freedom to design and carry out improved gene expression experiments.

1734

**A systematic genome-wide knockout generation and analysis of zebrafish protein-coding gene function.**

C. M. Dooley<sup>1</sup>, R. N. Kettleborough<sup>1</sup>, E. M. Busch-Nentwich<sup>1</sup>, S. A. Harvey<sup>1</sup>, E. de Bruijn<sup>2</sup>, F. van Eeden<sup>3</sup>, I. Sealy<sup>1</sup>, R. J. White<sup>1</sup>, C. Scahill<sup>1</sup>, C. Herd<sup>1</sup>, I. J. Nijman<sup>2</sup>, F. Fenyés<sup>1</sup>, S. Mehroke<sup>1</sup>, R. Gibbons<sup>1</sup>, N. Wali<sup>1</sup>, S. Carruthers<sup>1</sup>, A. Hall<sup>1</sup>, E. Cuppen<sup>2</sup>, D. L. Stemple<sup>1</sup>; <sup>1</sup>Wellcome Trust Sanger Institute, Hinxton, UK, <sup>2</sup>Hubrecht Institute, KNAW and University Medical Center Utrecht, Utrecht, Netherlands, <sup>3</sup>MRC-CDBG/Department of Biomedical Science, The University of Sheffield, Sheffield, UK

Recent advances in sequencing technology have opened the age of personalized genomics but even within the existing annotated vertebrate genomes less than half of the identified genes have been assigned a function. Detailed investigations involving model organisms have played a fundamental role in connecting genotype to phenotype but if we are to realize the dream of personalized medicine we will first require a functional analysis of all genes. The ability to thoroughly investigate the role of a gene in various biological processes greatly depends on loss of function analysis which has traditionally been carried out, in vertebrates, on a gene-by-gene basis.

The zebrafish is a genetically tractable organism with its external, transparent and rapidly developing embryo offering an *in toto* model of the complex cellular processes required for the formation of all major vertebrate organs. In recent years it has moved beyond being a model of early development and has become a first stop choice for human geneticists aiming to assign function to human orthologs or clinicians hoping to develop a model for a particular disease.

Enabled by a completed and annotated zebrafish reference genome sequence, high-throughput sequencing and efficient chemical mutagenesis, we describe the active Zebrafish Mutation Project (ZMP) at the Wellcome Trust Sanger Institute which aims to identify and phenotype disruptive mutations in every zebrafish protein-coding gene.

Thus far we have identified potentially disruptive mutations in more than 30% of all of the 26,000 known zebrafish protein coding genes. We have developed a multi-allelic phenotyping scheme to efficiently assess the effects of each allele during embryogenesis and have analyzed the phenotypic consequences of more than 1000 alleles. Our phenotyping scheme is also adaptable to phenotypic analysis beyond embryogenesis and we are currently expanding our analysis to encompass a wider array of phenotypes as we set forth to fully functionally annotate the zebrafish genome. A further goal is to place the rich collection of knockouts we are generating in the hands of specialists capable of carrying out detailed functional analysis. To this end, all knockout alleles and data are immediately made available to the community as we produce them via our website [http://www.sanger.ac.uk/cgi-bin/Projects/D\\_erio/zmp](http://www.sanger.ac.uk/cgi-bin/Projects/D_erio/zmp).

1735

**RapR analogs of Src, Fyn, Yes and Lyn: new tools for activation of specific kinase isoforms *in vivo* demonstrate specific roles for isoforms in cell motility.**

P-H. Chu<sup>1</sup>, A. V. Karginov<sup>1</sup>, D. M. Tsygankov<sup>1</sup>, M. E. Berginski<sup>2</sup>, S. M. Gomez<sup>1,2,3</sup>, T. C. Elston<sup>1</sup>, K. M. Hahn<sup>1</sup>; <sup>1</sup>Department of Pharmacology, University of North Carolina-Chapel Hill, Chapel Hill, NC, <sup>2</sup>Department of Biomedical Engineering, University of North Carolina-Chapel Hill, Chapel Hill and North Carolina State University, Raleigh, NC, <sup>3</sup>Department of Computer Science, University of North Carolina-Chapel Hill, Chapel Hill, NC

The Src family of kinases (SFK) is comprised of nine highly homologous members that participate in a diverse spectrum of signaling pathways, regulating proliferation, differentiation, cell migration, adhesion, and survival. Similarities in their structure and regulation have made it difficult to separate the roles of each family member. To identify unique functions for individual SFKs, we constructed rapamycin-regulated (RapR) analogs of Src, Fyn Yes and Lyn, enabling each isoform to be activated specifically and independently. The RapR approach (Karginov *et al.* 2011) takes advantage of the rapamycin-induced interaction between an engineered iFKBP domain and an FRB domain. The iFKBP domain is inserted into kinases at a conserved position in the catalytic domain, rendering the kinase inactive. The RapR kinase is expressed in living cells together with FRB. Addition of rapamycin or its nonimmunosuppressive analogs to the extracellular medium causes heterodimerization of the RapR-kinase with FRB, activating the kinase. This technology has proven broadly applicable, and to date has been used for Fak, Src, Fyn, Yes, Lyn, Pak1 and p38 MAPK. Morphological changes and changes in SFK distribution induced by activation of Src and Fyn were quantified using new computational methods. The methods use successive frames from time lapse movies of live cells to quantify key features of cell movement including the “uniformity” of cell spreading and the rate of cell edge change. The morphological dynamics are represented as a trajectory in the space of key parameters that characterize cell movement at each time point. The results of this analysis demonstrate that Src induces spreading followed by polarized movement, while Fyn generates uniform spreading, with each behavior occurring with well-defined kinetics following activation. Furthermore, activation of Src led to its redistribution from the perinuclear region to the cell periphery while Fyn remained more uniformly distributed throughout activation. Mutations were introduced into the RapR-SFKs to examine how these kinases are regulated and determine the role of cellular localization in their function. When RapR-Fyn could not be palmitoylated, it showed a distribution like RapR-Src and upon activation generated morphological changes like those produced by RapR-Src. Swapping of functional domains (SH3 and SH2) generated effects on both localization and polarized movement. Differences in focal adhesion dynamics driven by Src versus Fyn activation were quantified using a previously described method (Berginski *et al.* 2011). Our results provide a mechanistic model for the distinct morphological changes induced by each kinase.

1736

**Increasing protein expression to 1g/L in the next generation mammalian transient protein production system: Expi293™.**

S. Vasu<sup>1</sup>, C. Liu<sup>2</sup>, I. Cisneros<sup>1</sup>, M. Jones<sup>3</sup>, J. Zmuda<sup>3</sup>, J. Rogers<sup>1</sup>; <sup>1</sup>Life Technologies, Carlsbad, CA, <sup>2</sup>Life Technologies, Grand Island, NY, <sup>3</sup>Life Technologies, Frederick, MD

Transient expression provides a rapid, flexible and economical protein production alternative to the time consuming and costly process of generating and selecting stable high-expressing cell lines. However, there is a growing demand for higher protein yields necessary to feed the increasing needs of pharmaceutical research. This study shows how redesigning the transient

expression model enabled the superior protein yield and reproducibility typically obtained with stable cell lines while maintaining the simplicity and ease of use associated with current transient expression systems. The combination of a unique high-capacity media, a new 293F cell variant, and the ExpiFectamine293™ transfection reagent and enhancer, together enable the new Expi293™ system to achieve expression levels approaching and exceeding 1 gram per liter of protein within 7 days. We present data demonstrating the ability of the new media to support the increased growth rate, transfection and higher levels of protein productivity of the new Expi293F™ cell line. In some cases, expression of both IgG and non-IgG proteins were increased up to 10-fold over levels obtained with the FreeStyle™ 293 expression system. Proteins produced in the Expi293™ system exhibit biologically relevant target recognition, binding and native pharmacokinetic performance. The system is scalable, and as a result of the high yields, enables the use of microplates for high throughput applications. The system has been demonstrated to maintain high yields with a wide variety of proteins and applications including lentiviral and membrane protein production. By enabling the generation of substantially higher levels of protein in smaller culture volumes, the Expi293™ system represents a powerful, economical and unique expression technology for research and the production of therapeutic candidate proteins.

### Embryonic Airway Peristalsis: the Mechanical Framework.

K. Krishna<sup>1</sup>, E. C. Jesudason<sup>2</sup>, D. Warburton<sup>2</sup>, S. R. Lubkin<sup>3</sup>; <sup>1</sup>Mechanical Engineering, North Carolina State University, Raleigh, NC, <sup>2</sup>Childrens Hospital Los Angeles, Los Angeles, CA, <sup>3</sup>Mathematics, North Carolina State University, Raleigh, NC

The developing lung is a fluid filled, at times almost glandular structure that undergoes cyclic rounds of epithelial branching under cues from the surrounding mesenchyme and its derivatives. Some of these cues are mechanical, so full understanding of lung morphogenesis requires study of the mechanics of the developing lung. Fetal studies have revealed that the liquid filled developing airway is at a positive pressure relative to the amniotic fluid (from which it is distinct) and that this is maintained by net secretion by the lung. However the developing lung is also subject to a range of mechanical interactions including not only diaphragmatic 'breathing movements' but also the effects of propagating airway peristalsis. In this study, we have used measures and estimates from developing embryonic lung to build an in silico model of propagating waves of ASM-mediated airway peristalsis traveling to a closed distal end.

We can report a hitherto unexpected finding that airway peristalsis can be expected to regulate the speed of diffusion of luminal macromolecules in particular. Secondly, and perhaps contrary to expectations, proximal fetal airway occlusions, as used in human fetuses with congenital diaphragmatic hernia, would not appear to unduly affect the distal effects of airway peristalsis at least in larger airways. Third, airway peristalsis provides a synchronized mechanosignal to the airway distal to the point of peak contraction. Fourth, tissue stretch in the airway stalk is unaffected by luminal liquid viscosity, but flow sensing in that region would be predicted based on the model showing flow reversal in that area. Fifth, fluid velocities measured by the movement of luminal debris can yield straightforward surrogate information on fluid shearing. However, shearing of the epithelium is negligible which means there may be an absence of epithelial shear sensors at points they might otherwise have been expected. More generally, we find that tube size and its closed-end nature can affect a range of features that would be of

direct relevance from cancer angiogenesis and ureteric bud development to development of the major exocrine glands. In the latter, our prediction of enhanced diffusion for macromolecules may presage an exquisite physiological role for peristalsis in closed-end systems.

**Intrinsic, temporal mechanical oscillations of COS-7 cells.**

*N. A. Ray<sup>1</sup>, E. K. Dimitriadis<sup>1</sup>; <sup>1</sup>BEPS/NIBIB, NIH, Bethesda, MD*

Cellular oscillations are a natural phenomenon reflecting the dynamic nature of cytoskeletal and other cellular components. Recently, low frequency periodic oscillations of the mechanical properties of epithelial cells were measured using the atomic force microscope (AFM). For example, AFM nanoindentation was used to measure temporal changes in bronchial epithelial cells and in cerebral endothelial cells. For both cell types, periodic, low frequency oscillations with periods between 1 and 2 minutes were demonstrated. Nanoindentation was also utilized to measure temporal changes of the Young's modulus of vascular smooth muscle cells from both young and aged monkeys. This study revealed that the elasticity of these cells oscillates and those oscillations have pronounced periodic components whose frequencies increase with aged. However, these studies measure elasticity by repeatedly indenting the cell, a procedure which may be perturbing the cells and biasing the dynamics of the cytoskeleton in ways that are not clearly understood.

In this study, we extend the investigation of periodic oscillations to a different type of cell and aim to better understand the phenomenon by introducing a second, complimentary method of observation. In addition to the standard AFM nanoindentation methods, we also passively observe the elastic fluctuations of the cells while the AFM probe is in static, constant force contact with the cell. In these experiments we used COS-7 cells, fibroblast-like cells derived from monkey kidney cells. The experiments reveal that the elasticity of COS-7 cells also fluctuates and there are strong indications of periodic components at frequencies in the range observed in the previously investigated cells. The frequencies observed by the two methods are similar and the differences can be explained by the differing mechanics of the observations. We describe the methodologies of data acquisition and analysis and possible sources of such behavior.

**Estimation of forces driving a cytoplasmic flow in the *C. elegans* embryo using data assimilation.**

*R. Niwayama<sup>1,2,3</sup>, H. Nagao<sup>2,4</sup>, T. Higuchi<sup>2,4</sup>, A. Kimura<sup>1,2,3</sup>; <sup>1</sup>Cell Architecture Laboratory, National Institute of Genetics, Mishima, Japan, <sup>2</sup>Transdisciplinary Research Integration Center, Research Organization of Information and Systems, Tokyo, Japan, <sup>3</sup>Department of Genetics, The Graduate University for Advanced Studies (Sokendai), Mishima, Japan, <sup>4</sup>The Institute of Statistical Mathematics, Tokyo, Japan*

Cytoplasmic streaming is a collective flow of the cytoplasm observed in many eukaryotic cells. Cytoplasmic streaming can be observed in *Caenorhabditis elegans*, a widely used model organism, shortly after the fertilization. This streaming is important to establish anterior-posterior axis of the embryo. In a previous study, we succeeded in quantifying the velocity distribution of the cytoplasmic streaming in the *C. elegans* embryo. We also constructed hydrodynamic simulation model that well reproduces the velocity distribution observed in the cell [1]. Here we report that, using a statistical method called data assimilation, we estimated the distribution of forces generated by molecular motors to drive the cytoplasmic streaming. The spatial distribution of forces required to reproduce the streaming was not proportional to the velocity distribution: strong forces were estimated to be generated even at region where the streaming is

slow. In the presentation, we will discuss possible causes of this non-linearity between the driving forces and resultant flow velocity.

**Deformability Cytometry: High-Throughput Single-Cell Mechanical Measurements for Mechanophenotyping.**

*D. R. Gossett<sup>1</sup>, H. T. Tse<sup>1</sup>, O. O. Yang<sup>1</sup>, D. Di Carlo<sup>1</sup>; <sup>1</sup>University of California, Los Angeles, Los Angeles, CA*

There is growing evidence that cell deformability (i.e., the ability to change shape under load) is a useful indicator of cell state and may be a label-free biomarker of metastatic potential, cell cycle stage, degree of differentiation, and leukocyte activation. Clinically, a measure of metastatic potential could guide treatment decisions; a measure of degree of differentiation could prevent transplantation of undifferentiated, tumorigenic stem cells in regenerative therapies; and a measure of leukocyte activation could be employed to monitor progression of HIV or transplant rejection. In order for deformability measurements to be clinically valuable given the heterogeneity of complex biological samples, there exists a need for a high-throughput automated assay of these mechanical properties. We have developed a robust method for obtaining high-throughput single-cell mechanical measurements (~2000 cells/sec—comparable to flow cytometry). The method employs inertial focusing for uniformly positioning cells in flow, hydrodynamic stretching in an extensional flow, high-speed imaging, and automated image analysis to extract a size and deformability parameter. Thus far we have demonstrated the method's ability to distinguish mouse and human embryonic stem cells from their differentiated progeny, cancerous cells from benign mesothelial cells within pleural fluids, and activated white blood cells from resting white blood cells. For hundreds of thousands of cells, in this work we show that mechanical state as measured by our system can effectively discriminate between populations of leukocytes. In contrast to resting granulocytes and mononuclear blood cells, which we have measured to be rigid, both myeloid (HL60) and lymphoid (Jurkat and H9 lymphoma) leukemic cell lines cells are highly deformable. The differentiation of these cells, for example differentiation of HL60 by all-trans retinoic acid, greatly reduces their deformability. On the other hand, activation events such as stimulation with mitogenic compounds increase the deformability of primary blood cells. Both in immune activation and hematological malignancy, large scale cellular changes (e.g., relative nuclear size and structure and reorganization of intermediate filaments) are apparent along with the molecular changes that are usually assayed. These changes affect mechanical properties, and the accessibility and ease of their measurement will make them useful for monitoring disease and efficacy of therapy, drug screening, and biophysical studies.

**A geometry-dependent slow feedback from cell shapes to the spatial patterning of PIP3 / Rac1 / actin.**

*C-L. Guo<sup>1</sup>, J-Y. Yu<sup>1</sup>; <sup>1</sup>California Institute of Technology, Pasadena, CA*

The spatial patterns of cell shapes are critically important in many biological processes. The current theory is that cells use biochemical cues-induced patterning of signaling molecules (time scales: seconds - minutes) to guide cell shape patterning. However, how the patterns of cell shapes influence signaling molecule dynamics and how fast such influences are remain to be characterized. Using fabricated environments and quantitative image analysis, we show that in the absence of biochemical cues, non-uniform cell shapes can spontaneously emerge without

preceding patterning of signaling molecules including PIP3 and active Rac1. These spontaneously emerged shapes can guide the patterning of PIP3, active Rac1, and actin filaments which in turn stabilize the cell shapes. Moreover, the rate of shape-guided patterning (time scales: ~ hours) is much slower than that of biochemical cues-induced patterning. Numerical simulations show that shape-guided patterning can be simply a result of the boundary effect of non-uniform shapes, without the involvement of any molecular feedback circuits. We suggest that cell shapes can influence the dynamics of PIP3 / Rac1 / actin, after cells are committed to specific spatial patterns for a long period of time. The large gap of response times between biochemical cues-induced patterning and shape-guided patterning might allow cells to respond to fast environmental changes under minimal interferences from previously-developed cell shapes.

### **Changes in Cellular Mechanical Properties Following Cytoskeleton Components Disruption.**

*S. Barreto<sup>1,2</sup>, C. H. Clausen<sup>3,4,5</sup>, C. M. Perrault<sup>1,2</sup>, D. A. Fletcher<sup>3,4,5</sup>, D. Lacroix<sup>1,2</sup>; <sup>1</sup>Department of Mechanical Engineering, University of Sheffield, Sheffield, United Kingdom, <sup>2</sup>Institute for Bioengineering of Catalonia, Barcelona, Spain, <sup>3</sup>Biophysics Graduate Group, University of California, Berkeley, CA, <sup>4</sup>Bioengineering Department, University of California, Berkeley, CA, <sup>5</sup>Physical Biosciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA*

An unsolved problem in cellular biology is how the individual cytoskeleton components behave to permit or impair the transmission of the mechanical stimuli and how the magnitude of forces affects cellular functions. To address this gap, numerical simulation can be helpful to describe the contribution of the cytoskeleton to cell physiology. We propose a new 3D finite element model of a single adherent cell to study the role of different components of the cytoskeleton depending on the external stimuli and how these contribute to cell integrity. The model includes actin cortex, actin fibers and microtubules in a continuum cytoplasm and nucleus. Physiological values of prestress are simulated due to 24% pre-stretching of actin bundles. The cell model was compressed and stretched with a bead on the top of the cell simulating different single-cell stimulating techniques. Numerical simulations were combined with force-indentation measurements using atomic force microscopy (AFM) of U2OS GFP-actin cells and NIH-3T3 cells for model validation and further prediction of mechanical properties of different cell types. Our findings show that under a compressive load simulating AFM, the actin cortex and microtubules are the major components to resist compression. During stretching, simulating magnetic twisting cytometry (MTC), cell stiffness is mainly dependent on the stress transmission between actin bundles and microtubules. Therefore, the developed finite element model of the organization of the cell allows us to interpret and compare AFM and MTC for cytoskeleton disruption that characterizes biophysical changes associated with cytoskeleton functions. Visible differences in the distribution of actin in 3T3 and U2OS cells were observed before and after actin disruption with cytochalasin-D. A thicker network of actin at the cortical level was observed for the 3T3 cells compared to the U2OS before disruption. Treatment of 3T3-NIH cells with cytochalasin-D disrupted mainly the cortical network while the same concentration of drug disrupted the entire structure of F-actin in the U2OS cells. We found numerical differences in the structure of actin cortex and actin bundles that we were able to relate with different stiffness of the cells tested with AFM and therefore, predict whole cell strains for different cell lines. The model identifies which cytoskeleton components determine the physical properties of adherent cells and target cellular mechanosensitivity depending on cytoskeleton mechanical properties and on the type of external forces sensed by cells. This study illustrates that considering one elasticity to describe cellular mechanical properties on a whole cell basis is not sufficient, but we also need to consider variations of specific intracellular mechanical properties.

**Stretch Modulation of Cardiomyocyte Conduction.***E. Pfeiffer<sup>1</sup>, J. Stowe<sup>1</sup>, K. McNall<sup>1</sup>, J. Tan<sup>1</sup>, A. McCulloch<sup>1</sup>; <sup>1</sup>Bioengineering, UCSD, La Jolla, CA*

Cardiac volume overload and acute deformations have been linked to increased incidence of arrhythmia and sudden cardiac death, possibly due to proarrhythmic conduction slowing with tissue stretch. Both conduction velocity increases and decreases have been reported under mechanical loading *ex vivo*. These changes have been attributed to stretch modulation of ion channels, cell-cell junctions, cell capacitance, and properties of the interstitium.

To separate interstitial effects from intrinsic changes in myocyte conduction, neonatal murine cardiomyocytes were cultured on micropatterned stretchable substrates for optical mapping of excitation conduction velocity. A homogeneous anisotropic biaxial strain field of up to 14% in the primary direction and 3.6% in the secondary direction was applied to these substrates for five minutes, where the primary direction of stretch was oriented either parallel or perpendicular to the longitudinal axis of the aligned cell culture. Reversibility was demonstrated by measurements recorded five minutes following load removal.

When the primary direction of strain was oriented parallel to the longitudinal cell culture axis, longitudinal conduction slowed to  $72\% \pm 5\%$  of 264 mm/s, the baseline velocity along the longitudinal axis of the cell culture, and transverse conduction to  $80\% \pm 4\%$  of 141 mm/s, the baseline along its transverse axis ( $n=5$ , mean  $\pm$  SEM). Conduction velocities before and after loading were significantly different by paired t-test,  $p = 0.0064$  and  $p = 0.0144$  respectively. Five minutes after removal of stretch, conduction velocities recovered to  $90\% \pm 8\%$  and  $114\% \pm 18\%$  respectively. A repeated measures ANOVA of the effect of the three loading conditions on longitudinal conduction detected significant slowing with loading ( $F(2,4)=5.671$ ,  $p=0.0293$ ). These observations of conduction slowing with stretch are in line with our previous observations in isolated and perfused rabbit hearts, in which conduction velocity slowed by  $12 \pm 3\%$  with volume inflation, and recovered to  $95 \pm 1\%$  of the initial value of  $30.8 \pm 4.7$  cm/s following unloading ( $n=5$ , mean  $\pm$  SEM) (Mills 2008; Sung 2003).

Progressive conduction slowing occurred isotropically with biaxial stretch above 7% Lagrangian strain in the primary direction and 1.8% in the secondary direction, oriented along either axis of the cell culture. Lower stretch magnitudes resulted in conduction increases to 125-150% of initial conduction velocities. Both low-stretch speeding and high-stretch slowing continue after treatment with cation-selective mechanosensitive channel inhibitor GsMTx-4.

**Analyzing Contractile Functions of Gene Targeted Cardiomyocytes.***S. Lange<sup>1</sup>, X. Zhang<sup>2</sup>, J. Chen<sup>1</sup>; <sup>1</sup>School of Medicine, UC San Diego, La Jolla, CA, <sup>2</sup>ACEA Biosciences, San Diego, Cambodia*

Gene targeted mice are widely used model systems for human diseases and tools to investigate functions of a gene/protein in an *in vivo* context. One example of a widely studied animal model for cardiomyopathy is the muscle lim protein (MLP) knockout mouse. MLP mice develop a severe form of dilated cardiomyopathy (DCM) within 2 months after birth and exhibit many of the characteristic pathological hallmarks displayed by human DCM patients.

Despite its wide use in cardiovascular science, the MLP knockout mouse is just one example of a gene targeted mouse model that exhibits alterations to cardiac functions, with many other gene knockout models in need of better characterization on the physiological, histological and biochemical level. Although cardiac function of gene targeted animals can be assessed *in vivo*

through echocardiography analysis, or on the organ level by Langendorff systems, investigating contractile parameters on the cellular level is usually limited by small sample size and high variability: e.g. electrophysiological studies of single cardiomyocytes using patch clamp techniques, measurement of calcium transients in single cells, or force measurements on isolated, skinned cardiac myocytes.

We are taking advantage of the Roche/Acea xCelligence cardio-system to characterize contractile parameters of neonatal mouse cardiomyocyte cultures derived from gene knockout models in a high throughput, high replicate fashion. Data gathered from these experiments are a novel tool to further characterize pathological alterations in the contractile behavior of these gene targeted cardiomyocytes. Moreover, the treatment of cardiomyocytes derived from disease models with small molecule inhibitors/activators may help to elucidate the function of cardiac signaling pathways, optimal drug concentrations and effects on contractile functions.

### Single cell mechanics in the immortalization process investigated by atomic force microscopy.

Y. Mizutani<sup>1</sup>, P. G. Cai<sup>1</sup>, M. Tsuchiya<sup>1</sup>, T. Okajima<sup>1</sup>; <sup>1</sup>Hokkaido University, Sapporo, Japan

Mechanical properties of single cells are closely related to various cell functions. Previous studies<sup>[1]</sup> reported that the stiffness of metastatic cancer cells was softer than the benign cells, suggesting that mechanical properties of cells changed depending on the degree of various cell transformations. In general, normal cells have a finite life span so that they do not undergo spontaneous immortalization in culture. However, fibroblast cells from rat or mouse have the ability to multiply indefinitely in the process of transformations of growth (Phase II), senescence (Phase III) and immortalization (IM) and consequently the cells overcome the senescence. In this study, we measured the number distribution of complex shear modulus,  $G^*$ , of rat fibroblast cells during the transition from Phase II to IM by atomic force microscopy with a cell microarray substrate.. We observed that the frequency dependence of  $G^*$  of cells (N~100) in different phases commonly exhibited a single power-law behavior, which was well fitted to the structural damping model<sup>[2]</sup>.

The mean and standard deviation of the power exponent  $\alpha$  and Newtonian viscous damping coefficient  $\mu$  were different among these phases. The cells in phase II had a smaller  $\alpha$ , than those in other phases, indicating that the former cells exhibited a solid-like behavior compared with the latter. Moreover, the standard deviation of  $\alpha$  for the cells in phase III was broader than that in other phases. The mean of  $\mu$  significantly increased for the cells in the process of transformation. For the treatment of cells with cytochalasin D, which disrupts actin cytoskeleton by filament capping,  $\alpha$  increased, and the increased  $\alpha$  was independent of the phase.

### Measuring intracellular viscoelastic properties of human mammary epithelial cells by organelle tracking.

A. M. Smelser<sup>1</sup>, J. C. Macosko<sup>2</sup>, G. Holzwarth<sup>2</sup>; <sup>1</sup>Biochemistry, Wake Forest University, Winston-Salem, NC, <sup>2</sup>Physics, Wake Forest University, Winston-Salem, NC

We employ organelle tracking as a minimally perturbing method for measuring viscoelastic properties of live human mammary epithelial cells (HMEC's). From the mean-square displacements (MSDs) and radii of these organelles, we compute the viscoelastic moduli using a generalization of the Stokes-Einstein equation. We first validated our method by tracking and

analyzing the motion of beads in 2 mg/mL xanthan, a polysaccharide with similar viscoelastic properties to those of PC12 cytoplasm, and obtaining expected viscoelastic moduli over a range of frequencies. With this confirmation, we tracked the Brownian motion of fluorescently labelled peroxisomes and lysosomes in live HMEC's for 100 s at a rate of 100 fps. From our analysis of peroxisome motion, we obtained a curve for the viscoelastic moduli which exhibited shear-thinning over four orders of magnitude in frequency. We also observed a crossover in the relative contributions from the storage and loss components of the moduli; at low frequencies the viscous component is the predominant contributor to the complex viscoelastic modulus, while at higher frequencies the elastic component predominates. The mechanics of a cell, including its viscoelastic properties, affect its signaling, cytoadherence, migration, and metastatic potential, and thus may be influential in cancer development. In this vein, we plan to compare observed viscoelastic properties of normal HMEC's with two transformed, increasingly tumorigenic HME cell lines. We expect that a greater understanding of the connection between cell mechanics and cancer will pave the way for novel approaches to treatment.
